Welcome to Syncfusion Essential ASP.NET MVC

The **Syncfusion Essential Studio for ASP.NET MVC** is a set of server-side wrappers that is empowered by Essential JavaScript. The user can add the Syncfusion MVC components into their application with the help of the server-side wrapper helper classes. The MVC helper's values are passed from the server-side wrapper classes to browser via ScriptManager, the control creation and manipulations takes place in the client-side.

How to best read this User Guide

- The best way to get started is to read the common "Getting Started" document for the component that you would like to start using first. The "Getting Started" guide gives enough information that you need to know before starting to write code. This is the only section that is recommended to read end-to-end before starting to write code, all the other information can be referred when needed.
- Once you get familiar with the basics of using the component, the next step will be to start integrating the component into your application. A good starting point will be to refer to the code snippets in the online sample browser that contains hundreds of code samples, it is very likely that you will find a code sample that resembles your intended usage scenario.
- After integrating the component into your application using one of the sample code snippets as a starting point, it is likely that you would need additional information on specific features and API. The best option will be to search a specific topic using the search box that is available at the top of the user guide.
- Another valuable resource is the API reference that provides detailed information on the object hierarchy as well as the settings available on every object.

Additional Help Resources

- The Knowledge Base section contains responses to some of the most common questions that other customers have asked us before. So this will be a good place to search for topics that are not covered in the user guide.
- Similar to the Knowledge Base, the forum section also contains responses to questions that other customers have asked us before.

Create a Support Incident

If you are still not able to find the information that you are looking for in the self-help resources mentioned above, please contact us by creating a support ticket.

System Requirement

he following topic describes the system requirements for ASP.NET MVC platform.

Operating Systems

- Windows 10
- Windows 8, 8.1
- Windows 7
- Windows vista
- Windows server 2008 and later

Copyright © 2001 - 2020 Syncfusion Inc.

Hardware Environment

- Processor: x86 or x64
- RAM : 512 MB (minimum), 1 GB (recommended)
- Hard disk: up to 5 GB of available space may be required. However, 500 MB free space is required in boot drive even if you are installing in other drive.

Web browsers

Syncfusion components are also mostly compatible with all the major browsers that we use on these days that includes the following.

- Internet Explorer 8+
- Microsoft Edge
- Mozilla Firefox 22 +
- Chrome 17 +
- Opera 12 +
- Safari 5 +

Development Environment

- Microsoft Visual Studio 2010/2012/2013/2015/2017/2019
- .NET Framework 3.5/4.0/4.5/4.5.1/4.6
- MVC Version: MVC3/MVC4/MVC5
- Microsoft SQL Server 2005 or higher
- Web browsers with JavaScript enabled

Download Installer

You can download the installer from Syncfusion.com website.

Download the Trial Version

There are two ways to download our 30-day trial.

Free Trial Page

1. You can evaluate our 30-day free trial from Free Trial page.
2. Once you fill the required form or made the login using the your Syncfusion registered account you can download the trial installer in the confirmation page.
3. You can download the latest version trial installer.
4. You can unlock the installer using the unlock key, also you can unlock the installer using the Syncfusion registered login credential.
5. You can download the trial installer using the Trials & Downloads page under your registered account at any time before the trial expire. (Refer the below screenshot).

Copyright © 2001 - 2020 Syncfusion Inc.

Start Trial Page

1. You can evaluate our 30-day free trial from Start Trial page.
2. You should login using your Syncfusion account to access this page.
3. You can start your trail by clicking on the required product.

Note: If you already using the trail products and it's not expired, you couldn't start the trial again for same product.

4. After you started the trial, you can download the latest version trial installer using the Trials & Downloads page.
5. In Trials & Downloads page, you can find your current active trial products. Trials, which you done in both Free Trial Page and Start trial pages are listed here.
6. Use the Download (element 1 in below screenshot) button to download the installer of respective product.
7. Online installer can be downloaded from this page.
8. No need of unlock key to unlock the online installer.
9. You can unlock the installer using the Syncfusion registered login credential.

Note: You can generate the license key for your active trial products from Trials & Downloads page. This license key will be mandatory to use our trial products in your application. To know more about License key, refer this help topic.

Download the License Version

1. You can find your available licensed products which under your registered Syncfusion account in License & Downloads page.
2. You can find all the licenses (both active licenses and expired licenses) which are under your account.
3. You can find the licenses listed based on SKU names.

Copyright © 2001 - 2020 Syncfusion Inc.

4. Use the Download (element 1 in below screenshot) button to download the installer of respective product.
5. Latest version installer will be downloaded from this page.
6. You can navigate to Downloads Older Versions (element 2 in below screenshot) to download older version installers.
7. From 16.2 version online installer will be downloaded by default, and earlier versions offline installer will be downloaded.

Note: Online Installer have been introduced from the release version 16.2.

8. You can navigate to More Downloads Options (element 3 in below screenshot) to download other installers.
9. EXE and Zip format available to download for Windows OS. Both are Offline Installer.
10. No need of unlock key to unlock the online installer.
11. You can unlock the installer using the unlock key for versions earlier to 16.2, also you can unlock the installer using the Syncfusion registered login credential.

Note: You can generate the license key for your licensed products from License & Downloads page. This license key will be required only from release version 16.2. To know more about License key, refer this help topic.

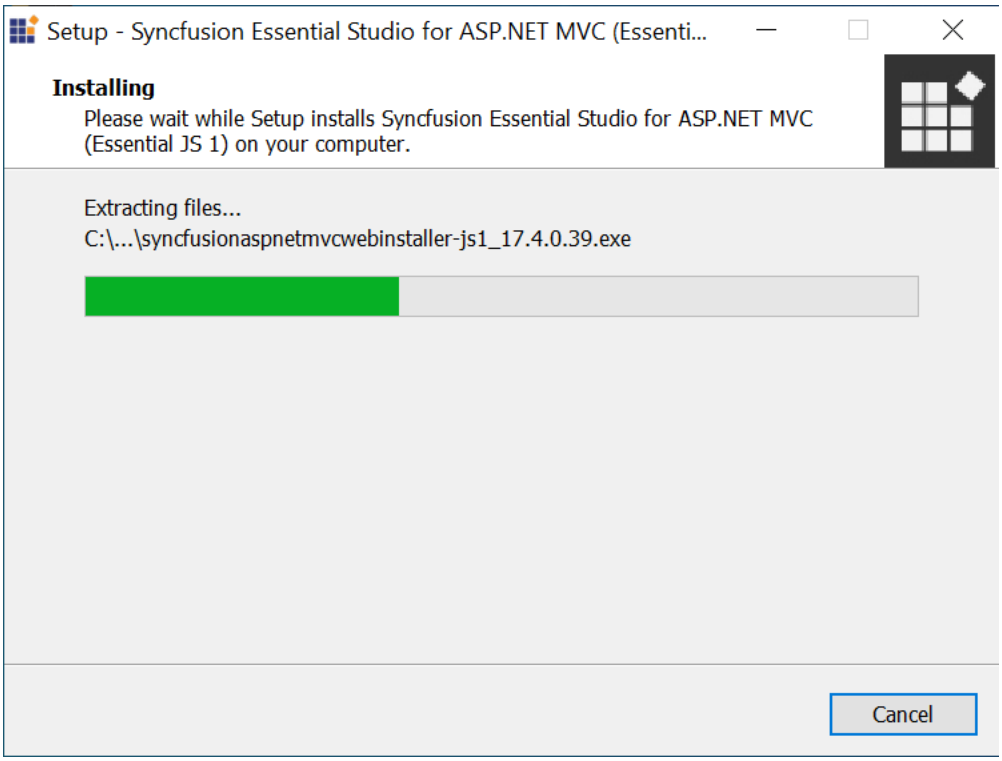
Installation and Upgrade

Installation

The following procedure illustrates how to install Essential Studio for ASP.NET MVC Online Installer.

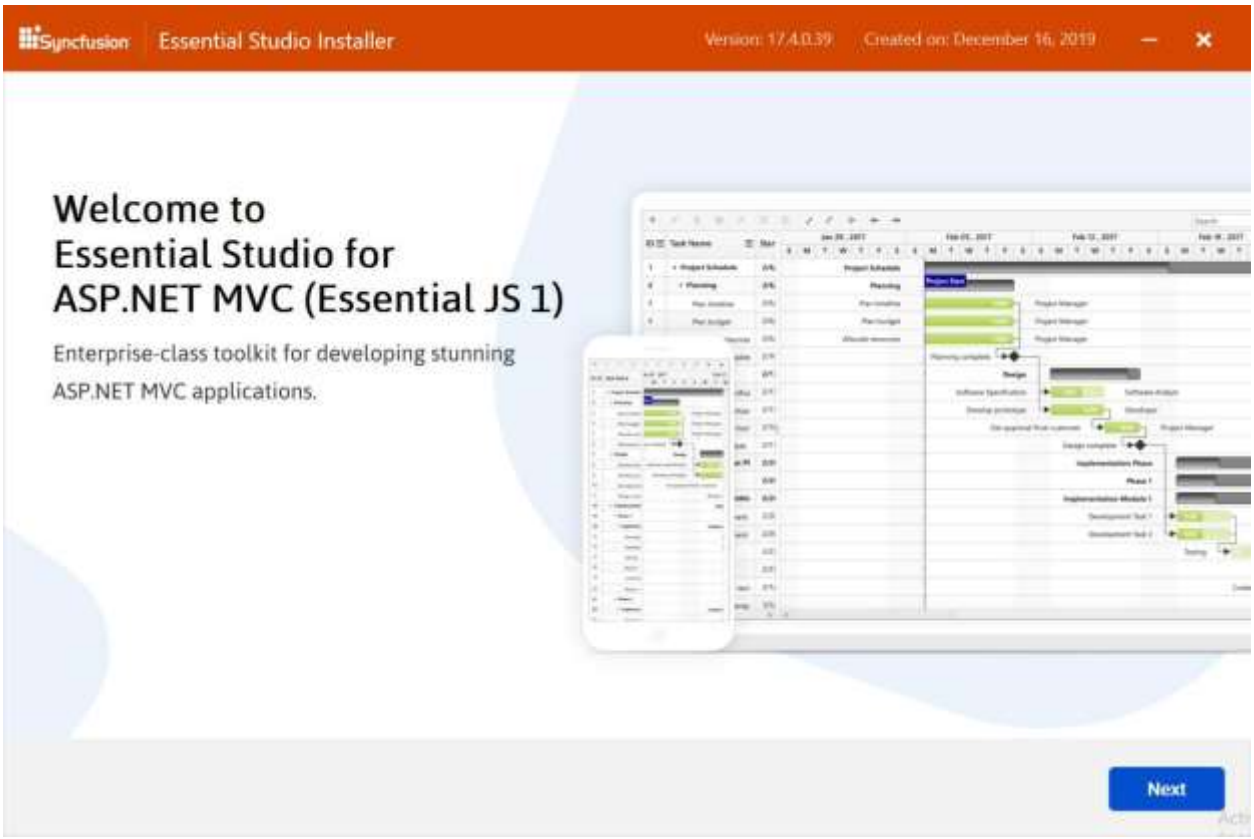
1. Double-click the Syncfusion ASP.NET MVC Online Installer file. The installer Wizard opens and extracts the package automatically.

Copyright © 2001 - 2020 Syncfusion Inc.



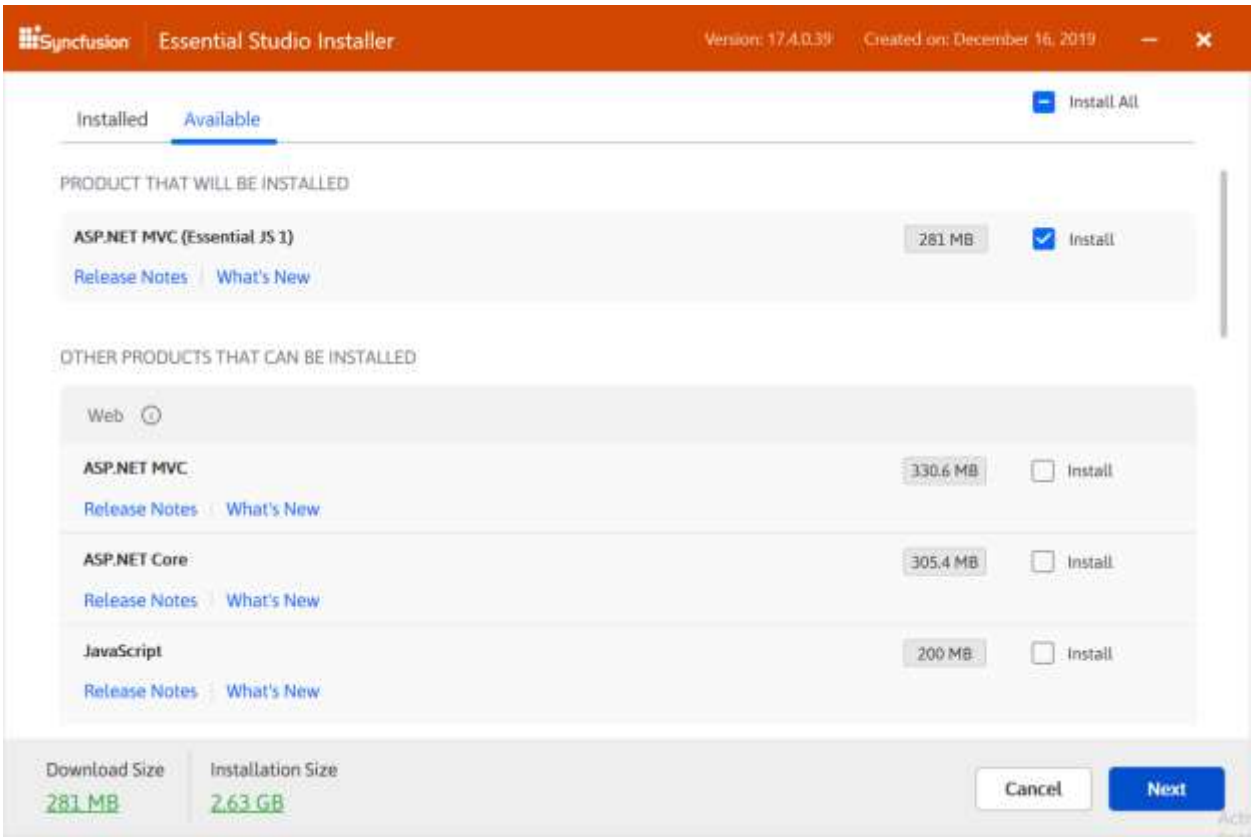
Note: The installer wizard extracts the syncfusionasnpetmvcwebinstaller_{version}.exe dialog, displaying the unzip operation of the package.

2. Welcome wizard of the Syncfusion ASP.NET MVC Online Installer will be displayed. Click Next.

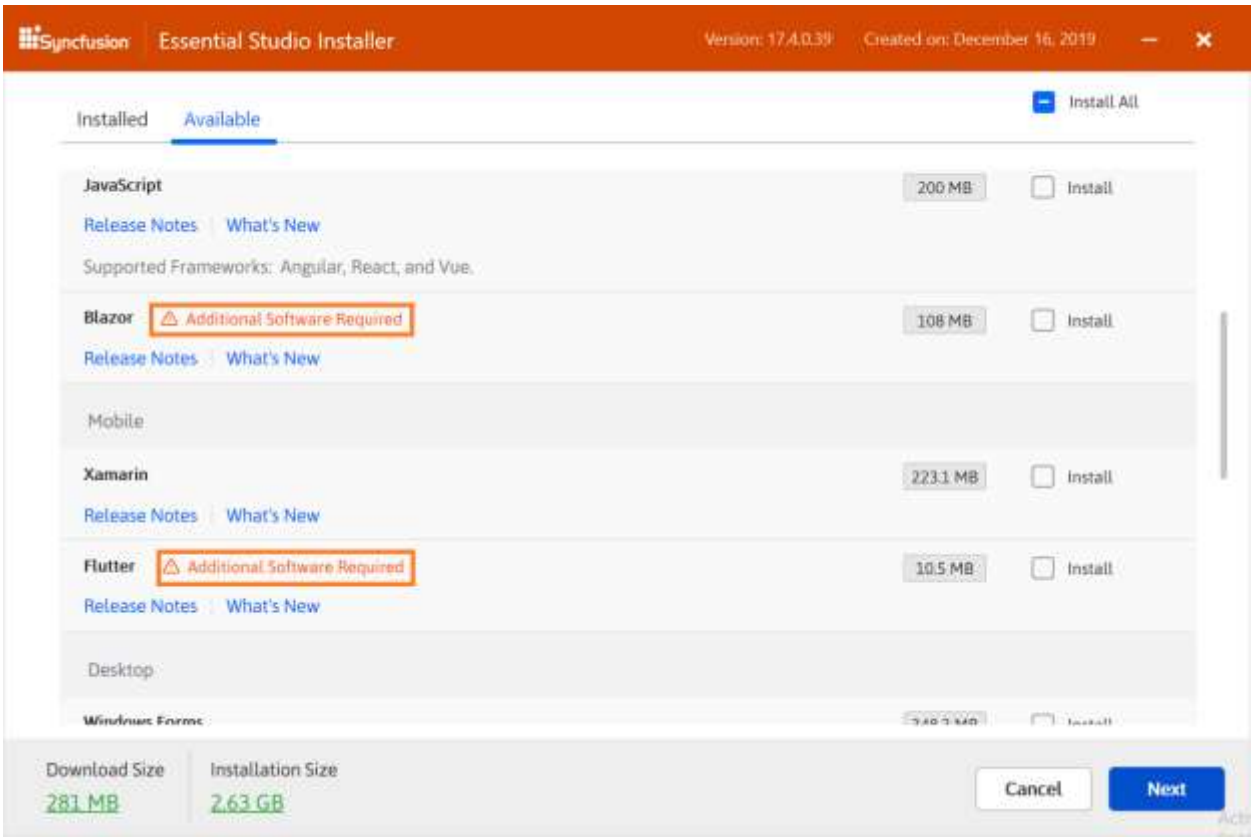


3. Platform Selection wizard will be displayed. Select the platforms to be installed from the **Available** tab. Select **Install All** checkbox to select all the platforms. Click Next.

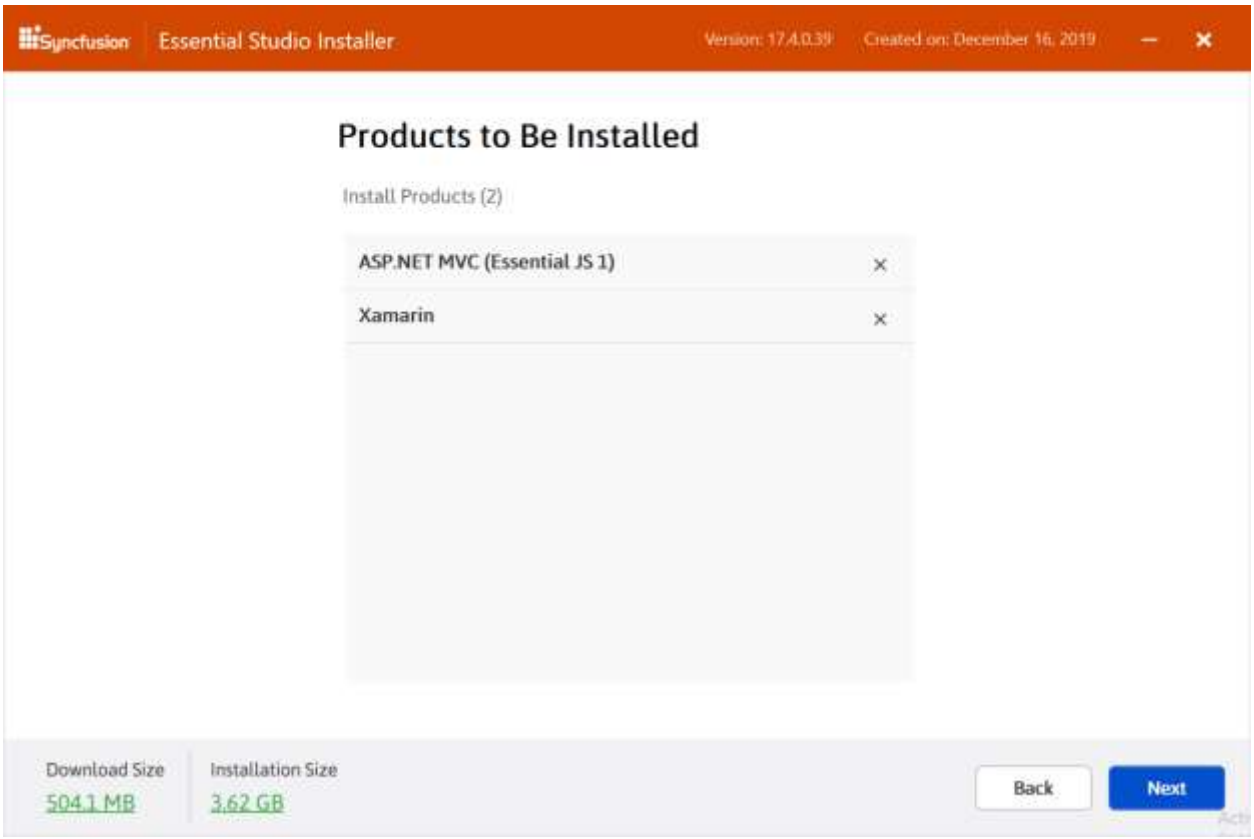
Copyright © 2001 - 2020 Syncfusion Inc.



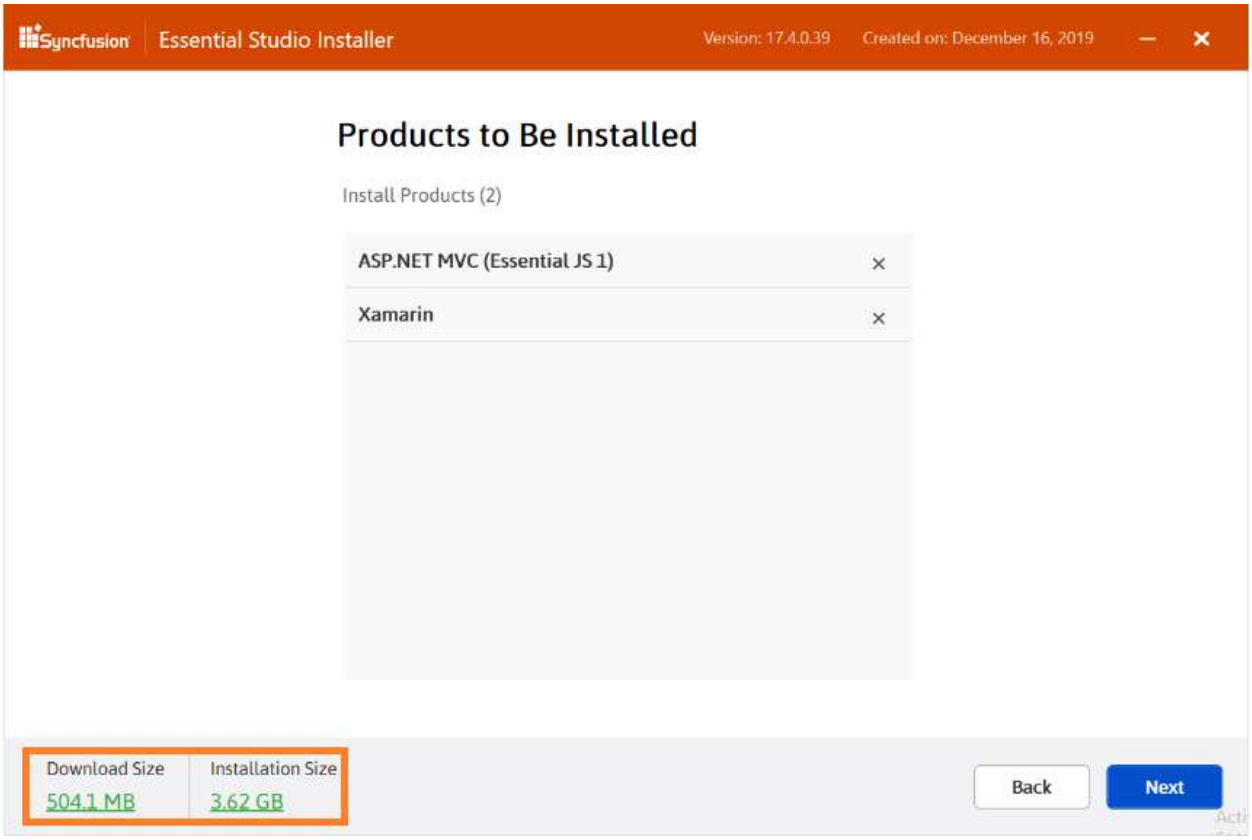
Information: If the required software of the selected platform was not already installed, **Additional Software Required** alert will be displayed. However, you can continue the installation and install the required software later.



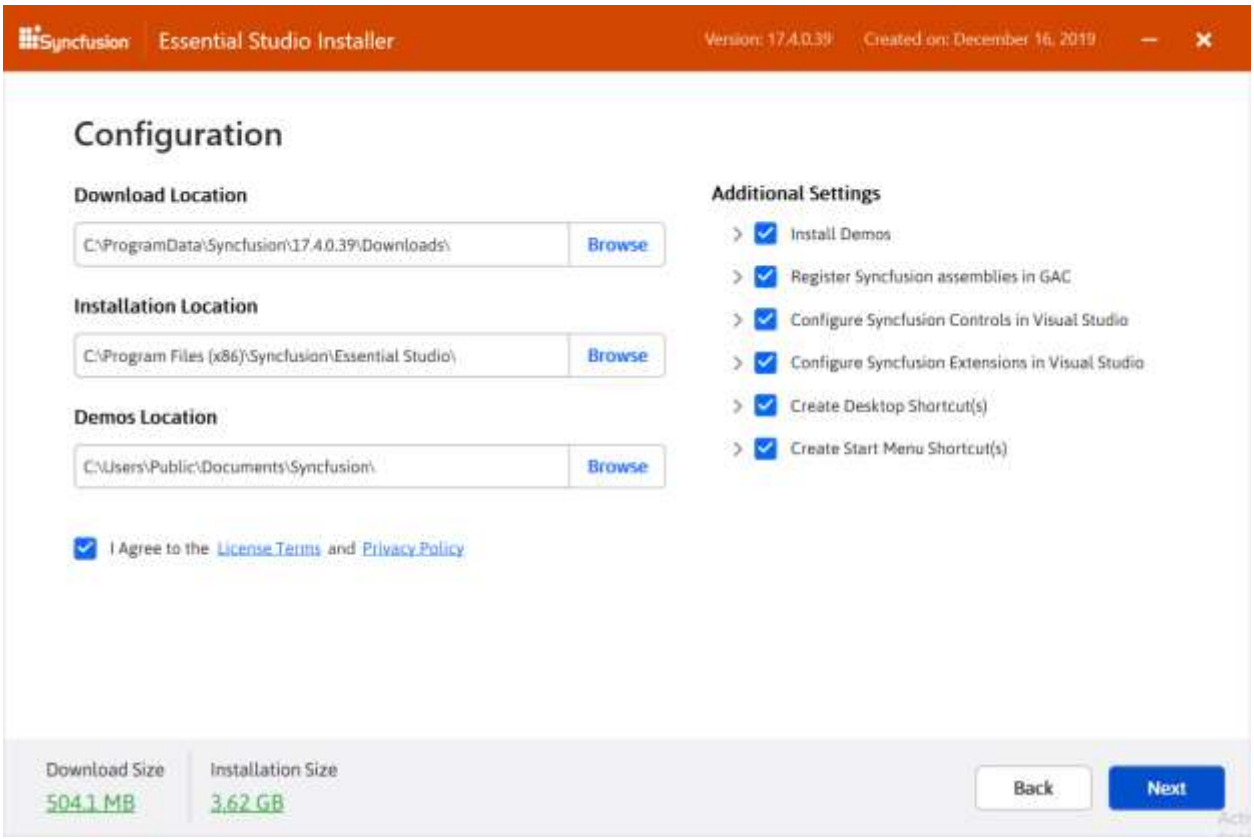
4. Confirmation wizard will be displayed. Here you can view and modify the list of platforms that will be installed.



Note: You can check the Estimated size of the Download and Installation by clicking the **Download Size and Installation Size** link.



5. Configuration wizard will be displayed. Here you can change the Download, Install and samples location. Also, you can change the Additional settings by platform basis. To install using the default configuration, click Next.



Information: From version 17.3 (2019 Vol 3), Syncfusion provides option to provide custom download location.

Note: From the 2018 Volume 2 release, Syncfusion has changed the install and samples location

Default Install location: {ProgramFilesFolder}\Syncfusion\{Platform}\{version}

Default Samples location: C:\Users\Public\Documents\Syncfusion\{platform}\{version}

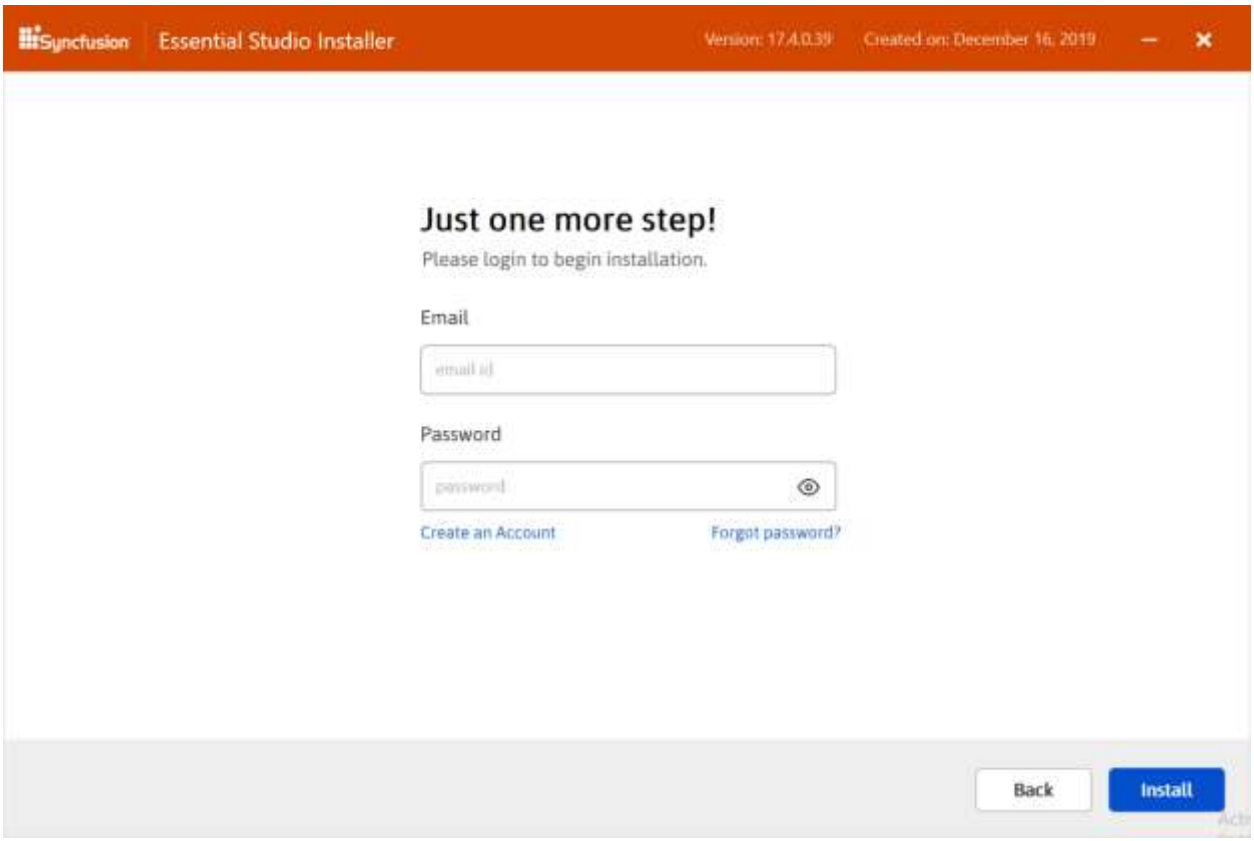
However, you can change the locations by clicking browse button.

- Select the **Install Demos** check box to install Syncfusion samples, or leave the check box clear, when you do not want to install Syncfusion samples.
- Select the **Register Syncfusion Assemblies in GAC** check box to install the latest Syncfusion assemblies in GAC, or clear this check box when you do not want to install the latest assemblies in GAC.
- Select the **Configure Syncfusion Extensions in Visual Studio** checkbox to configure the Syncfusion Extensions in Visual Studio or clear this check box when you do not want to configure the Syncfusion Extensions in Visual Studio.
- Select the **Create Desktop Shortcut** checkbox to create the desktop shortcut for Syncfusion Control Panel.

6. After reading the License Terms and Conditions, check the **I agree to the License Terms and Privacy Policy** check box. Click Next.
7. Login wizard will be displayed. You should enter your Syncfusion Direct-Trac login credentials. If you don't have Syncfusion Direct-Trac login credentials, then you can click on **Create an**

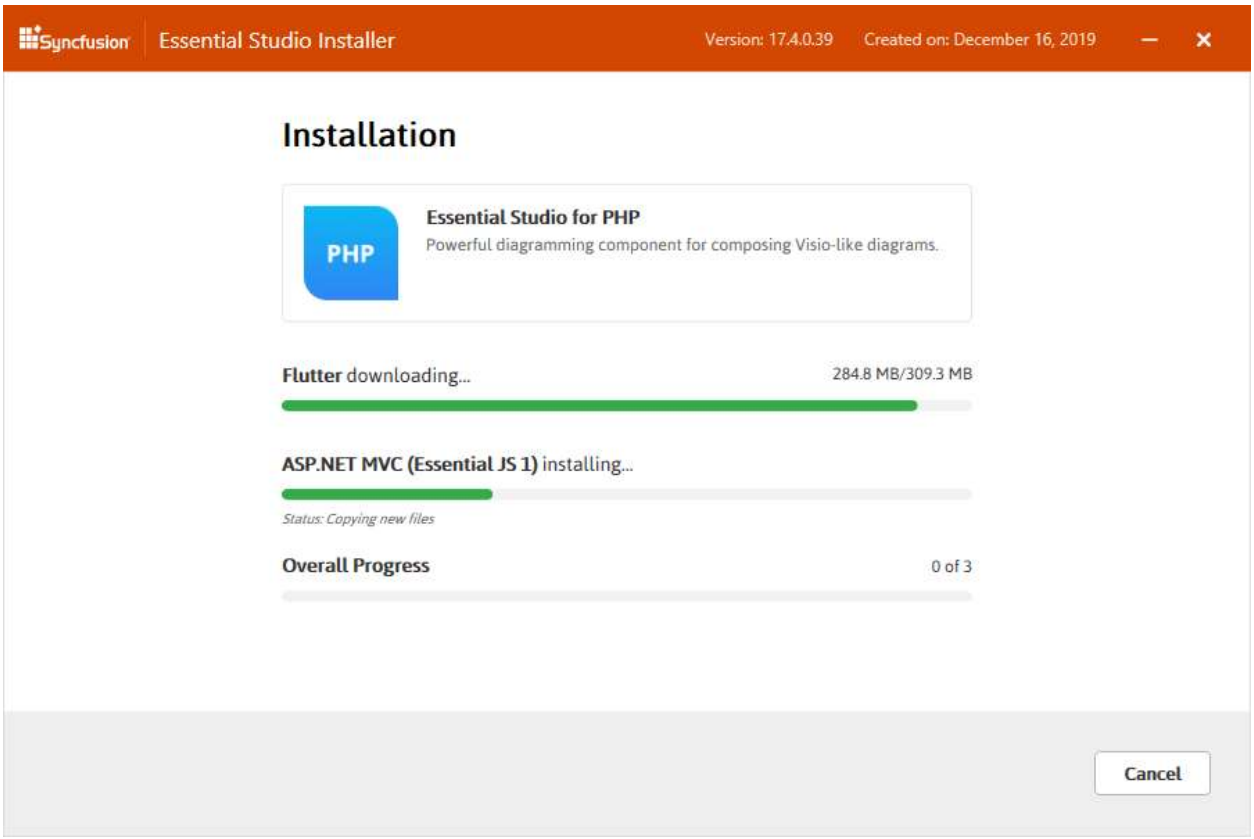
Copyright © 2001 - 2020 Syncfusion Inc.

Account. Else if you forgot your password, click on **Forgot Password** to create new password. Click Install.



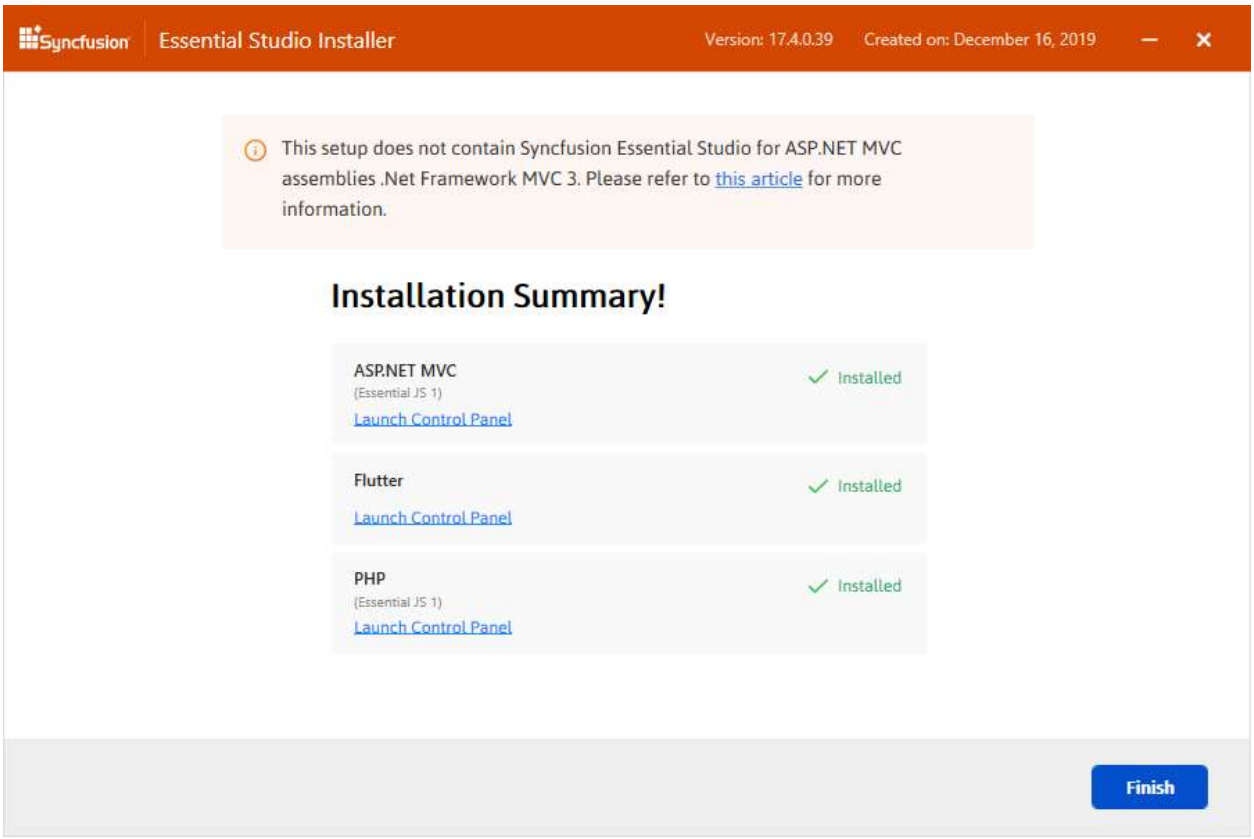
Information: The selected platforms will be installed based on your Syncfusion License (Trial or Licensed).

8. Download and Installation progress will be displayed.



9. Once the Installation is complete, **Summary** wizard will be displayed. Here you can check the list of platforms which are installed successfully and failed. Click Finish to exit the Summary wizard.

Copyright © 2001 - 2020 Syncfusion Inc.



- Click **Launch Control Panel** to open the Syncfusion Control Panel.

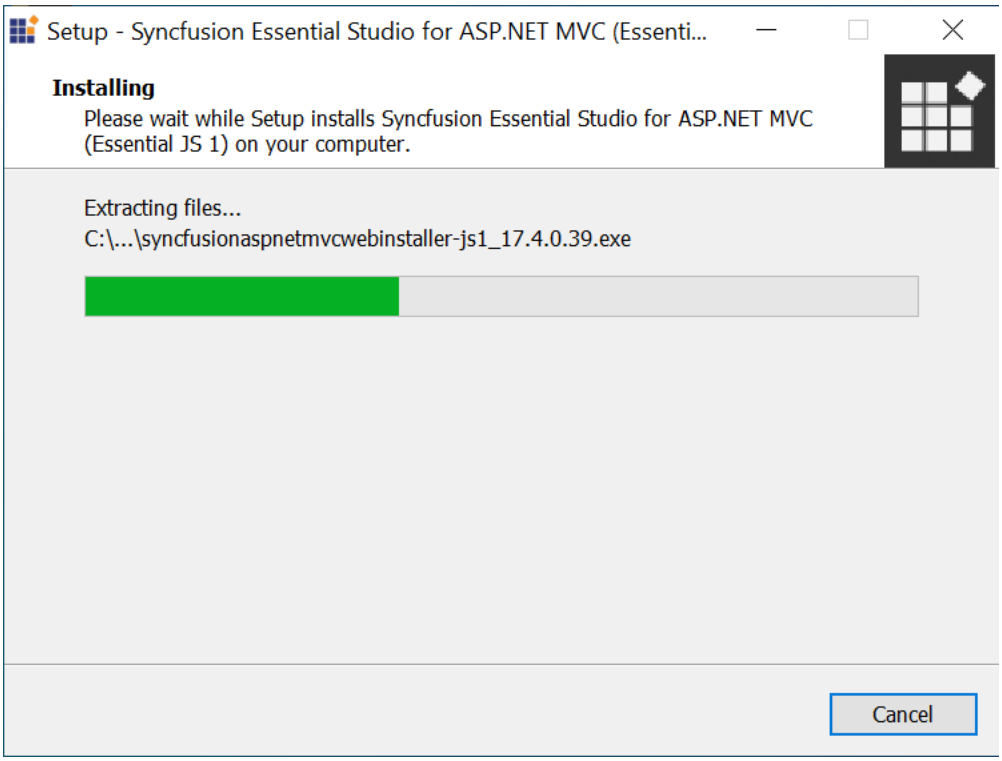
Uninstallation

Till version 17.2, Syncfusion Web Installer had option for installation alone. Starting with the version 17.3 (2019 Vol 3), Syncfusion provides option for uninstalling the platforms of the same version from the Web Installer application itself. Select the list of the platforms to be uninstalled and Web Installer will uninstall those platforms one by one.

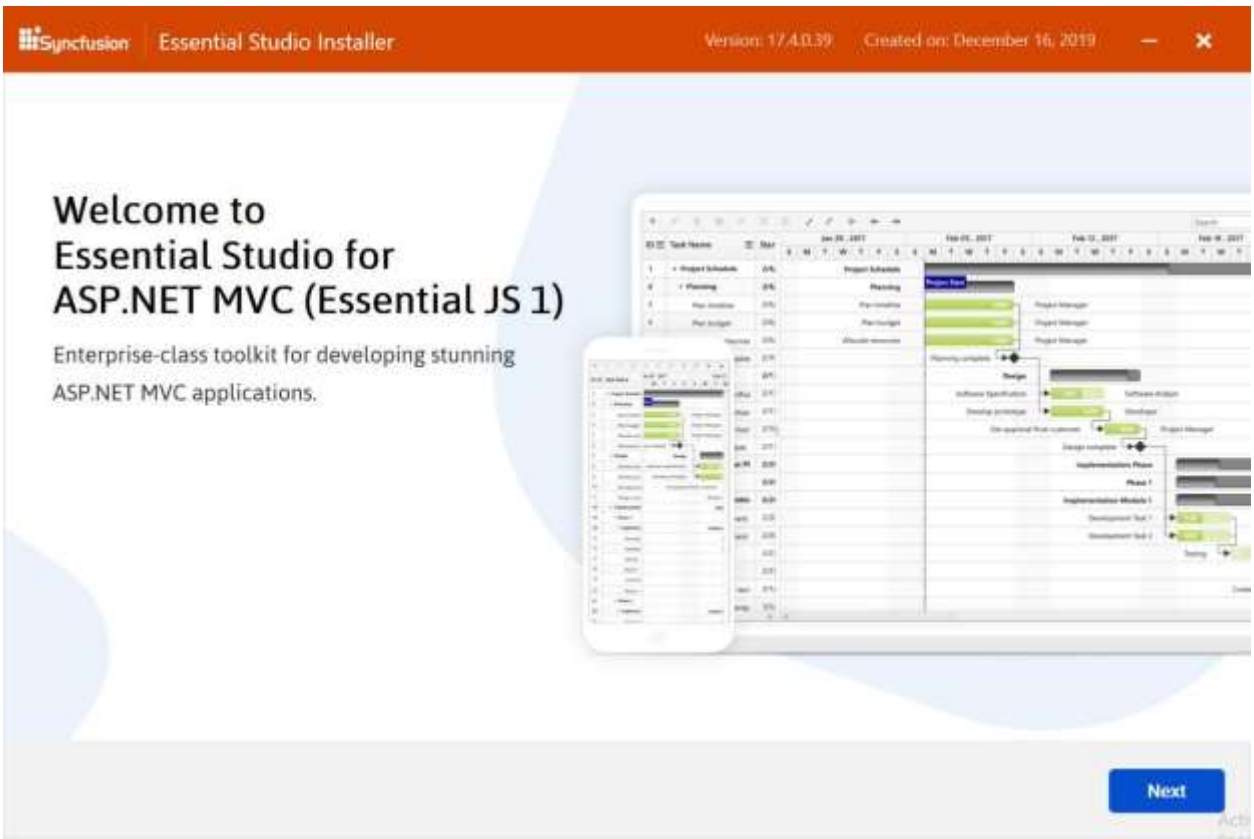
The following procedure illustrates how to uninstall Essential Studio ASP.NET MVC from Web Installer.

1. Double-click the Syncfusion ASP.NET MVC Online Installer file. The installer Wizard opens and extracts the package automatically.

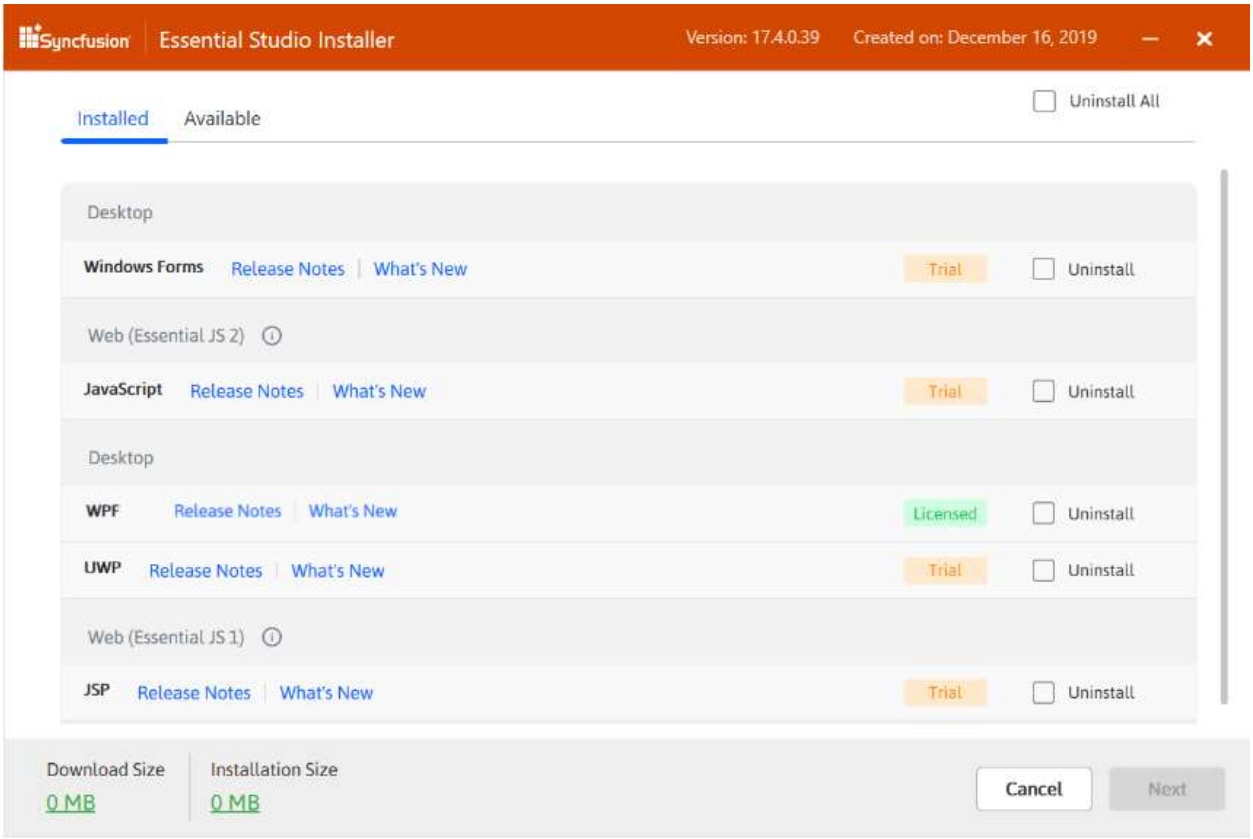
Copyright © 2001 - 2020 Syncfusion Inc.



2. Welcome wizard of the Syncfusion ASP.NET MVC Online Installer will be displayed. Click Next.

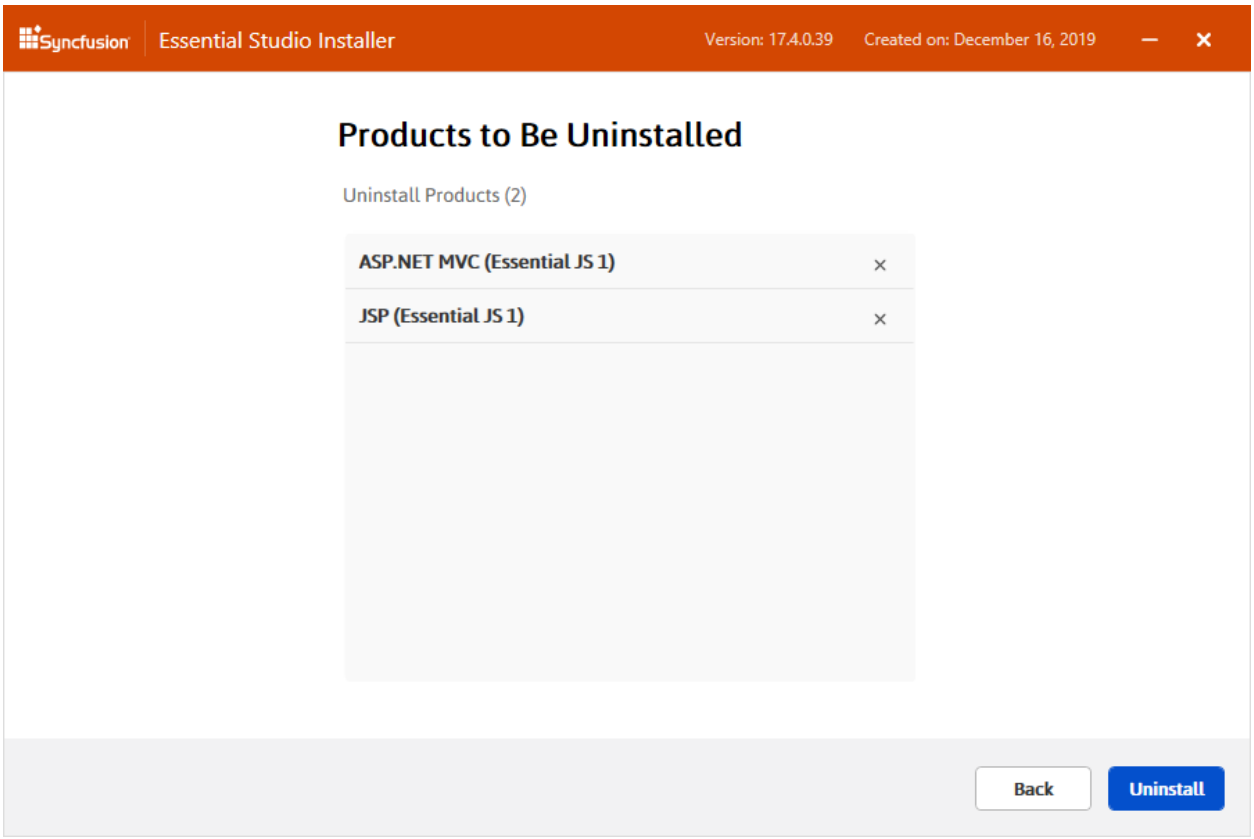


3. Platform Selection wizard will be displayed. Select the platforms to be uninstalled from the **Installed** tab. Select **Uninstall All** checkbox to select all the platforms. Click Next.



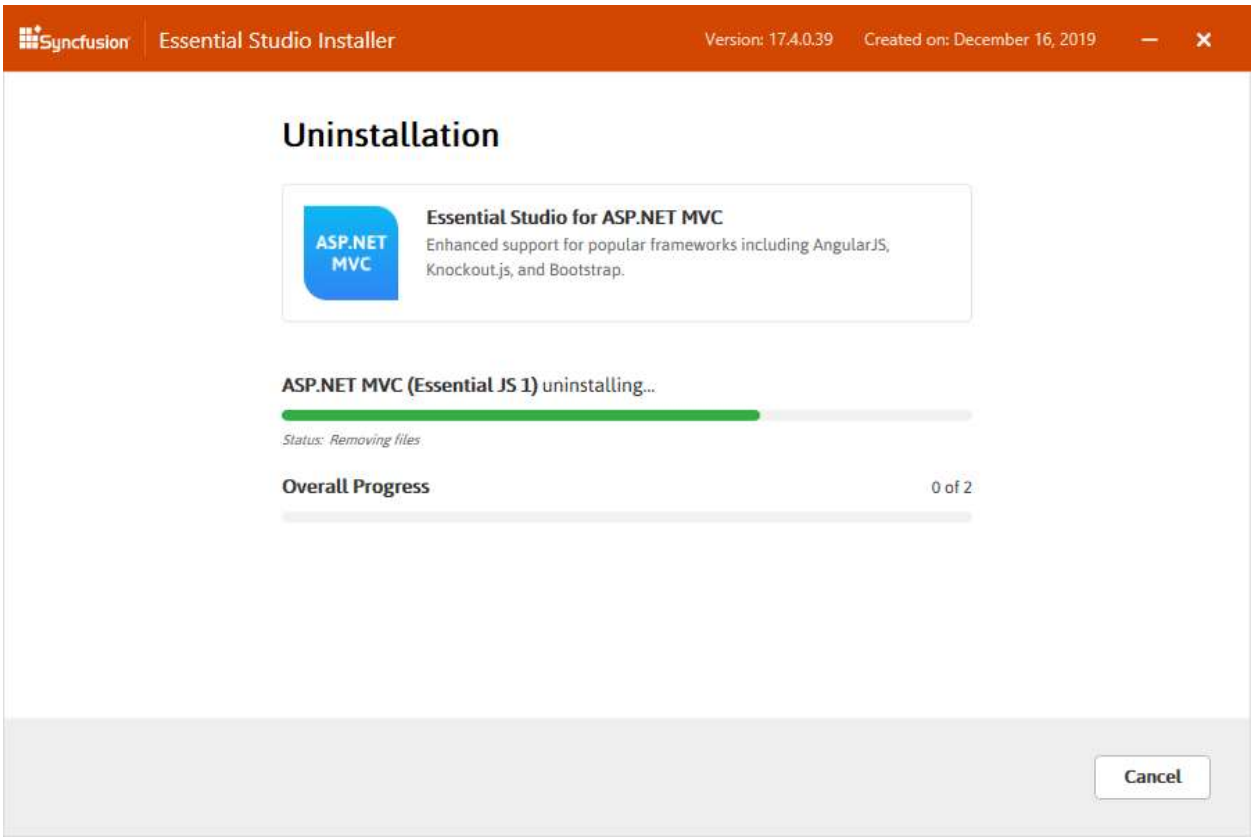
4. Confirmation wizard will be displayed. Here you can view and modify the list of platforms that will be uninstalled. Click Uninstall.

Copyright © 2001 - 2020 Syncfusion Inc.



5. Uninstallation progress will be displayed.

Copyright © 2001 - 2020 Syncfusion Inc.



6. Once the Uninstallation is complete, **Summary** wizard will be displayed. Here you can check the list of platforms which are uninstalled successfully and failed. Click Finish to exit the Summary wizard.

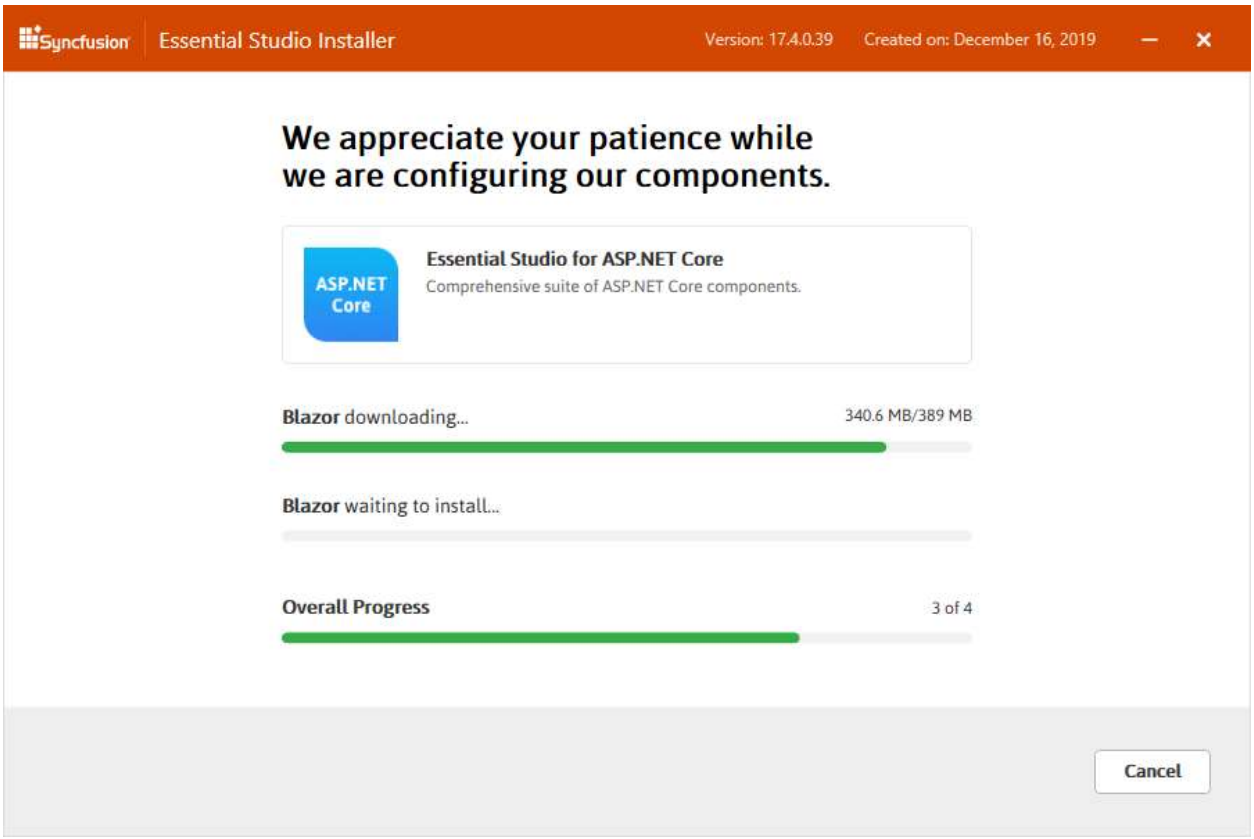
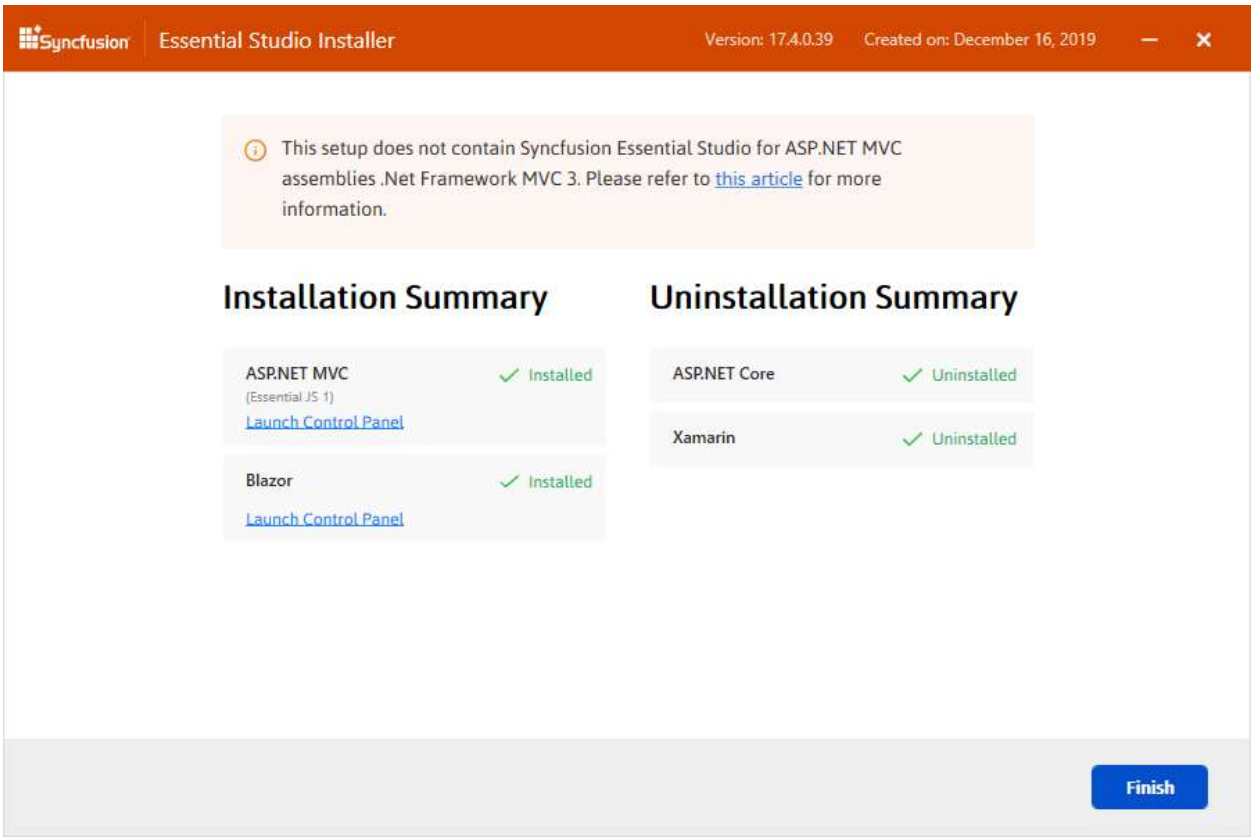
Information: The selected platforms will be installed based on your Syncfusion License (Trial or Licensed).

8. Download, Installation and Uninstallation progress will be displayed.



9. Once the Installation is complete, **Summary** wizard will be displayed. Here you can check the list of platforms which are **installed/uninstalled** successfully and failed. Click Finish to exit the Summary wizard.

Copyright © 2001 - 2020 Syncfusion Inc.



- Click **Launch Control Panel** to open the Syncfusion Control Panel.

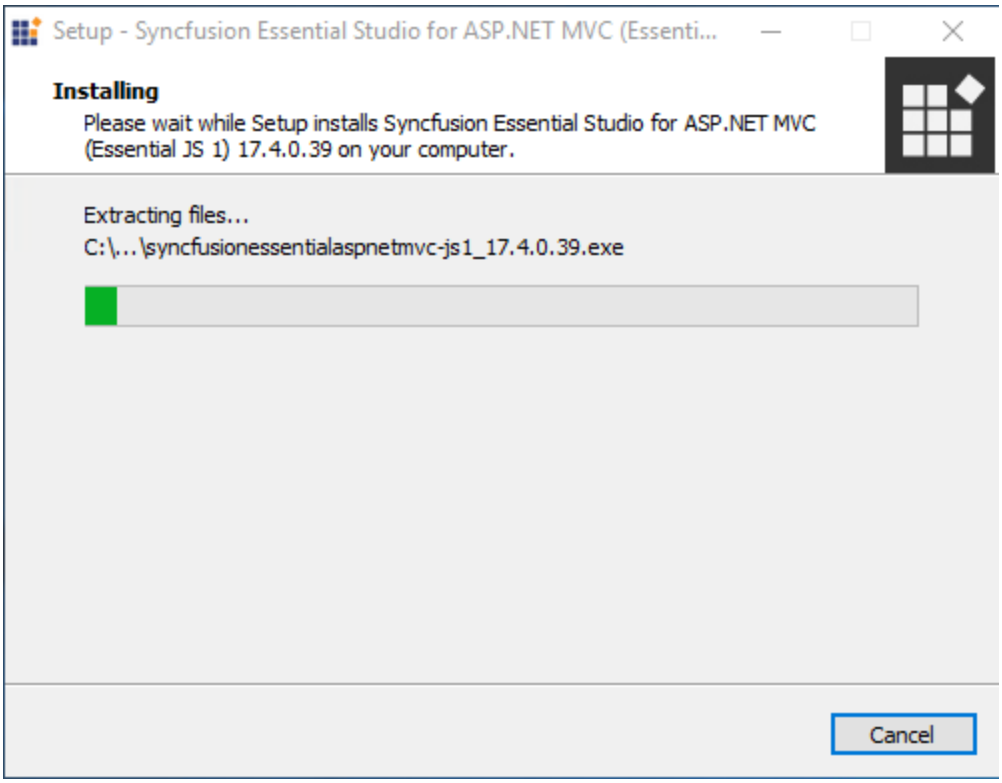
Installation using Offline Installer

Installing with UI

The following procedure illustrates how to install Essential Studio ASP.NET MVC platform.

1. Close all the running Visual Studio instances.
2. Double-click the Syncfusion ASP.NET MVC platform installer file. The installer Wizard opens and extracts the package automatically.

Copyright © 2001 - 2020 Syncfusion Inc.



Note: The installer wizard extracts the syncfusionessentialaspnetmvc_(version).exe dialog, displaying the unzip operation of the package.

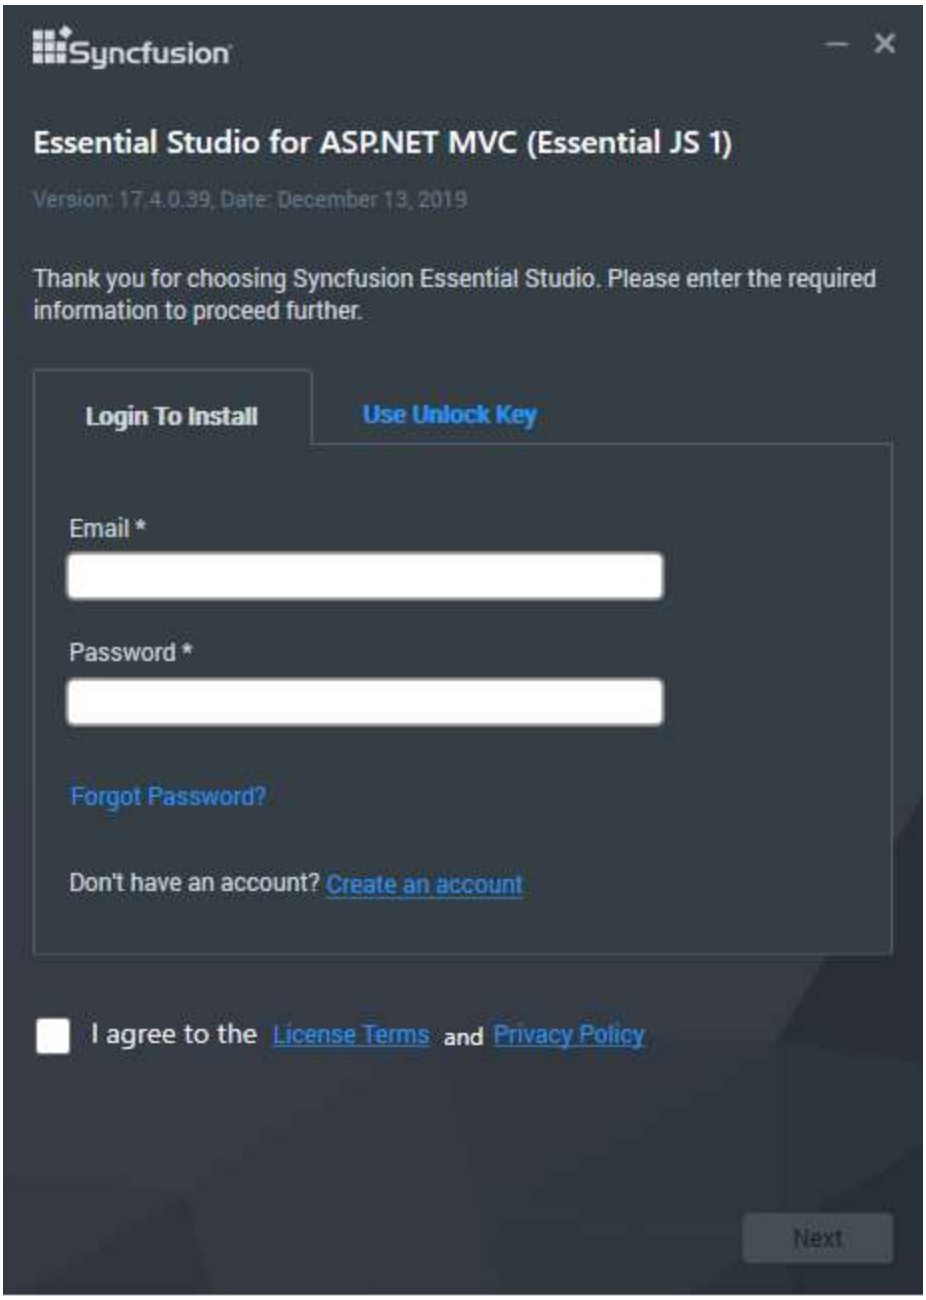
3. You have two options to unlock the Syncfusion installer:

- *Login To Install*
- *Use Unlock Key*

Login To Install

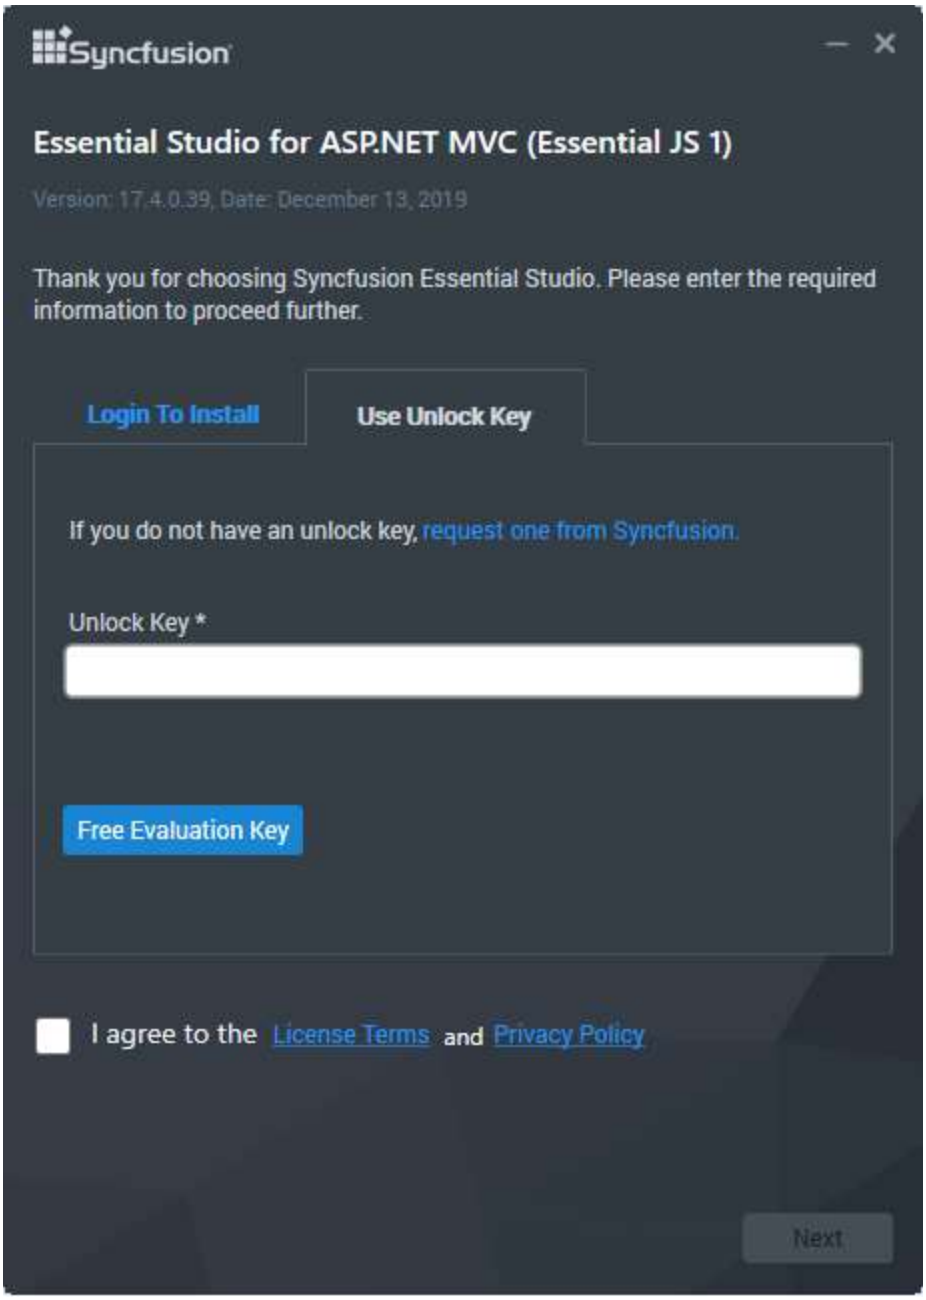
You should enter your Syncfusion Direct-Trac login credentials. If you don't have Syncfusion Direct-Trac login credentials, then you can click on Sign Up to a create new account. Else if you forgot your password, click on Reset Password to create new password. Here Email address and Password is validated and the Platform Selection window opens.

Copyright © 2001 - 2020 Syncfusion Inc.



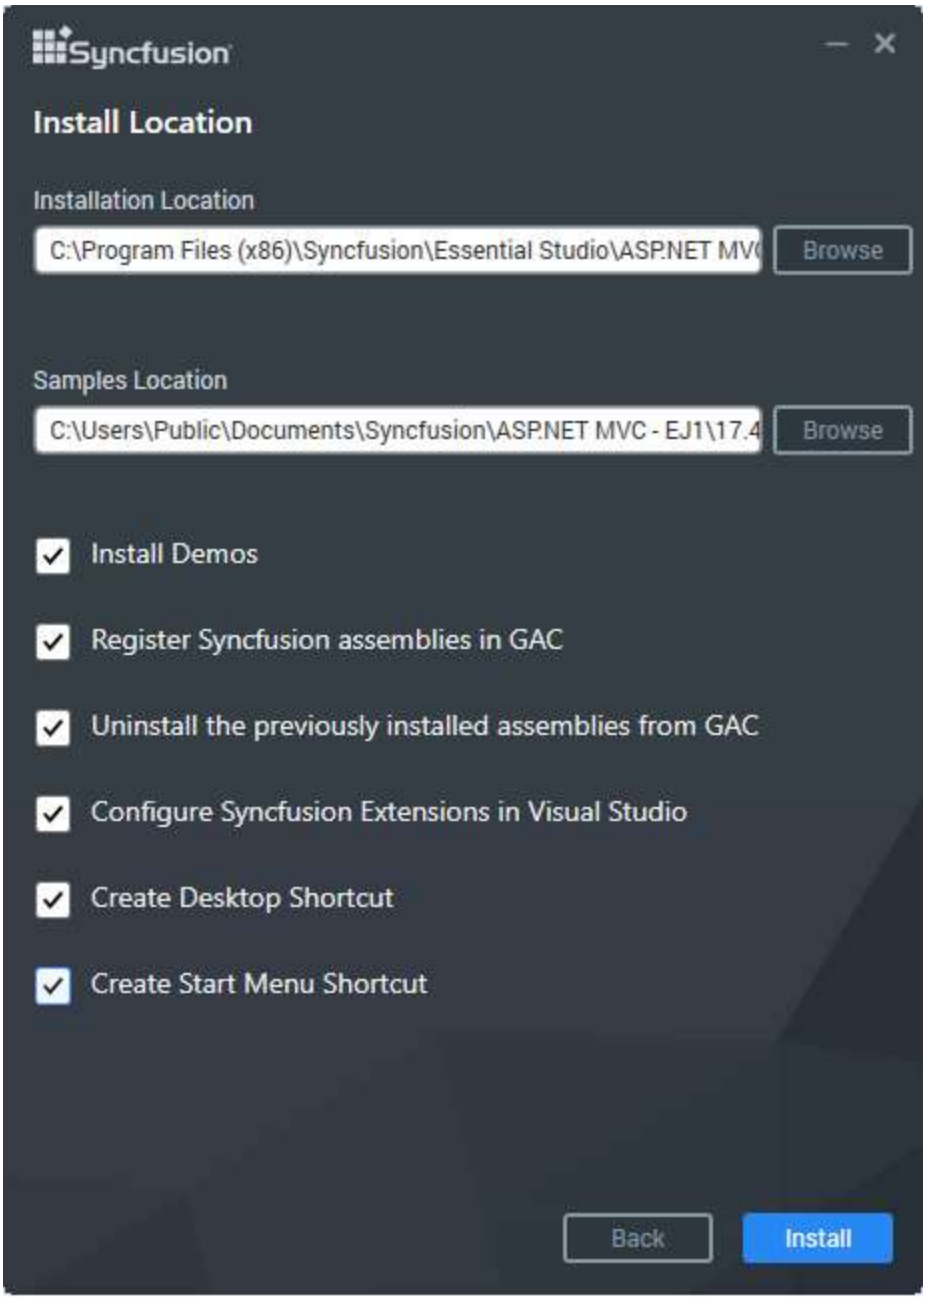
Use Unlock Key

You should use the Syncfusion License/Trial key. Trial key is valid for 30 days and the installer won't accept the expired trial key. Licensed customer can generate key from here.



4. After reading the License Terms and Conditions, check the **I agree to the License Terms and Conditions** check box.

5. Click Next. Select the Installation, Samples Folder and Advanced Options screen opens. To install in the displayed default location, click Install



Note: From the 2018 Volume 2 release, Syncfusion has changed the install and samples location

Default Install location: {ProgramFilesFolder}\Syncfusion\{Platform}\{version}

Default Samples location: C:\Users\Public\Documents\Syncfusion\{platform}\{version}

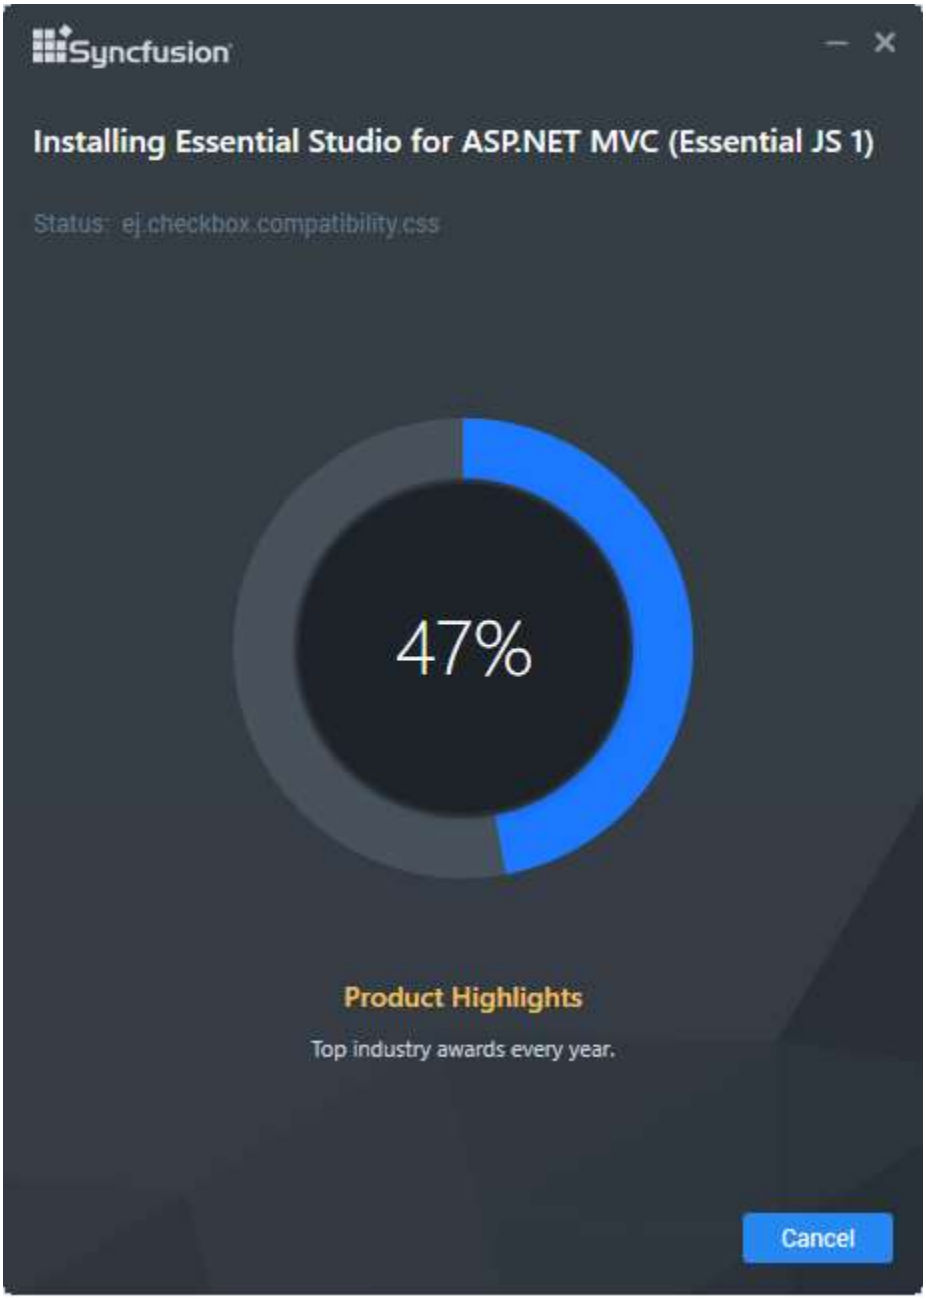
However, you can change the locations by clicking browse button.

- Select the **Install Syncfusion Samples** check box to install Syncfusion samples, or leave the check box clear, when you do not want to install Syncfusion samples.
- Select the **Register Syncfusion Assemblies in GAC** check box to install the latest Syncfusion assemblies in GAC, or clear this check box when you do not want to install the latest assemblies in GAC.

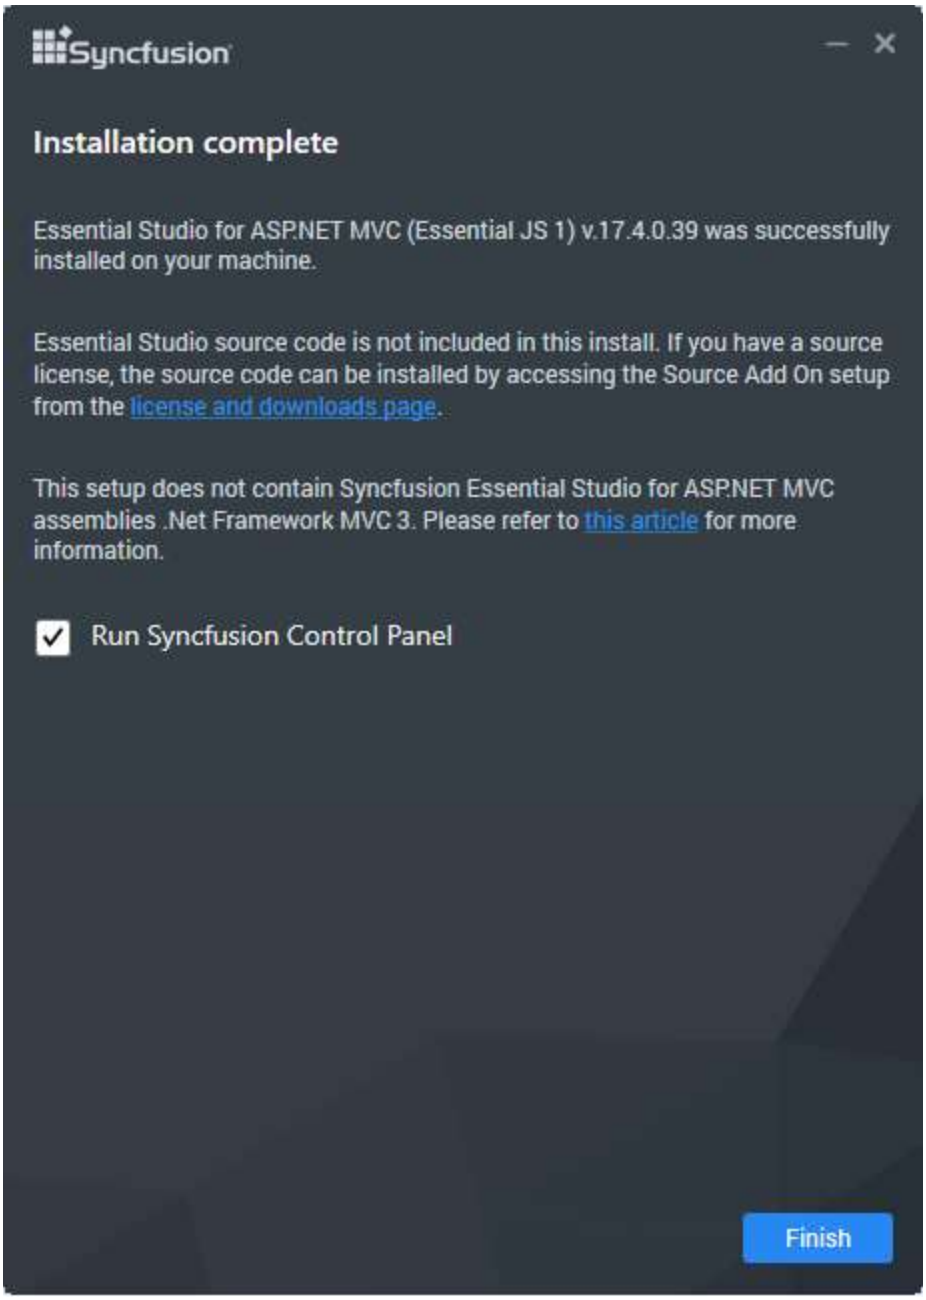
Copyright © 2001 - 2020 Syncfusion Inc.

- Select the **Uninstall the previously installed Syncfusion assemblies from GAC** check box to uninstall the previously installed Syncfusion assemblies from GAC, or clear this check box to maintain the previously installed assemblies.
- Select the **Install Syncfusion Extensions** checkbox to configure the Syncfusion Extensions in Visual Studio or clear this check box when you do not want to configure the Syncfusion Extensions in Visual Studio.

6. Click Install.



7. The Completed screen is displayed once the ASP.NET MVC platform is installed.



8. Select the **Run Syncfusion Control Panel** check box to launch the Syncfusion Control Panel after installing.

9. Click Finish. Syncfusion ASP.NET MVC platform is installed in your system and the Syncfusion Essential Studio Syncfusion Control Panel is launched automatically.

Installing in silent mode

The Syncfusion Essential Studio Platform Installer supports installing/uninstalling through Command Line. The following sections illustrate this ability.

Command Line Installation

Follow the steps below to install through Command Line in Silent mode.

1. Double-click the Syncfusion Essential Studio platform installer file. The installer Wizard opens and extracts the package automatically.
2. The syncfusionessentialaspnetmvc_(version).exe file is extracted into the Temp folder.
3. Run %temp%. The Temp folder will open. The syncfusionessentialaspnetmvc_(version).exe file is available in one of the folders.
4. Copy the extracted syncfusionessentialaspnetmvc_(version).exe file in local drive.
5. Cancel the Wizard.
6. Open the Command Prompt in administrator mode and pass the following arguments.

Arguments: “Installer file path\SyncfusionEssentialStudio(platform)_(version).exe” /Install silent /PIDKEY:“(product unlock key)” [/log “{Log file path}”] [/InstallPath:{Location to install}] [/InstallSamples:{true/false}] [/InstallAssemblies:{true/false}] [/UninstallExistAssemblies:{true/false}] [/InstallToolbox:{true/false}]

Note: [..] – Arguments inside the square brackets are optional.

Example: “D:\Temp\syncfusionessentialaspnetmvc*x.x.x.x.exe” /Install silent /PIDKEY:“product unlock key” /log “C:\Temp\EssentialStudio*Platform.log” /InstallPath:C:\Syncfusion\x.x.x.x /InstallSamples:true /InstallAssemblies:true /UninstallExistAssemblies:true /InstallToolbox:true

7. Essential Studio for ASP.NET MVC (Essential JS1) is installed.

Note: x.x.x.x needs to be replaced with the Essential Studio version and the Product Unlock Key needs to be replaced with the Unlock Key for that version.

Command Line Uninstallation

Syncfusion Essential Studio supports uninstalling through Command Line in Silent mode. The following steps illustrate this.

1. When you do not have the extracted installer (syncfusionessentialaspnetmvc_(version).exe) then follow the steps from 2 to 7.
2. Double-click the Syncfusion Essential Studio platform installer file. The installer Wizard opens and extracts the package automatically.
3. The syncfusionessentialaspnetmvc_(version).exe file is extracted into the Temp folder.
4. Run %temp%. The Temp folder will open. The syncfusionessentialaspnetmvc_(version).exe file is available in one of the folders.
5. Copy the syncfusionessentialaspnetmvc_(version).exe file in local drive.
6. Cancel the Wizard.
7. Open the Command Prompt in administrator mode and pass the following arguments.

Arguments: “Copied installer file path\syncfusionessentialaspnetmvc_(version).exe” /uninstall silent

Example: “D:\Temp\syncfusionessentialaspnetmvc_x.x.x.x.exe" /uninstall silent

8. Essential Studio for ASP.NET MVC (Essential JS1) is uninstalled.

Copyright © 2001 - 2020 Syncfusion Inc.

Note: x.x.x.x needs to be replaced with the Essential Studio version installed in your machine.

Installation FAQ

Refer this topic for more information regarding the issues related to installation.

Upgrade from one version to another version.

You can upgrade to the latest version by downloading and installing the platforms you require from this link. After upgrading to the latest version, instead of upgrading your projects manually, you can use the Syncfusion Project Migration for migrating your projects.

ASP.NET MVC	https://help.syncfusion.com/extension/aspnet-mvc-extension/project-migration

Upgrade from major version to service pack version

Syncfusion provides a new Volume release once in every three months which has exciting new features. For that Volume release, there may be one or two Service Pack releases. The issues in the Volume release will be addressed in the Service Pack releases. You can download and install the latest Service Pack installer here.

It is not required to install the Volume release before installing the Service Pack release. As Volume and Service Packs releases works independently, you can directly install the latest Service Pack which contains major issue fixes.

Upgrade from trial version to license version

To upgrade from trial version, there are two possible solutions.

- Uninstall the trial version and install the fully licensed build from the License & Downloads section of our website.
- Replace the currently used trial license key with a paid license key that can be generated from the License & Downloads section of our website. Refer to this topic for more information regarding registering the license in the application.

Note: License registration is not required if you reference Syncfusion assemblies from Licensed installer. These licensing changes applicable to all evaluators who refers the Syncfusion assemblies from evaluation installer and those who use Syncfusion NuGet packages from nuget.org.

Configuration and Deployment

Configuring Syncfusion Bower Packages

Overview

The Bower is a package manager for the Web. Syncfusion Bower package allows to use the Syncfusion JavaScript Widgets in an efficient way.

Information: Syncfusion JavaScript Bower package is available in public Git Repository and also registered as Syncfusion-JavaScript in the Bower registry.

Bower Installation

To configure the Bower in your machine you need to install node, npm and git. For more information to configure the Bower package, please refer to the official site for bower.

Syncfusion JavaScript Bower package can be configured in the following ways.

1. Using command prompt.
2. Using bower.json file.
3. From local directory.

Using command prompt

Perform the following steps to install the Syncfusion Bower Package via command prompt in your web application.

1. Open your web project's location in a command prompt window.
2. Then run the command Bower install .

view-details	file-resize-four-direction	file-resize-horizontal		

CDN

In case, if the users need to make use of the CDN links instead of the normal above specified scripts and stylesheet references in their application, then have a look at the link here.

Getting Started

Starting with v16.2.0.x, if you reference Syncfusion assemblies from trial setup or from the NuGet feed, you also have to include a license key in your projects. Please refer to this link to know about registering Syncfusion license key in your ASP.NET MVC application to use our components.

What is Html.EJ() ?

EJ refers to Essential JavaScript or Syncfusion Essential JS 1. It is a comprehensive collection of over 80 enterprise-grade HTML5 JavaScript components for building modern web applications. Refer to this JavaScript Package for more information. This is inherited from Syncfusion.EJ Assembly and Syncfusion.JavaScript namespace. Syncfusion.EJ and Syncfusion.EJ.MVC assemblies have to be referred in the project to use this, and these namespaces have to be added in the Web.config file as shown in this KB article.

Getting started with Syncfusion MVC

This section describes how to configure the Syncfusion ASP.NET MVC components into the ASP.NET MVC applications. There are four ways for embedding our controls into ASP.NET application:

1. Through Syncfusion Project Template
2. Through Syncfusion Project Conversion
3. Through Syncfusion NuGet Packages
4. Through Manual Integration into the new/existing Application

The procedures that are followed in manual integration process are entirely automated, when we create an application using Syncfusion Project template.

The similar steps are followed for integrating the Syncfusion controls into MVC 3, MVC 4, MVC 5, and MVC6 applications, the only thing that makes it a little bit different is the reference assemblies version chosen for each of the target MVC application.

Through Syncfusion Project Template

Syncfusion provides the Visual Studio Project Templates for the Syncfusion ASP.NET MVC platform to create a Syncfusion MVC application.

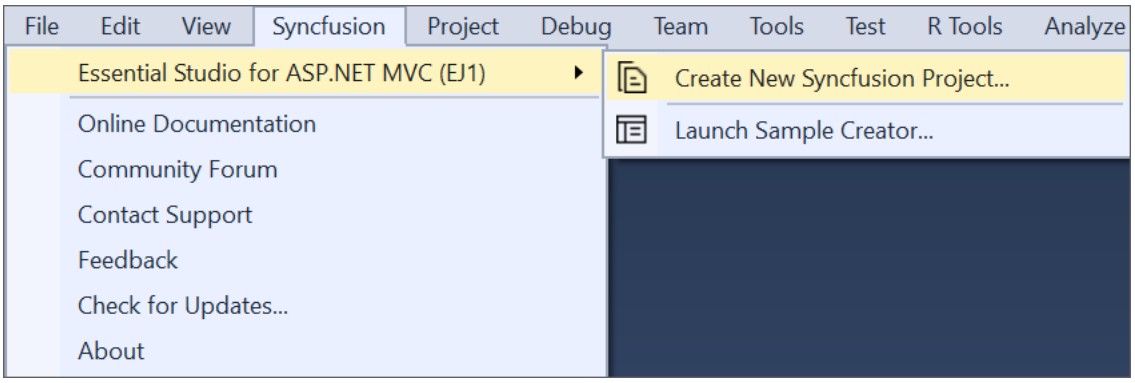
The **Project Configuration Wizard** automates the process of configuring the required Syncfusion assemblies, scripts and their styles within the newly created application. Lets look onto these topics in detail in the following sections.

1. To create a Syncfusion ASP.NET MVC (Essential JS 1) project, follow either one of the options below:

Option 1:

Copyright © 2001 - 2020 Syncfusion Inc.

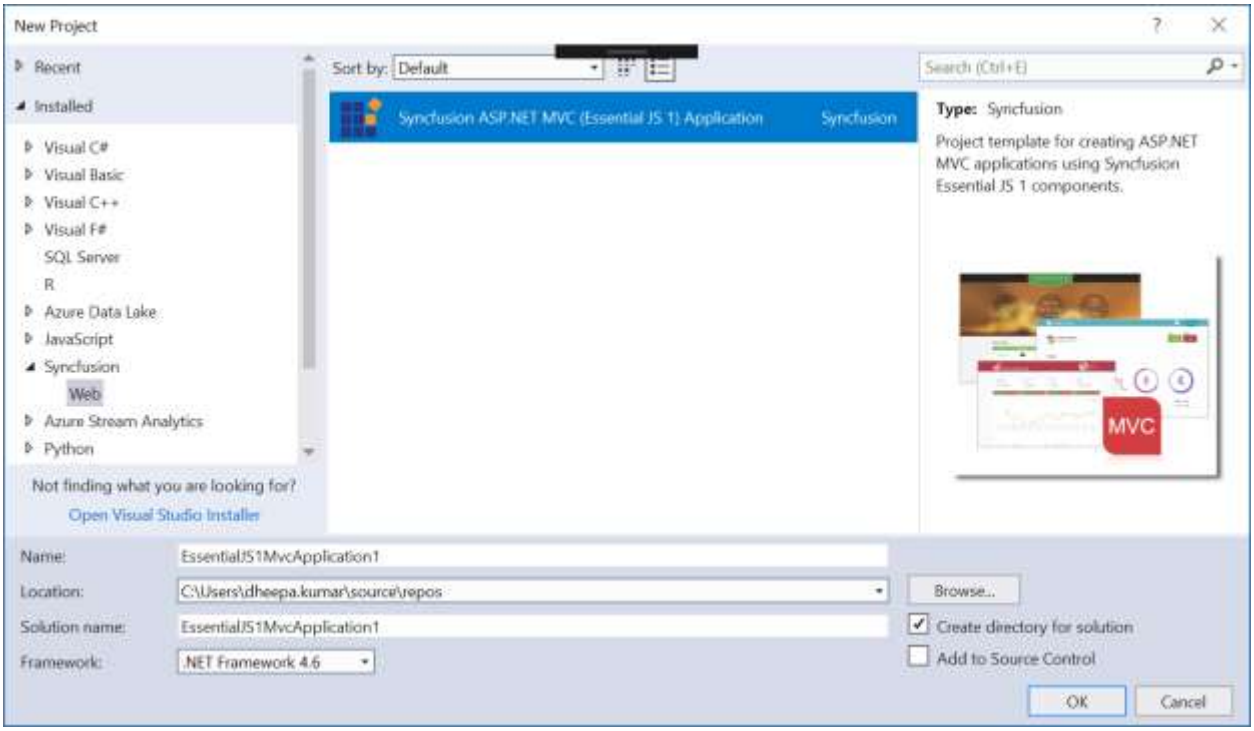
Click **Syncfusion Menu** and choose **Essential Studio for ASP.NET MVC (EJ1) > Create New Syncfusion Project…** in **Visual Studio**.



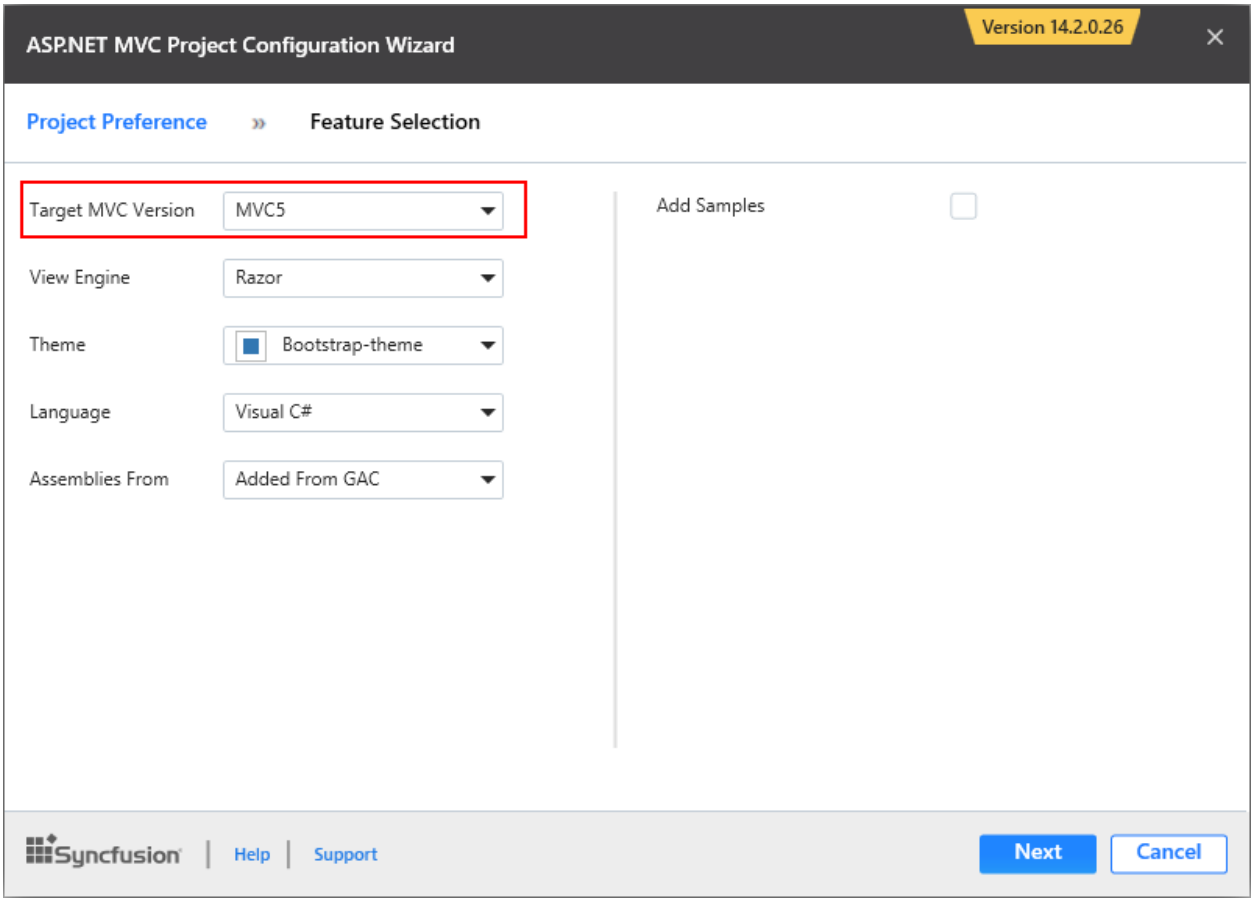
Note: In Visual Studio 2019, Syncfusion menu available under Extension in Visual Studio menu.

Option 2:

Choose **File > New > Project** and navigate to **Syncfusion > Web > Syncfusion ASP.NET MVC (Essential JS 1) Application** in **Visual Studio**.

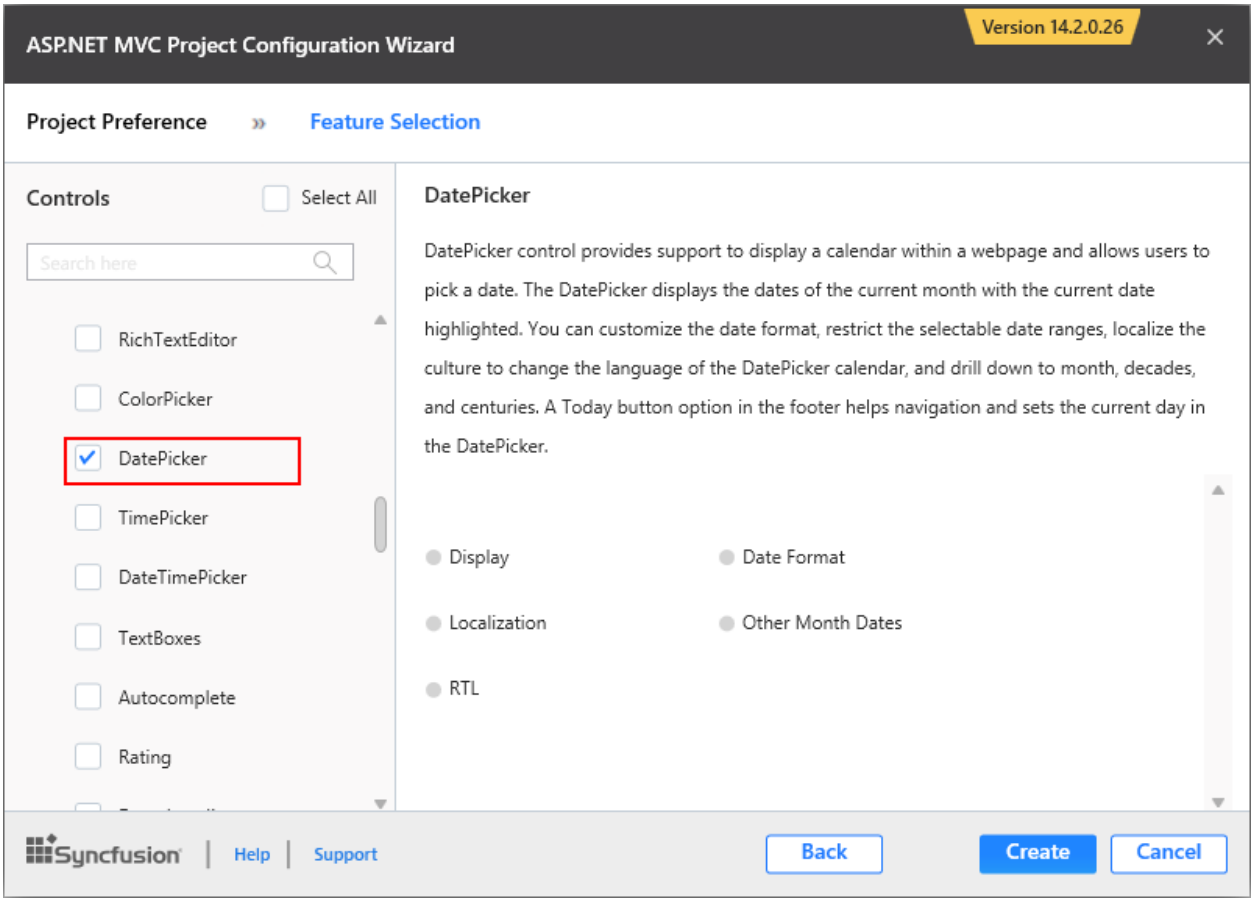


2. Then it opens **Project Configuration Wizard** as shown below. In this Wizard, select **Target MVC Version** as **MVC5** and keep the **other** options as default. Click **Next**.



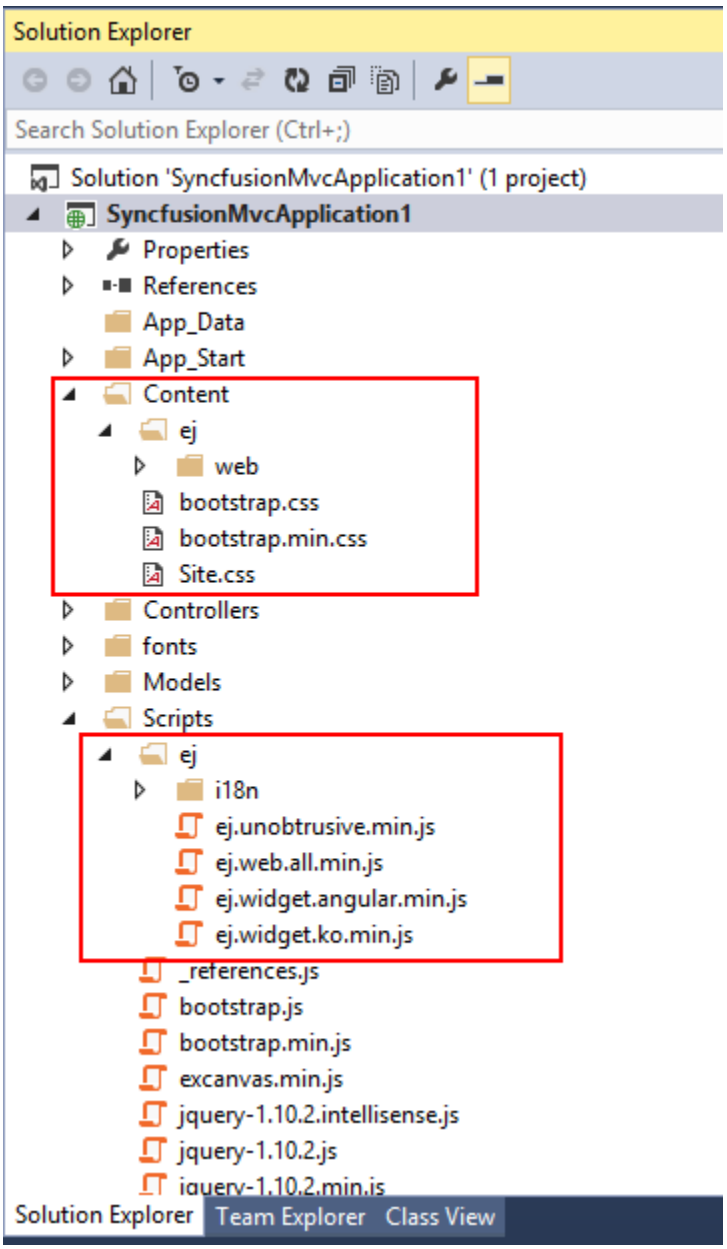
3. Next window will be shown with the list of Syncfusion MVC controls. Choose the required controls and then click **Create**.

Copyright © 2001 - 2020 Syncfusion Inc.

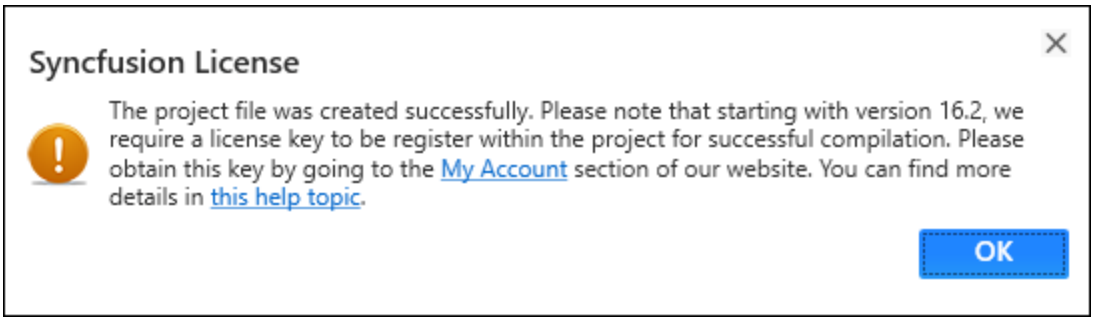


4. Now you can notice the **Syncfusion MVC 5 References**, **Scripts** and **Styles** are configured into Scripts and Content folders. Also it configures the **web.config** and **_Layout.cshtml** files.

Copyright © 2001 - 2020 Syncfusion Inc.



5. Then, Syncfusion licensing registration required message box will be shown as follow, if you are installed the trial setup or NuGet packages since Syncfusion introduced the licensing system from 2018 Volume 2 (v16.2.0.41) Essential Studio release. Please navigate to the help topic which is shown in the licensing message box to generate and register the Syncfusion license key to your project. Refer to this blog post for understanding the licensing changes introduced in Essential Studio.

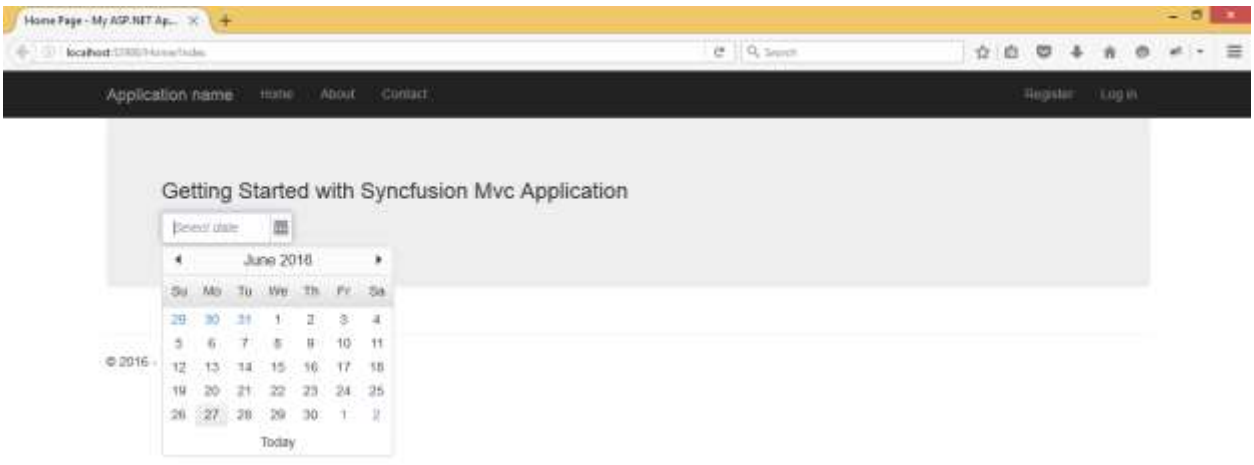


6. Now you can add the control **DatePicker** in the **Index.cshtml** file present within **~/Views/Home** folder.

ASPX-CS

```
@Html.EJ().DatePicker("MyFirstDatepicker")
```

7. Compile and execute the application. You can able to see the following output in the browser.



For more information about Project Configuration Templates and their options details, please visit here

Note: Ensure whether your project has only a single reference to jQuery. Because, multiple reference to jQuery in same project will throws console error and control will not be rendered. For more details refer to the KB here

Through Syncfusion Project Conversion

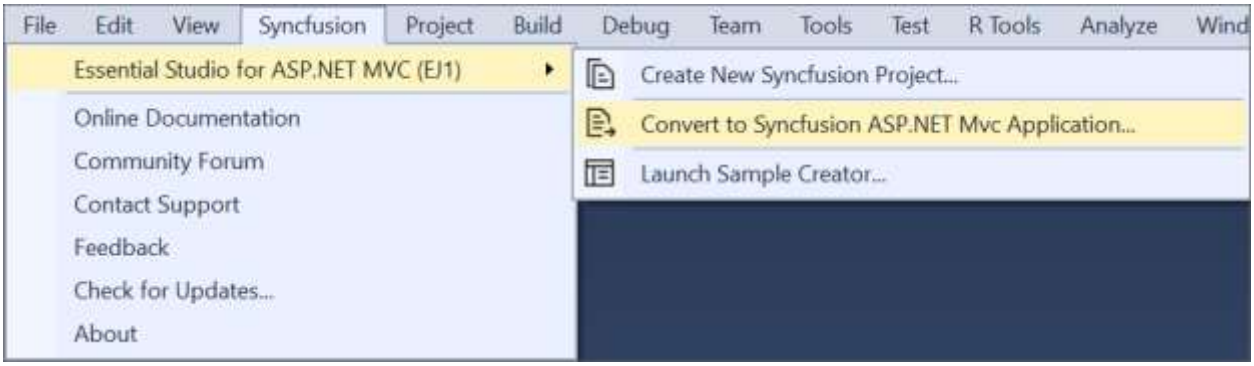
Syncfusion Project Conversion is a Visual Studio add-in that converts an existing ASP.NET MVC Project into a Syncfusion ASP.NET MVC Project by adding the required assemblies and resource files.

The following steps help you use the Syncfusion Project Conversion in the existing ASP.NET MVC (Web) Project.

1. Open an existing Microsoft MVC Project or create a new Microsoft MVC Project.
2. To open Project Conversion Wizard, follow either one of the options below:

Option 1:

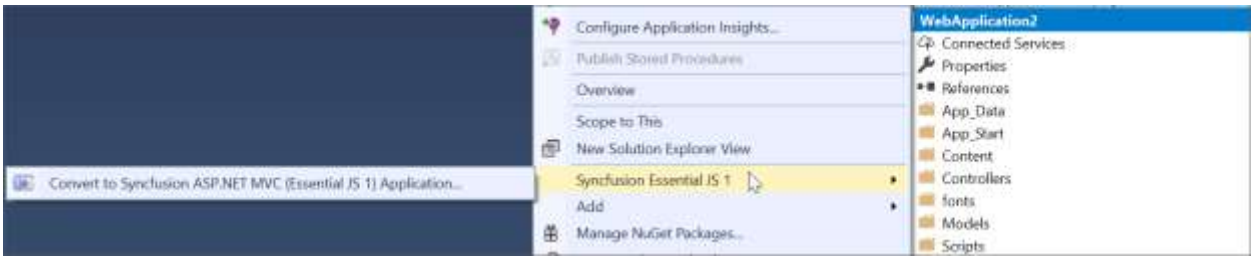
Click **Syncfusion Menu** and choose **Essential Studio for ASP.NET MVC (EJ1) > Convert to Syncfusion ASP.NET MVC Application…** in **Visual Studio**.



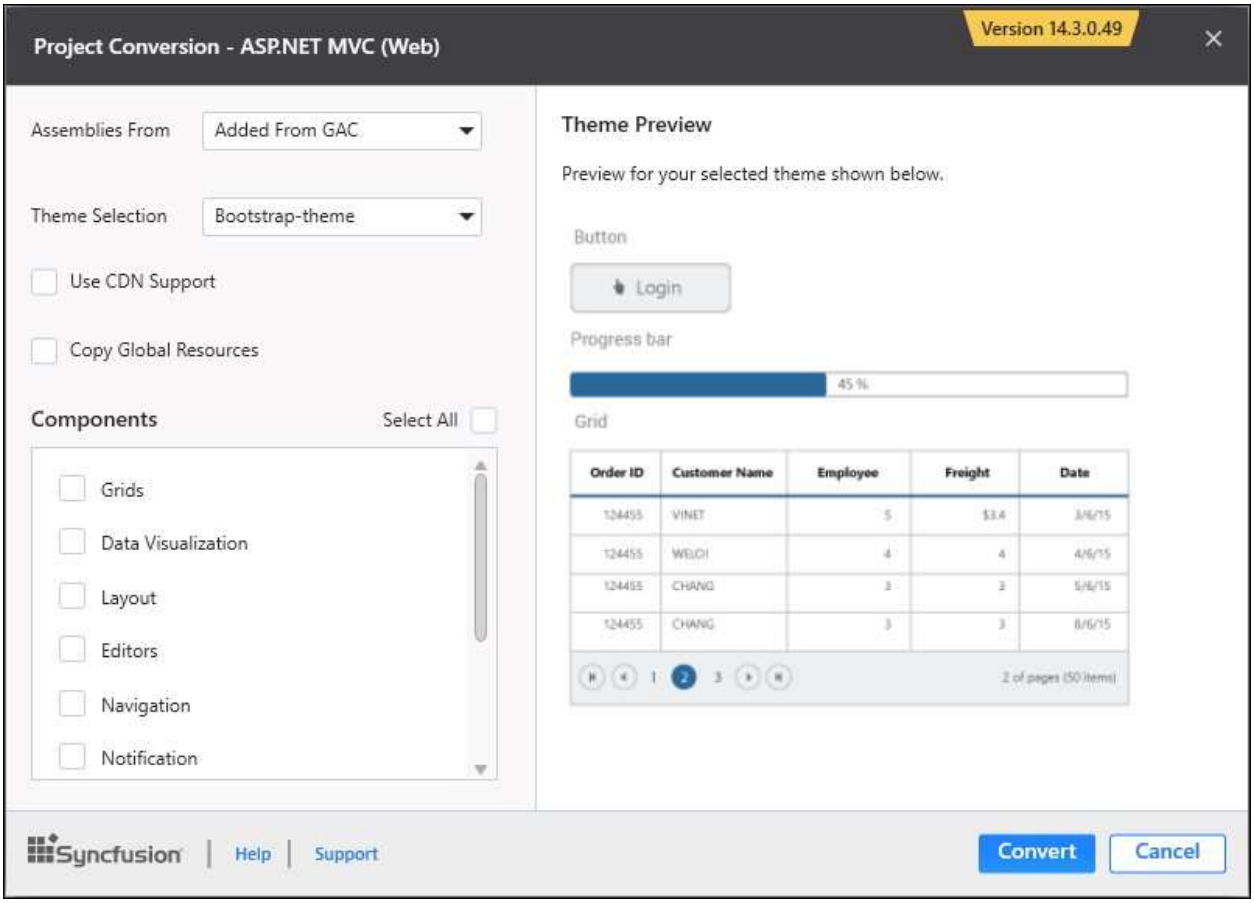
Note: In Visual Studio 2019, Syncfusion menu available under Extension in Visual Studio menu.

Option 2:

Right-click the Project from Solution Explorer, select **Syncfusion Essential JS 1**, and choose **Convert to Syncfusion MVC (Essential JS 1) Application...** Refer to the following screenshot for more information.



3. Project Conversion Wizard opens so that you can configure the project.

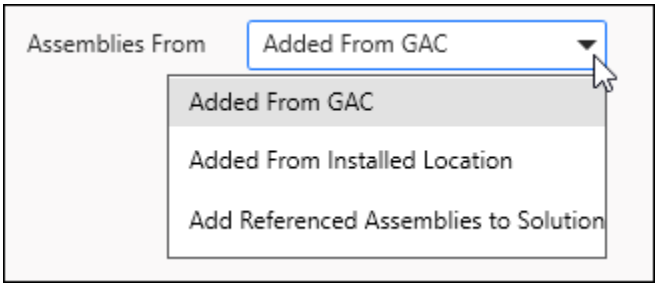


The following configurations are used in the Project Conversion Wizard.

Assemblies From:

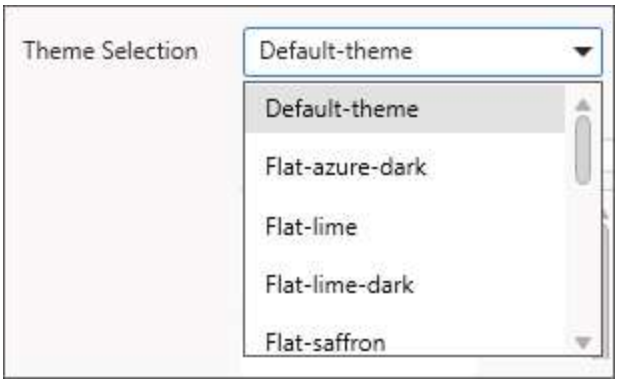
Choose the assembly location:

1. Added From GAC: Refer the assemblies from the Global Assembly Cache
2. Added from Installed Location: Refer the assemblies from the Syncfusion Installed locations.
3. Add Referenced Assemblies to Solution: Copy and refer to the assemblies from project's solution file lib directory.



Choose the Theme:

The master page of project will be updated based on the selected theme. The Theme Preview section shows the controls preview before convert into a Syncfusion project.



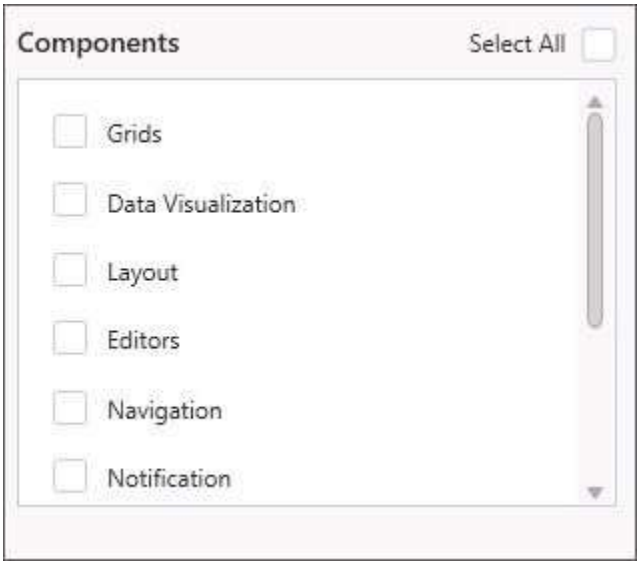
Choose CDN Support:

The master page of the project will be updated based on the required Syncfusion CDN links.

Choose Copy Global Resources:

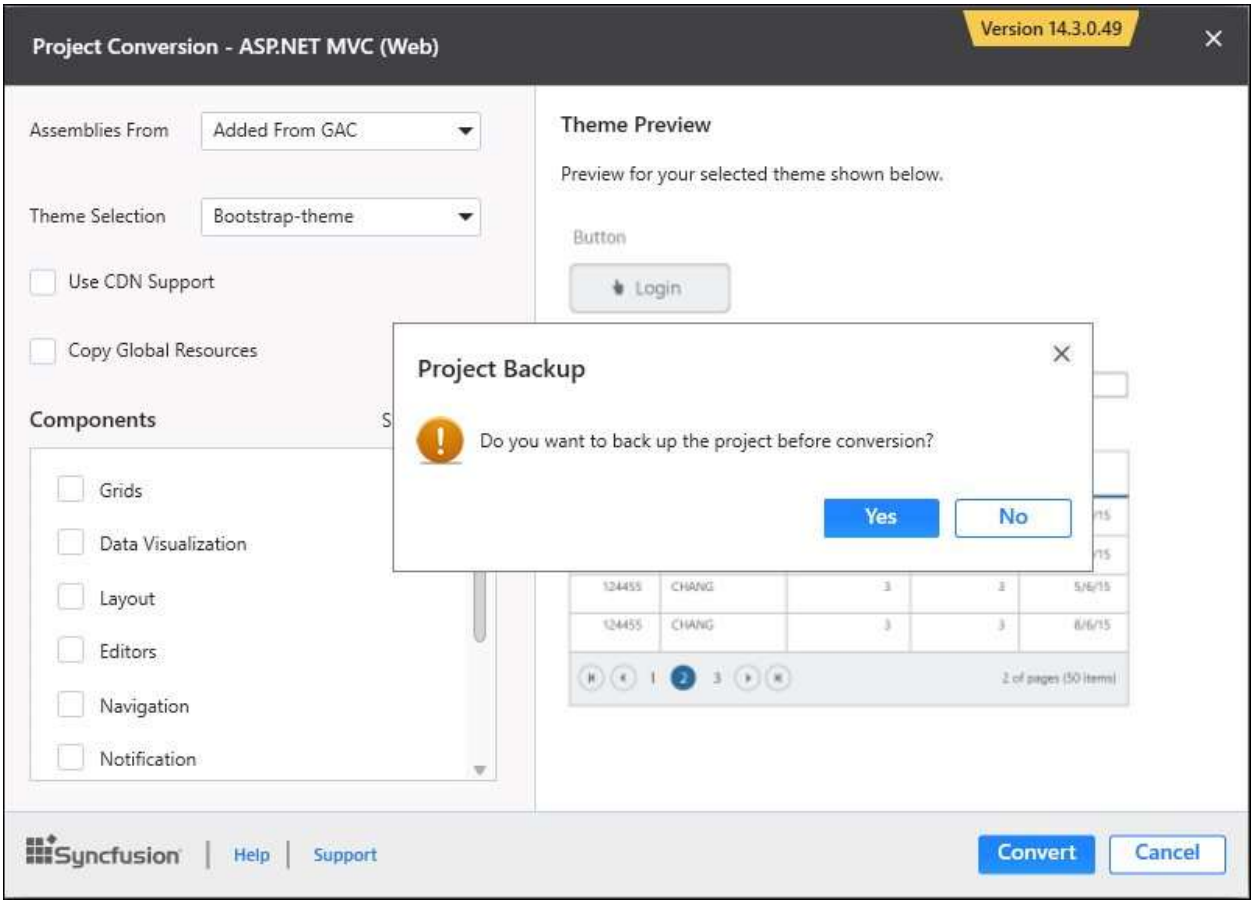
The localization culture files will be shipped into Scripts\ej\i18n directory of the project.

4. Choose the required controls from Components section and Click the **Convert** button to convert it into a Syncfusion Project.

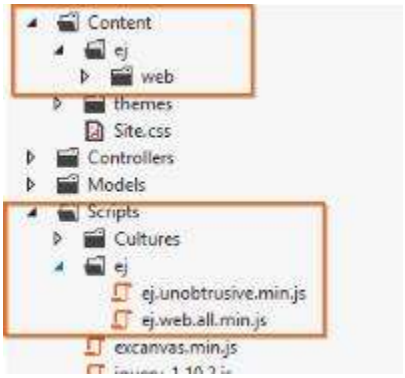


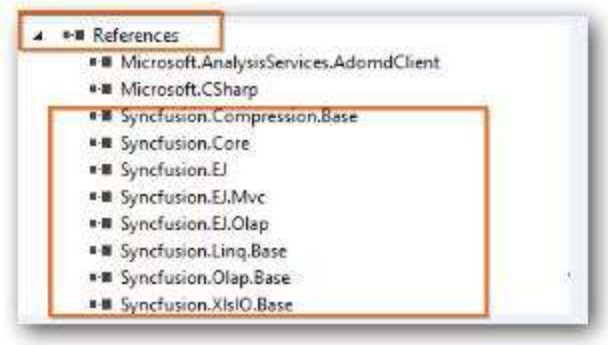
5. The **Project Backup** dialog will be opened. If Yes is clicked, it will backup the current project before converting it to Syncfusion project. If No is clicked it will convert the project to Syncfusion project without backup.

Copyright © 2001 - 2020 Syncfusion Inc.



6. The required Syncfusion Reference Assemblies, Scripts and CSS are included in the MVC Project. Refer to the following screenshots for more information.





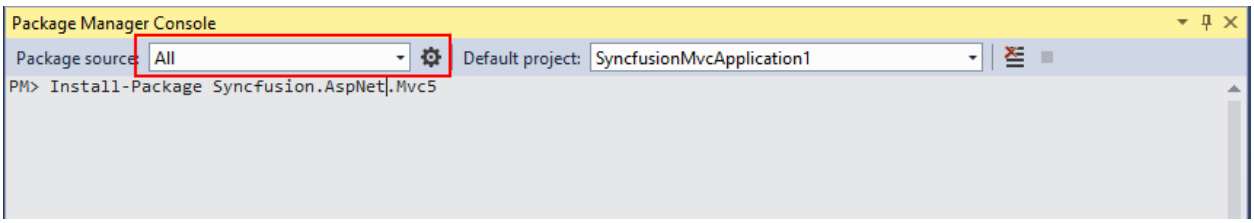
```
<compilation debug="true" targetFramework="4.5">
  <assemblies>
    <add assembly="Syncfusion.EJ.Export, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.Compression.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"
    <add assembly="Syncfusion.EJ, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.EJ.Mvc, Version=14.3500.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.Linq.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.XlsIO.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.EJ.Pivot, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.Olap.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
  </assemblies>
</compilation>
```

Through Syncfusion NuGet Packages

To add our Syncfusion MVC controls into the new ASP.NET MVC5 application by making use of the **Syncfusion Nuget Packages**, refer to the following steps.

1. The steps to download and configure the required **Syncfusion NuGet Packages** in Visual Studio is mentioned here
2. Once Configured the Packages source, search and install the **Syncfusion.AspNet.Mvc5** from **Package Manager console** by using following commands.

PM>Install-Package Syncfusion.AspNet.Mvc5



3. While initial creation, by default, the **Unobtrusive** setting is enabled in your applications web.config file. You need to change its value to **false** in your application as shown in the following:

ASPX-CS

```
<appSettings>
<add key="ClientValidationEnabled" value="true" />
<add key="UnobtrusiveJavaScriptEnabled" value="false" />
</appSettings>
```

4. You need to add the script manager code in the ***Layout.cshtml file present within the ~/Views/Shared folder of your application. Add it before the closing body tag in the*** Layout.cshtml file.

ASPX-CS

```
<body>
@RenderSection("scripts", required: false)
@Html.EJ().ScriptManager()
</body>
```

Note: The main reason for referring the Script manager in *Layout file is that, it can be referred as common by all the View files present within your application. If unobtrusive is set to true in the application, the script manager can be excluded, as the control is initialized using HTML5 attributes. Also for control rendering, you need to include ej.unobtrusive.min.js file along with ej.web.all.min.js in* **Layout.cshtml** page. Refer to the unobtrusive section.

5. Syncfusion specific stylesheets are loaded into the **Content** folder of your application, include the below specified theme reference **(bootstrap-theme/ej.web.all.min.css)** file in the **~/Views/Shared/_Layout.cshtml** file, within the head section as this file contains the default theme styles applied for all the Syncfusion MVC controls.

ASPX-CS

```
<head>
<title>@ViewBag.Title</title>
@Styles.Render("~/Content/ej/web/bootstrap-theme/ej.web.all.min.css")
</head>
```

6. It is mandatory to include the reference to the required JavaScript files in your **_Layout.cshtml**, so as to render the Syncfusion MVC controls properly.

ASPX-CS

```
<head>
<meta charset="utf-8" />
<title>@ViewBag.Title - My ASP.NET MVC Application</title>
@Styles.Render("~/Content/ej/web/bootstrap-theme/ej.web.all.min.css")
</head>
<body>
@Scripts.Render("~/bundles/jquery")
@Scripts.Render("~/bundles/bootstrap")
@Scripts.Render("~/Scripts/jsrender.min.js")
@Scripts.Render("~/Scripts/ej/web/ej.web.all.min.js")
@RenderSection("scripts", required: false)
@Html.EJ().ScriptManager();
</body>
```

The order of the reference to the script files made in the above section should be maintained in the same manner as mentioned above.

Copyright © 2001 - 2020 Syncfusion Inc.

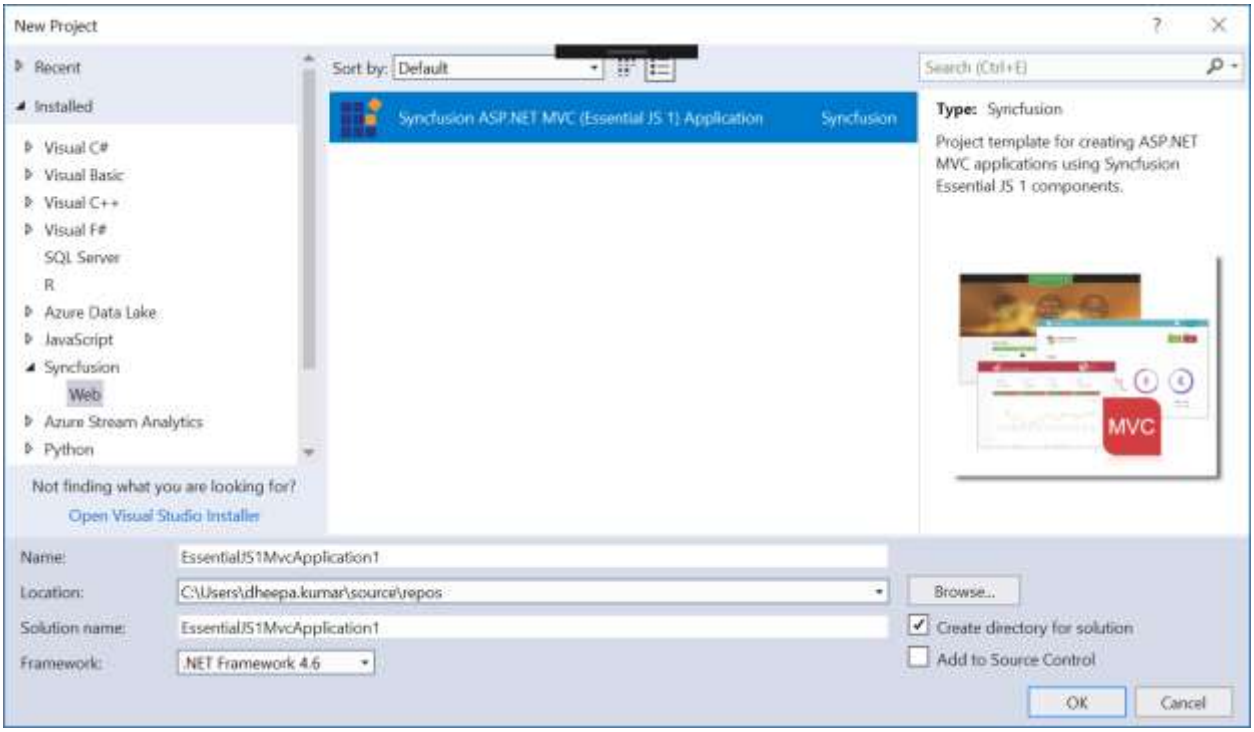
If your application contains duplicate/multiple references to the jQuery files, remove it as the explicit reference to the **jquery-1.10.2.min.js** script file that is added to the application as specified above.

7. Now you can add the control **DatePicker** in the **Index.cshtml** file present within **~/Views/Home** folder.

ASPX-CS

```
@Html.EJ().DatePicker("MyFirstDatepicker")
```

8. Compile and execute the application. You can able to see the below output in the browser.



For more details - View

Manual Integration

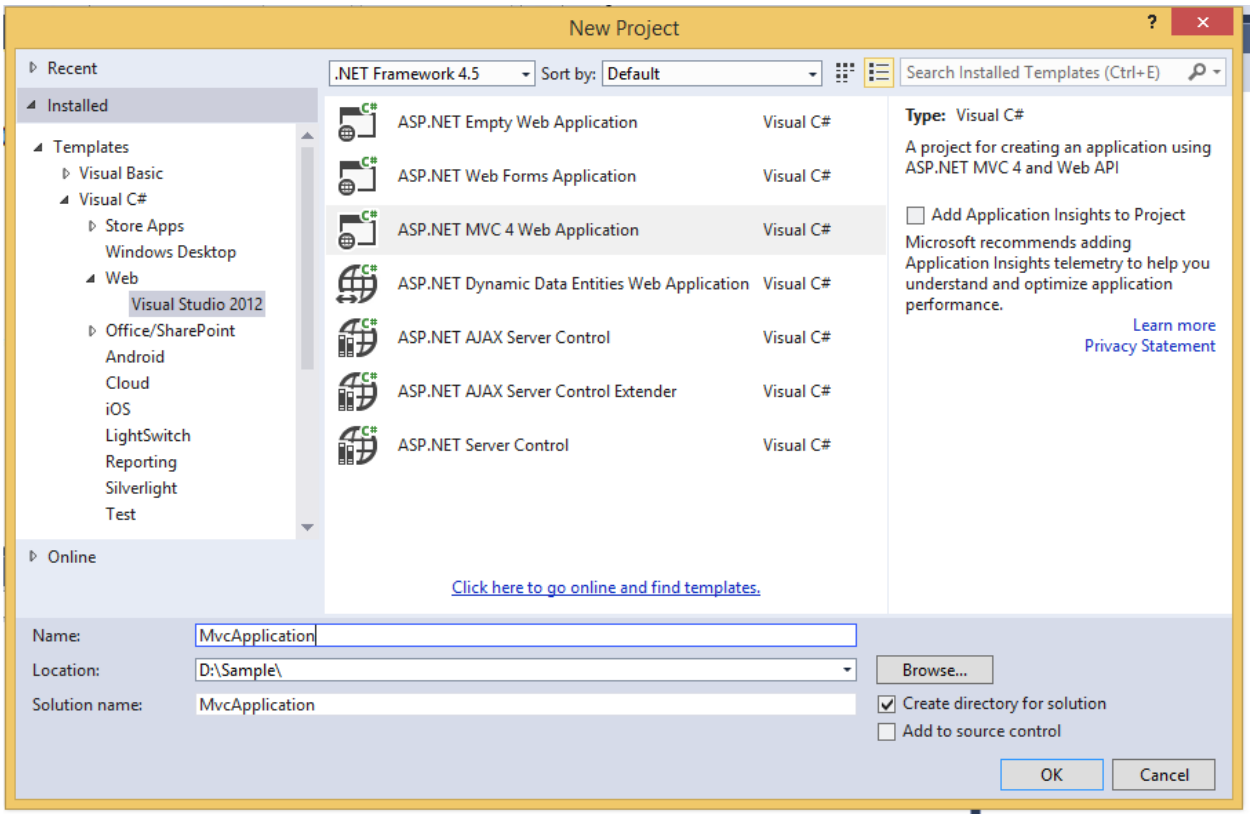
This topic mainly focuses on how to integrate the Syncfusion ASP.NET MVC controls manually into the newly created/existing ASP.NET MVC application. The procedure for making use of any of our ASP.NET MVC controls within the ASP.NET MVC application are explained in the following.

Creation of First ASP.NET MVC Application

Follow the below steps to create a normal ASP.NET MVC application.

1. Start the Visual Studio. Create a new MVC application by selecting File -> New -> Project and save it with a meaningful name as shown in the following.

Copyright © 2001 - 2020 Syncfusion Inc.



2. Build and run your application by pressing Ctrl+F5.

It is time to add some other essential things to your application that allows you to make use of our Syncfusion ASP.NET MVC controls. For that, follow steps explained in the Existing Application section.

For Existing Applications

To add our Syncfusion ASP.NET MVC controls to your existing application, open your existing application and proceed with the following steps.

Adding the required StyleSheets

To render the Syncfusion ASP.NET MVC controls with its unique style and theme, it is necessary to refer to the required CSS files into your application. Copy all the required CSS files into your application from the following location.

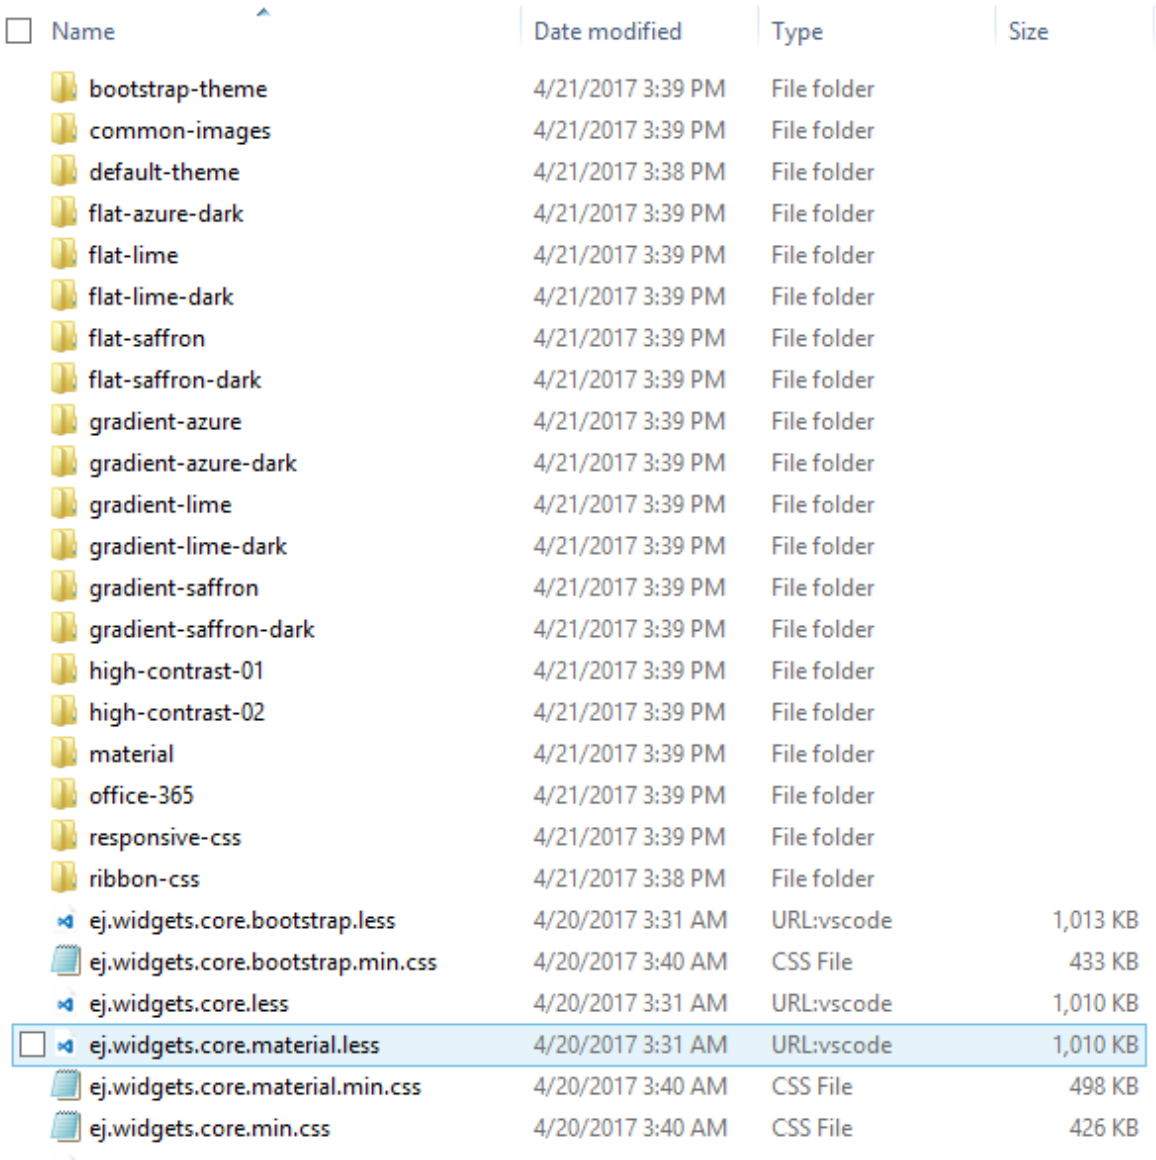
Note: <installed location>\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\css\web

For example, If you have installed the Essential Studio within C:\Program Files (x86), then navigate to the below location,

C:\Program Files (x86)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\css\web

Navigate to above mentioned location, find the files as shown in the below image. Copy entirely and paste it into your root application.

Copyright © 2001 - 2020 Syncfusion Inc.



Name	Date modified	Type	Size
bootstrap-theme	4/21/2017 3:39 PM	File folder

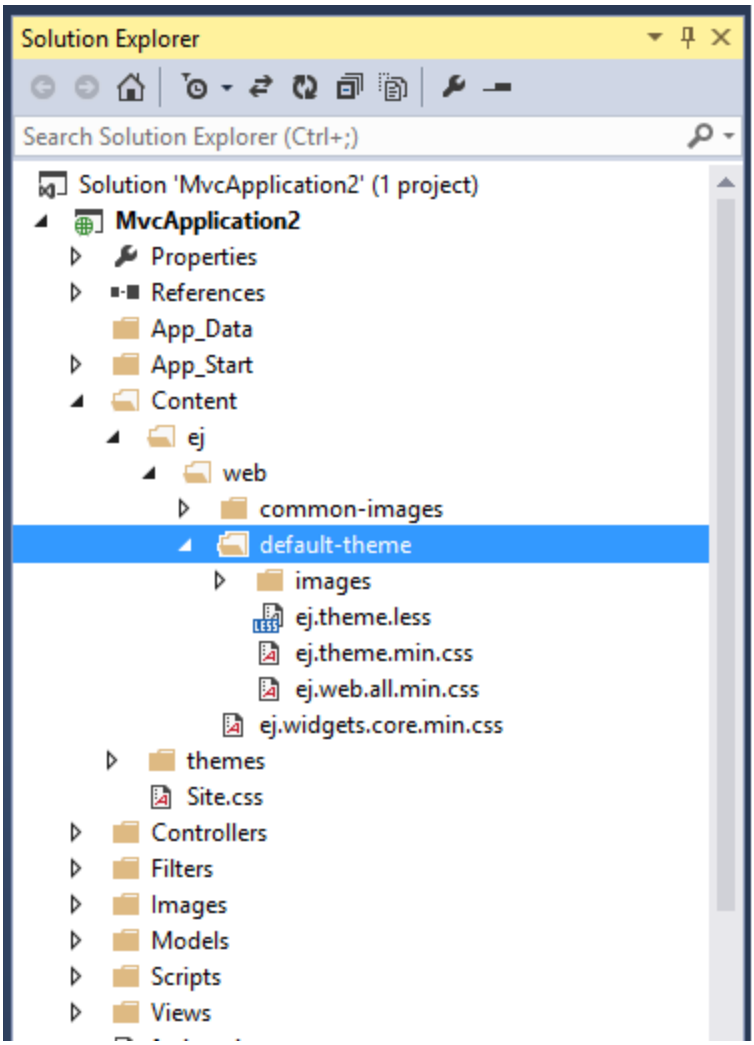
ej.widgets.core.bootstrap.less	4/20/2017 3:31 AM	URL:vscode	1,013 KB
ej.widgets.core.bootstrap.min.css	4/20/2017 3:40 AM	CSS File	433 KB
ej.widgets.core.less	4/20/2017 3:31 AM	URL:vscode	1,010 KB
ej.widgets.core.material.less	4/20/2017 3:31 AM	URL:vscode	1,010 KB
ej.widgets.core.material.min.css	4/20/2017 3:40 AM	CSS File	498 KB
ej.widgets.core.min.css	4/20/2017 3:40 AM	CSS File	426 KB

Before pasting it into your application, create a folder structure with names ej/web within the Content folder of your application and place all the copied files into it as shown in the following.

Copyright © 2001 - 2020 Syncfusion Inc.



Solution Explorer - Project with CSS files copied into the Content folder

Note: The common-images folder is needed to be copied into your application mandatorily, as it includes all the common font icons and other images required for the control to render.

Once the CSS files are added in your application, include the reference to "ej.web.all.min.css" file in the _Layout.cshtml page, within the head section.

HTML

```
<link href="~/Content/ej/web/default-theme/ej.web.all.min.css"
rel="stylesheet" />
```

Adding the required JavaScript files

Adding the required JavaScript files into your application plays an important role, without that the Syncfusion controls cannot be created. It requires the following mandatory common script files.

- jquery.min.js (1.7.1 and later versions)
- jsrender.min.js

Copyright © 2001 - 2020 Syncfusion Inc.

Note: jQuery-2.1.4, jQuery-3.0.0 support has been given from ejVersion 13.2.0.29, 14.3.0.49 onwards respectively.

- ej.globalize.min.js library avails as built-in within ej.web.all.min.js file, therefore it is not necessary to externally refer it in your application (applicable for version 13.4.0.53 and higher). For version lower than 13.4.0.53, refer jQuery.globalize.min.js along with ej.web.all.min.js

Apart from the above common scripts, it is also necessary to refer the ej.web.all.min.js file in your application that plays a major role in control creation.

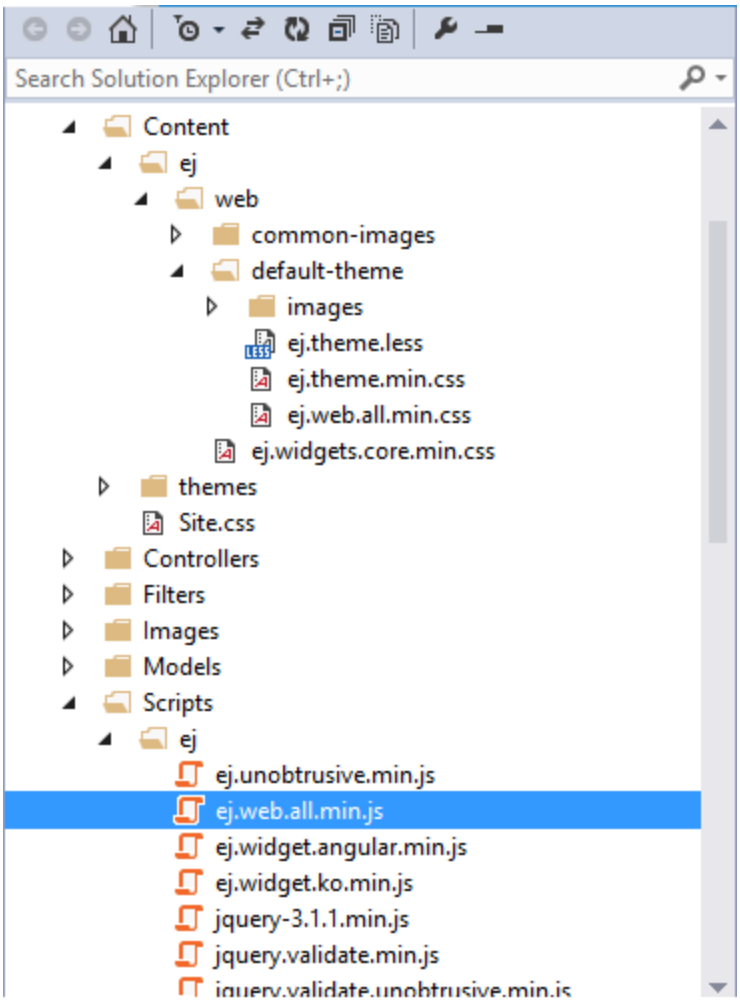
The dependencies are available in the following locations of your machine. Please copy these files from location given.

Files	Location
jquery-1.10.2.min.js jsrender.min.js	<Syncfusion Installed Location>\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\external
ej.web.all.min.js	<Syncfusion Installed Location>\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\web

Note: Example for "Syncfusion Installed location" is "C:\Program Files (x86)\Syncfusion"

Now, create a folder named ej, under the Scripts folder of your application and place the copied files ej.web.all.min.js into it as shown in the following.

Copyright © 2001 - 2020 Syncfusion Inc.



Solution Explorer - Script files copied into the Scripts folder of the project

Once the scripts are added in your application, now it is necessary to include the reference to it in your application. This should be done within the _Layout.cshtml page, as we did previously for CSS files.

Add the following script references in the _Layout.cshtml file within the head section.

HTML

```
<link href="Content/ej/web/default-theme/ej.web.all.min.css"
rel="stylesheet" />
<script src='<%= Page.ResolveClientUrl("~/Scripts/jquery-1.10.2.min.js")%>'
type="text/javascript"></script>
<script src='<%= Page.ResolveClientUrl("~/Scripts/jsrender.min.js")%>'
type="text/javascript"></script>
<script src='<%= Page.ResolveClientUrl("~/Scripts/ej/ej.web.all.min.js")%>'
type="text/javascript"></script>
```

While initial creation, by default, the **Unobtrusive** setting is enabled in your applications web.config file. You need to change its value to **false** in your application as shown in the following.

HTML

```
<appSettings>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<add key="ClientValidationEnabled" value="true" />
<add key="UnobtrusiveJavaScriptEnabled" value="false" />
</appSettings>
```

You need to add the script manager code in the ***Layout.cshtml file present within the ~/Views/Shared folder of your application. Add it before the closing body tag in the*** Layout.cshtml file.

HTML

```
<body>
@RenderSection("scripts", required: false)
@Html.EJ().ScriptManager()
</body>
```

Note: The main reason for referring the Script manager in *Layout file is that, it can be referred as common by all the View files present within your application. If unobtrusive is set to true in the application, the script manager can be excluded, as the control is initialized using HTML5 attributes. Also for control rendering, you need to include ej.unobtrusive.min.js file along with ej.web.all.min.js in* **Layout.cshtml** page. Refer to the unobtrusive section.

CDN Link reference

If you want to refer the CDN links instead of the direct script and CSS references in your application, you need to make use of the following references in the _Layout.cshtml page.

HTML

```
<head>
<meta charset="utf-8" />
<title><%: Page.Title %> - My ASP.NET Application</title>
<link href="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/default-theme/ej.web.all.min.css" rel="stylesheet" />
<script src="http://cdn.syncfusion.com/js/assets/external/jquery-
1.10.2.min.js"></script>
<script
src="http://cdn.syncfusion.com/js/assets/external/jquery.easing.1.3.min.js">
</script>
<script
src="http://cdn.syncfusion.com/js/assets/external/jquery.globalize.min.js"><
/script>
<script
src="http://cdn.syncfusion.com/js/assets/external/jsrender.min.js"></script>
<script src="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/ej.web.all.min.js"></script>
</head>
```

Assembly Reference

Refer the following assemblies in your newly created ASP.NET MVC application that allows you to use any of the Syncfusion ASP.NET MVC controls within it.

- Syncfusion.EJ
- Syncfusion.EJ.MVC

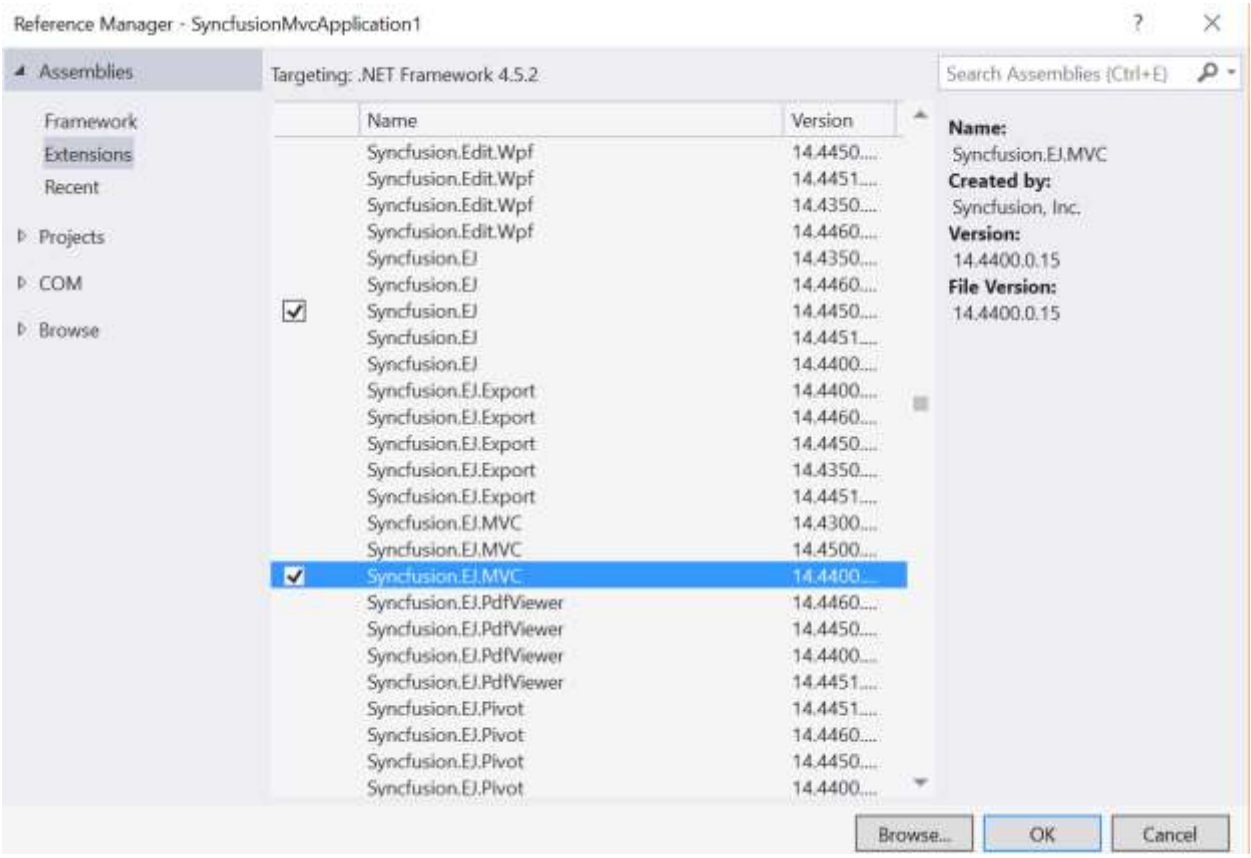
Copyright © 2001 - 2020 Syncfusion Inc.

The reference to the Syncfusion assemblies can be added to your application in either of the following ways.

- Referring from GAC - Referring from the installed location

Referring from GAC

1. Once you have installed the Essential Studio package in your system, the Syncfusion assemblies are automatically registered in the GAC. You can easily add the reference assemblies to your project by choosing Add Reference option. 2. Now the Reference Manager pop-up will appear on the screen. In that pop-up, select the required assemblies from the Extensions tab as below, by choosing the appropriate versions (13.1450.0.21). The version to be chosen for the reference assemblies is based on the Framework used in the application.



Reference Manager Pop-up

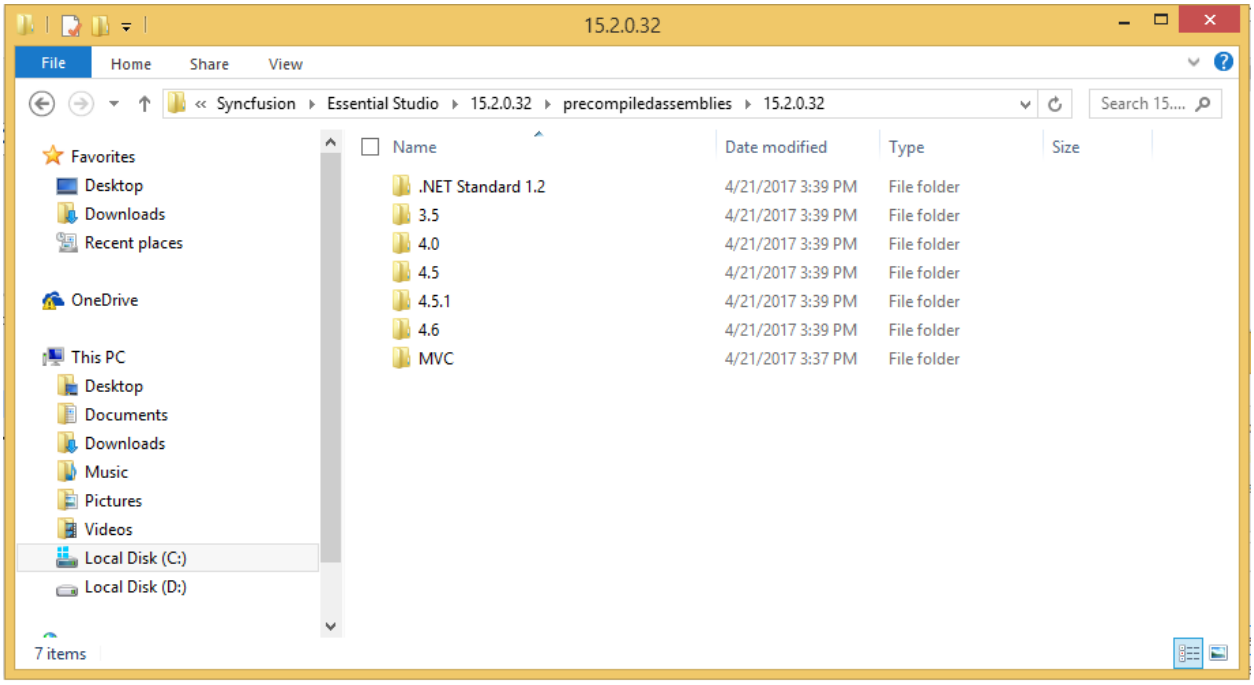
Referring from the installed location

1. Add the reference assemblies to your project by choosing Add Reference option, 2. Now the Reference Manager pop-up will appear on the screen. Select the Browse tab in it and navigate to the installed location of the Syncfusion Essential Studio package in your system. (As depicted in the below image.)

Note: <installed location>\Syncfusion\Essential Studio\{{ site.releaseversion }}\precompiledassemblies\14.4.0.15

For example, If you have installed the Essential Studio package within C:\Program Files (x86), then navigate to the following location:

C:\Program Files (x86)\Syncfusion\Essential Studio\{{ site.releaseversion }}\precompiledassemblies\14.4.0.15



Reference Manager Pop-up with Browse button clicked

Note: In the above image, the folders 3.5, 4.0, 4.5, 4.5.1 denotes the .NET Framework version. Based on the Framework version used in your application, you can choose assemblies from the appropriate folders. The Syncfusion.EJ.MVC and other core assemblies like Syncfusion.Core, Syncfusion.EJ are available within these folders.

3. Add the Syncfusion.EJ, Syncfusion.EJ.MVC, and Syncfusion.Core assemblies to your application from the following specified location.

Note: <installed location>\Syncfusion\Essential Studio\{{ site.releaseversion }}\precompiledassemblies\{{ site.releaseversion }}\4.5

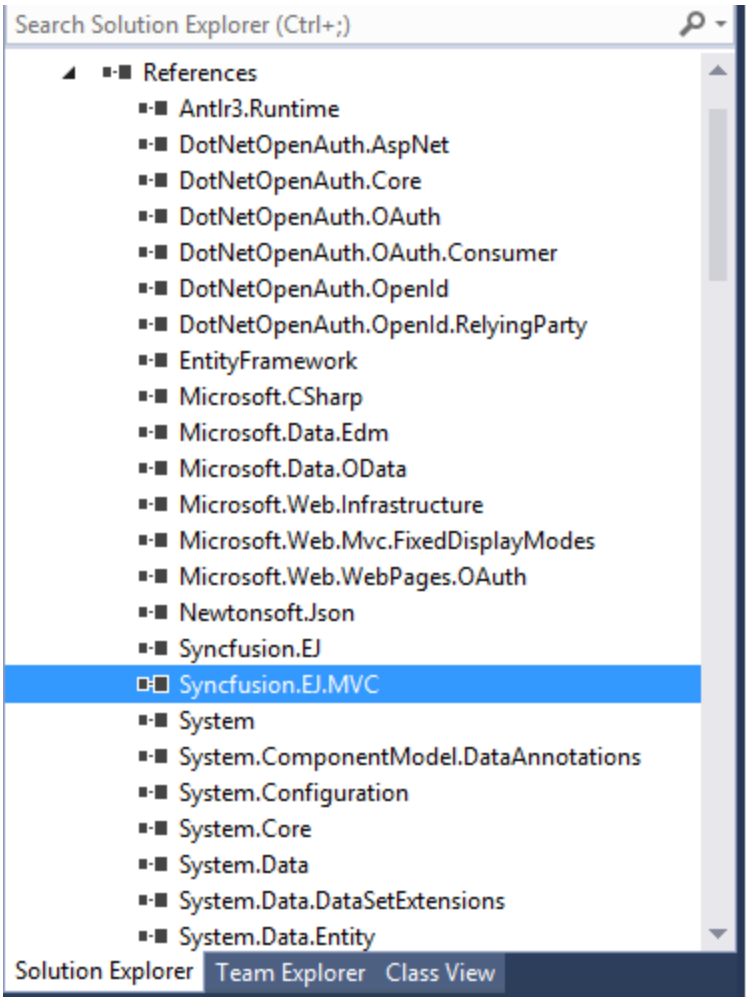
For example, If you have installed the Essential Studio package within C:\Program Files (x86), then navigate to the below location,

C:\Program Files (x86)\Syncfusion\Essential Studio\{{ site.releaseversion }}\precompiledassemblies\{{ site.releaseversion }}\4.5

Note: Syncfusion.Core dependency has been removed from 13.2.0.29 and it is not required to refer this assembly when you are using 13.2.0.29 and later versions.

4. Once the assembly selection is done, click OK to add the selected references to your project. You can view the assembly references added to your application, in the solution explorer as shown in the following.

Copyright © 2001 - 2020 Syncfusion Inc.



Selected Assemblies added to the Project reference

Registering Syncfusion Assemblies within the Web.config

In your application's web.config file, add the below assembly information within the <assemblies> tag.

XML

```
<system.web>
<compilation debug="true" targetFramework="4.5">
<assemblies>
<add assembly="Syncfusion.EJ, Version=15.4450.0.20, Culture=neutral,
PublicKeyToken=3d67ed1f87d44c89" />
<add assembly="Syncfusion.EJ.Mvc, Version=15.4500.0.20, Culture=neutral,
PublicKeyToken=3d67ed1f87d44c89" />
</assemblies>
</compilation>
<authentication mode="Forms">
…
</system.web>
```

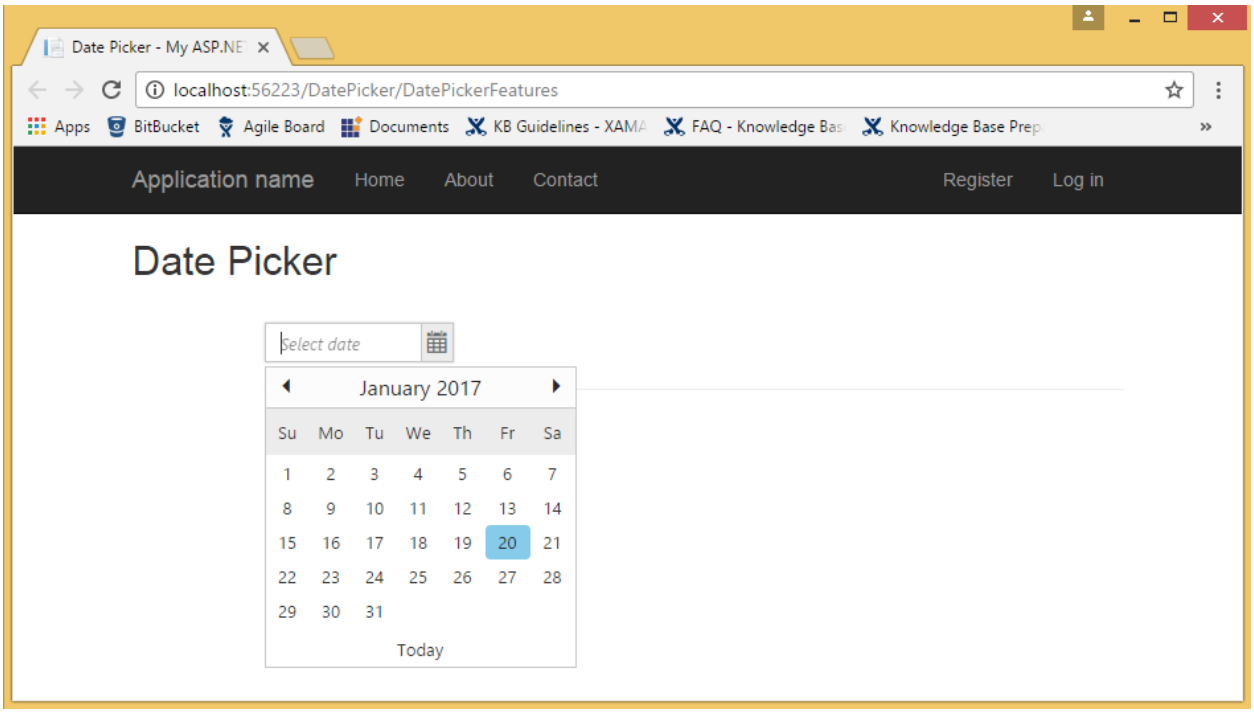
1. Add the below DatePicker code in your view page as shown in the following.

HTML

```
@Html.EJ().DatePicker("DatePick").DateFormat("MM/dd/yyyy").ShowOtherMonths(f
alse).EnableRTL(false).Locale("en-US")
```

Note: Add the DatePicker code within the Content section, by removing the unwanted code within it.

2. Finally build and run the project by pressing F5, so that you can now see the output similar to the following screenshot in your web browser.



DatePicker control displaying on the web browser

Thus the DatePicker control is rendered successfully with its default appearance. You can then use its various properties to set its value and also make use of its available events to trigger when necessary.

Version compatibility with respect to framework

The Syncfusion.EJ.MVC assembly supports only till framework 4.5, so the dependent Syncfusion.EJ assembly will also be installed in that version even if the framework chosen is 4.6 or above. Find the supported MVC versions for the target framework in the following table.

MVC Version	Assembly	Version	Example Version
MVC 3	Syncfusion.EJ Syncfusion.EJ.Mvc	XX.X400.X.XX XX.X300.X.XX	16.4400.0.52 16.4300.0.52
MVC 4	Syncfusion.EJ Syncfusion.EJ.Mvc	XX.X400.X.XX XX.X400.X.XX	16.4400.0.52 16.4400.0.52
MVC 5	Syncfusion.EJ Syncfusion.EJ.Mvc	XX.X450.X.XX XX.X500.X.XX	16.4400.0.52 16.4500.0.52

Copyright © 2001 - 2020 Syncfusion Inc.

Note: For Framework 4.6 and above, support has been provided in ASP.NET Core. So, the assembly version “XX.X460.X.XX” cannot be used in MVC platform.

Getting Started

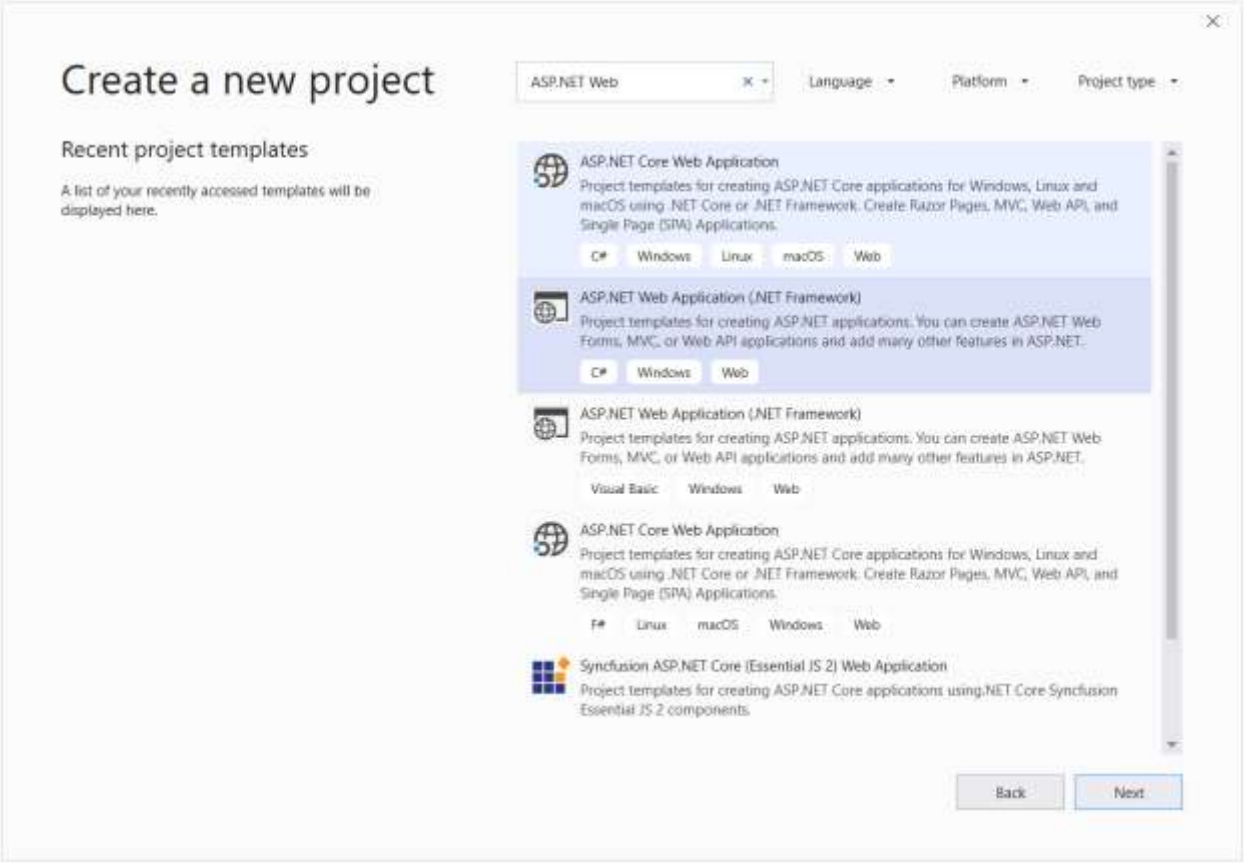
Starting with v16.2.0.x, if you reference Syncfusion assemblies from trial setup or from the NuGet feed, you also have to include a license key in your projects. Please refer to this link to know about registering Syncfusion license key in your ASP.NET MVC application to use our components.

Configuring EJ MVC in Visual Studio 2019

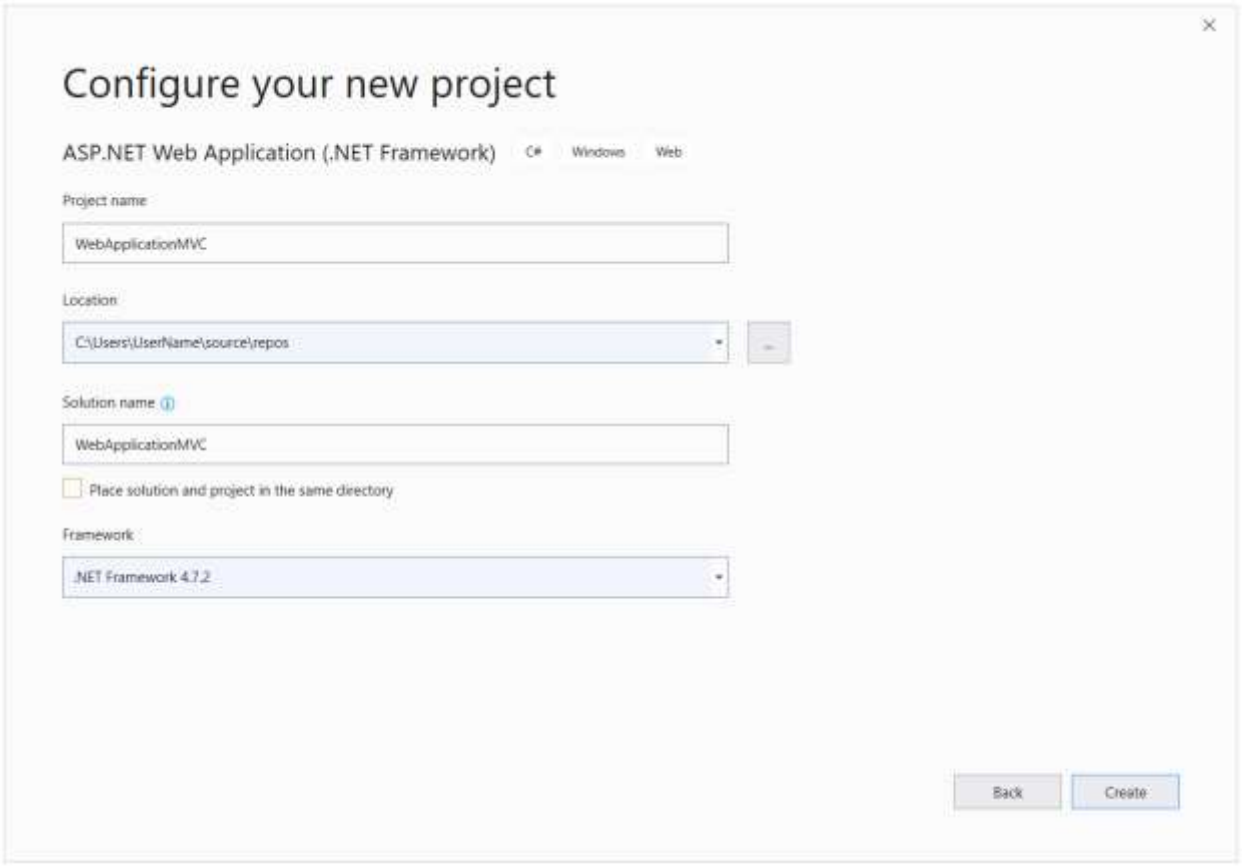
This section describes how to configure the Syncfusion ASP.NET MVC components into the ASP.NET MVC applications using Visual Studio 2019.

To add our Syncfusion MVC controls into the new ASP.NET MVC5 application by making use of the **Syncfusion NuGet Packages**, refer to the following steps.

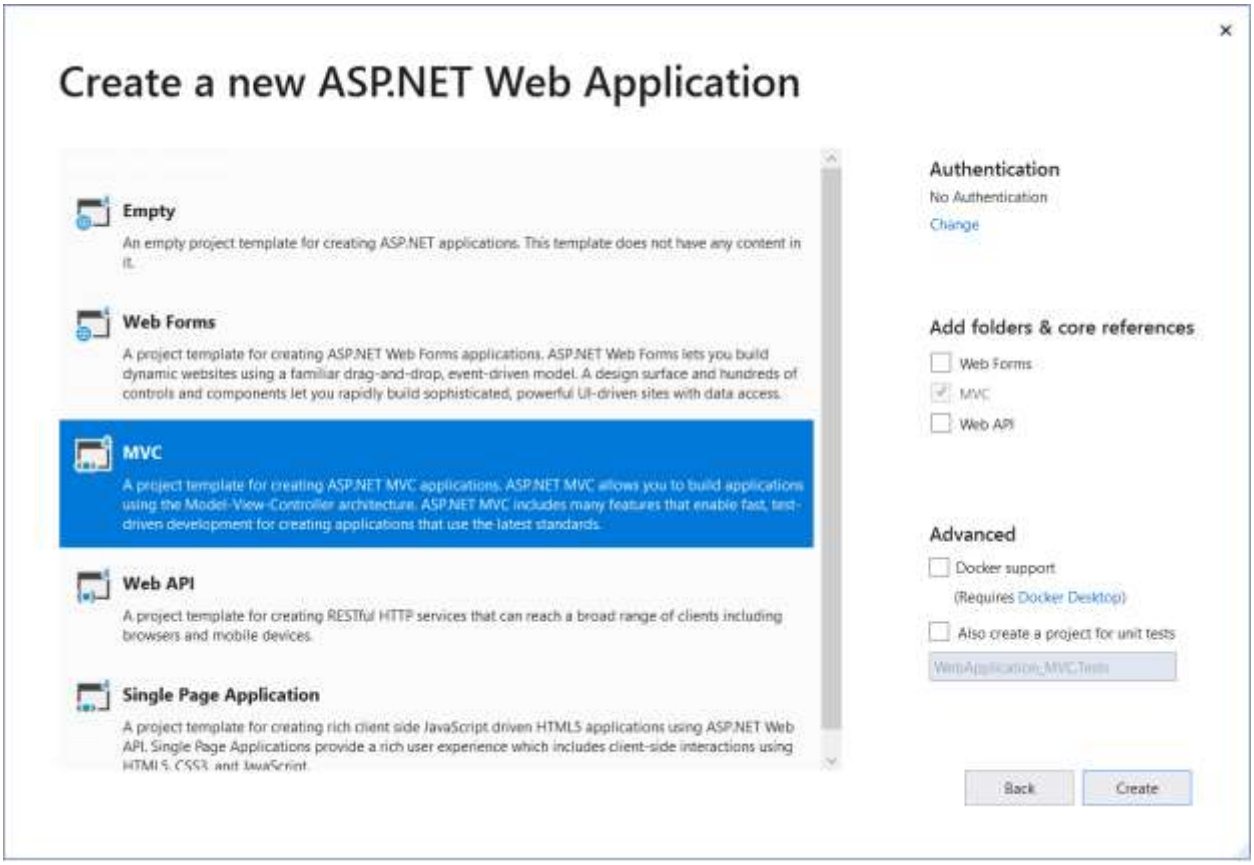
- Open Visual Studio 2019 and Create a new ASP.NET Web Application project and click on the **Next** button.



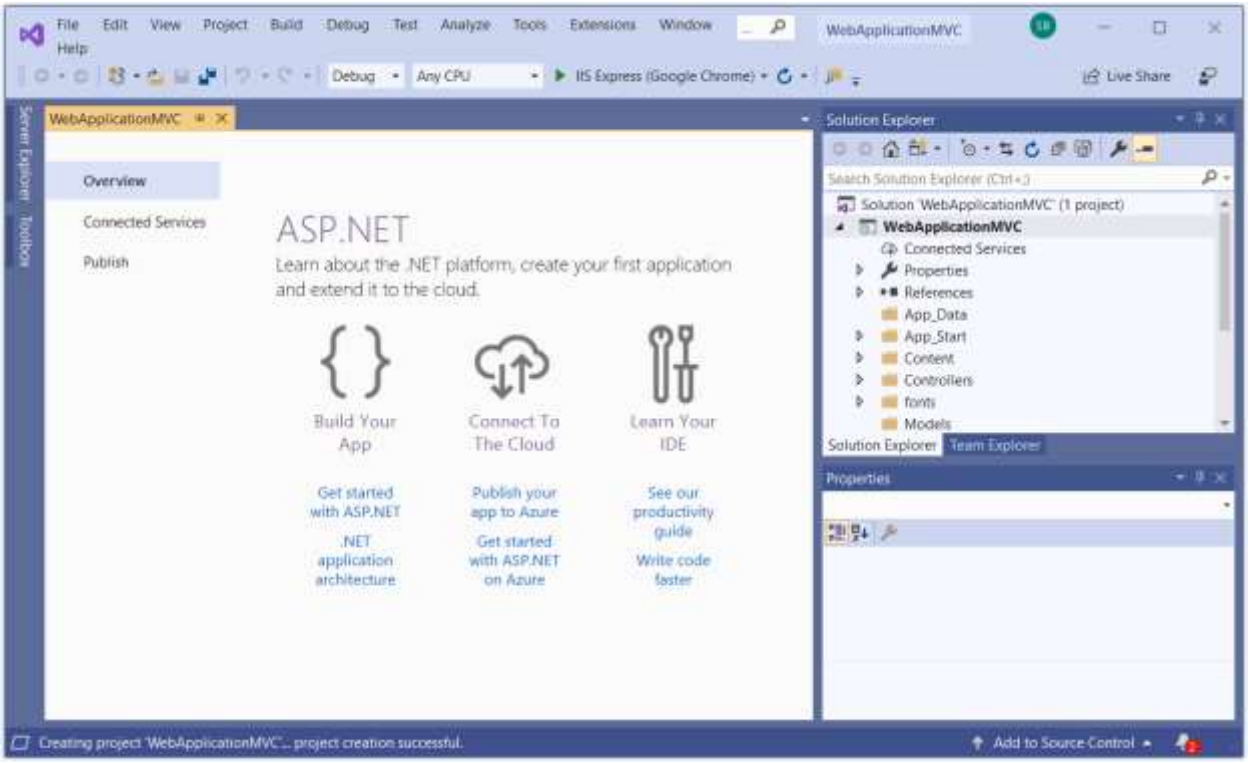
- Name your project and configure its settings and after click on the **Create** button.



- Select **MVC** project template, then click on **Create** button.



- A new project MVC application has been created successfully using Visual Studio 2019 (IDE).

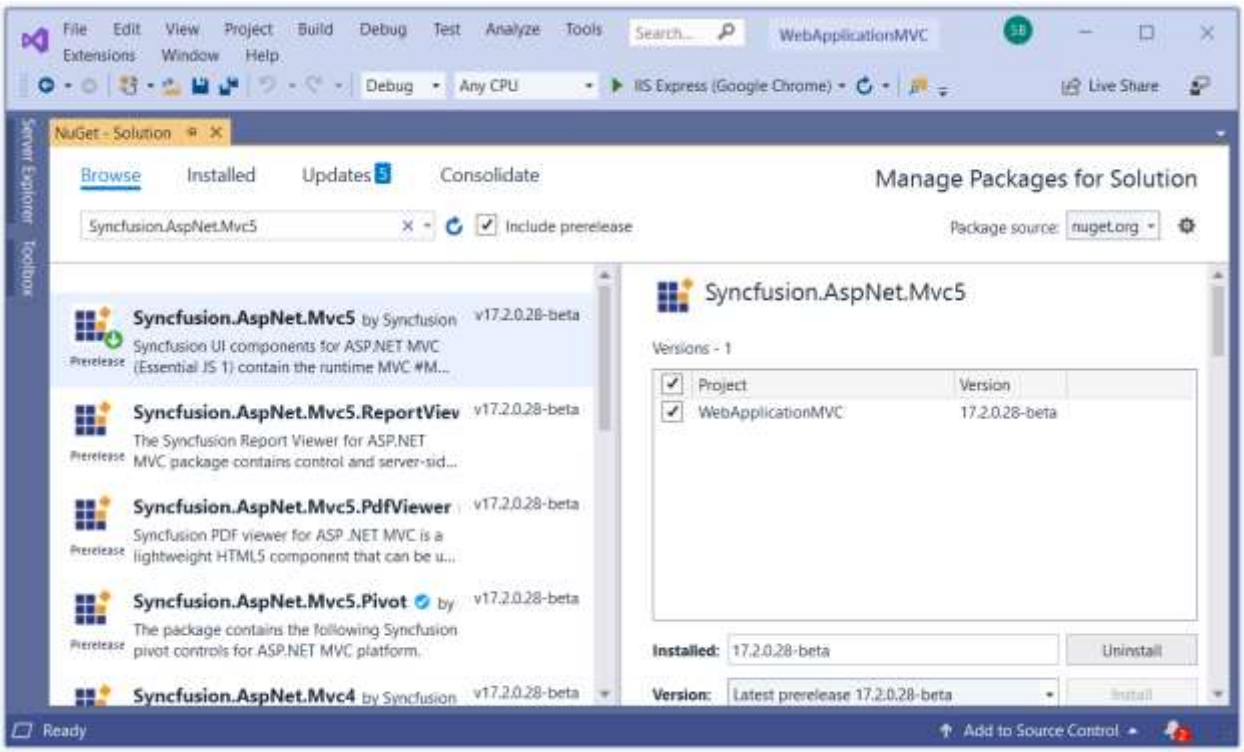


- After project creation, install the Syncfusion Packages in your application.
- Select the **Tools->NuGet Package Manager->Package Manager settings** the dialog window will open.
- Navigate to the **NuGet Package Manager->Package Sources** from the options dialog.
- Click the Add button to create the new package sources.
- Select the newly created Package Source and rename the source name using the Name input box.

Name: Name of the package that listed in Available package sources

Source: Syncfusion ASP.NET MVC NuGet Package feed URL

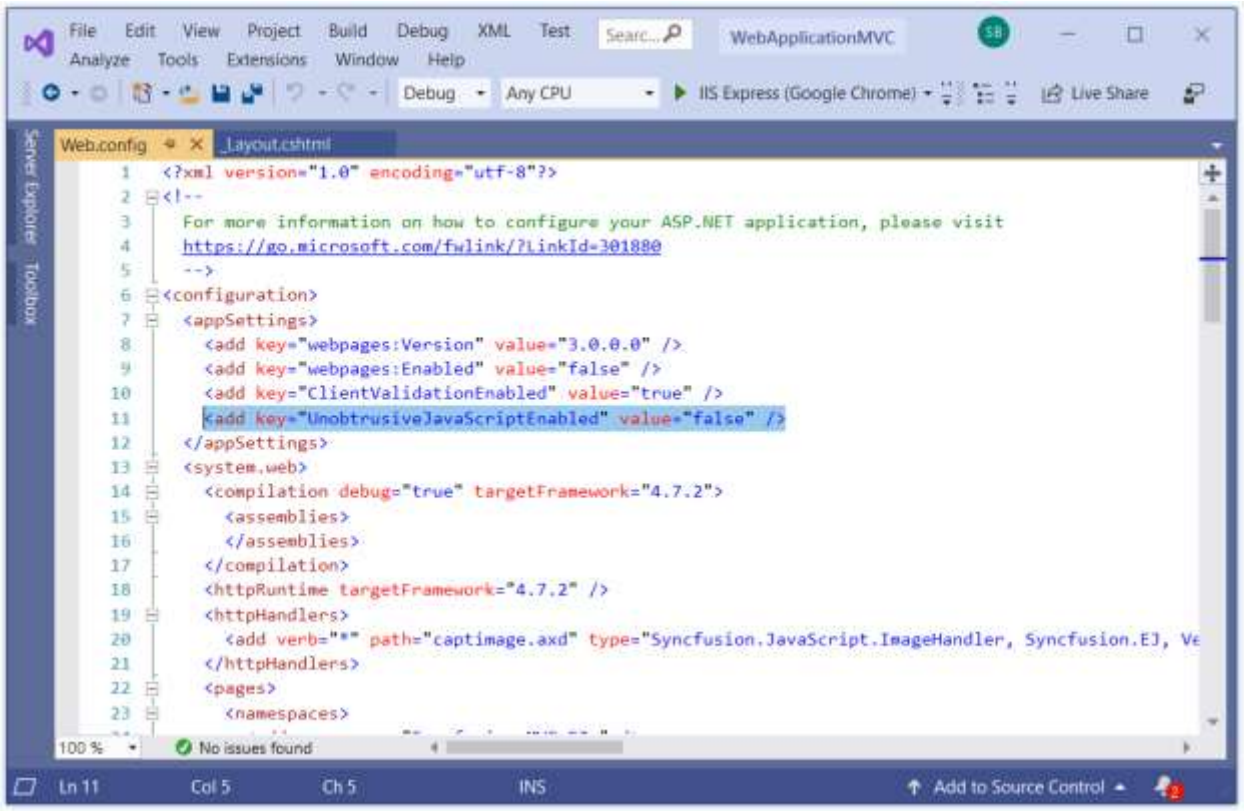
- The Syncfusion ASP.NET MVC NuGet Package can be installed from https://www.nuget.org/packages/Syncfusion.AspNet.Mvc5
- Select the Update and then click the OK button. The package's source get added to the list of available package sources.
- Right click your project references and then select "**Manage NuGet Package**" option. In this window choose the "**Syncfusion Packages registered name**" from the package source dropdown. And check the "**include prerelease**" option.
- Now, our Syncfusion Packages will list in this window. Select and install the "**Syncfusion.EJ.AspNet.Mvc5**" package from this list.



- Then the packages will get installed and it will be automatically referred to your application.
- While initial creation, by default, the **Unobtrusive** setting is enabled in your applications **web.config** file. Change its value to **false** in your application as shown in the following:

ASPX-CS

```
<appSettings>
<add key="ClientValidationEnabled" value="true" />
<add key="UnobtrusiveJavaScriptEnabled" value="false" />
</appSettings>
```

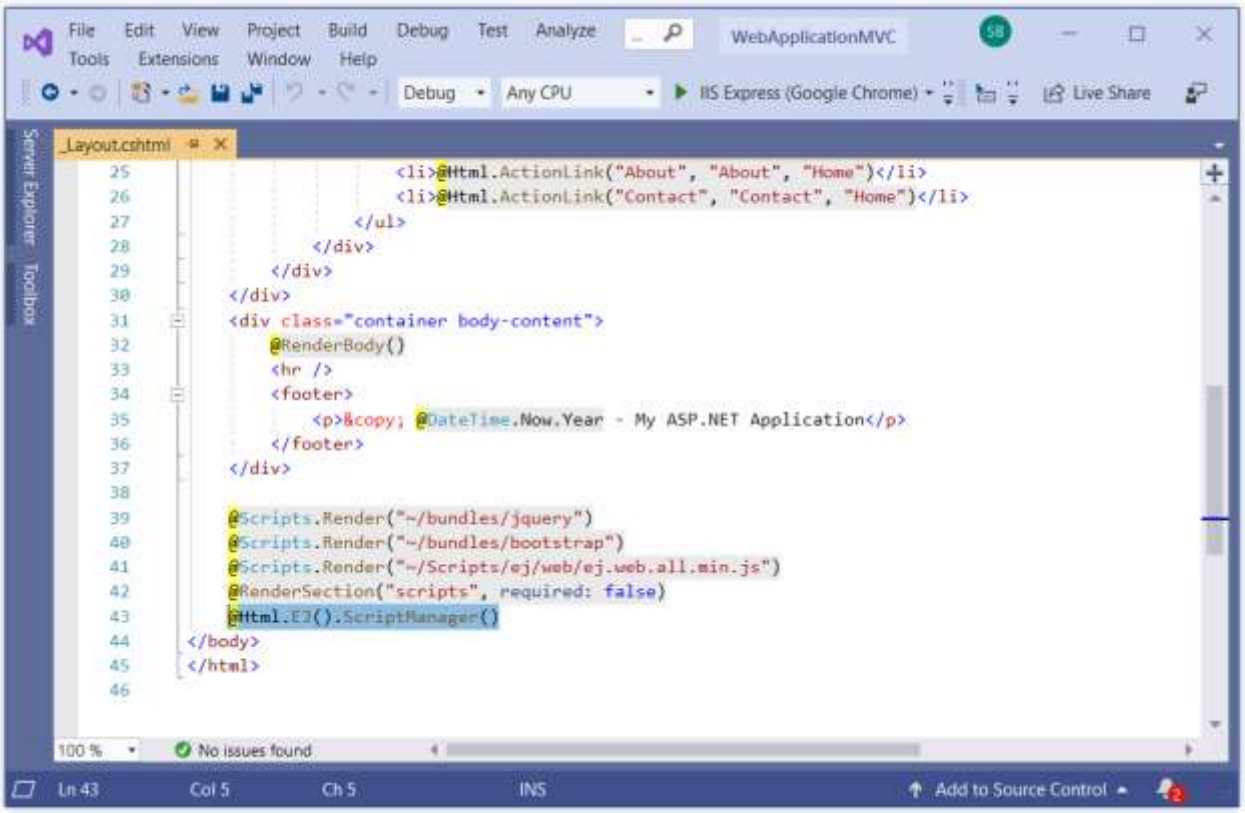


- Add the script manager code in the ***Layout.cshtml file present within the ~/Views/Shared folder of your application. Add it before the closing body tag in the*** Layout.cshtml file.

ASPX-CS

```
<body>
@RenderSection("scripts", required: false)
@Html.EJ().ScriptManager()
</body>
```

Copyright © 2001 - 2020 Syncfusion Inc.



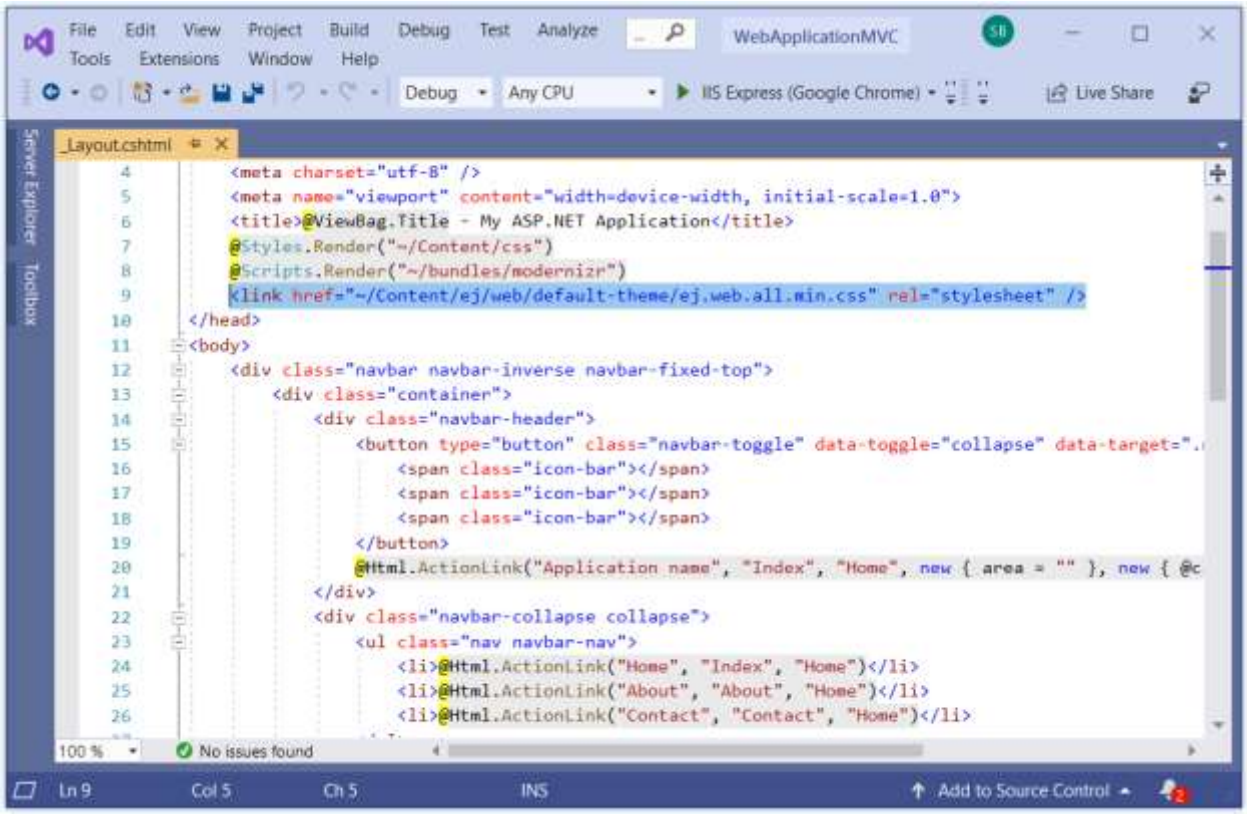
If **unobtrusive** is set to true in the application, the script manager can be excluded, as the control is initialized using HTML5 attributes. Also for control rendering, you need to include **ej.unobtrusive.min.js** file along with ej.web.all.min.js in **_Layout.cshtml** page. Refer to the unobtrusive section.

- Syncfusion specific stylesheets are loaded into the **Content** folder of your application, include the below specified theme reference **(default-theme/ej.web.all.min.css)** file in the **~/Views/Shared/_Layout.cshtml** file, within the head section as this file contains the default theme styles applied for all the Syncfusion MVC controls.

ASPX-CS

```
<head>
<title>@ViewBag.Title</title>
@Styles.Render("~/Content/ej/web/default-theme/ej.web.all.min.css")
</head>
```

Copyright © 2001 - 2020 Syncfusion Inc.



- It is mandatory to include the reference to the required JavaScript files in your **_Layout.cshtml**, so as to render the Syncfusion MVC controls properly.

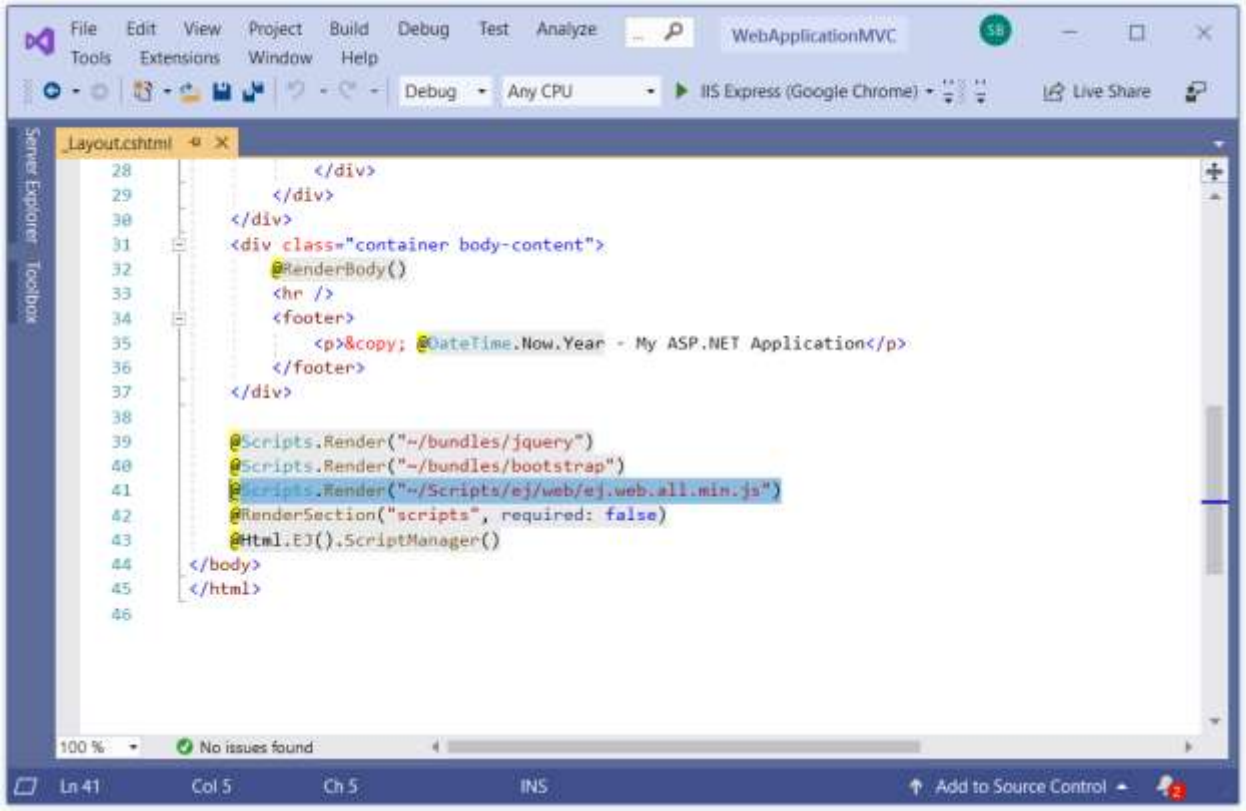
ASPX-CS

```
<head>
<meta charset="utf-8" />
<title>@ViewBag.Title - My ASP.NET MVC Application</title>
@Styles.Render("~/Content/ej/web/bootstrap-theme/ej.web.all.min.css")
</head>
<body>
@Scripts.Render("~/bundles/jquery")
@Scripts.Render("~/bundles/bootstrap")
@Scripts.Render("~/Scripts/jsrender.min.js")
@Scripts.Render("~/Scripts/ej/web/ej.web.all.min.js")
@RenderSection("scripts", required: false)
@Html.EJ().ScriptManager();
</body>
```

The order of reference for the script files made in the above section should be maintained. Any change in order reference may cause rendering issues in EJ Controls.

If your application contains duplicate/multiple references to the jQuery files, remove it as the explicit reference to the **jquery-{version}.js** script file that is added to the application as specified above.

Copyright © 2001 - 2020 Syncfusion Inc.



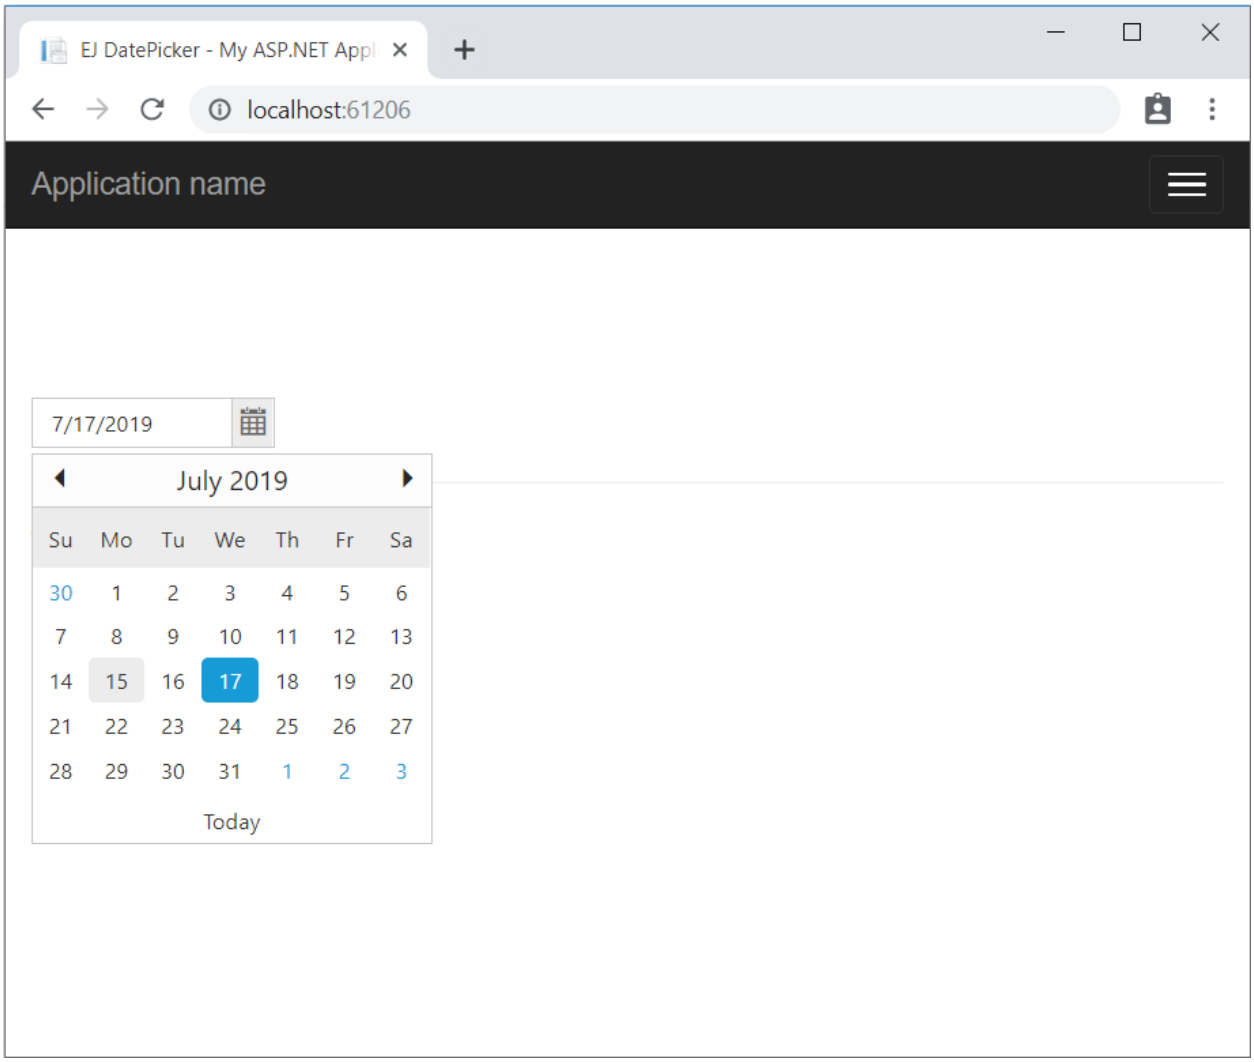
- Now you can add the control **DatePicker** in the **Index.cshtml** file present within **~/Views/Home** folder.

ASPX-CS

```
@Html.EJ().DatePicker("MyFirstDatepicker")
```

- Compile and execute the application. You can able to see the below output in the browser.

Copyright © 2001 - 2020 Syncfusion Inc.



Utilities

The Syncfusion MVC Extension provides you quick access, so that you can create or configure the Syncfusion MVC projects. The Syncfusion ASP.NET MVC Extensions has the following features.

- Syncfusion Sample Creator for ASP.NET MVC
- Syncfusion Project Conversion for ASP.NET MVC
- Syncfusion Project Migration for ASP.NET MVC

Project Conversion

The Project Conversion is a Visual Studio add-in that converts an existing ASP.NET MVC Project into a Syncfusion ASP.NET MVC Project by adding the required assemblies and resource files.

Convert into Syncfusion ASP.NET MVC (Web) project

The following steps help you to use the Syncfusion Project Conversion in the existing ASP.NET MVC (Web) Project.

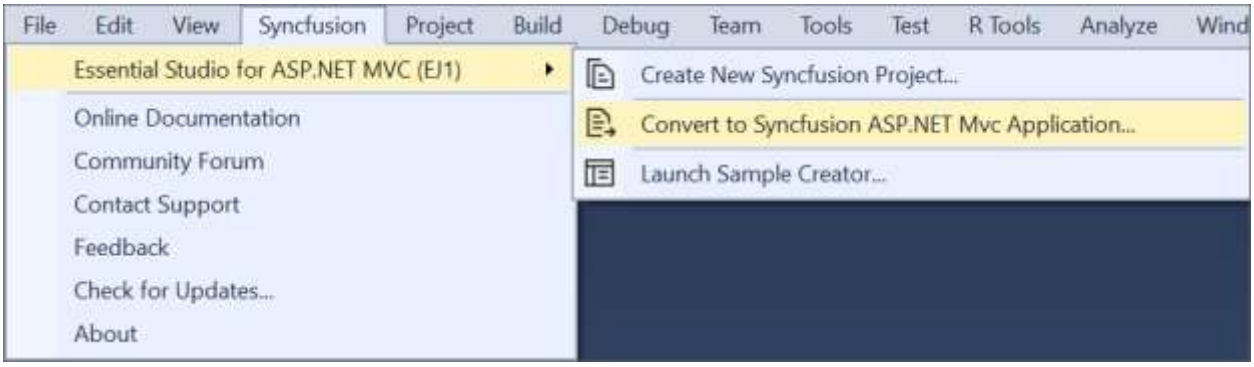
1. Open an existing Microsoft MVC Project or create a new Microsoft MVC Project.

Copyright © 2001 - 2020 Syncfusion Inc.

2. To open Project Conversion Wizard, follow either one of the options below:

Option 1:

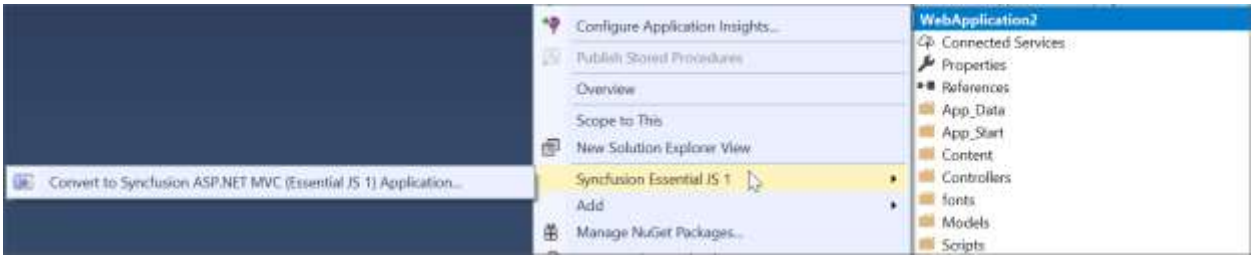
Click **Syncfusion Menu** and choose **Essential Studio for ASP.NET MVC (EJ1) > Convert to Syncfusion ASP.NET MVC Application…** in **Visual Studio**.



Note: In Visual Studio 2019, Syncfusion menu available under Extension in Visual Studio menu.

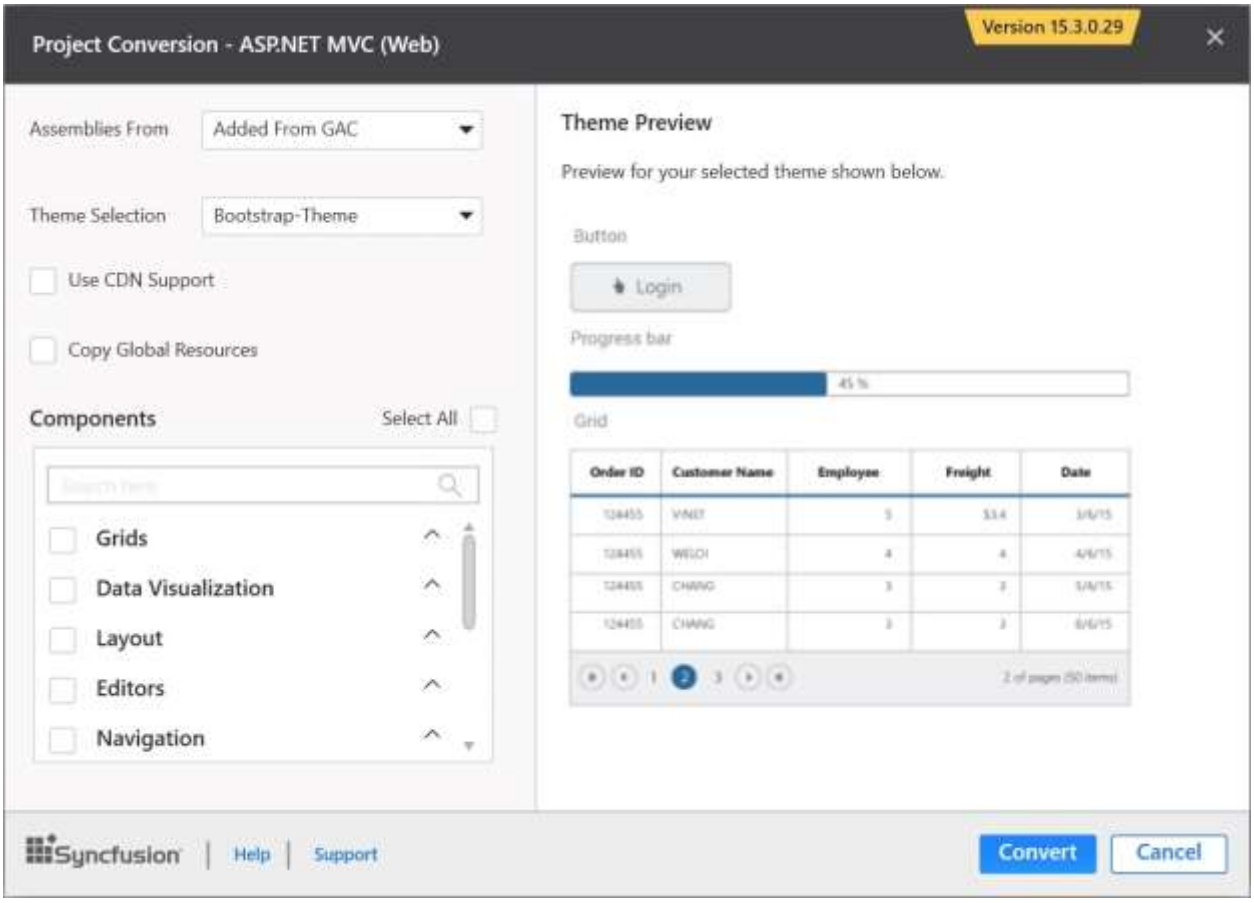
Option 2:

Right-click the Project from Solution Explorer, select **Syncfusion Essential JS 1**, and choose **Convert to Syncfusion MVC (Essential JS 1) Application...** Refer to the following screenshot for more information.



3. Project Conversion Wizard opens so that you can configure the project.

Copyright © 2001 - 2020 Syncfusion Inc.

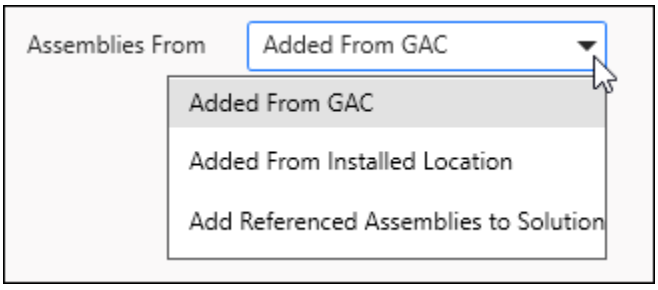


The following configurations are used in the Project Conversion Wizard.

Assemblies From:

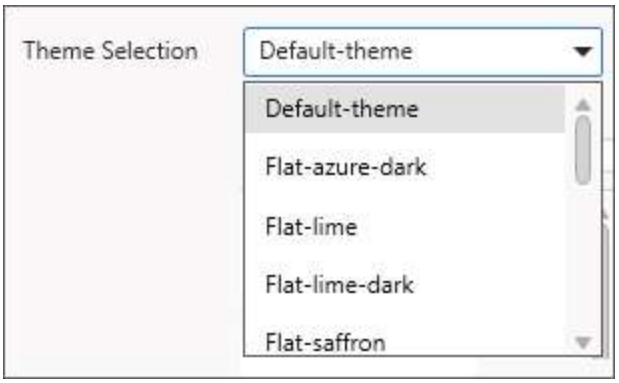
Choose the assembly location:

1. Added From GAC: Refer to the assemblies from the Global Assembly Cache.
2. Added from Installed Location: Refer to the assemblies from the Syncfusion Installed locations.
3. Add Referenced Assemblies to Solution: Copy and refer to the assemblies from project's solution file lib directory.



Choose the Theme:

The master page of project will be updated based on the selected theme. The Theme Preview section shows the controls preview before converting to a Syncfusion project.



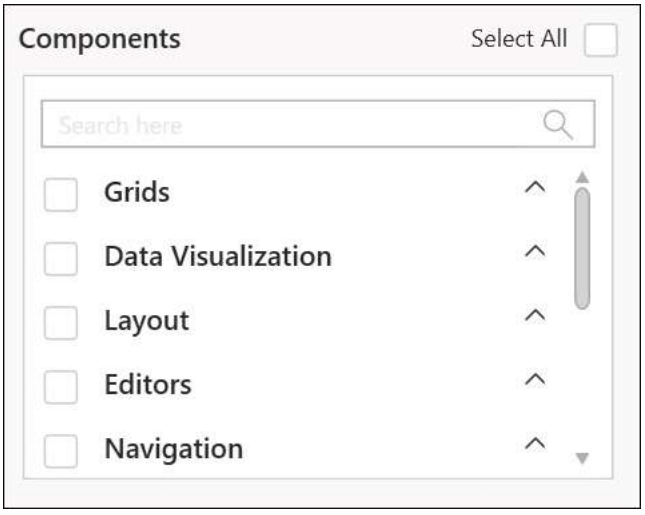
Choose CDN Support:

The master page of the project will be updated based on the required Syncfusion CDN links.

Choose Copy Global Resources:

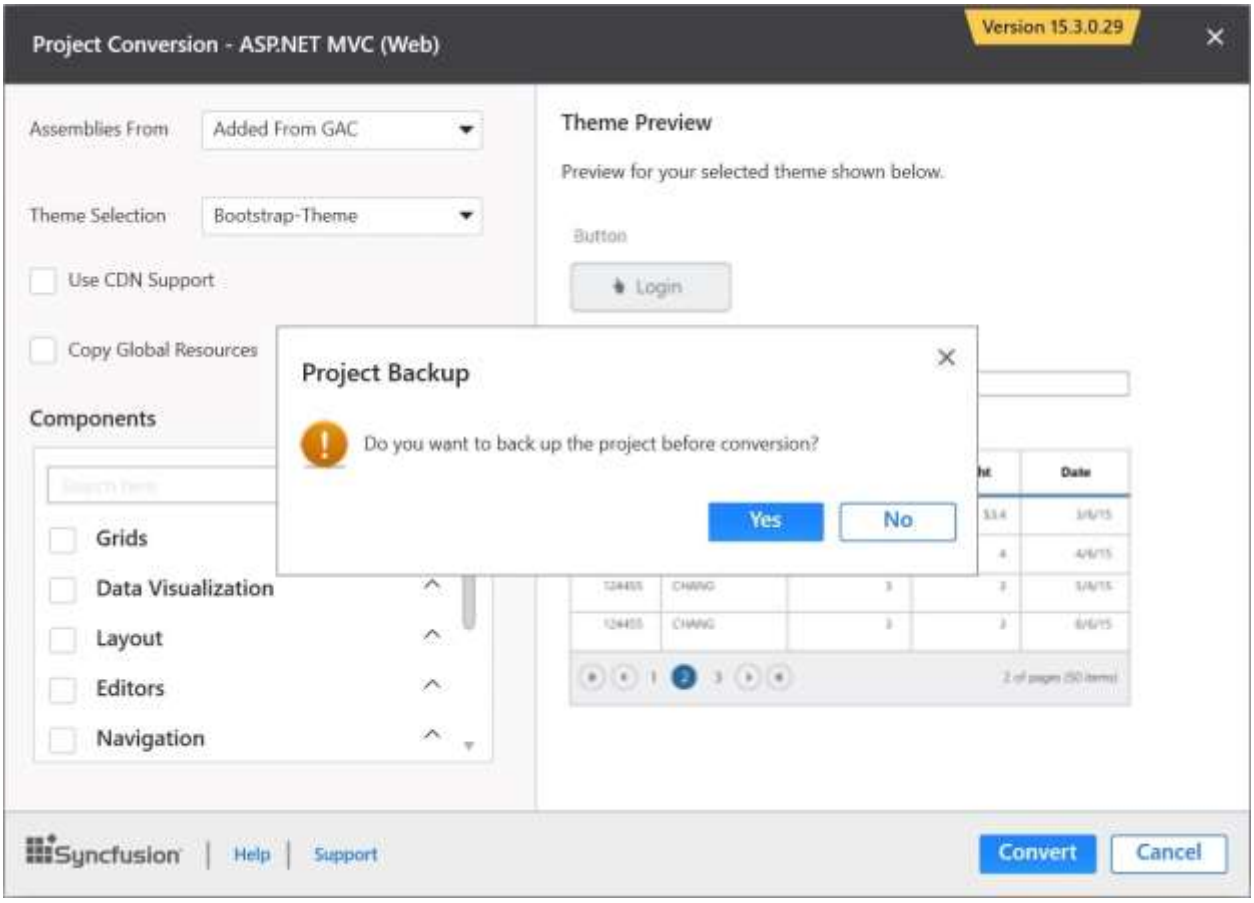
The localization culture files will be shipped into Scripts\ej\i18n directory of the project.

4. Choose the required controls from Components section and Click the **Convert** button to convert it into a Syncfusion Project.

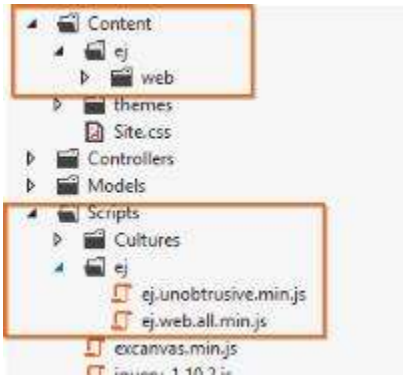


5. The **Project Backup** dialog will be opened. Click yes, to backup the current project before converting it to Syncfusion project. Click No to convert the project to Syncfusion project without backup.

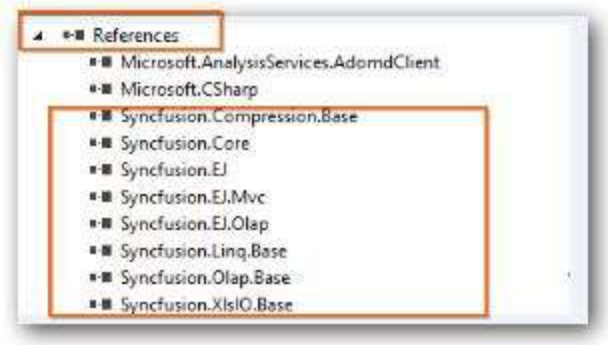
Copyright © 2001 - 2020 Syncfusion Inc.



6. The required Syncfusion Reference Assemblies, Scripts and CSS are included in the MVC Project. For more information, refer to the following screenshots.



Copyright © 2001 - 2020 Syncfusion Inc.



```
<compilation debug="true" targetFramework="4.5">
  <assemblies>
    <add assembly="Syncfusion.EJ.Export, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.Compression.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"
    <add assembly="Syncfusion.EJ, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.EJ.Mvc, Version=14.3500.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.Linq.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.XlsIO.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.EJ.Pivot, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.Olap.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
  </assemblies>
</compilation>
```

Rendering Control after Syncfusion ASP.NET MVC (Web) Conversion:

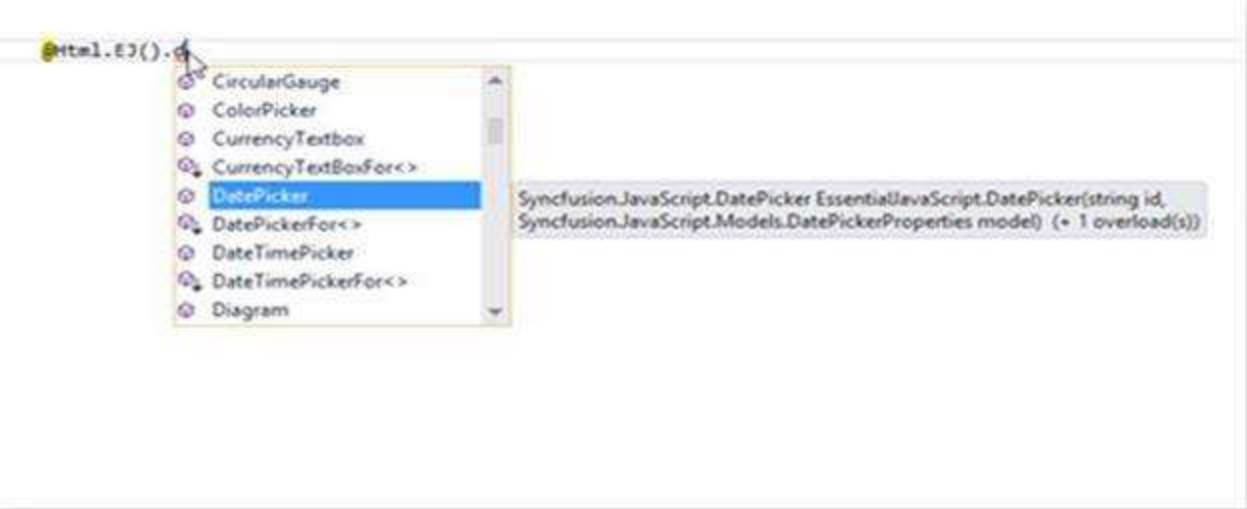
Once you convert your ASP.NET MVC project to Syncfusion ASP.NET MVC Project, perform the following steps to render the Syncfusion Controls to your project.

1. The CSS, Scripts, Syncfusion References, and required Web.config file entries are added to your project by Syncfusion ASP.NET MVC Conversion.
2. Add the required Script and CSS files references in the master page (_Layout.cshtml/Layout.vbhtml file). For more information, please refer to the following screenshot.

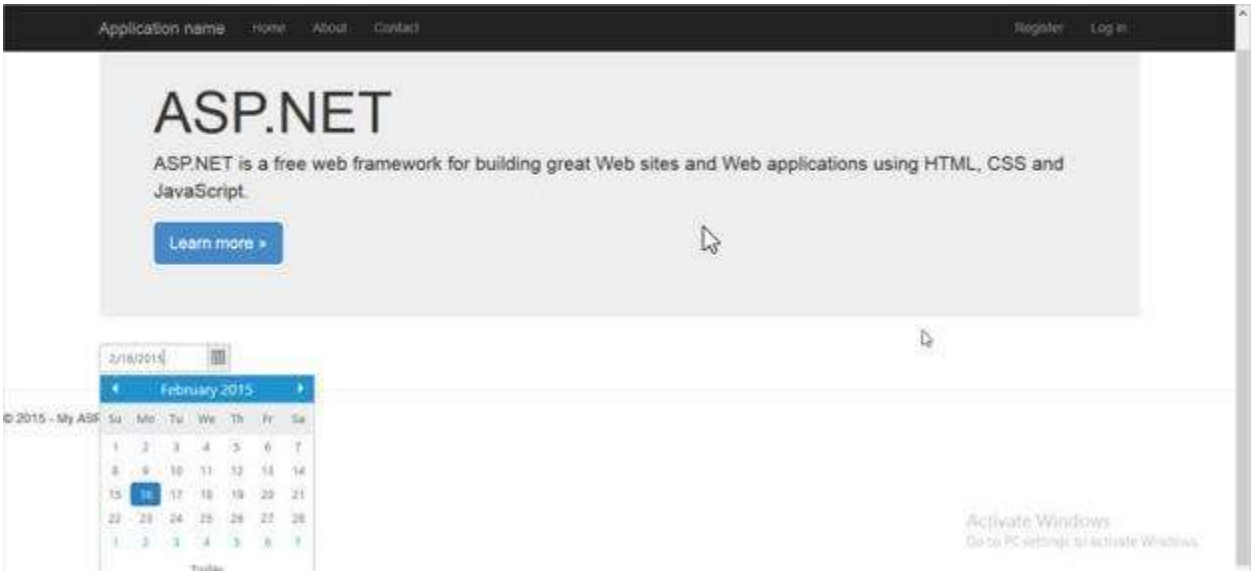
```
<title>@ViewBag.Title - My ASP.NET Application</title>
@Styles.Render("~/Content/css")
@Scripts.Render("~/bundles/modernizr")
<link href="@Url.Content("~/Content/ej/web/Default-theme/ej.widgets.all.min.css")" rel="stylesheet" />
<script src="@Url.Content("~/Scripts/jquery-1.10.2.min.js")"></script>
<script src="@Url.Content("~/Scripts/jsrender.min.js")"></script>
<script src="@Url.Content("~/Scripts/jquery.easing-1.3.min.js")"></script>
<script src="@Url.Content("~/Scripts/jquery.globalize.min.js")"></script>
<script src="@Url.Content("~/Scripts/ej/ej.web.all.min.js")"></script>
<script src="@Url.Content("~/Scripts/ej/ej.unobtrusive.min.js")"></script>
```

3. Now, include the Syncfusion controls to your project. For more information, refer to the following screenshot.

Copyright © 2001 - 2020 Syncfusion Inc.



4. Run the project and the following output will be displayed.



Project Migration

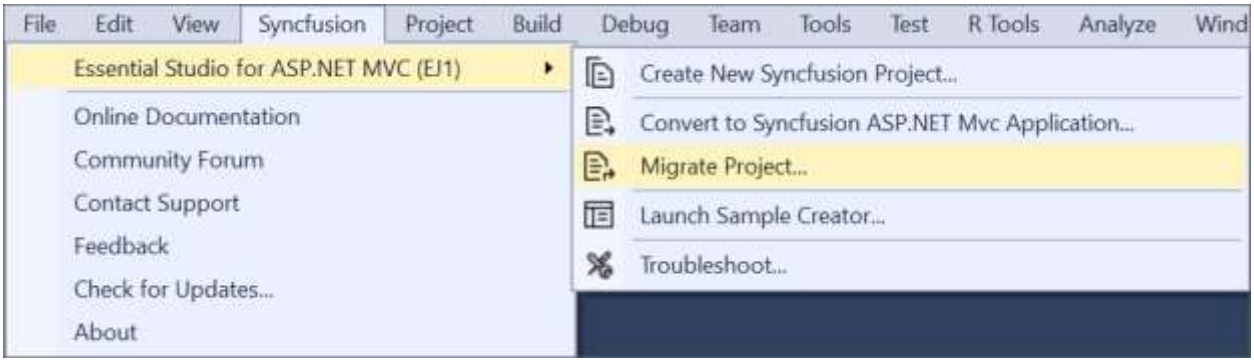
The Project Migration is a Visual Studio add-in that helps to migrate the existing Syncfusion ASP.NET MVC (Web) project from one Syncfusion version to another Syncfusion version.

The following steps help you to migrate from one version to another version of your existing Syncfusion ASP.NET MVC(web) application.

1.To open Migration Wizard, follow either one of the options below:

Option 1:

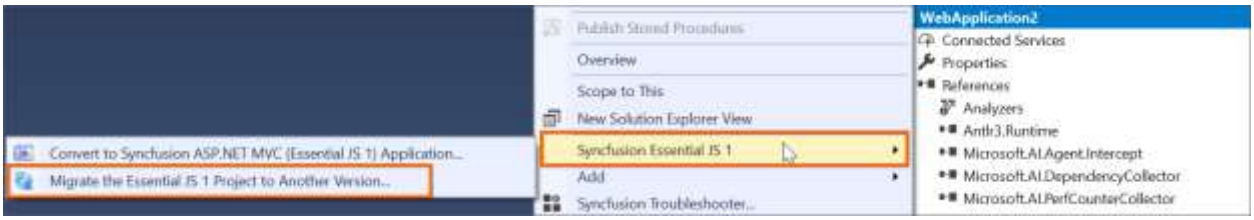
Click **Syncfusion Menu** and choose **Essential Studio for ASP.NET MVC (EJ1) > Migrate Project…** in **Visual Studio**.



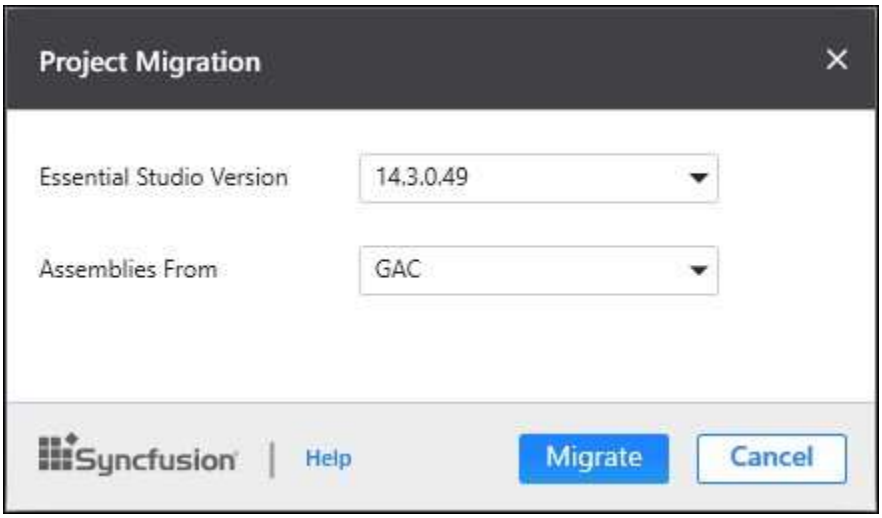
Note: In Visual Studio 2019, Syncfusion menu available under Extension in Visual Studio menu.

Option 2:

Right-click the **Syncfusion ASP.NET MVC Application** from Solution Explorer and select **Syncfusion Essential JS 1**. Choose **Migrate the Essential JS 1 Project to Another Version...**



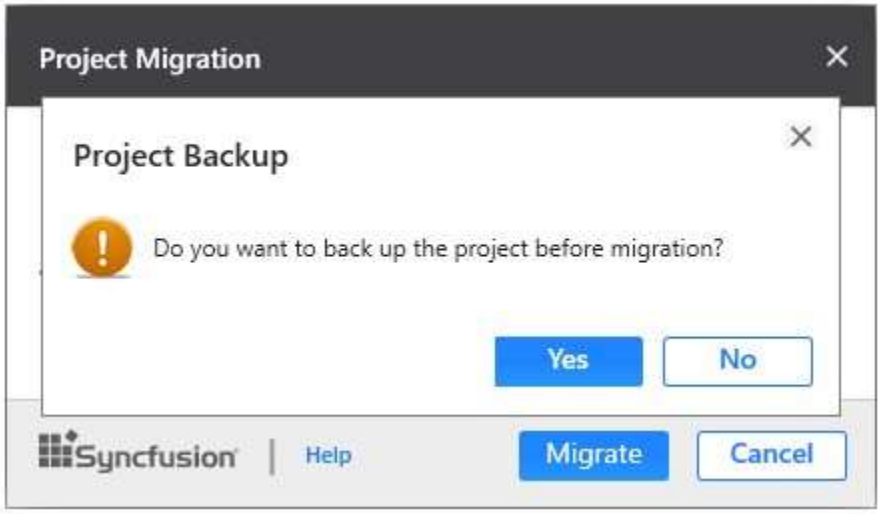
2. The Project Migration window appears. You can choose the required Syncfusion version that is installed in the machine, that can be either Syncfusion ASP.NET MVC.



3. The Project Migration window allows you to configure the following options:
    - Essential Studio Version: Select any version from the list of Installed Versions.
    - Assemblies From: Add the assembly to project from the following locations.
4. Added From GAC: Refer the assemblies from the Global Assembly Cache.
5. Added from Installed Location: Refer to the assemblies from the Syncfusion Installed locations.
6. Add Referenced Assemblies to Solution: Copy and refer to the assemblies from project's solution file lib directory.

Copyright © 2001 - 2020 Syncfusion Inc.

7. Click the Migrate Button and the **Project Backup** dialog will be opened. Click Yes to backup the current project before migrating the Syncfusion project. Click No to migrate the project to required Syncfusion version without backup.



5. The Syncfusion Reference Assemblies, Scripts and CSS are updated to the corresponding version in the project.

Sample Creator

Sample Creator is the utility that allows you to create Syncfusion ASP.NET MVC Projects along with the samples based on Controls and Features selection.

Create Syncfusion MVC Project from Sample Creator

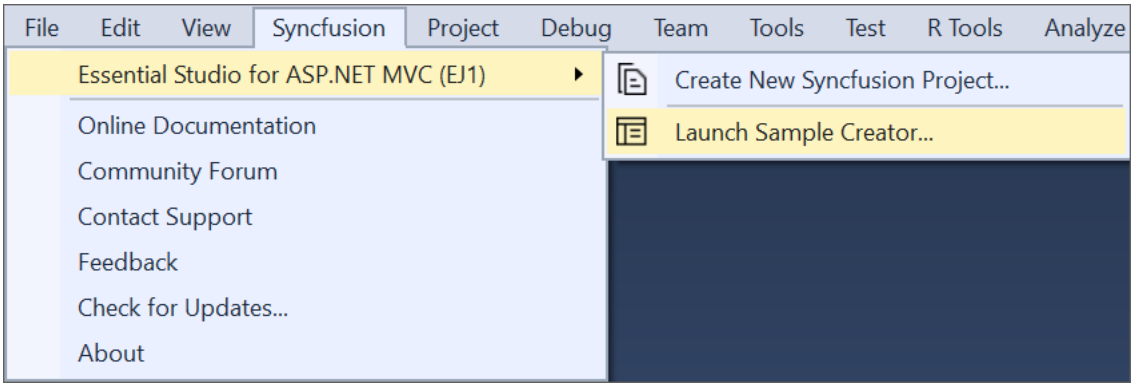
Sample Creator can be download from the Syncfusion Dashboard. After installing the complete Essential Studio suite or ASP.NET MVC setup, follow the given steps:

1. To launch ASP.NET MVC (Essential JS 1) Sample Creator application, follow either one of the options below:

Option 1:

Click **Syncfusion Menu** and choose **Essential Studio for ASP.NET MVC (EJ1) > Launch Sample Creator…** in **Visual Studio**.

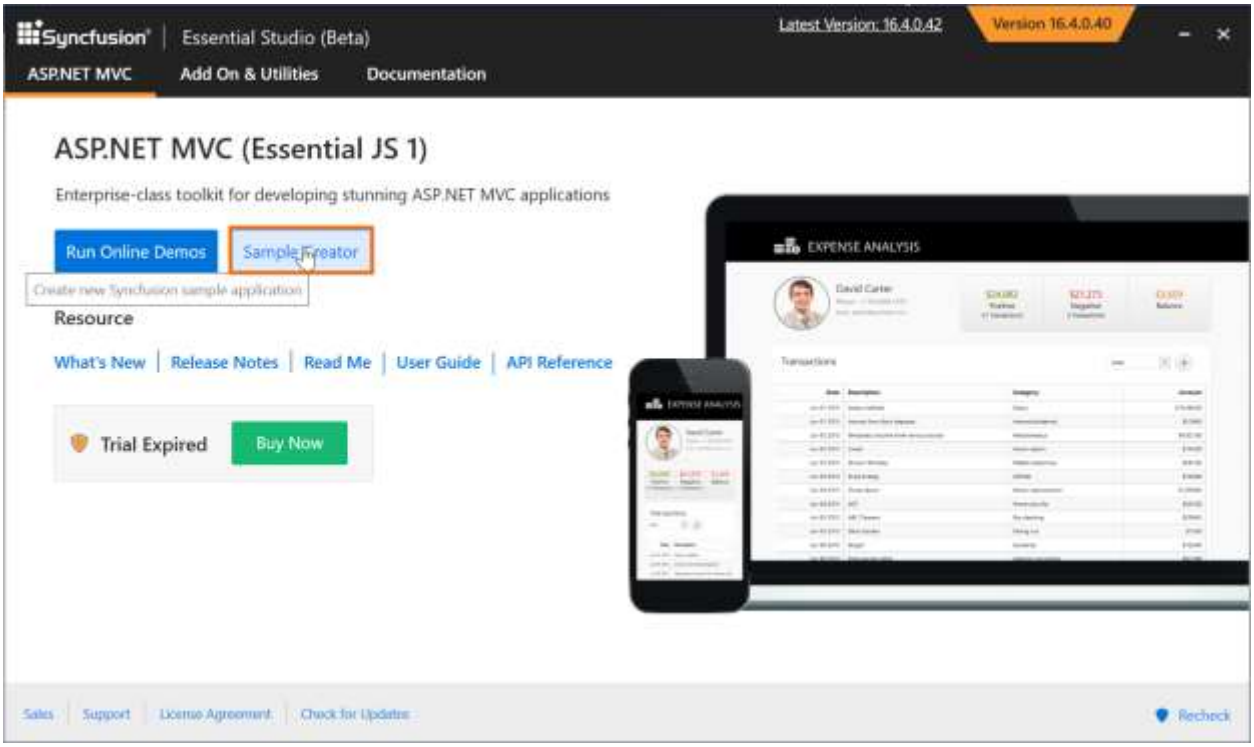
Copyright © 2001 - 2020 Syncfusion Inc.



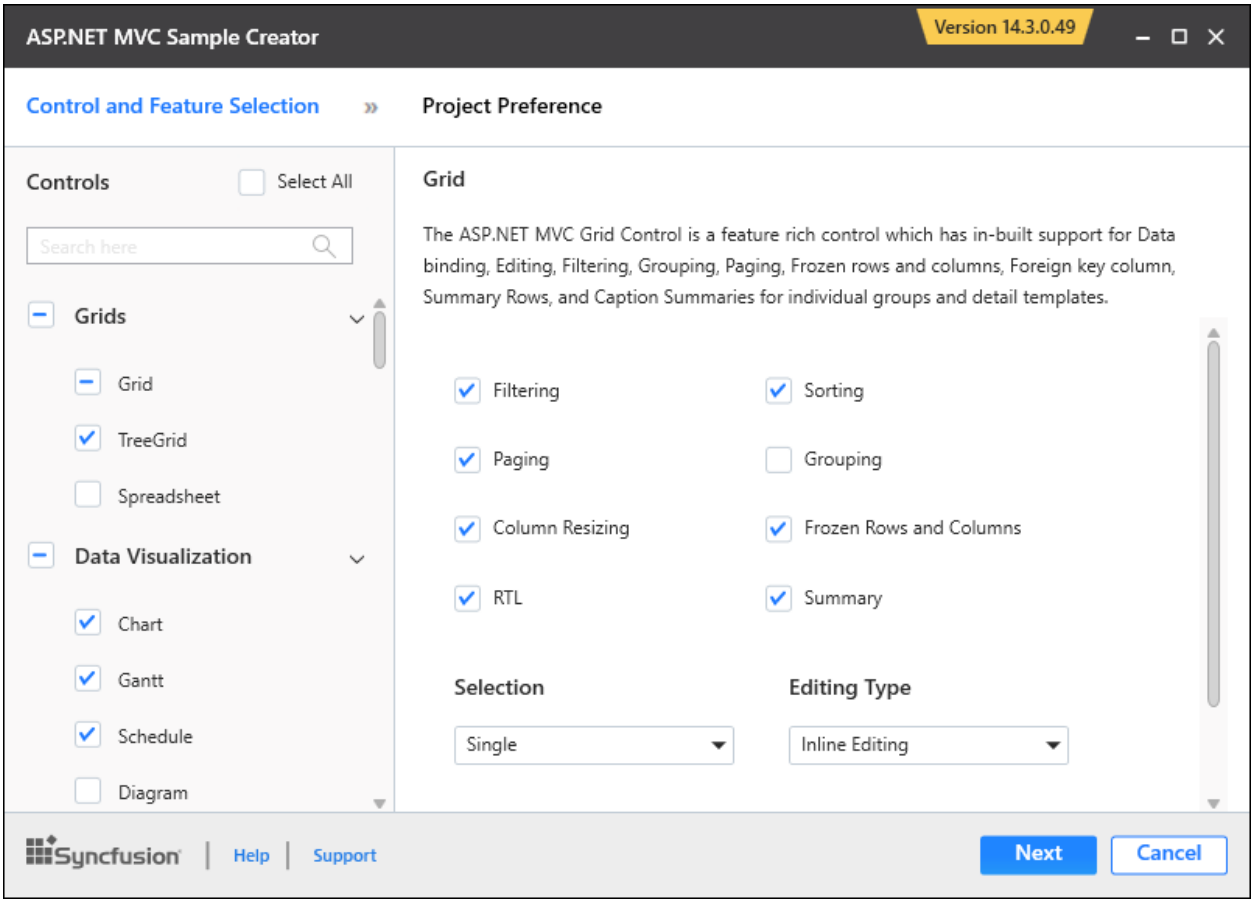
Note: In Visual Studio 2019, Syncfusion menu available under Extension in Visual Studio menu.

Option 2:

Launch the Syncfusion Essential Studio Dashboard and select the ASP.NET MVC (Essential JS 1)/ASP.NET MVC (Classic) platform. Select the Sample Creator button to launch the ASP.NET MVC (Essential JS 1) Sample Creator application. Refer to the following screenshot for more information.

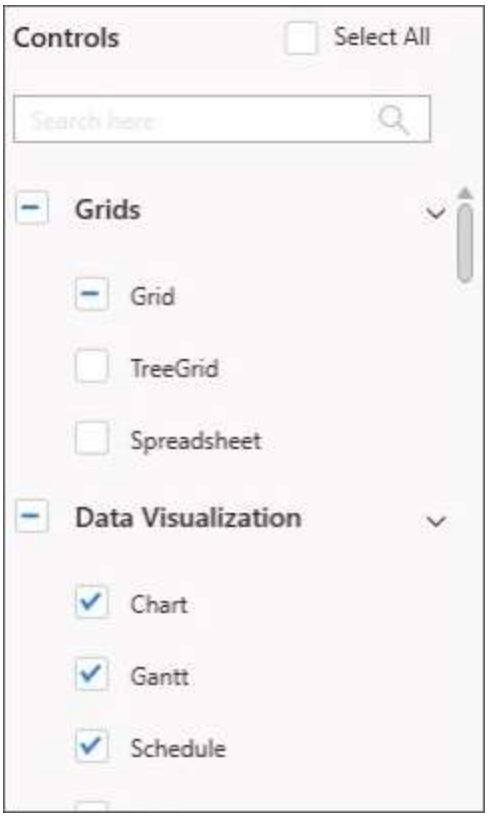


2. Syncfusion Sample Creator Wizard displays the **Controls and its Feature Selection** section.



Controls Selection

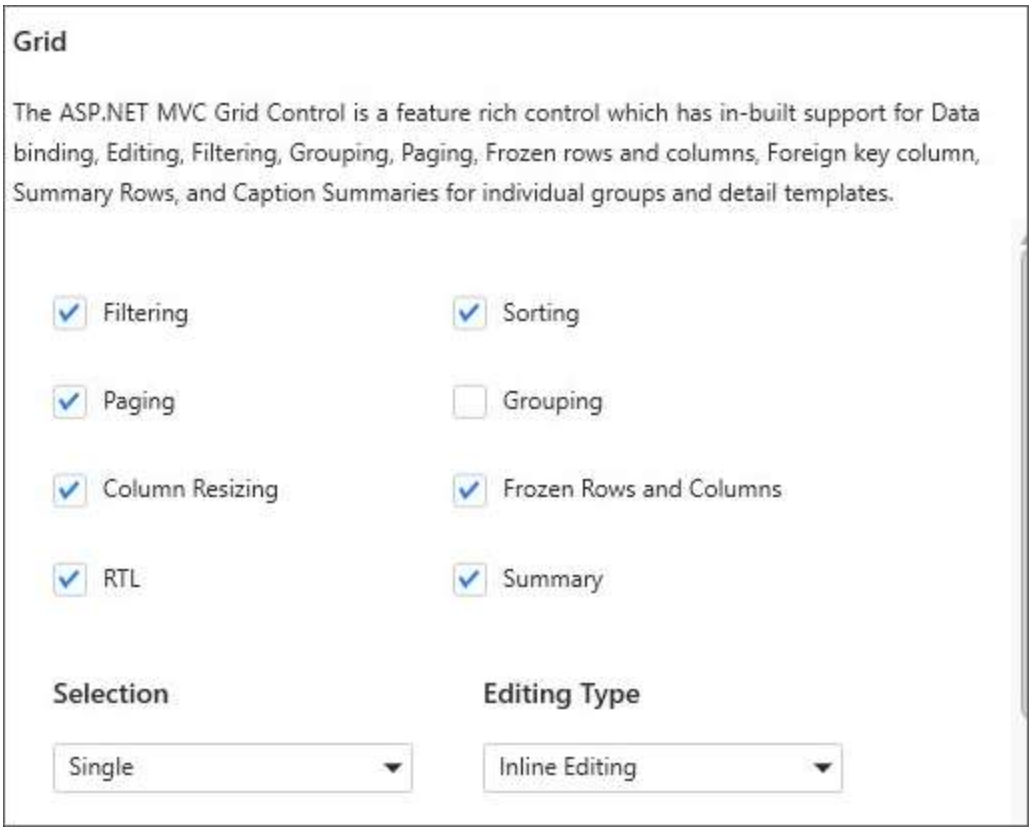
The Syncfusion ASP.NET MVC controls are listed here and you can choose the required controls. The controls are grouped product wise.



Feature Selection

Based on the controls, the Feature is enabled to choose the features of the corresponding controls.

Copyright © 2001 - 2020 Syncfusion Inc.

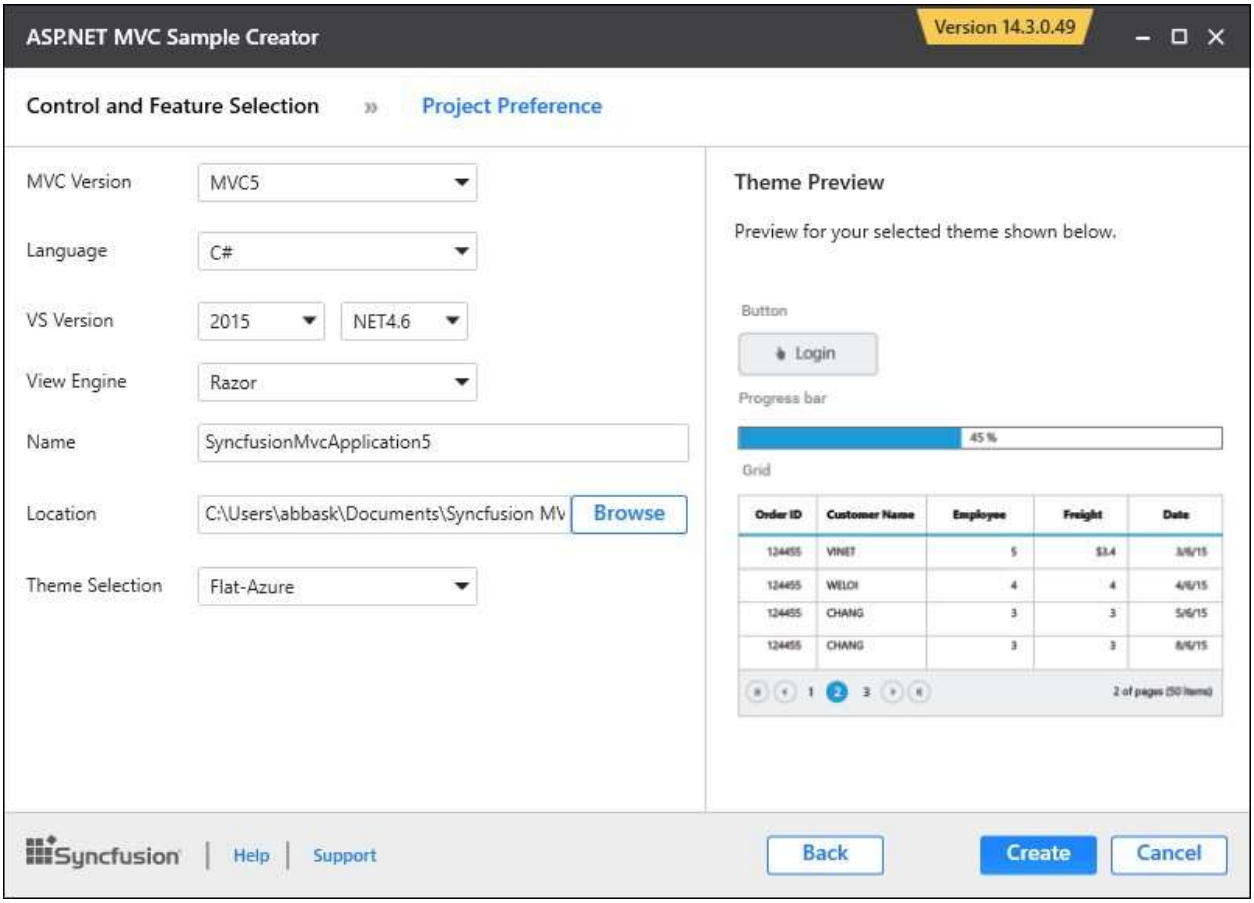


Project Configuration

You can configure the following project details in the Sample Creator.

- MVC Version: Choose the required MVC Version.
- Language: Select the language, either C# or VB.
- VS Version: Choose the Project version.
- .NET Framework: Choose the .NET Framework version.
- View Engine: Select either Razor or ASPX. By default, Syncfusion supports only Razor view engine for ASP.NET MVC projects.
- Compress Style Sheets: Option to compress style sheets.
- Compress Scripts: Option to compress the scripts.
- Name: Name your Syncfusion MVC Application.
- Location: Choose the target location of your project.
- Theme Selection: Choose the required theme. The Theme Preview section shows the controls preview before creating the Syncfusion project.

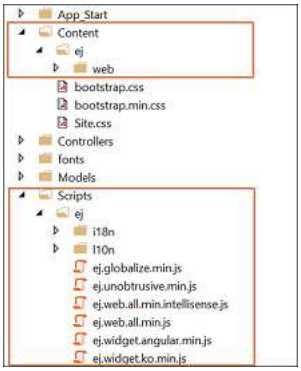
Copyright © 2001 - 2020 Syncfusion Inc.



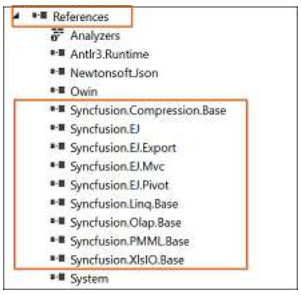
When you click the Create button, the new Syncfusion ASP.NET MVC project is created. The following is added in the project:

- Added the required Controller and View files in the project.

- Included the required Syncfusion ASP.NET MVC scripts and themes files.



- The required Syncfusion assemblies are added for selected controls under Project Reference.

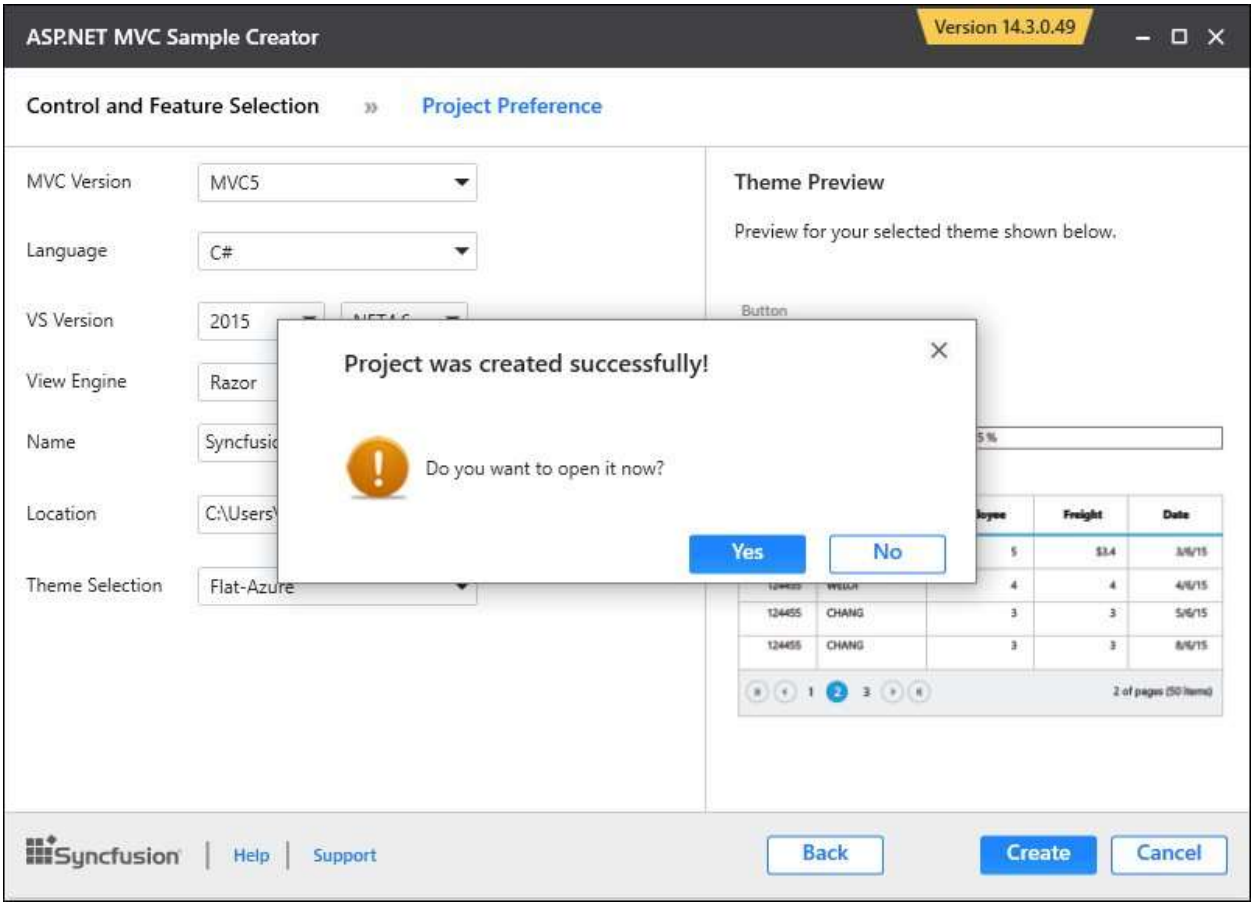


- Configure the Web.Config file by adding the Syncfusion reference assemblies.

```
<compilation debug="true" targetFramework="4.5">
  <assemblies>
    <add assembly="Syncfusion.EJ.Export, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.Compression.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"
    <add assembly="Syncfusion.EJ, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.EJ.Mvc, Version=14.3500.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.Linq.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.XlsIO.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.EJ.Pivot, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
    <add assembly="Syncfusion.Olap.Base, Version=14.3450.0.49, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
  </assemblies>
</compilation>
```

- Once the project is created you can open the project by clicking the Yes button. Refer to the following screenshot for more information.

Copyright © 2001 - 2020 Syncfusion Inc.



Core Concepts

Core Concepts

Basics

API Configuration

Set the values to Syncfusion Widget properties during or after the creation by using fluent helper methods.

```
<div class="jumbotron">
    <h3>Syncfusion MVC Application</h3>
    @(Html.EJ().DatePicker("MyFirstDatepicker")
                .MinDate(new DateTime(2016,5,1))
                .MaxDate(new DateTime(2016,12,31))
                .
    )
</div>
```

TagName
ToHtmlString
TooltipFormat
ToString
ValidationMessage
ValidationRules
Value
WatermarkText
Width

DatePickerPropertiesBuilder DatePickerPropertiesBuilder.Value(string value) (+ 1 overload(s))
Sets current value of DatePicker in string return type.

In the above example, minimum and maximum ranges are defined for DatePicker component.

Wiring Client Side Events

Client side events can be wired in the same way as properties. But here all the client side events are grouped into **"ClientSideEvents"** Action method.

1. Specify the client side event name in string format.

For example:

ASPX-CS

```
@(Html.EJ().DatePicker("MyFirstDatepicker")
.MinDate(new DateTime(2016,5,1))
.MaxDate(new DateTime(2016,12,31))
.Value(DateTime.Now.AddDays(1) )
.ClientSideEvents( events =>
events.Change("datepicker_change") // To handle datepicker change event
.Select("datepicker_select") // To handle datepicker select event
)
)
```

2. Declare the client side events in Script sections.

ASPX-CS

```
@section scripts{
<script>
function datepicker_change(args) {
// event handler
//args contains entire model of DatePicker to get the value of all
properties
}
function datepicker_select(args) {
// event handler
//args contains entire model of DatePicker to get the value of all
properties
}
</script>
}
```

Invoking methods

Syncfusion JavaScript widget client side methods can be accessed via their client side object. You can access the client side object via jQuery.data() utility method.

1. Create server side component in CSHTML.

ASPX-CS

```
@(Html.EJ().DatePicker("MyFirstDatepicker")
.MinDate(new DateTime(2016,5,1))
.MaxDate(new DateTime(2016,12,31))
.Value(DateTime.Now.AddDays(1) )
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

2. Access the client side object using jQuery.data() as shown in the following:

ASPX-CS

```
<script>
$(document).ready(function () {
var datepickerObject = $("#MyFirstDatepicker").data("ejDatePicker");
});
</script>
```

3. Access the method from client side object like properties access, as shown in the following.

ASPX-CS

```
<script>
$(document).ready(function () {
var datepickerObject = $("#MyFirstDatepicker").data("ejDatePicker");
datepickerObject.disable(); // to disable the datepicker object
var selectedDate = datepickerObject.getValue(); // to access the selected
value
});
</script>
```

Localization

Localization is the process of customizing an application for given language and region.

Configure the Syncfusion Components to a particular language by the following steps.

1. Specify the target culture in **web.config** file under root.

XML

```
<system.web>
<globalization uiCulture="fr-FR" culture="fr-FR"
enableClientBasedCulture="true"/>
</system.web>
```

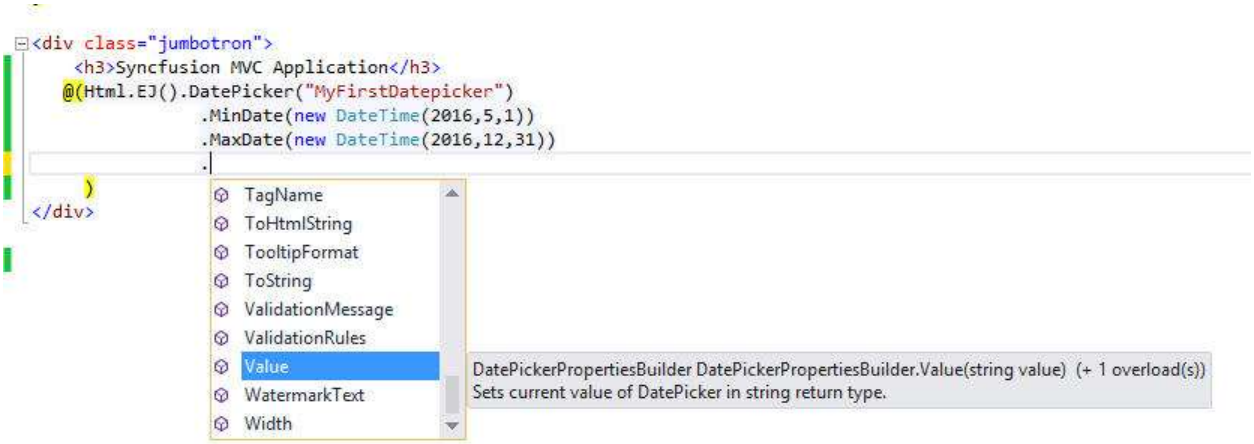
2. Load the globalize culture file from **i18n** folder dynamically by using the following codes.

ASPX-CS

```
@Scripts.Render("~/Scripts/ej/i18n/ej.culture." +
System.Globalization.CultureInfo.CurrentCulture.Name.ToString() + ".min.js")
```

3. Download and refer to the Syncfusion UI component localized text from ej-global repository.

Copyright © 2001 - 2020 Syncfusion Inc.



4. Load the Localized text file from **localetexts** folder like the previous step.

ASPX-CS

```
@Scripts.Render("~/Scripts/ej/localetexts/ej.localetexts." +
System.Globalization.CultureInfo.CurrentCulture.Name.ToString() + ".js")
```

5. Set the culture to Syncfusion UI components using the **Locale** helper method as shown in the following:

ASPX-CS

```
@(Html.EJ().DatePicker("MyFirstDatepicker")
.MinDate(new DateTime(2016, 5, 1))
.MaxDate(new DateTime(2016, 12, 31))
.Locale(System.Threading.Thread.CurrentThread.CurrentCulture.Name) //
Specify the UI culture
.ClientSideEvents(events =>
events.Change("datepicker_change") // To handle datepicker change event
.Select("datepicker_select") // To handle datepicker select event
)
)
```

6. Compile and execute the application. You can be able to see the following output in the browser.

Globalization

As per MSDN, “Globalization involves designing and developing a world-ready app that supports localized interfaces and regional data for users in the multiple cultures”.

The **ejGlobalize** plugin provides options parse numeric, currency, and date values by using culture file. The **assets/scripts/i18n** contains more than 350 cultures currently. You can load the particular culture into application by using the **preferredCulture** method.

Copyright © 2001 - 2020 Syncfusion Inc.

To Internationalize any of our Syncfusion components/page into particular culture, please follow the below steps:

1. Add the reference ej.globalize.min.js script into your application.

Note: The **ej.globalize.min.js** library already avails in within **ej.web.all.min.js** file, therefore it is not necessary to externally refer it in your application if you have referred **ej.web.all.min.js** already. For version lower than 13.4.0.53 refer to the **jQuery.globalize.min.js** along with the **ej.web.all.min.js**.

2. Add the required culture file into the page which is located in **assets/scripts/i18n**.

ASPX-CS

```
@Scripts.Render("~/Scripts/ej/common/ej.globalize.js")
@Scripts.Render("~/Scripts/ej/i18n/ej.culture.fr-FR.min.js")
```

3. Set the culture by using the **preferredCulture()** method. Here, French (fr-FR) culture is used as current culture.

ASPX-CS

```
<script>
if (typeof (ej.globalize) != 'undefined') {
ej.globalize.preferredCulture("fr-FR");//set Culture fr-FR
}
</script>
```

4. Use **format()** method to format the object like numbers, date, price, etc.

ASPX-CS

```
<script>
if (typeof (ej.globalize) != 'undefined') {
console.log("en-US Culture : ");
ej.globalize.preferredCulture("en-US");  //set Culture. Default culture is
en-US
console.log(ej.globalize.format(53422, 'C', "en-US")); // Formatting Price
console.log(ej.globalize.format(new Date(2016,07,15), 'D', "en-US"));
//Formatting date
console.log(ej.globalize.format(123123.576, 'n2', "en-US")); // Formatting
number
console.log("fr-FR Culture : ");
ej.globalize.preferredCulture("fr-FR");//set Culture fr-FR
console.log(ej.globalize.format(53422, 'C', "fr-FR"));// Formatting Price
console.log(ej.globalize.format(new Date(2016, 07, 15), 'D', "fr-FR"));
//Formatting date
console.log(ej.globalize.format(123123.576, 'n2', "fr-FR")); // Formatting
number
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Dynamic Globalization

The steps to globalize the MVC application are as follows:

1. Specify the target culture in **web.config** file under root.

XML

```
<system.web>
<globalization uiCulture="fr-FR" culture="fr-FR"
enableClientBasedCulture="true"/>
</system.web>
```

2. Load the culture file based on current culture that is specified in **web.config** as shown in the following.

ASPX-CS

```
@Scripts.Render("~/Scripts/ej/i18n/ej.culture." +
System.Globalization.CultureInfo.CurrentCulture.Name.ToString() + ".min.js")
```

3. Access the current culture using System.Globalization.CultureInfo and set the culture to ej.globalize widget.

ASPX-CS

```
<script>
if (typeof (ej.globalize) != 'undefined') {
ej.globalize.preferredCulture('@System.Threading.Thread.CurrentThread.Curren
tCulture.Name');//access the current culture from web.config and set it
console.log(ej.globalize.format(53422, 'C'));// Formatting Price
console.log(ej.globalize.format(new Date(2016, 07, 15), 'D')); //Formatting
date
console.log(ej.globalize.format(123123.576, 'n2')); // Formatting number
}
</script>
```

Please refer the below DatePicker sample which uses globalization,

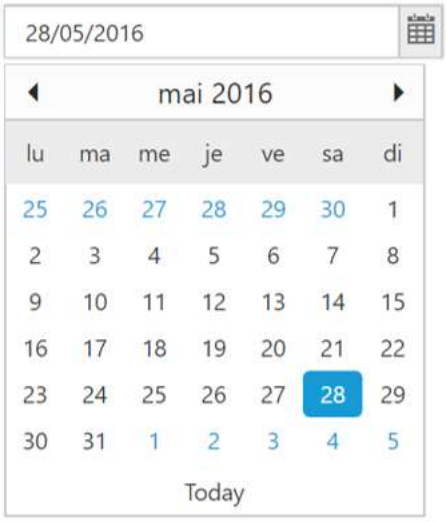
Follow the above steps 1 and 2 and then add the control in the view page

HTML

```
@Html.EJ().DatePicker("DatePick").Value("28/05/2016").Width("100%")
```

The following screenshot exhibits the output of the above code,

Copyright © 2001 - 2020 Syncfusion Inc.



Unobtrusive

Many uncertainties and difficulties are involved in a usual **JavaScript programming** environment, like some of the browsers may ignore the JavaScript codes under the scripts section completely or partially due to its complexity, and so on. To overcome all such inconveniences, the Unobtrusive JavaScript support has been introduced to make it easier for the users to create all our Syncfusion components with basic level HTML tag-like structure.

One of the main goal of the unobtrusive support is to achieve the clear separation of both the HTML content and behavior, so as to enhance the page loading time and to make the code updation easier. The **Essential JavaScript** have separate integration library to achieve the **Unobtrusive JS** support. To make use of Unobtrusive support with our Essential JavaScript components, it is necessary to refer to the **ej.unobtrusive.min.js** file in your application.

The **ej.unobtrusive.min.js** file can be accessed from the following location, that can then be copied and referred in your application.

(installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\common
For example, If you have installed the Essential Studio package within C:\Program Files (x86), navigate to the following location. C:\Program Files (x86)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\common

When you enable the **unobtrusive** in your application, refer to the **ej.unobtrusive.min.js** file in the application.

You have to set the value of **UnobtrusiveJavaScriptEnabled** to **true** in Root directory web.config file as shown in the following code example.

HTML

```
<appSettings>
```

```
<add key="ClientValidationEnabled" value="true" />
<add key="UnobtrusiveJavaScriptEnabled" value="true" />
</appSettings>
```

After setting the value as true, refer to the unobtrusive script file in the _Layout page as shown in the following code example.

HTML

```
<script src="~/Scripts/ej/ej.unobtrusive.min.js"></script>
```

Note: The ej.unobtrusive.min.js script should be referred next to the ej.web.all.min.js file reference, since it is dependent on it.

By default, it is necessary to add Script Manager code in the _Layout.cshtml file present within the ~/Views/Shared folder of your application.

HTML

```
<body>
@Html.EJ().ScriptManager()
@RenderSection("scripts", required: false)
</body>
```

Note: The main reason for referring the Script manager in _Layout file is that, it can be referred as common by all the View files present within your application.

If unobtrusive is set to true in the application, the script manager can be excluded, as the control is initialized by using HTML5 attributes.

A simple example by using the DropDownList control is as follows:

Render the DropDownList control as follows in your view page and enable the unobtrusive mode in your application.

HTML

```
@Html.EJ().DropDownList("selectCar").TargetID("carsList").Width("100%").Wate
rmarkText("Select a Car")
<div id="carsList">
<ul>
<li>Audi A4</li>
<li>Audi A5</li>
<li>Audi A6</li>
<li>Audi A7</li>
<li>Audi A8</li>
</ul>
</div>
```

When the above code is executed on the browser, the DropDownList control will be rendered with the following equivalent HTML DOM attributes created for it.

Copyright © 2001 - 2020 Syncfusion Inc.

Enabling Client Side Validation

Refer to the required jQuery validation scripts to perform Client-side Validation before postback, when the form is submitted. This can be enabled or disabled by ClientValidationEnabled key in app settings of web.config file.

In this section, how to perform Client-Side Validation for DropDownList control with DataAnnotations attribute is explained.

Define the view model for DropDownList control as follows.

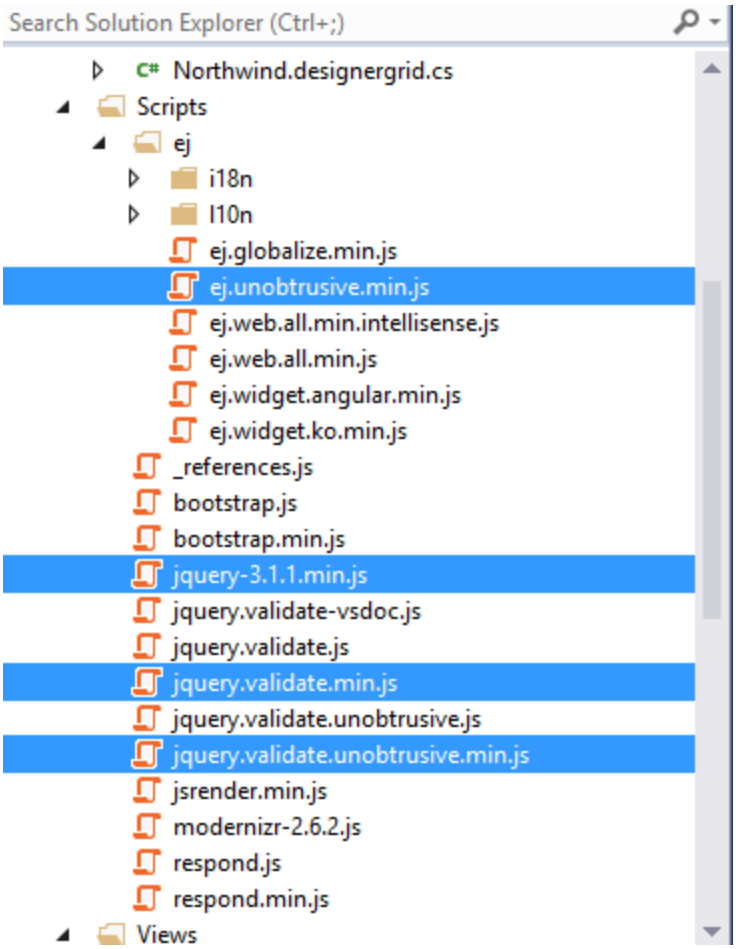
HTML

```
using System.ComponentModel.DataAnnotations;
namespace Dropdown
{
public class DropValue
{
[Required(ErrorMessage = "DropDownList value is Required")]
public List<DropDownValue> DropData { get; set; }
}
public class DropDownValue
{
public string Text { get; set; }
public string Value { get; set; }
}
}
```

Four sets of files are needed to implement the Unobtrusive.

- The jQuery library
- The jQuery Validate plugin
- The Unobtrusive extensions to Validate
- Ej unobtrusive library

Copyright © 2001 - 2020 Syncfusion Inc.



Refer the above mentioned necessary scripts files in your layout.cshtml page.

HTML

```
<script src="~/Scripts/jquery-3.1.1.min.js"></script>
<script src="~/Scripts/jquery.validate.min.js"></script>
<script src="~/Scripts/jquery.validate.unobtrusive.min.js"></script>
<script src="~/Scripts/ej/ej.web.all.min.js"></script>
<script src="~/Scripts/ej/ej.unobtrusive.min.js"></script>
```

Note: While creating a sample through Syncfusion ProjectTemplate or SampleCreator, the "ej.unobtrusive.min.js" file will be found in the "Scripts/ej" folder, whereas ,installing NuGet will ship the "ej.unobtrusive.min.js" file inside the "Scripts/ej/common" folder. Modify the script reference in the layout page based on this folder structure.

After that you need to create the controller's action methods. These render views on the UI and bind a model with the view. So let us create a controller as follows:

HTML

```
using Syncfusion.JavaScript.Models;
namespace Dropdown
{
public partial class DropdownlistController: Controller
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult DropdownlistFeatures()
{
BindingData();
return View();
}
public void BindingData()
{
List<DropDownValue> data = new List<DropDownValue>() { };
data.Add(new DropDownValue() { Value = "item1", Text = "List Item 1" });
data.Add(new DropDownValue() { Value = "item2", Text = "List Item 2" });
data.Add(new DropDownValue() { Value = "item3", Text = "List Item 3" });
data.Add(new DropDownValue() { Value = "item4", Text = "List Item 4" });
data.Add(new DropDownValue() { Value = "item5", Text = "List Item 5" });
DropDownListProperties obj = new DropDownListProperties();
obj.DataSource = data;
DropDownListFields fields = new DropDownListFields();
fields.Text = "Text";
fields.Value = "Value";
obj.DropDownListFields = fields; ViewData["properties"] = obj;
}
[HttpPost]
public ActionResult DropdownlistFeatures(DropDownListModel model)
{
BindingData();
return View(model);
}
}
}
```

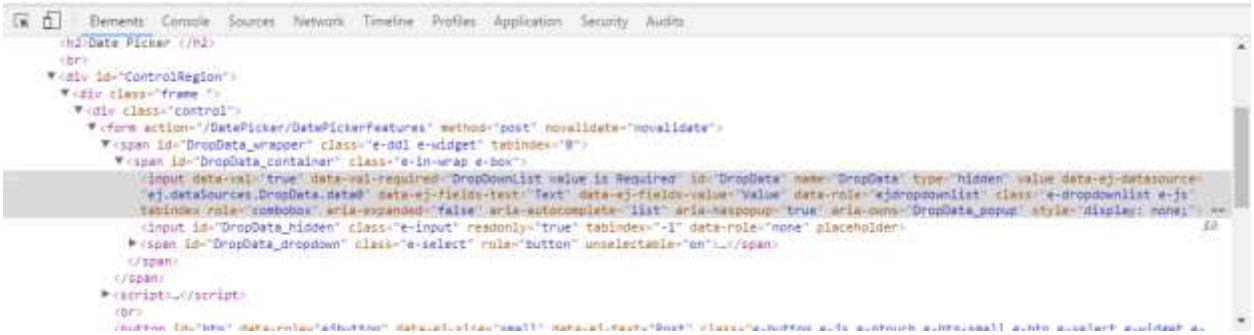
The view is created as in the following code snippet:

HTML

```
@using (Html.BeginForm())
{
@Html.ValidationSummary(true)
@Html.EJ().DropDownListFor(Model => Model.DropData,
(Syncfusion.JavaScript.Models.DropDownListProperties)ViewData["properties"])
<br />
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("Post").Type(ButtonType
.Submit)
}
```

When the above code is executed on the browser, the DropDownList control will be rendered with the following equivalent HTML DOM attributes created for it.

Copyright © 2001 - 2020 Syncfusion Inc.



Now, some interesting new attributes are there to look at:

- data-val specifies that the DropDownList needs validation.
- data-val-required is the error message to be displayed, if a value is not provided.

This is part of the magic of Unobtrusive: it uses HTML5-compatible "data-" attributes to store all the information it needs to perform validation. This is why you don't need to use any other code besides attributes to enable client-side validation with this library.

Validation

jQuery Validation

To perform the jQuery validation for EJ form controls, refer to the following steps.

Step 1: First you need to include the jquery.validate (1.15.0) script in your HTML page.

Step 2: After adding this script file, you can validate the EJ form controls in same way as you have performed the jQuery validation for HTML form elements. But, here you have to do some little bit configuration along with that. It is discussed in the following.

If validation gets fail, you have to place the error message in proper position using the “errorPlacement” API that is available in the default settings of jQuery validation. Also, built-in “error” class will be added to the corresponding form element. Here, you have to specify a custom class with your own style using the “errorClass” API. These are the common settings for all of our EJ form controls.

And some of our EJ form controls contains the form values in hidden element for its functionality purpose and by default, these hidden elements are not validated. If you want to include the hidden elements in jQuery validation, set “[]” in “ignore” API of “$.validator.setDefaults”. Refer to the following list to find out the EJ form controls that contains the values in hidden element.

- Checkbox
- MaskEdit
- NumericTextbox
- CurrencyTextbox
- PercentageTextbox
- RTE
- Dropdownlist

Refer to the following code block to configure the above mentioned jQuery validation settings.

JAVASCRIPT

```
$.validator.setDefaults({
```

```
//to validate all fields(hidden also)
ignore: [],
//if we don't set custom class, default "error" class will be added
errorClass: 'e-validation-error',
//it specifies the error message display position
errorPlacement: function (error, element) {
$(error).insertAfter(element.closest(".e-widget"));
}
});
```

Up to 13.4.0.58 version, the above specified jQuery validation settings were configured in source level of EJ form controls. Since 14.1.0.41 release onwards, the above specified settings has been removed from the source and it needs to be specified in sample level to improve the customization of this validation.

The EJMVC DatePicker provides cool way to validate the value by custom rules and messages before it get processed. Enhanced APIs and built-in validation support in EJWEB DatePicker provides the quick validation in client side itself, that provides easy customization and better user experience than validating the values in server side.

HTML

```
@using (Html.BeginForm())
{
//Sets the field to be required with validation message
@Html.EJ().DatePicker("datePicker").ValidationRules(rule =>
rule.AddRule("required", true)).ValidationMessage(msg =>
msg.AddMessage("required", "Required Date value"));
<input type="submit" value="click here!" />
}
```

Accessibility

The term Accessibility in general, refers to the process of designing a product that is easily accessible to all kinds of people irrespective of their disabilities. The developer should keep in mind the concept of Accessibility as their prime intention while creating any of the web applications, so that the application and the web content will be easily accessible to the people with disabilities. Such applications created with Accessibility support is generally termed as Accessible Rich Internet Applications (ARIA).

Sometimes, the content and the functionalities used in the websites cannot be conveyed to the users who mainly relies on screen readers and one who cannot use the mouse. To overcome such circumstances and to address these accessibility challenges, Web Accessibility Initiative (WAI-ARIA) has defined a new way/specification to achieve those functionalities with the use of some assistive technologies. The assistive technologies will make use of the widget's attribute information (roles, states, and properties) and then convey the appropriate information to the persons with disabilities.

The WAI-ARIA specification suite defines a set of roles, states, and properties for the user-accessible DOM elements that makes the accessibility and interoperability of the web content and applications easier than before.

Creating accessible widgets using WAI-ARIA

This section describes about the approaches followed to make the widgets accessible using the Roles, States, and Properties defined by WAI-ARIA specifications. The WAI-ARIA specifications recommends several attributes to be used along with the DOM element structure to make it accessible.

Copyright © 2001 - 2020 Syncfusion Inc.

The common widgets that can be made accessible by using the WAI-ARIA are listed here. The various ARIA attributes that are used to make the widgets accessible are listed here.

The basic steps for converting a common widget into accessible are as follows:

1. Choose the appropriate role for your widget that defines the general component type. For example, if you need to create a button, set the role to the button.

HTML

```
<button id="button1" role="button">Submit</button>
```

2. Once the role is selected, now you can set its state/properties avails for it from the link given here.

HTML

```
<button id="button1" role="button" aria-disabled="false" aria-
describedby="Submit the Form" >Submit</button>
```

i. The above code will make the button widget accessible, as it was defined with the aria-disabled state as false. It states that if none of that button actions are currently available, then the button is said to be in an aria-disabled state.

ii. The property aria-describedby has been assigned with some related button text that denotes the button description to be notified to the user.

Note: Note: If your button is a togglebutton, it can be defined with an additional aria-pressed state, that returns the value true if the button undergoes toggling, else the state remains as false.

An example with button control that has been made accessible can be referred from this link.

Usage of Accessibility in Syncfusion Widgets

All our Syncfusion Widgets are developed based on the standards mentioned in the ARIA specifications, therefore it supports the full-fledged feature of Web Accessibility Initiative (WAI). Since our Essential JavaScript has provided the built-in support for accessibility in all its UI widgets, therefore it allows the user to create the widgets that are easily used by the assistive technologies. The two major concepts that has been mainly focused for providing such accessibility support are as follows.

- Keyboard navigation
- Defining ARIA attributes to the required DOM elements

As of now, the keyboard navigation functionality is provided as a default feature for all the Syncfusion widgets which allows all the keyboard enabled widgets to interact with the user.

Keyboard Navigation

Any Syncfusion widgets used within an application are easily accessible to all, especially for the visually disabled peoples and those who cannot use mouse for navigating through the application. To make it more accessible, the built-in keyboard navigation support has been provided for almost all the components available within the Essential Studio package. Simply by pressing the TAB key will move the focus from one element to another within the application.

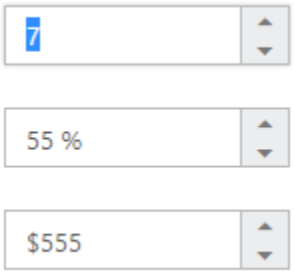
With this support enabled for the widgets, the various elements present within that particular widget can be easily focused by pressing the appropriate keyboard shortcuts. The currently focused element

Copyright © 2001 - 2020 Syncfusion Inc.

within the widget is clearly indicated with its unique visual style that denotes that it is now ready to accept the user inputs.

Such visual indications through keyboard navigation are very useful for the accessibility support, as it needs to be properly conveyed to the assistive technologies that the focus has been changed.

Each and every widget available within the Syncfusion Essential JavaScript suite has its unique behavior and responds appropriately to the keyboard actions. As an example, we will look onto the following 3 editors placed on the same page and how to navigate between them through the keyboard.



Initially, the focus is on the first editor (numeric textbox) that is indicated with the text selection and the border effect is provided for the widget's outline through the CSS.

Having the current focus on the numeric text box, now pressing the up arrow will increase the numeric value and down arrow will decrease the value. Pressing tab key will advance the focus to the next widget present in the page - here the percentage textbox that is placed as second will get focused on pressing the tab key.

To enable the default tab key navigation, all the Syncfusion widgets are set with appropriate tabIndex property with the provided value as 0 (zero). The element with keyboard focus is essential because it communicates essential information about the widget to the assistive technologies like screen readers.

Pressing Tab key will traverse the focus in a forward direction and if the shift + Tab combination of keys are pressed, the focus will be moved to the previous elements (focus traverse through backward direction).

Defining ARIA attributes to the required DOM elements

As discussed in the previous topics - To make a component more accessible by all kind of users, it needs to be defined with some essential information along with its initial element creation. Here, the essential information to be defined for the components are its suitable role, state, and its properties. Usually the assistive technologies will make use of these information retrieved from the specific attributes and use it to convey the appropriate information to the users.

Roles, States and Properties

As the widget role defines the component type, therefore all the Syncfusion widgets are provided with corresponding roles. The roles can be anything like button, toolbar, checkbox, radiobutton, and so on.

All the Syncfusion widgets are assigned with built-in States and properties based on its role. Usually the states and properties are defined for a widget using the ARIA attributes that will convey the appropriate current state and action of the control to the assistive technologies.

Copyright © 2001 - 2020 Syncfusion Inc.

For example, our Syncfusion button widget, when created through JavaScript code will be rendered in the web browser with HTML DOM elements (along with the assigned built-in ARIA attributes) as shown in the following.

HTML

```
@Html.EJ().Button("button11").Text("Login").Size(ButtonSize.Normal).ShowRoun
dedCorner(true)
```

When the above code is executed on the browser, the Syncfusion button widget will be rendered with the following equivalent HTML DOM attributes created for it.

HTML

```
<button id="button11" class="e-button e-js e-btn-normal e-btn e-select e-
widget e-corner-all" tabindex="" type="submit" role="button" aria-
describedby="login" aria-disabled="false"></button>
```

Here, the aria-describedby is the ARIA property assigned to the Syncfusion button widget as built-in, so that the button description is notified to the user through assistive technologies.

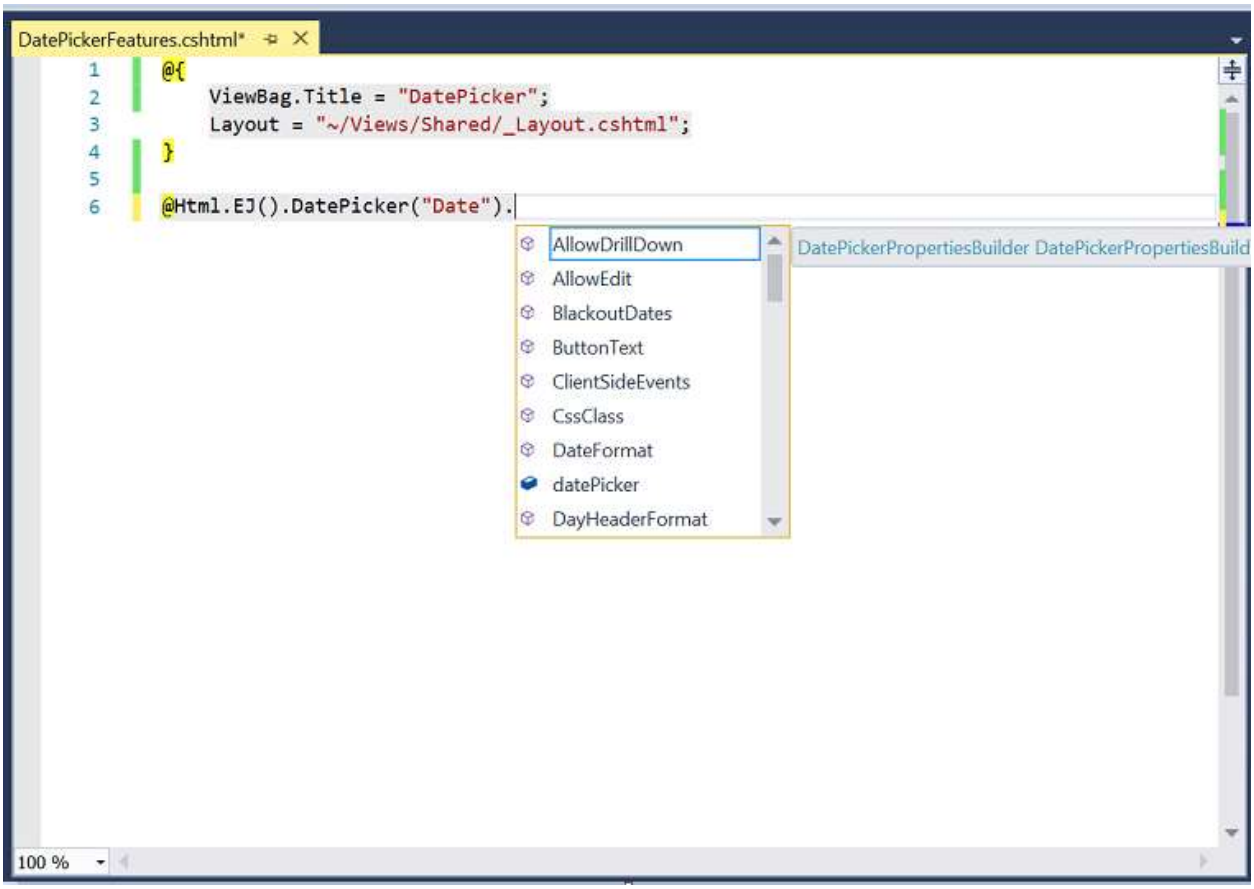
Likewise, the aria-disabled is one of the ARIA state assigned to the button as built-in, that states that if none of that button actions are currently available, the button is said to be in an aria-disabled state.

IntelliSense

The IntelliSense support is provided like the default ASP.NET MVC controls. It has the object list that holds the properties, public methods and event arguments of respective controls. On pressing the (.) Dot operator it displays those properties, public methods and event arguments of the corresponding control in the dropdown.

Refer to the following screenshot where the DatePicker control is used in the sample.

Copyright © 2001 - 2020 Syncfusion Inc.



Exporting Multiple Syncfusion Controls

We can export multiple Syncfusion controls like Grid, Chart, TreeGrid, etc., in a single document.

This can be achieved by calling ej.exportAll method. exportAll method accepts two necessary parameters; one for routing URL (either to export Excel or PDF) and other for passing multiple controls ID's as an array.

In the server side we can handle exporting multiple control either Excel or PDF exporting by calling ExportAll method

The following code example describes the above behavior.

RAZOR

```
@Html.EJ().Button("ExcelExport").Size(ButtonSize.Medium).ShowRoundedCorner(t
rue).Text("Excel Export").ClientSideEvents(eve=>eve.Click("ExcelExport"))
@Html.EJ().Button("PdfExport").Size(ButtonSize.Medium).ShowRoundedCorner(tru
e).Text("Pdf Export").ClientSideEvents(eve => eve.Click("PdfExport"))
@(Html.EJ().Grid<EmployeeView>("MasterGrid")
.Datasource((IEnumerable<object>)ViewBag.datasource)
.Columns(col =>
{
col.Field("EmployeeID").HeaderText("Employee
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(100).Add();
col.Field("FirstName").HeaderText("First Name").Width(100).Add();
col.Field("LastName").HeaderText("Last Name").Width(100).Add();
col.Field("Title").HeaderText("Title").Width(90).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Field("BirthDate").HeaderText("Birth
Date").TextAlign(TextAlign.Right).Width(100).Format("{0:MM/dd/yyyy}").Add();
col.Field("Country").Width(120).HeaderText("Country").Add();
})
)
@(Html.EJ().TreeGrid("TreeGridContainer")
.ChildMapping("Children")
.TreeColumnIndex(1)
.Columns(co =>
{
co.Field("TaskId").HeaderText("Task Id").Width(80).Add();
co.Field("TaskName").HeaderText("Task Name").Add();
co.Field("StartDate").HeaderText("Start Date").Add();
co.Field("EndDate").HeaderText("End Date").Add();
co.Field("Duration").HeaderText("Duration").Add();
})
.EditSettings(es => es.AllowDeleting(false))
.SizeSettings(ss => ss.Width("100%").Height("350px"))
.Datasource(ViewBag.data)
)
@(Html.EJ().Chart("ChartContainer").ChartArea(cr => cr.Border(ab =>
ab.Color("transparent")))
.Border(border => border.Opacity(1))
.Series(sr =>
{
sr.Points(pt =>
{
pt.X("John").Y(10).Add();
pt.X("Jake").Y(12).Add();
pt.X("Peter").Y(18).Add();
pt.X("James").Y(11).Add();
pt.X("Mary").Y(9.7).Add();
}).Name("Person").Type(SeriesType.Column).XName("XValue").YName("YValue1").E
nableAnimation(true).Tooltip(d => d.Visible(true)).Add();
})
.EnableCanvasRendering(true))
```

C#

```
public class GridController : Controller
{
public ActionResult GridFeatures()
{
var MasterData = new NorthwindDataContext().EmployeeViews.Take(5).ToList();
ViewBag.dataSource = MasterData;
var data = this.GetDefaultData();
ViewBag.data = data;
return View();
}
public void ExcelExport (FormCollection controlModel)
{
Dictionary<string, string> val =controlModel.AllKeys.ToDictionary(k => k,
v=>controlModel[v]);
ExcelExport exp = new ExcelExport();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
var EmployeeData = new
NorthwindDataContext().EmployeeViews.Take(5).ToList();   //DataSource for
Grid.
var treeData = this.GetDefaultData();
//DataSource for TreeGrid.
List<ExportChartData> chartData = new List<ExportChartData>();
chartData.Add(new ExportChartData("John", 10));
chartData.Add(new ExportChartData("Jake", 12));
chartData.Add(new ExportChartData("Peter", 18));
chartData.Add(new ExportChartData("James", 11));
chartData.Add(new ExportChartData("Mary", 9.7));
var chartDataSource = chartData;
//DataSource for Chart
Dictionary<string, object> items = new Dictionary<string, object>();
items.Add("ejGrid",EmployeeData);
items.Add("ejTreeGrid", treeData);
items.Add("ejChart", chartDataSource);
exp.ExportAll(val, items, "Export.xlsx", ExcelVersion.Excel2010, "flat-
saffron");
}
public void PdfExport (FormCollection controlModel)
{
Dictionary<string, string> val = controlModel.AllKeys.ToDictionary(k => k, v
=> controlModel[v]);
PdfExport exp = new PdfExport();
var EmployeeData = new
NorthwindDataContext().EmployeeViews.Take(5).ToList();    //DataSource for
TreeGrid.
var treeData = this.GetDefaultData();
//DataSource for TreeGrid.
List<ExportChartData> chartData = new List<ExportChartData>();
chartData.Add(new ExportChartData("John", 10));
chartData.Add(new ExportChartData("Jake", 12));
chartData.Add(new ExportChartData("Peter", 18));
chartData.Add(new ExportChartData("James", 11));
chartData.Add(new ExportChartData("Mary", 9.7));
var chartDataSource = chartData;
//DataSource for Chart
Dictionary<string, object> items = new Dictionary<string, object>();
items.Add("ejGrid", EmployeeData);
items.Add("ejTreeGrid", treeData);
items.Add("ejChart", chartDataSource);
exp.ExportAll(val, items, "Export.pdf", "flat-saffron");
}
}
```

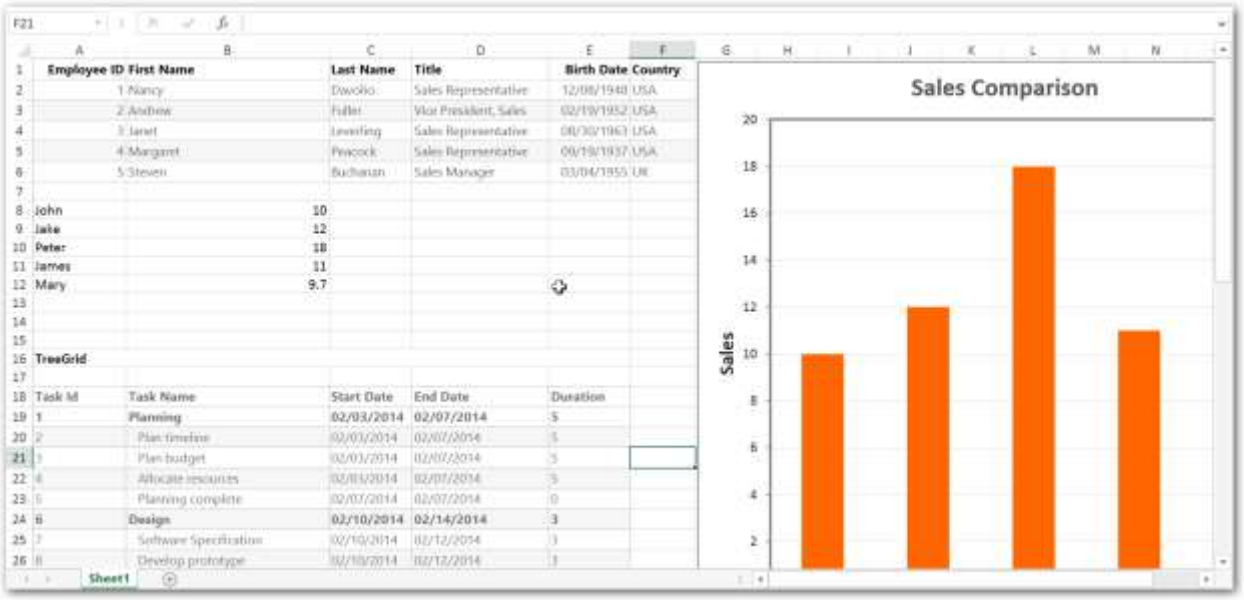
JS

```
<script>
function ExcelExport(args) {
ej.exportAll("/Grid/ExcelExport", ['MasterGrid', 'ChartContainer',
'TreeGridContainer'])
}
function PdfExport(args) {
ej.exportAll("/Grid/PdfExport", ['MasterGrid','TreeGridContainer' ]);
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</script>
```

The following output is displayed as a result of the above code example.



Strongly-Typed HTML Helper

The Syncfusion editor controls supports the strongly typed HTML helpers represented by lambda expressions that have the model or template passed into the view. The Extension method is used to get a value from the model.

The Strongly-Typed HTML helper (i.e., NumericTextBox) takes lambda as a parameter that tells the helper, which element of the model to be used in the typed view.

The Strongly typed views are used for rendering specific types of model objects, instead of using the general ViewData structure.

The following list of controls supports the Strongly-Typed HTML Helper:

- Autocomplete
- Checkbox and Radio Button
- DatePicker
- DateTimePicker
- DropDownList
- Mask Edit
- Numeric, Currency, and Percentage Textbox
- RichTextEditor
- TimePicker

The following steps explain how to use the strongly typed helpers to create a NumericTextBox.

The NumericTextBox control supports strongly typed HTML helpers that uses lambda expression to refer to the models or view models passed to a view template. These helpers allows you to define the value of the NumericTextBoxFor from the model.

Copyright © 2001 - 2020 Syncfusion Inc.

Add a class name “EditorValue” in the Models folder and replace the code with the following code:

HTML

```
public class EditorValue
{
public int number { set; get; }
public EditorValue(int value)
{
number = value;
}
public EditorValue (){}
}
```

Create an action method that renders the NumericTextBox on the view page, and passes the model to be bound to the view page.

C#

```
using Syncfusion.JavaScript.Models;
using MVCSampleBrowser.Models;
public ActionResult EditorFor()
{
//Editor For
EditorProperties editor = new EditorProperties();
editor.EnableStrictMode = true;
ViewData["editmodel"] = editor;
return View(new EditorValue(66));
}
```

In View, invoke the strongly typed NumericTextBoxFor helper with the lambda expression to set the default value.

RAZOR

```
@model MVCSampleBrowser.Models.EditorValue
@using (Html.BeginForm())
{
@Html.EJ().NumericTextBoxFor(model => model.number,
(Syncfusion.JavaScript.Models.EditorProperties)ViewData["editmodel"])
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("PayBill").Type(ButtonT
ype.Submit)
}
```

The following steps explain how to get the values by using the Scaffolding methods in Post back.

Copyright © 2001 - 2020 Syncfusion Inc.

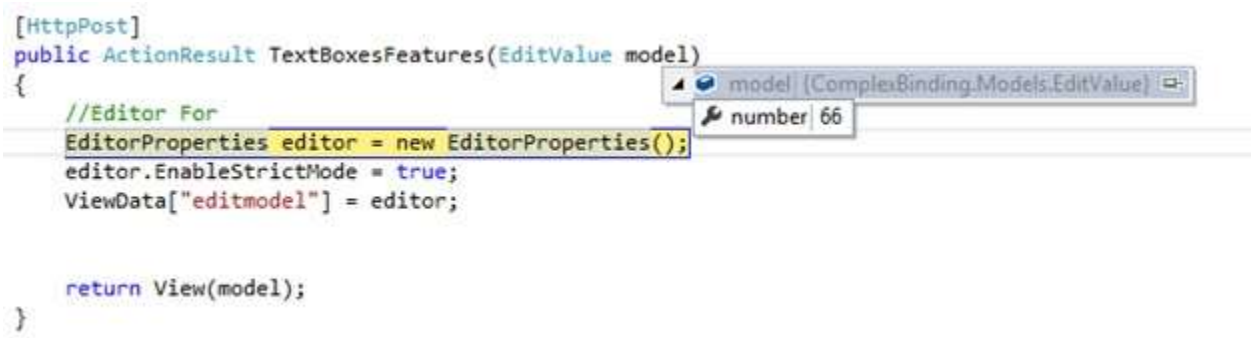
1. Create an action method, FormPost that handles the Post request and processes the data.

In the action method, you can pass the model as the parameter and that model has the NumericTexBox's value.

C#

```
[HttpPost]
public ActionResult EditorFor(EditorValue model)
{
//Editor For
EditorProperties editor = new EditorProperties();
editor.EnableStrictMode = true;
ViewData["editmodel"] = editor;
return View(model);
}
```

On clicking the button, the Post method will be triggered. In that, the selected value will be obtained as follows.



Client Side Validation

With the client-side validation, the input data is checked as soon as they are submitted, so there is no postback to the server and no page refresh.

By default, client-side validation is enabled. But it can be easily enabled or disabled by the writing of the following app setting code snippet in the web.config file.

HTML

```
<appSettings>
<add key="ClientValidationEnabled" value="true" />
<add key="UnobtrusiveJavaScriptEnabled" value="true" />
</appSettings>
```

Note: Enable client side validation for specific view only by adding the Html.EnableClientValidation(true) at the top in view page.

After setting the value as true, refer to the jQuery validation script file in the _Layout page as shown in the following code example.

HTML

```
<script src="~/Scripts/jquery.validate.min.js"></script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script src="~/Scripts/jquery.validate.unobtrusive.js"></script>
<script src="~/Scripts/ej/ej.unobtrusive.min.js"></script>
```

The jQuery validation plug-in takes the advantage of the Data Annotation attributes defined in the model.

Step 1: Add the following namespace to the “EditorValue” model.

HTML

```
using System.ComponentModel.DataAnnotations;
```

The Data Annotations allows to decorate model classes with the metadata. This metadata describes a set of rules that are used to validate a property.

The following Data Annotation attributes are used for the Numeric Textbox.

Required: Indicates that the property is a required field.

Step 2: Next, Update the number property of the “EditorValue” class as “Required Field” by adding the following line.

C#

```
using System.ComponentModel.DataAnnotations;
public class EditorValue
{
[Required(ErrorMessage = "Numeric Textbox is Required")]
public int number { set; get; }
public EditorValue(int value)
{
number = value;
}
}
```

Step 3: Modify the view page as follows:

RAZOR

```
@model ComplexBinding.Models.EditorValue
@using (Html.BeginForm())
{
@Html.ValidationSummary(true)
@Html.EJ().NumericTextBoxFor(model => model.number,
(Syncfusion.JavaScript.Models.EditorProperties)ViewData["editmodel"])
@Html.ValidationMessageFor(model => model.number)
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("PayBill").Type(ButtonT
ype.Submit)
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Server Side Validation

In the server-side validation, the page must be submitted via a postback to validate on the server and if the model data is not valid, the server sends a response back to the client.

The best way to validate a model is by using the Data Annotations that has a set of attributes and classes defined in the System.ComponentModel.DataAnnotations assembly.

Step 1: Add the following namespace to the “EditorValue” model.

HTML

```
using System.ComponentModel.DataAnnotations;
```

The Data Annotations allows to decorate model classes with the metadata. This metadata describes a set of rules that are used to validate a property.

The following Data Annotation attributes are used for the Numeric Textbox.

Required: Indicates that the property is a required field.

Step 2: Next, Update the number property of the “EditorValue” class as “Required Field” by adding the following line

C#

```
using System.ComponentModel.DataAnnotations;
public class EditorValue
{
[Required(ErrorMessage = "Numeric Textbox is Required")]
public int number { set; get; }
public EditorValue(int value)
{
number = value;
}
}
```

Step 3: Modify the view page as follows:

RAZOR

```
@model ComplexBinding.Models.EditorValue
@using (Html.BeginForm())
{
@Html.ValidationSummary(true)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().NumericTextBoxFor(model => model.number,
(Syncfusion.JavaScript.Models.EditorProperties)ViewData["editmodel"])
@Html.ValidationMessageFor(model => model.number)
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("PayBill").Type(ButtonT
ype.Submit)
}
```

When you press the “PayBill” button on this page then it will post the data to the server and the code written with in EditorFor action will validate the NumericTextBox value by checking the ModelState.IsValid property. If the NumericTextBox value is not selected, the ModelState.IsValid will return false and display error message.

Complex Model Binding

The lambda expressions are quite powerful, allows you to build quite complex edit models and have model binding that put everything back together again. A complex view model type such as:

C#

```
public class Person
{
public string Name { get; set; }
public BillingInfo BillingInfo { get; set; }
public Person(BillingInfo info){
BillingInfo = info;
}
public Person() { }
}
public class BillingInfo
{
public int BillingNo { get; set; }
public BillingInfo(int no)
{
BillingNo = no;
}
public BillingInfo() { }
}
```

Create an action method that renders NumericTextbox on the view page, and passes the model to be bound to the view page.

C#

```
using ComplexBinding.Models;
using Syncfusion.JavaScript.Models;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult Complex()
{
//Editor For
EditorProperties editor = new EditorProperties();
editor.EnableStrictMode = true;
ViewData["editmodel"] = editor;
return View(new Person(new BillingInfo(1121)));
}
```

In View, invoke the strongly typed NumericTextBoxFor helper with the lambda expression to set the default value.

RAZOR

```
@model ComplexBinding.Models.Person
@using (Html.BeginForm())
{
@Html.EJ().NumericTextBoxFor(x => x.BillingInfo.BillingNo,
(Syncfusion.JavaScript.Models.EditorProperties)ViewData["editmodel"])
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("PayBill").Type(ButtonT
ype.Submit)
}
```

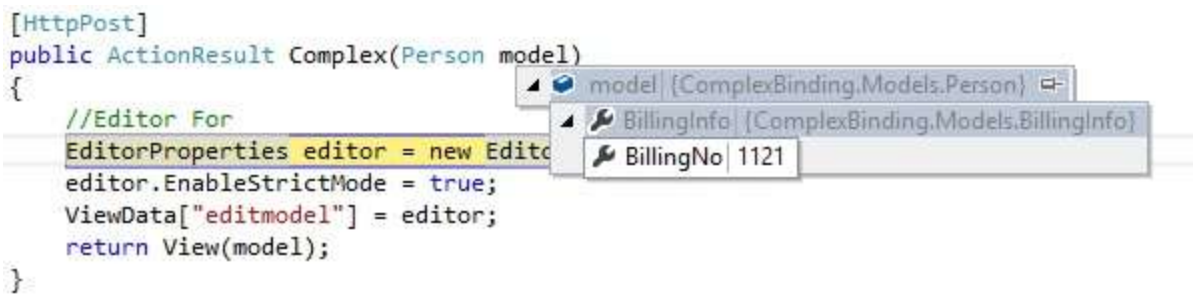
When the form is submitted, it will perform an HTTP Post request to the controller. The action with the HttpPost attribute will handle the request.

C#

```
[HttpPost]
public ActionResult Complex(Person model)
{
//Editor For
EditorProperties editor = new EditorProperties();
editor.EnableStrictMode = true;
ViewData["editmodel"] = editor;
return View(model);
}
```

In the above code, the selected value of NumericTextBox will be obtained as follows:

Copyright © 2001 - 2020 Syncfusion Inc.



Syntax for VB

Our Syncfusion ASP.NET MVC components can render the control either by using **C#** or **VB**. As only the control declaration syntax varies across languages and other functionalities are usually performed in the client-side.

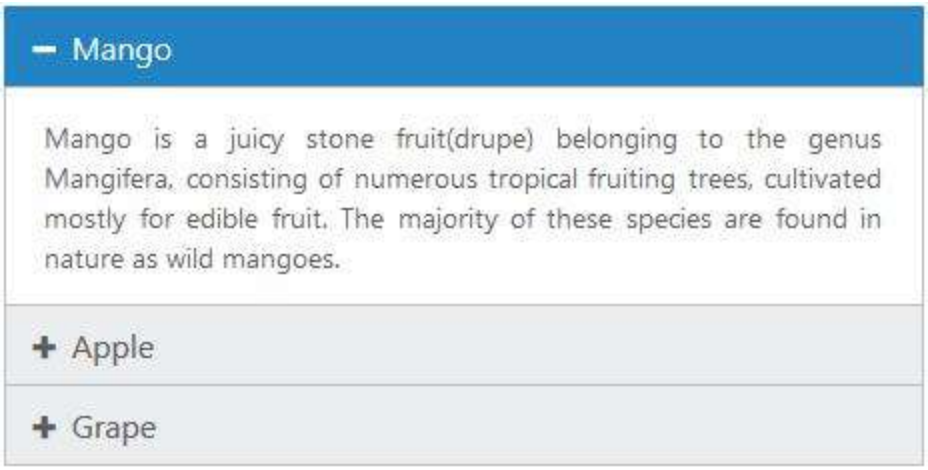
The following example code illustrates the VB syntax to be used within the server-side wrapper declaration – **to create an Accordion control** using the lambda expression.

VB.NET

```
@Code
Html.EJ().Accordion("basicAccordion").Items(Sub(data)
data.Add().Text("Mango").ContentTemplate(Sub()@<div> Mango is a juicy stone
fruit(drupe) belonging to the genus Mangifera, consisting of numerous
tropical fruiting trees, cultivated mostly for edible fruit. The majority of
these species are found in nature as wild mangoes.</div>End Sub)
data.Add().Text("Apple").ContentTemplate(Sub()@<div>Apple is a sweet,
pomaceous fruit originated in Central Asia, where its wild ancestor, Malus
sieversii, is still found today. Apples have been grown for thousands of
years in Asia and Europe, and were brought to North America by European
colonists.</div> End Sub)
data.Add().Text("Grapes").ContentTemplate(Sub()@<div>Grapes are a non-
climacteric type of fruit, generally occurring in clusters. It is a fruiting
berry of the deciduous woody vines of the botanical genus Vitis. The
cultivation of the domesticated grape began 6,000–8,000 years ago in the
Near East.</div> End Sub)
End Sub).Render()
End Code
```

The output for the above code will be like the following:

Copyright © 2001 - 2020 Syncfusion Inc.



Accordion

Accordion

The Accordion control is an interface where lists of items can be collapsed or expanded. It has several collapsible panels where only one/more can be expanded at a time that is useful for dashboards where space is limited. Each Accordion control has a template for its header and its content.

Key Features

- Collapsible Header: All headers are collapsible.
- AJAX Load: Load AJAX content in the Accordion content panel.
- Icon Customization: Expand and collapse icons can be customized.
- Custom Event for Expand Header: By default, Accordion panels can be expanded and collapsed on a single click. However, this action can be customized to occur on mouse-over or mouse-up through custom events.
- Multiple Open: Multiple items can be expanded.
- Auto Size: The content panel height can be predefined with values such as content, auto, and fill.
- Theme: Essential ASP.NET MVC controls feature 13 built-in themes (six flat themes and six with gradient effects and a bootstrap theme), and also supports custom skin options to set user-defined themes.
- RTL: Accordion headers and content text can display RTL languages.
- Keyboard Navigation: You can expand and collapse panels using the keyboard.

Getting Started

This section explains briefly about how to create an Accordion in your application with ASP.NET MVC.

Copyright © 2001 - 2020 Syncfusion Inc.

Create your first Accordion in ASP.NET

The ASP.NET MVC Accordion control allows you to provide multiple panes and display them one/more at a time. In this section, you can learn how the Accordion control is configured and how to use it in your application.

Configure Accordion

This section explains you the details on how to configure the Accordion control in your application and how to customize it with various properties such as multiple open, rounded corner and icons for the Accordion header according to your requirement.

The following screenshot illustrates you the usage of Accordion control in listing the controls under the Essential Studio products.

Copyright © 2001 - 2020 Syncfusion Inc.

In the above screenshot , the Accordion contains a template for its Header and its content. In this Accordion application, you can list the controls under Essential Studio.

Create a Simple Accordion

ASP.NET MVC Accordion basically renders using a div element. The following step describes the creation of Accordion control.

- You can create a MVC Project and add necessary Dll's with the help of the given MVC-Getting Started Documentation.
- Please add the below code in layout._cshtml file head section to add the necessary script and CSS files to render the Accordion control.

ASPX-CS

```
<head>
<link href="http://cdn.syncfusion.com/13.1.0.21/js/web/flat-
azure/ej.web.all.min.css" rel="stylesheet" />
<!--Scripts-->
<script src="http://cdn.syncfusion.com/js/assets/external/jquery-
1.10.2.min.js"></script>
<script
src="http://cdn.syncfusion.com/js/assets/external/jquery.easing.1.3.min.js">
</script>
<script src="http://cdn.syncfusion.com/13.1.0.21/js/web/ej.web.all.min.js">
</script>
</head>
```

Copyright © 2001 - 2020 Syncfusion Inc.

- Add the following code example to the corresponding view page for Accordion rendering.

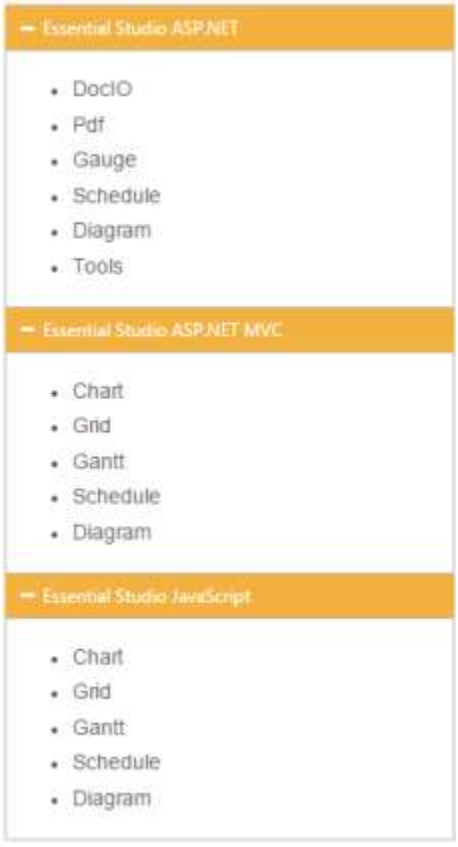
ASPX-CS

```
@{Html.EJ().Accordion("basicAccordion").Width("400px").EnableMultipleOpen(tr
ue).Items(data =>
{
data.Add().Text("Essential Studio ASP.NET").ContentTemplate(@
<div>
<ul>
<li>
<h4>DocIO</h4>
</li>
<li>
<h4>PDF  </h4>
</li>
<li>
<h4>Gauge  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
<li>
<h4>Tools </h4>
</li>
</ul>
</div>);
data.Add().Text("Essential Studio ASP.NET MVC").ContentTemplate(@
<div>
<ul>
<li>
<h4>Chart </h4>
</li>
<li>
<h4>Grid  </h4>
</li>
<li>
<h4>Gantt  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
</ul>
</div>);
data.Add().Text("Essential Studio JavaScript").ContentTemplate(@
<div>
<ul>
<li>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<h4>Chart </h4>
</li>
<li>
<h4>Grid  </h4>
</li>
<li>
<h4>Gantt  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
</ul>
</div>);
}).Render();}
```

Execute the above code example to display the Accordion control with simple control list.



You can customize the Accordion control using various properties. The Accordion control properties and its default values are described in the following section.

Configure Multiple Open

You can open multiple Accordion tabs to view all products at a time. To render this set the EnableMultipleOpen property of the Accordion control to true.

Copyright © 2001 - 2020 Syncfusion Inc.

Note: EnableMultipleOpen property is false by default.

You can also open all the panels during initialization using the SelectedItems property of the Accordion control. The following code sample illustrates the opening of multiple tabs by passing the tab index values of tab.

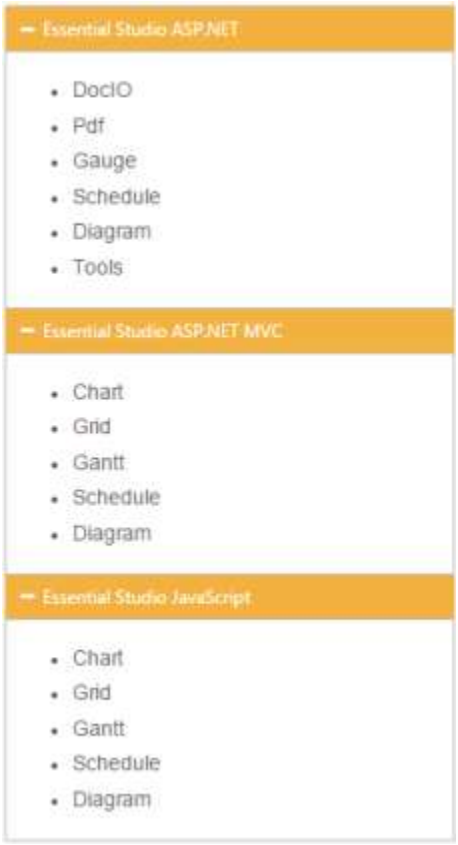
HTML

```
@{
List
<int> selected = new List
<int>() { 0, 1, 2 };
}
@{Html.EJ().Accordion("basicAccordion").EnableMultipleOpen(true).SelectedIte
ms(selected).Items(data =>
{
data.Add().Text("Essential Studio ASP.NET").ContentTemplate(@
<div>
<ul>
<li>
<h4>DocIO</h4>
</li>
<li>
<h4>PDF  </h4>
</li>
<li>
<h4>Gauge  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
<li>
<h4>Tools </h4>
</li>
</ul>
</div>);
data.Add().Text("Essential Studio ASP.NET MVC").ContentTemplate(@
<div>
<ul>
<li>
<h4>Chart </h4>
</li>
<li>
<h4>Grid  </h4>
</li>
<li>
<h4>Gantt  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</ul>
</div>);
data.Add().Text("Essential Studio JavaScript").ContentTemplate(@
<div>
<ul>
<li>
<h4>Chart </h4>
</li>
<li>
<h4>Grid  </h4>
</li>
<li>
<h4>Gantt  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
</ul>
</div>);
}).Render();
}
```

Accordion control with EnableMultipleOpen property is illustrated in the following screenshot.



Copyright © 2001 - 2020 Syncfusion Inc.

Set Rounded corner

Accordion control by default is rendered in a regular rectangle. You can modify the regular rectangles with rounded corners by setting the ShowRoundedCorner property to true.

Note: ShowRoundedCorner property is false by default.

ASPX-CS

```
<div id="ProductsAccordion" style="width: 400px">
@{
List<int> selected = new List<int>() { 0, 1, 2 };
}
@{Html.EJ().Accordion("basicAccordion").EnableMultipleOpen(true).SelectedIte
ms(selected).ShowRoundedCorner(true).Items(data =>
{
data.Add().Text("Essential Studio ASP.NET").ContentTemplate(@<div>
<ul>
<li>
<h4>DocIO</h4>
</li>
<li>
<h4>PDF  </h4>
</li>
<li>
<h4>Gauge  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
<li>
<h4>Tools </h4>
</li>
</ul>
</div>);
data.Add().Text("Essential Studio ASP.NET MVC").ContentTemplate(@<div>
<ul>
<li>
<h4>Chart </h4>
</li>
<li>
<h4>Grid  </h4>
</li>
<li>
<h4>Gantt  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
</ul>
</div>);
data.Add().Text("Essential Studio JavaScript").ContentTemplate(@<div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<ul>
<li>
<h4>Chart </h4>
</li>
<li>
<h4>Grid  </h4>
</li>
<li>
<h4>Gantt  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
</ul>
</div>);
}).Render();
}
```

The following screenshot illustrates the Accordion control with rounded corners.

Customize Icon

You can customize the Header icon using Custom Icon property. This property is having two features such as Header and SelectedHeader. By default, the classes of Header and SelectedHeader are e-collapse and e-expand respectively.

You can change the + and - symbols in the Accordion header, that are default icons with Up and Down arrow icons.

Up and Down arrow icons are available in e-arrowheadup and e-arrowheaddown classes respectively in the ej.widgets.core.min.css stylesheets from the sample.

You can set the Up/Down arrow icon to Accordion header, by adding e-arrowheadup and e-arrowheaddown class to SelectedHeader and Header properties respectively.

ASPX-CS

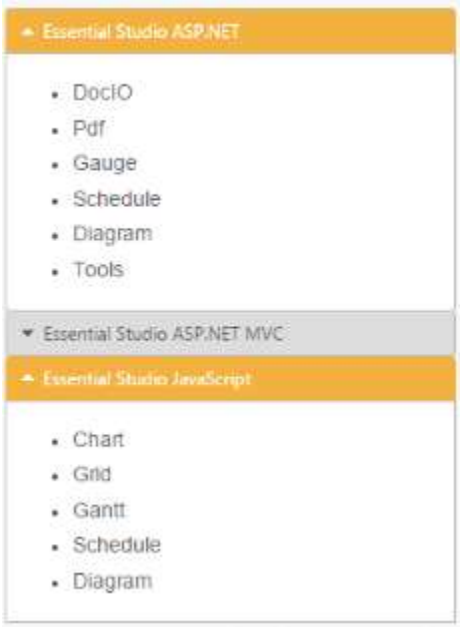
```
@{Html.EJ().Accordion("basicAccordion").EnableMultipleOpen(true).ShowRounded
Corner(true).CustomIcon(icon => icon.SelectedHeader("e-
arrowheadup").Header("e-arrowheaddown")).Items(data =>
```

```
{
data.Add().Text("Essential Studio ASP.NET").ContentTemplate(@<div>
<ul>
<li>
<h4>DocIO</h4>
</li>
<li>
<h4>PDF  </h4>
</li>
<li>
<h4>Gauge  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
<li>
<h4>Tools </h4>
</li>
</ul>
</div>);
data.Add().Text("Essential Studio ASP.NET MVC").ContentTemplate(@<div>
<ul>
<li>
<h4>Chart </h4>
</li>
<li>
<h4>Grid  </h4>
</li>
<li>
<h4>Gantt  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
<h4>Diagram  </h4>
</li>
</ul>
</div>);
data.Add().Text("Essential Studio JavaScript").ContentTemplate(@<div>
<ul>
<li>
<h4>Chart </h4>
</li>
<li>
<h4>Grid  </h4>
</li>
<li>
<h4>Gantt  </h4>
</li>
<li>
<h4>Schedule  </h4>
</li>
<li>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<h4>Diagram  </h4>
</li>
</ul>
</div>);
}).Render();
}
```

The following screenshot illustrates the customization of SelectedHeader and Header of the Accordion control.



Header customization

Collapsible

Accordion widget allows you to set Collapsible state for an Accordion header. Thus you can expand and collapse accordion contents. By default Collapsible is set to false.

Enable Collapsible settings

The following code explains to enable Collapsible state for Accordion using MVC helper.

ASPX-CS

```
// In the View page, render Accordion with corresponding data and enable
Collapsible property.
<div style="width: 400px">
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>
Essential Chart for ASP.NET MVC is a visually stunning, high-performance
charting component that is easy to use. It includes 35 chart types ranging
from simple column charts to specialized financial charts. The charts are
highly customizable and have a powerful data model that makes data binding
simple.
</div>);
data.Add().Text("Essential Schedule").ContentTemplate(@<div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Essential Schedule for ASP.NET MVC is an Outlook Calendar-like scheduler
control that lets you add rich scheduling capabilities to your web
applications. It includes an advanced set of features including data
binding, multiple resource views, rich interactivity, support for AJAX,
client-side events, and much more.
</div>);
data.Add().Text("Essential Grid").ContentTemplate(@<div>
Essential Grid for ASP.NET MVC is a feature-rich control that provides
extensive appearance customization options with support for grouped records.
With Essential Grid for ASP.NET MVC, you can create a grid with a highly
customizable look and feel. This grid is very useful for generating complex
grid-based reports with rich formatting. It supports paging, sorting,
grouping, filtering, and editing features. It also supports a JSON mode in
which you can handle all the operations like paging and sorting. The
performance of these operations in the JSON mode will be much faster than if
the grid were to handle them. Essential Grid generates clean HTML in
compliance with XHTML 1.0. It supports any kind of IEnumerable data source.
It uses LINQ data retrieval techniques for handling data sources, and offers
high performance.</div>);
}).Collapsible(true).Render();}
</div>
```

Output for Accordion control with collapsible headers.

Enable Header expand

Accordion widget provides you support to set the event, where the headers should expand and collapse. The events properties takes default events like mouseout, mouseover, and click.

Configure header expand event

The following code explains you to configure header expand event for Accordion.

ASPX-CS

```
// In the View page, render Accordion with corresponding data and configure
the Events property.
<div style="width: 400px">
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>
Essential Chart for ASP.NET MVC is a visually stunning, high-performance
charting component that is easy to use. It includes 35 chart types ranging
from simple column charts to specialized financial charts. The charts are
highly customizable and have a powerful data model that makes data binding
simple.
</div>);
data.Add().Text("Essential Schedule").ContentTemplate(@<div>
Essential Schedule for ASP.NET MVC is an Outlook Calendar-like scheduler
control that lets you add rich scheduling capabilities to your web
applications. It includes an advanced set of features including data
binding, multiple resource views, rich interactivity, support for AJAX,
client-side events, and much more.
</div>);
data.Add().Text("Essential Grid").ContentTemplate(@<div>

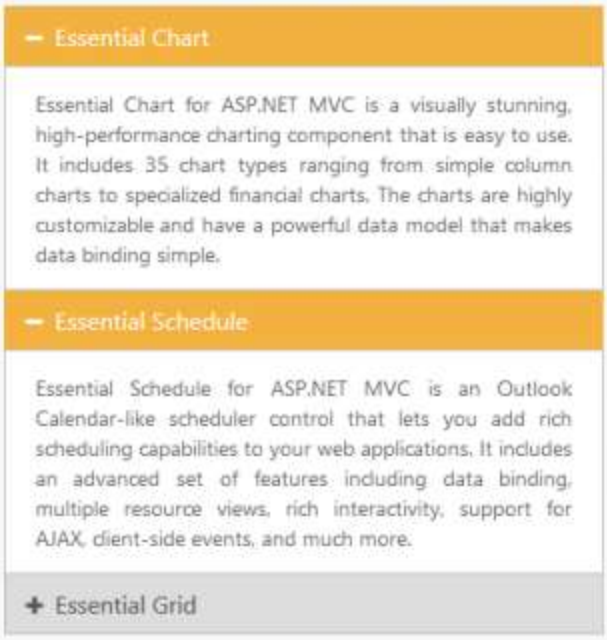
high performance.</div>);
}).Events("mouseout").Render();}
</div>
```

Output for Accordion control that expands header on mouseout event is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Single selection

BY using SelectedItemIndex property you can modify the expanded panel when the control is rendered. By default SelectedItemIndex is '0' that always activate the first Accordion panel.

Specify the selected item in Accordion panel

Using SelectedItemIndex property you can modify the expanded panel when the control is rendered. By default SelectedItemIndex is '0' that always activate the first Accordion panel.

Specify the selected item in Accordion panel

The following code explains you to configure selected item for Accordion.

ASPX-CS

```
// In the View page, render Accordion with corresponding data and configure
selected item for Accordion based on the index.
<div style="width: 400px">
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>
Essential Chart for ASP.NET MVC is a visually stunning, high-performance
charting component that is easy to use. It includes 35 chart types ranging
from simple column charts to specialized financial charts. The charts are

}).SelectedItemIndex(2).Render();}
</div>
```

Output for Accordion control with the selected item by index is as follows.

Multiple selection

In Accordion widget you can select multiple panel items using SelectedItems property. It takes array of indices that needs to be selected on rendering the control. As you need to select multiple items, you can set EnableMultipleOpen to true.

Configure multiple selection in Accordion panel

The following code explains to configure selected items for Accordion.

ASPX-CS

```
// In the View page, render Accordion with corresponding data and configure
multiple items selection for Accordion.
<div style="width: 400px">
@{      //List of integer array with index values.
List<int> selected = new List<int>() { 0, 1, 2 };
}
```

```
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>
Essential Chart for ASP.NET MVC is a visually stunning, high-performance
charting component that is easy to use. It includes 35 chart types ranging

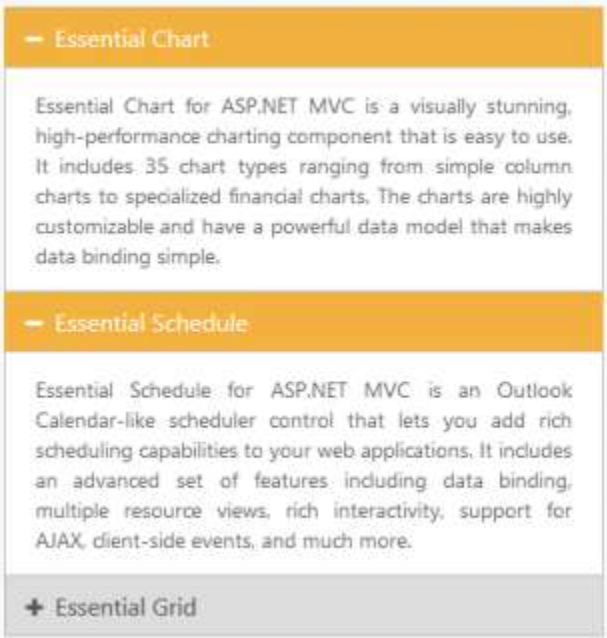
}).SelectedItems(selected).EnableMultipleOpen(true).Render();}
</div>
```

Output for Accordion control with the multiple selected items is as follows.



Copyright © 2001 - 2020 Syncfusion Inc.

AJAX settings

Accordion widgets allow you to load content for the Accordion panel using AJAX. This renders content from the specified URL location that is set to the anchor tag. You can set the destination file URL string by using AjaxUrl property AJAX contents enables you to load the content of the Accordion panel when it is expanded. This enhances the Accordion control efficiency when a large content is to be loaded into the panel.

Populate accordion with AJAX content

The following code explains about loading accordion content using AjaxUrl property.

ASPX-CS

```
// In the View page, render Accordion with corresponding data and set
AjaxUrl property for the corresponding headers.
<div style="width: 800px; float:left;">
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("MVC").AjaxUrl("../../Content/mvccontent.html");
data.Add().Text("WPF").AjaxUrl("../../Content/wpfcontent.html");
data.Add().Text("WCF").ContentTemplate(@<div>
WCF is a tool often used to implement and deploy a service-oriented
architecture (SOA).It is designed using service-oriented architecture
principles to support distributed computing where services have remote
consumers. Clients can consume multiple services; services can be consumed
by multiple clients. Services are loosely coupled to each other. Services
typically have a WSDL interface (Web Services Description Language) that any
WCF client can use to consume the service, regardless of which platform the
service is hosted on. WCF implements many advanced Web services (WS)
standards such as WS-Addressing, WS-ReliableMessaging and WS-Security. With
the release of .NET Framework 4.0, WCF also provides RSS Syndication
Services, WS-Discovery, routing and better support for REST
services.</div>);
}).Render();}
</div>
```

Output for Accordion control with loaded AJAX content is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

View multiple contents

By default Accordion allows only one panel to be in expanded state. You can enable multiple panels in expand state by setting EnableMultipleOpen to true.

Enabling multiple panel open

The following code explains you to enable multiple panel for Accordion.

ASPX-CS

```
// In the View page, render Accordion with corresponding data and set
EnableMultipleOpen property as true.
<div style="width: 400px">
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>
Essential Chart for ASP.NET MVC is a visually stunning, high-performance
charting component that is easy to use. It includes 35 chart types ranging
from simple column charts to specialized financial charts. The charts are
highly customizable and have a powerful data model that makes data binding
simple.
</div>);
data.Add().Text("Essential Schedule").ContentTemplate(@<div>

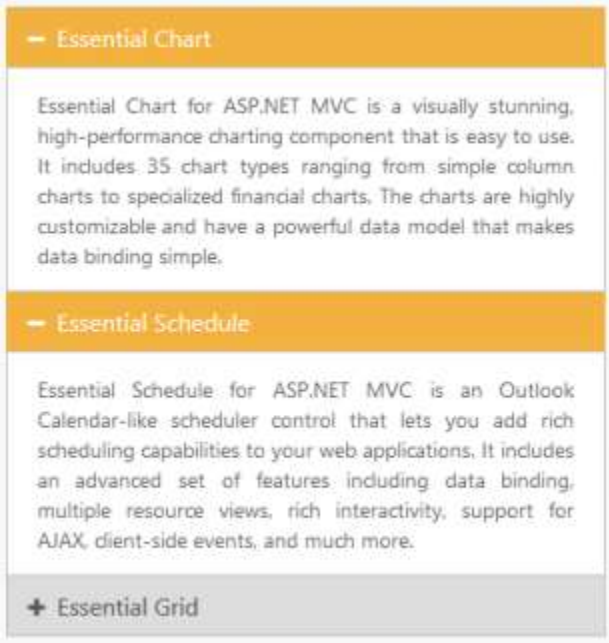
}).EnableMultipleOpen(true).Render();}
</div>
```

Following screenshot is the output for Accordion control on EnableMultipleOpen set to true.



Accordion Panel enabler

Enable or Disable control

You can enable or disable the Accordion widget on initial rendering using the Enabled property. By default Enabled property is set to true and the Accordion panels are active always.

The following code explains you on how to enable or disable the Accordion widget

ASPX-CS

```
// In the View page, render Accordion with corresponding data and disable
the control actions.
<div style="width: 400px">
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>
Essential Chart for ASP.NET MVC is a visually stunning, high-performance
charting component that is easy to use. It includes 35 chart types ranging
from simple column charts to specialized financial charts. The charts are
highly customizable and have a powerful data model that makes data binding
simple.
</div>);
data.Add().Text("Essential Schedule").ContentTemplate(@<div>
```

```
Essential Schedule for ASP.NET MVC is an Outlook Calendar-like scheduler
control that lets you add rich scheduling capabilities to your web
applications. It includes an advanced set of features including data
binding, multiple resource views, rich interactivity, support for AJAX,
client-side events, and much more.
</div>);
data.Add().Text("Essential Grid").ContentTemplate(@<div>
Essential Grid for ASP.NET MVC is a feature-rich control that provides
extensive appearance customization options with support for grouped records.
With Essential Grid for ASP.NET MVC, you can create a grid with a highly
customizable look and feel. This grid is very useful for generating complex
grid-based reports with rich formatting. It supports paging, sorting,
grouping, filtering, and editing features. It also supports a JSON mode in
which you can handle all the operations like paging and sorting. The
performance of these operations in the JSON mode will be much faster than if
the grid were to handle them. Essential Grid generates clean HTML in
compliance with XHTML 1.0. It supports any kind of IEnumerable data source.
It uses LINQ data retrieval techniques for handling data sources, and offers
high performance.</div>);
}).Enabled(false).Render();}
</div>
```

Output for disabled Accordion control is as follows.

Enable panel items

You can enable the Accordion widget items on initial loading using EnabledItems property. This property takes array of indices whose panel needs to be enabled in Accordion widget.

The DisabledItems property disables the Accordion items based on the index. This takes array of indices whose panel is to be disabled.

Enabling accordion panel items

The following code explains you on how to enable the panel items in Accordion widget.

ASPX-CS

```
// In the View page, configure Accordion with the corresponding data, and to
enable and disable Accordion panel items set the values for EnabledItems and
DisabledItems.
@{      //List of integer array with index values.
List<int> enabled = new List<int>() { 1, 2 };
List<int> disabled = new List<int>() { 0 };
}
<div style="width: 400px">
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>

}).SelectedItemIndex(1).EnabledItems(enabled).DisableItems(disabled).EnableM
ultipleOpen(true).Render();}
</div>
```

Output for Accordion control with some enabled and disabled items, where first panel is disabled and it can’t be expanded or collapsed is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

State Persistence

Accordion widget can store the model value in the browser cookies and on every time after initial rendering, the control get the model from the cookie only. Using EnablePersistence property you can store the model value in cookies. Thus when any changes are made dynamically then those values are updated in cookie. On refreshing the page the past state of the Accordion control is maintained in cookie and control is rendered from it.

Configure state persistence of Accordion panel

The following code explains to enable state maintenance for Accordion.

ASPX-CS

```
// In the View page, configure Accordion with corresponding data and enable
the state persistence.
<div style="width: 400px">
@{Html.EJ().Accordion("accordion").Items(data =>
{

```

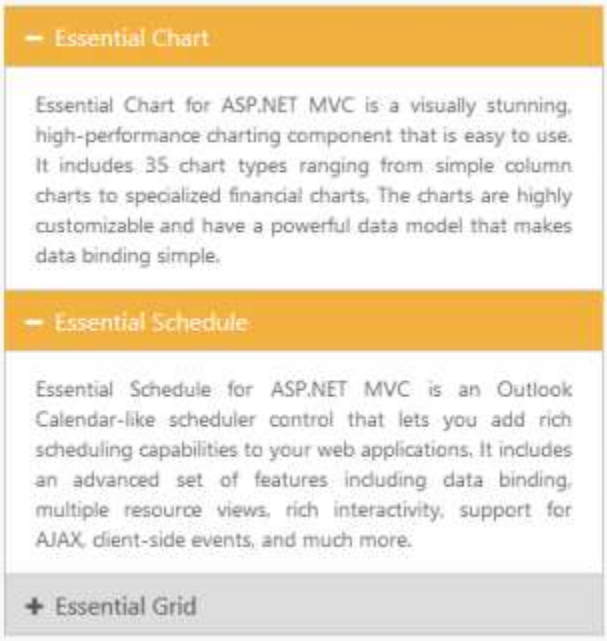
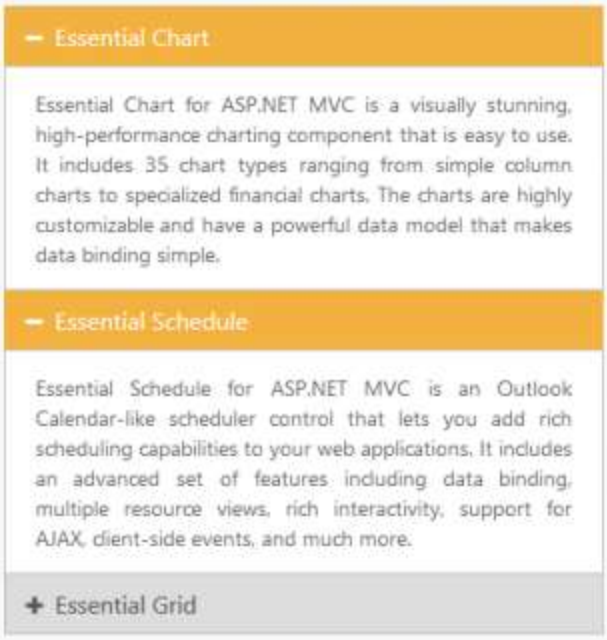
Output after page refresh maintaining the previous state of Accordion widget is as follows.



1. Accordion Selected Item changed

Copyright © 2001 - 2020 Syncfusion Inc.



2. Accordion state persisted after page refresh

Appearance and Styling

Adjusting Accordion size

You can customize the Accordion panel height using HeightAdjustMode property. It can be set to enum values like content, fill or auto. By default HeightAdjustMode is set to content so the panel height is adjusted to the content size.

Configure Height of Accordion panel

The following code explains to configure the height of the Accordion content panel.

ASPX-CS

```
// In the View page, configure Accordion with corresponding data and define
HeightAdjustMode.
<div style="width:850px">
<div style="width: 400px; float:left;">
<div style="width: 400px; float:right;">
@{Html.EJ().Accordion("accordionFill").Items(data =>
{

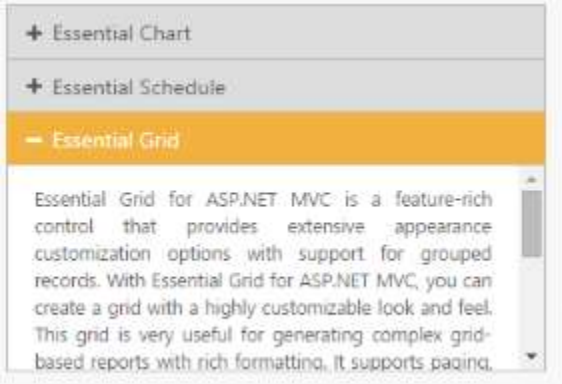
}).HeightAdjustMode(HeightAdjustMode.Fill).Render();}
</div>
</div>
```

Output for Accordion control when panel height is set to auto so that the maximum content height and Fill for minimum content height in all the panels is as follows.



Rounded corner

You can customize the shape of the Accordion widget from regular rectangular shape to rounded rectangle shape enabling RoundedCorner property that is set to false by default.

Enabling Rounded corner property

The following code explains you in enabling the ShowRoundedCorner property for an Accordion control.

ASPX-CS

```
// In the View page, configure Accordion with corresponding data and enable
the ShowRoundedCorner property for it.
<div style="width: 400px; float:left;">
@{Html.EJ().Accordion("accordion").Items(data =>
{

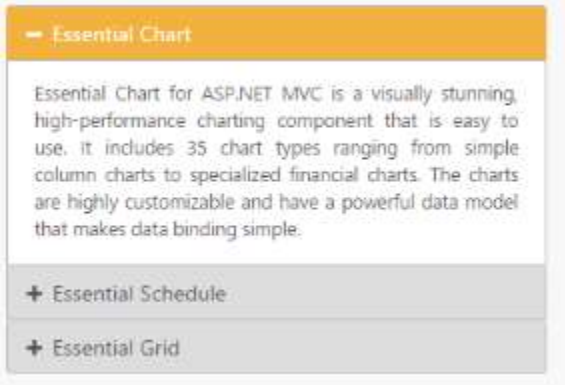
}).ShowRoundedCorner(true).Render();}
</div>
```

Output for accordion widget when “ShowRoundedCorner” is set to “true” is as follows.



Customize Accordion icon

Accordion widget allows you to customize the icons using CustomIcon option that has two properties header and SelectedHeader. By default, the classes of header and selectedHeader are e-collapse and e-expand respectively. By setting the desired CSS class names for these properties as required overrides the default icons with customized icons.

Configuring custom icon for Accordion

The following code explains you the configuration of icon for an Accordion control.

ASPX-CS

```
// In the View page, configure Accordion with corresponding data and set the
“e-arrowheaddown” and “e-arrowheadup” classes to Header and SelectedHeader
properties.  “E-arrowheaddown” and “e-arrowheadup” are available in
ej.widgets.core.min.css file.
<div style="width: 400px; float:left;">
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>
```

```

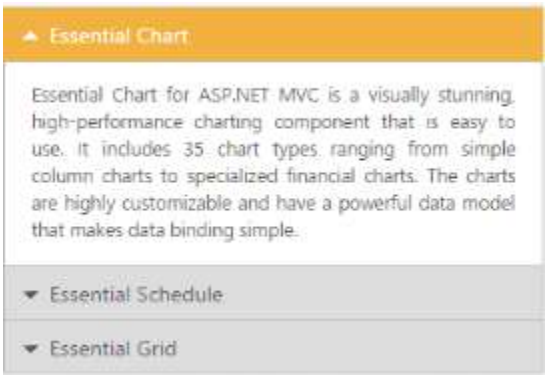
}).CustomIcon(icon =>icon.SelectedHeader("e-arrowheadup").Header("e-
arrowheaddown")).Render();}
</div>
```

Output for Accordion widget with customized icons is as follows.



Animation Options

Set animation

By default the Animation for expanding and collapsing is enabled. To remove the Animation you can set the EnableAnimation property to false. This restricts customizing animations as well. By default EnableAnimation is set to true.

Following code disables Animation for Accordion.

ASPX-CS

```
@{Html.EJ().Accordion("accordion").Items(data =>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>

}).CollapseSpeed("1000").ExpandSpeed("600").Render();}
</div>
```

Theme

You can control the style and appearance of Accordion control based on CSS classes. In order to apply styles to the Accordion control, you can refer two files, ej.widgets.core.min.css and ej.theme.min.css. When you refer ej.widgets.all.min.css file, then it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these two.

By default, there are 13 themes support available for Accordion control namely

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark
- bootstrap-theme

CSS class

CSS class can be used to customize the Accordion control appearance. Define a CSS class as you're your requirement and assign the class name to CssClass property. The custom CSS class must override the predefined CSS styles applied in the Accordion control.

Class or Element name	Description
.e-acrdn	Base class that is added to the Accordion wrapper div element where the custom CSS class will also be added
h3	Header element for the Accordion panel

Copyright © 2001 - 2020 Syncfusion Inc.

span .e-icon	Accordion icon in the header that change on expand and collapse panels
.e-content	Class for the div element that holds the Accordion panelâ€™s content.

Configure Accordion using CSS class

The following code allows you to configure CSS class for an Accordion widget.

ASPX-CS

```
// In the View page, configure Accordion with corresponding data and set the
CssClass property with corresponding CSS class name.
<div style="width: 400px; float:left;">
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>
Essential Chart for ASP.NET MVC is a visually stunning, high-performance
charting component that is easy to use. It includes 35 chart types ranging
from simple column charts to specialized financial charts. The charts are
highly customizable and have a powerful data model that makes data binding
simple.
</div>);
data.Add().Text("Essential Schedule").ContentTemplate(@<div>
Essential Schedule for ASP.NET MVC is an Outlook Calendar-like scheduler
control that lets you add rich scheduling capabilities to your web
applications. It includes an advanced set of features including data
binding, multiple resource views, rich interactivity, support for AJAX,
client-side events, and much more.
</div>);
data.Add().Text("Essential Grid").ContentTemplate(@<div>

compliance with XHTML 1.0. It supports any kind of IEnumerable data source.
It uses LINQ data retrieval techniques for handling data sources, and offers
high performance.</div>);
}).CssClass("customCss").Render();}
</div>
```

Define CSS class for customizing the Accordion.

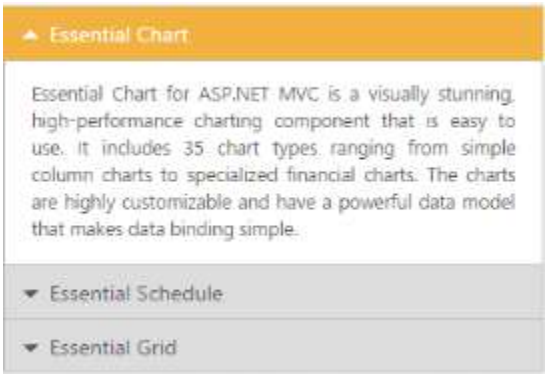
ASPX-CS

```
<style class="cssStyles">
.customCss
{
font-style: italic;
text-align:justify;
}
.customCss span.e-icon {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
display: none !important;
}
.customCss h3
{
text-decoration:underline;
text-align:center;
}
</style>
```

Output for Accordion with customized CSS property to hide the Accordion icon and format its content is as follows.



RTL Support

This feature supports to change the left-to-right alignment of the Accordion control to right-to-left (RTL).

Enabling RTL Support

ASPX-CS

```
// In the View page, configure Accordion with corresponding data and set
EnableRTL property value as true.
<div style="width: 400px; float:left;">
@{Html.EJ().Accordion("accordion").Items(data =>
{
data.Add().Text("Essential Chart").ContentTemplate(@<div>

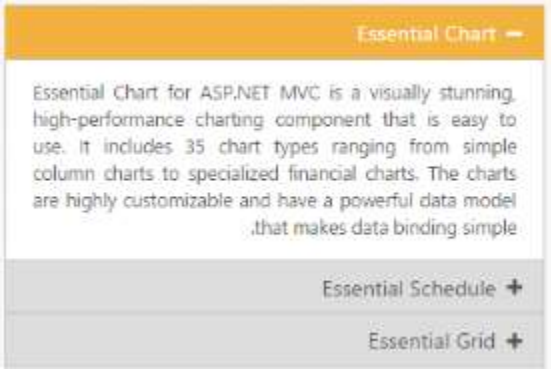
}).EnableRTL(true).Render();}
</div>
```

Output for accordion when “EnableRTL” is set to “true” is as follows,



Keyboard Navigation

You can use Keyboard shortcut keys as an alternative to the mouse on using Accordion control using AllowKeyboardNavigation property. However you will have to focus the control to enable the keyboard navigation. Accordion Control allows you to perform all kind of actions using keyboard shortcuts.

Shortcut Key	Description
Access keyÂ + j	Focuses into the accordion control
Up	Moves to previous panel
Down	Moves to next panel
Left	Moves to previous panel
Right	Moves to next panel
Home	Moves to the first accordion panel
End	Moves to the last accordion panel

Configure keyboard interaction

The following code explains you on how to enable keyboard interaction for an Accordion widget.

ASPX-CS

```
// In the View page, configure Accordion with corresponding data and
configure Keyboard navigation for Accordion by setting
AllowKeyboardNavigation property to true.
<div style="width: 400px; float:left;">
```

```
@{Html.EJ().Accordion("accordion").Items(data =>
{            data.Add().Text("Essential Chart").ContentTemplate(@<div>

}).AllowKeyboardNavigation(true).Render();}</div>
```

JS

```
// Define script to focus into the Accordion control on Alt + J shortcut
keys.
<script>
$(function () {
$(document).on("keydown", function (e) {
if (e.altKey && e.keyCode === 74) { // j- key code.
$("#accordion").focus();
}
});
});
</script>
```

Output for Accordion widget focused and navigated to last item using Keyboard navigation is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Template Support

Content Template

The Content template option provided in MVC is used to specify the HTML elements inside the Accordion control. You can use this option to load any HTML elements and display it in the Accordion panels as per your requirement.

The following code example explains how to use content template option in the Accordion control.

ASPX-CS

```
<div style="width:500px;">
@{Html.EJ().Accordion("pizzaMenu").Items(data =>
{
data.Add().Text("GARDEN FRESH (Veg)").ContentTemplate(@<div>
<img src="~/Content/accordion/garden-veggie.png" alt="garden-fresh" />
<div class="ingredients">
Rate     : $50
<br />
Ingredients : cheese, onions, green capsicums & tomatoes.
</div>
</div>);
data.Add().Text("CORN & SPINACH (Veg)").ContentTemplate(@<div>
<img src="~/Content/accordion/corn-and-spinach-05.png" alt="garden-fresh" />
<div class="ingredients">
Rate     : $70
<br />
Ingredients : cheese, sweet corn & green capsicums.
</div>
</div>);
data.Add().Text("CHICKEN DELITE (Non-veg)").ContentTemplate(@<div>
<img src="~/Content/accordion/chicken-delite.png" alt="garden-fresh" />
<div class="ingredients">
Rate     : $100
<br />
```

```
Ingredients : cheese, chicken chunks, onions & pineapple chunks.
</div>
</div>);
data.Add().Text("KEEMA LA JAWAB (Non-veg)").ContentTemplate(@<div>
<img src="@Url.Content("~/Images/accordion/chicken-delite.png")"
alt="garden-fresh" />
<div class="ingredients">
Rate     : $95
<br />
Ingredients : lamb keema, onions, garlic & tandoori seasoning.
</div>
</div>);
}).EnableMultipleOpen(true).Render();}
</div>
```

Output:

Header Template

The Header template option provided in MVC is used to specify the HTML elements inside the Accordion control.

The following code example explains how to use header template option in the Accordion control.

ASPX-CS

```
@{
ViewBag.Title = "Accordion";
Layout = "~/Views/Shared/_Layout.cshtml";
}
@model AccordionIcons.AccordionController.SI_MODULO
<h2>Accordion</h2>
<br/>
<br/>
<div id = "ControlRegion">
<div style="width: 400px;">
@{Html.EJ().Accordion("iconAccordion").Items(data =>
{
foreach (var m in Model.image)
{
var node = data.Add().Text(m.text).HeaderTemplate(@<div>
```

}
public class SI_MODULO {
public List<ImagesID> image { get; set; }
}
```

How To

Render Accordion from code behind

Accordion can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of Accordion using Accordion properties from code behind.

RAZOR

```
@{
Html.EJ().Accordion("multiAccordion",
(Syncfusion.JavaScript.Models.AccordionProperties)ViewData["accordion"]).Ren
der();
}
```

C#

```
public ActionResult Index()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
AccordionProperties obj = new AccordionProperties();
obj.Items.Add(new AccordionBaseItem() {Text = "ASP.NET", ContentTemplate =
new MvcTemplate<AccordionBaseItem> { RazorViewTemplate = (data) => { return
"Microsoft ASP.NET is a set of technologies in the Microsoft .NET Framework
for building Web applications and XML Web services. ASP.NET pages execute on
the server and generate markup such as HTML, WML, or XML that is sent to a
desktop or mobile browser. ASP.NET pages use a compiled, event-driven
programming model that improves performance and enables the separation of
application logic and user interface."; } } });
obj.Items.Add(new AccordionBaseItem() {Text = "ASP.NET MVC", ContentTemplate
= new MvcTemplate<AccordionBaseItem> { RazorViewTemplate = (data) => {
return " The Model-View-Controller (MVC) architectural pattern separates an
application into three main components: the model, the view, and the
controller. The ASP.NET MVC framework provides an alternative to the ASP.NET
Web Forms pattern for creating Web applications. The ASP.NET MVC framework
is a lightweight, highly testable presentation framework that (as with Web
Forms-based applications) is integrated with existing ASP.NET features, such
as master pages and membership-based authentication."; } } });
obj.Items.Add(new AccordionBaseItem() {Text = "JavaScript", ContentTemplate
= new MvcTemplate<AccordionBaseItem> { RazorViewTemplate = (data) => {
return "JavaScript (JS) is an interpreted computer programming language."; }
} });
obj.EnableAnimation = true;
ViewData["accordion"] = obj;
return View();
}
```

AutoComplete

AutoComplete

The Essential ASP.NET MVC AutoComplete control is a textbox control that provides a list of suggestions based on the user query. When users enter text into the text box, the control performs a search operation and provides a list of results. There are several filter types available to perform the search.

Key Features

- Delimiter: Supports search for multiple words using a delimiter symbol.
- Suggestion box customization: Supports customization of the suggestion box height and width, and also provides you option to customize the items count to be displayed in the suggestion list.
- minCharacter: Sets the minimum number of characters required to perform the search.
- Filter Types: Supports various search filters with case sensitivity search option.
- Watermark: Supports custom watermark text.
- Data binding: Supports data binding with the List of objects and remote data.
- Template: Supports templates for the suggestion list content.
- Highlight search: Supports highlighting the typed text in the suggestion list.
- Auto fill: Allows the control to automatically fill the autocomplete textbox based on the character typed.
- Keyboard navigation: Provides complete support to work with the control by using the keyboard keys.
- RTL: Supports displaying the text box and suggestion list from right to left.

Copyright © 2001 - 2020 Syncfusion Inc.

- Themes: The AutoComplete control features 12 built-in themes (six flat and six with gradient effects), and also supports custom skin options for user defined themes.

Getting Started

This section explains briefly about how to create an AutoComplete in your ASP.NET MVC application.

Create your first AutoComplete in MVC

This section helps you to configure the AutoComplete control in your application and also helps you to learn how to pass the required data to it and to customize its various options according to your requirements.

In this section, the flat-saffron theme (default) for the Autocomplete is explained.

The following screen shot illustrates the AutoComplete control that searches the list of components available in the database.

AutoComplete control with search

Create an AutoComplete

ASP.NET MVC AutoComplete textbox widget basically renders with built-in features like keyboard navigation with animations and flexible API's. You can easily create the AutoCompleteTextbox widget by the following steps.

1. You can create a MVC Project and add necessary Dll's and Scripts with the help of the given MVC-Getting Started Documentation.
2. Initialize the corresponding AutoComplete widget in the view page.

ASPX-CS

```
<div>
Select Component/s:
@Html.EJ().Autocomplete("ComponentList")
</div>
```

3. Execute the code to render a AutoComplete widget as follows

Output

Copyright © 2001 - 2020 Syncfusion Inc.

Populate Data to AutoComplete

You can provide either local data or remote data to the Autocomplete.

Local Data Binding

AutoComplete provides extensive data binding support to populate AutoComplete items, so that the values are mapped to the AutoComplete fields, namely Key and Text. DataBinding helps you bind a key value pair to AutoComplete textbox. Key field takes the unique id of the dataSource elements. Text field gets the value to be displayed in the AutoComplete textbox.

Defining the Local data for AutoComplete

The following steps explain local data binding to an AutoComplete textbox.

You need to add the class in the Models. Define the Class with key and text field. Then create a List of that class and add the data.

C#

```
public class ComponentsList
{
public int ComponentId { get; set; }
public string ComponentName { get; set; }
public static List<ComponentsList> GetComponentsList()
{
List<ComponentsList> component = new List<ComponentsList>();
component.Add(new ComponentsList { ComponentName = "Autocomplete" });
component.Add(new ComponentsList { ComponentName = "Accordion" });
component.Add(new ComponentsList { ComponentName = "BulletGraph" });
component.Add(new ComponentsList { ComponentName = "Chart" });
component.Add(new ComponentsList { ComponentName = "DatePicker" });
component.Add(new ComponentsList { ComponentName = "Dialog" });
component.Add(new ComponentsList { ComponentName = "Diagram" });
component.Add(new ComponentsList { ComponentName = "DropDown" });
component.Add(new ComponentsList { ComponentName = "Gauge" });
component.Add(new ComponentsList { ComponentName = "Schedule" });
component.Add(new ComponentsList { ComponentName = "Scrollbar" });
component.Add(new ComponentsList { ComponentName = "Slider" });
component.Add(new ComponentsList { ComponentName = "RangeNavigator" });
component.Add(new ComponentsList { ComponentName = "Rating" });
component.Add(new ComponentsList { ComponentName = "RichTextEditor" });
component.Add(new ComponentsList { ComponentName = "Tab" });
component.Add(new ComponentsList { ComponentName = "TagCloud" });
component.Add(new ComponentsList { ComponentName = "Toolbar" });
component.Add(new ComponentsList { ComponentName = "TreeView" });
return component;
}
}
```

In the controller page, you need to pass the model class to the corresponding view.

C#

```
public ActionResult Index()
{
return View(ComponentsList.GetComponentsList());
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

In the View page, add Autocomplete helper and map the local data list to corresponding DataSource and AutoCompleteFields. You need to refer the model class at the top of the page.

ASPX-CS

```
@model List<MvcApplication7.Models.ComponentsList>
<div>
Select Component/s:
@Html.EJ().Autocomplete("ComponentList").Datasource(Model).AutocompleteFields(f=> f.Text("ComponentName").Key("ComponentId")).Width("500")
</div>
```

Run this code to render the AutoComplete with components list.

AutoComplete with Component list

You can also set some common customization changes to the AutoComplete textbox like enabling multiple-selection, highlight search and add dropdown icon based on your requirement.

Configure Visual Mode with filter option

By default, the AutoComplete is rendered with single-value selection. For multiple-value selection using the property MultiSelectMode that allows you to select multiple Data. There are two types of multiple selection one is ‘delimiter’ and another one is ‘visual mode’. In ‘Delimiter’ mode, the multiple values chosen are separated by using the delimiter character specified. In ‘visual mode’, the values chosen are displayed as box model. Here, the ‘visual mode’ is shown. You can set the FilterType option as StartsWith to sort the suggestion list based on the starting character.

ASPX-CS

```
<div>
Select Component/s:
@Html.EJ().Autocomplete("ComponentList").Datasource(Model).AutocompleteFields(f=>
f.Text("ComponentName").Key("ComponentId")).Width("500").MultiSelectMode(MultiSelectModeTypes.VisualMode).FilterType(FilterOperatorType.StartsWith).Width("500")
</div>
```

The following screen shot displays the AutoComplete textbox with selection visual mode.

Copyright © 2001 - 2020 Syncfusion Inc.

AutoComplete textbox with selection visual mode

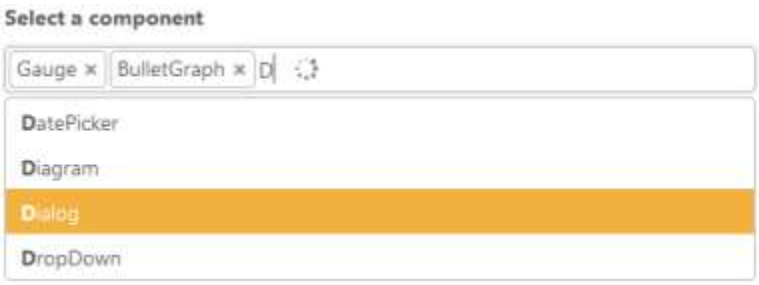
Configure Highlight Search and Rounded corners

When you set the HighlightSearch property to ‘true’, the characters typed in textbox gets highlighted in the suggestion list. To display textbox reforms from sharp ends to rounded ends, you can enable the ShowRoundedCorner property.

ASPX-CS

```
<div>
Select Component/s:
@Html.EJ().Autocomplete("ComponentList").Datasource(Model).AutocompleteFields(f=>
f.Text("ComponentName").Key("ComponentId")).Width("500").MultiSelectMode(MultiSelectModeTypes.VisualMode).FilterType(FilterOperatorType.StartsWith).HighlightSearch(true).ShowRoundedCorner(true).Width("500")
</div>
```

The following screen shot displays the AutoComplete textbox with highlight search enabled.



AutoComplete text box with highlight search enabled

Configure Popup button

To enable the DropDown button, you can set ShowPopupButton property to ‘true’ that displays the DropDown icon at the end of textbox. By default, search icon replaces other icons and so you need to override the CSS classes and replace the content to DropDown arrow icon available in core CSS file as follows.

CSS

```
<style>.e-icon.e-search:before
{
content:"\e63b";
}
</style>
```

ASPX-CS

```
<div>
Select Component/s:
@Html.EJ().Autocomplete("ComponentList").Datasource(Model).AutocompleteFields(f=>
f.Text("ComponentName").Key("ComponentId")).Width("500").MultiSelectMode(MultiSelectModeTypes.VisualMode).FilterType(FilterOperatorType.StartsWith).HighlightSearch(true).ShowRoundedCorner(true).Width("500").ShowPopupButton(true)
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screen shot displays the AutoComplete textbox with dropdown icon.

AutoComplete textbox with dropdown icon

Data-Binding

In order to render the AutoComplete control, the data needs to be bound to it in a proper way. The following sub-properties provide a way to bind either the local or remote data to the AutoComplete widget by binding the appropriate data fields to the corresponding options.

Fields

DataSource

This property assigns the List of objects to the AutoComplete control. Either local data or remote data can be specified.

Query

It accepts the data of object type, usually the query string to fetch the required data from a specific table based on certain condition. This property is optional hence when it is not specified the entire records that are initially assigned through DataSource are taken into consideration.

Key

It maps the corresponding key field name from the data table or the List of objects that is assigned to the DataSource with the Key property of the AutoComplete control. The Key value that is fetched from the table is unique for each records.

Text

It maps the corresponding Text field name from the data table or the List of Objects that is assigned to the DataSource with the Text property of the AutoComplete control. The text value that is fetched from the table represents the value to be displayed in the AutoComplete textbox.

GroupBy

It maps the groupBy field name from the data table or JSON data that is assigned to the dataSource. The groupBy value that is fetched from the table is made to group the values in the datasource.

HtmlAttributes

This allows you to map the CSS styles or classes to the corresponding data from table or the List of Objects data with the AutoComplete items. The HtmlAttributes value customizes the AutoComplete items based on HTML styling or class assigned to it.

Local data

AutoComplete provides extensive data binding support to populate AutoComplete items, so that the values are mapped to the AutoComplete fields, namely Key and Text. DataBinding helps you bind a key

Copyright © 2001 - 2020 Syncfusion Inc.

value pair to AutoComplete textbox. Key field takes the unique id of the dataSource elements. Text field gets the value to be displayed in the AutoComplete textbox.

Defining the Local data for AutoComplete

The following steps explain local data binding to an AutoComplete textbox.

1. In the Controller page, define the Class with key and text field. Then create a List of that class and add the data.

CSHARP

```
public class CarsList
{
public int UniqueKey { get; set; }
public string Text { get; set; }
}
public partial class AutocompleteController : Controller
{
List<CarsList> cars = new List<CarsList>();
public ActionResult AutocompleteFeatures()
{
cars.Add(new CarsList { UniqueKey = 1, Text = "Audi S6" });
cars.Add(new CarsList { UniqueKey = 2, Text = "Austin-Healey" });
cars.Add(new CarsList { UniqueKey = 3, Text = "Alfa Romeo" });
cars.Add(new CarsList { UniqueKey = 4, Text = "Aston Martin" });
cars.Add(new CarsList { UniqueKey = 5, Text = "BMW 7" });
cars.Add(new CarsList { UniqueKey = 6, Text = "Bentley Mulsanne" });
cars.Add(new CarsList { UniqueKey = 7, Text = "Bugatti Veyron" });
cars.Add(new CarsList { UniqueKey = 8, Text = "Chevrolet Camaro" });
cars.Add(new CarsList { UniqueKey = 9, Text = "Cadillac" });
cars.Add(new CarsList { UniqueKey = 10, Text = "Duesenberg J " });
cars.Add(new CarsList { UniqueKey = 11, Text = "Dodge Sprinter" });
cars.Add(new CarsList { UniqueKey = 12, Text = "Elantra" });
cars.Add(new CarsList { UniqueKey = 13, Text = "Excavator" });
cars.Add(new CarsList { UniqueKey = 14, Text = "Ford Boss 302" });
cars.Add(new CarsList { UniqueKey = 15, Text = "Ferrari 360" });
cars.Add(new CarsList { UniqueKey = 16, Text = "Ford Thunderbird" });
cars.Add(new CarsList { UniqueKey = 17, Text = "GAZ Siber" });
cars.Add(new CarsList { UniqueKey = 18, Text = "Honda S2000" });
cars.Add(new CarsList { UniqueKey = 19, Text = "Hyundai Santro" });
cars.Add(new CarsList { UniqueKey = 20, Text = "Isuzu Swift" });
cars.Add(new CarsList { UniqueKey = 21, Text = "Infiniti Skyline" });
cars.Add(new CarsList { UniqueKey = 22, Text = "Infiniti Skyline" });
cars.Add(new CarsList { UniqueKey = 23, Text = "Kia Sedona EX" });
cars.Add(new CarsList { UniqueKey = 24, Text = "Koenigsegg Agera" });
cars.Add(new CarsList { UniqueKey = 25, Text = "Lotus Esprit" });
cars.Add(new CarsList { UniqueKey = 26, Text = "Lamborghini Diablo" });
cars.Add(new CarsList { UniqueKey = 27, Text = "Mercedes-Benz" });
cars.Add(new CarsList { UniqueKey = 28, Text = "Mercury Coupe" });
cars.Add(new CarsList { UniqueKey = 29, Text = "Maruti Alto 800" });
cars.Add(new CarsList { UniqueKey = 30, Text = "Nissan Qashqai" });
cars.Add(new CarsList { UniqueKey = 31, Text = "Oldsmobile S98" });
cars.Add(new CarsList { UniqueKey = 32, Text = "Opel Superboss" });
cars.Add(new CarsList { UniqueKey = 33, Text = "Porsche 356" });
cars.Add(new CarsList { UniqueKey = 34, Text = "Pontiac Sunbird" });
cars.Add(new CarsList { UniqueKey = 35, Text = "Scion SRS/SC/SD" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
cars.Add(new CarsList { UniqueKey = 36, Text = "Saab Sportcombi" });
cars.Add(new CarsList { UniqueKey = 37, Text = "Subaru Sambar" });
cars.Add(new CarsList { UniqueKey = 38, Text = "Suzuki Swift" });
cars.Add(new CarsList { UniqueKey = 39, Text = "Triumph Spitfire" });
cars.Add(new CarsList { UniqueKey = 40, Text = "Toyota 2000GT" });
cars.Add(new CarsList { UniqueKey = 41, Text = "Volvo P1800" });
cars.Add(new CarsList { UniqueKey = 42, Text = "Volkswagen Shirako" });
cars.Add(new CarsList { UniqueKey = 43, Text = "Ford Boss 302" });
cars.Add(new CarsList { UniqueKey = 44, Text = "Ferrari 360" });
cars.Add(new CarsList { UniqueKey = 45, Text = "Ford Thunderbird" });
ViewBag.datasource = cars;
return View();
}
}
```

2. In the View page, add Autocomplete helper and map the Local data list to corresponding DataSource and AutoCompleteFields.

ASPX-CS

```
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
```

The following image is the output for AutoComplete control with local data binding.

AutoComplete with local data-binding

Remote data

AutoComplete provides remote data binding support to populate AutoComplete items, so that the values are mapped to the AutoComplete fields from a remote web service using DataManager and Query.

DataManager is used to manage relational data. It supports CRUD that is Create, Read, Update, and Destroy, in individual requests and batches. DataManager uses two different classes, ej.DataManager, for processing and ej.Query, for serving data. ej.DataManager communicates with dataSource and ej.Query generates data queries that are read by the DataManager.

Configuring remote data for AutoComplete

The below following types are used to bind remote datasource to an AutoComplete textbox.

Copyright © 2001 - 2020 Syncfusion Inc.

OData

OData is a standardized protocol for creating and consuming data. You can provide the OData service URL directly to the Datasource URL property.

HTML

```
@Html.EJ().Autocomplete("selectCar").Datasource("http://js.syncfusion.com/ej
services/Wcf/Northwind.svc/").Query("ej.Query().from('Customers').take(10)")
.AutocompleteFields(af => af.Text("CustomerID")).Width("300")
```

Run the code to get the following output

OData Version 4

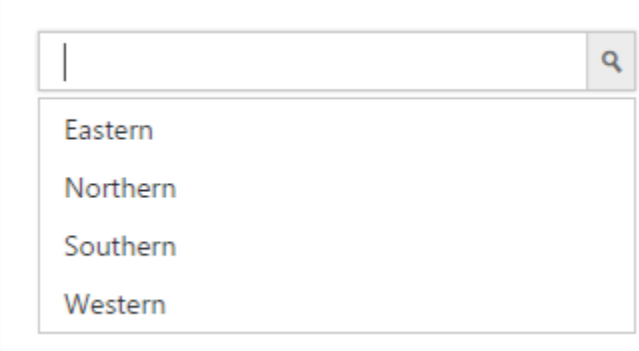
For OData Version 4 support ODataV4Adaptor should be used. By using URL property of Datasource, you can bind OData Version 4 Service link and specify Adaptor value as enum AdaptorType.ODataV4Adaptor.

For further details about OData service please refer the link.

HTML

```
@Html.EJ().Autocomplete("selectData").Datasource(dataSource =>
dataSource.URL("http://services.odata.org/V4/Northwind/Northwind.svc/Regions
/").Adaptor(AdaptorType.ODataV4Adaptor)).AutocompleteFields(af =>
af.Text("RegionDescription")).Width("300").ShowPopupButton(true)
```

Run the code to get the following output.



URL Adaptor

URL Adaptor of **DataManager** can be used when you are required to use remote service to retrieve data. It interacts with server-side for all **DataManager** Queries and **CRUD** operations.

Copyright © 2001 - 2020 Syncfusion Inc.

Now, in the following code example the data is retrieved from **Controller**.

HTML

```
@Html.EJ().Autocomplete("selectCar").Datasource(dataSource =>
dataSource.URL(Url.Action("DataSource",
"Autocomplete")).Adaptor(AdaptorType.UrlAdaptor)).Query("ej.Query()").Autoco
mpleteFields(af =>
af.Text("text")).Width("300").FilterType(FilterOperatorType.Contains)
```

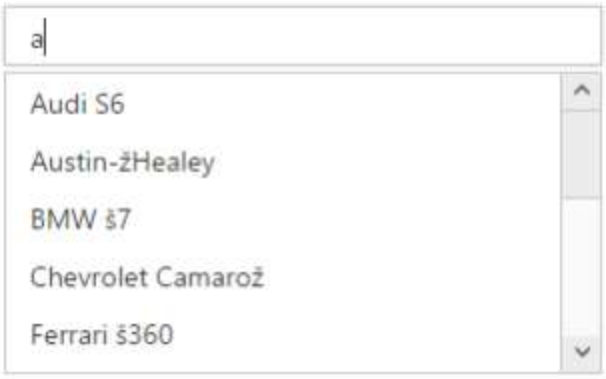
Controller:

C#

```
public JsonResult DataSource()
{
IEnumerable Data = setListSource();
return Json(Data, JsonRequestBehavior.AllowGet);
}
public static List<CarsList> setListSource()
{
List<CarsList> cars = new List<CarsList>();
cars.Add(new CarsList { uniqueKey = 1, text = "Audi S6", company = "Audi"
});
cars.Add(new CarsList { uniqueKey = 2, text = "Austin-žHealey", company =
"Austin" });
cars.Add(new CarsList { uniqueKey = 3, text = "BMW š7", company = "BMW" });
cars.Add(new CarsList { uniqueKey = 4, text = "Chevrolet Camarož", company =
"Chevrolet" });
cars.Add(new CarsList { uniqueKey = 6, text = "Ferrari š360", company =
"Ferrari" });
cars.Add(new CarsList { uniqueKey = 7, text = "Honda S2000", company =
"Honda" });
cars.Add(new CarsList { uniqueKey = 8, text = "Hyundai Santroš", company =
"Hyundai" });
cars.Add(new CarsList { uniqueKey = 9, text = "Isuzu Swift", company =
"Isuzu" });
cars.Add(new CarsList { uniqueKey = 10, text = "Jaguar XJS", company =
"Jaguar" });
cars.Add(new CarsList { uniqueKey = 11, text = "iLotus Esprit", company =
"Lotus" });
cars.Add(new CarsList { uniqueKey = 12, text = "Mercedes-Benz", company =
"Mercedes" });
cars.Add(new CarsList { uniqueKey = 13, text = "Toyota ž2000GT", company =
"Toyota" });
cars.Add(new CarsList { uniqueKey = 14, text = "Volvo P1800", company =
"Volvo" });
return cars;
}
```

Run the code to get the following output

Copyright © 2001 - 2020 Syncfusion Inc.



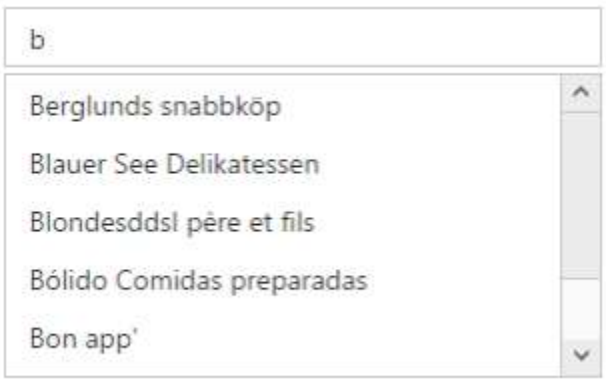
WebAPI

WebApi Adaptor, extended from **ODataAdaptor**, of **DataManager** is used for retrieving data from WebApi service. ASP.NET Web API is a Framework for building HTTP services. You can retrieve data from ASP.NET Web API by using DataManager. Using WebApiAdaptor, you can bind WebApi service's data to Autocomplete. The data from WebApi service must be returned as an object that has its value as data source and field property customerID with its value as Datasource total records count.

HTML

```
@(Html.EJ().Autocomplete("selectAuto").Datasource(dataSource =>
dataSource.URL(Url.Action("http://js.syncfusion.com/ejservices/Wcf/Northwind
.svc/")).Adaptor(AdaptorType.WebApiAdaptor)).Query("ej.Query().from('Custome
rs')").Width("300").AutocompleteFields(fieldSetting =>
fieldSetting.Text("CustomerID")))
```

Run the code to get the following output.



Behavior Settings

Filtering Type

AutoComplete textbox supports a wide range of filtering options to search items in the PopUp list. The FilterType takes enum or string values. The default value is StartsWith. Other supported values are Contains, EndsWith, LessThan, GreaterThan, GreaterThanOrEqual, LessThanOrEqual, Equal and NotEqual.

Copyright © 2001 - 2020 Syncfusion Inc.

Defining the Filter type

The following steps explain the configuration of the filtering conditions for an AutoComplete textbox.

1. In the View page, define the AutoComplete control and add the filter type as contains.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.FilterType(FilterOperatorType.Contains)
```

The following image is the output for AutoComplete control that filters list items based on the ‘contains’ option.

AutoComplete using "contains" filterType

AutoFill

The AutoComplete textbox widget offers an AutoFill option. This feature is used to automatically fill the item when text is entered when EnableAutoFill is set to ‘true’. The first Item in the suggestions list that matches the entered text is automatically displayed in the AutoComplete textbox. The search text is selected in the AutoComplete textbox for identification.

This feature reduces the need to type the entire text and makes the search box more efficient. This is used only with filterType “StartsWith”, since text is filled automatically based on the text entered.

Configure AutoFill property in AutoComplete

The following steps explain how to enable the AutoFill property for an AutoComplete textbox.

1. In the View page, add the Autocomplete helper and enable the EnableAutoFill property

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@(Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>
)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.EnableAutoFill(true))
```

The following image is the output for AutoComplete when EnableAutoFill is set to ‘true’.

Copyright © 2001 - 2020 Syncfusion Inc.

AutoComplete with AutoFill

Sorting Items

AutoComplete widget allows you to sort the suggestions list items and set the sorting order. To enable sorting, set AllowSorting to 'true'. It is enabled by default. The SortOrder property takes enum values, either in ascending or descending order.

Steps to define sorting order and distinct

The following steps explain how to enable the sorting property for an AutoComplete textbox.

1. In the View page, define the AutoComplete control and enable AllowSorting.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.AllowSorting(true).SortOrder(SortOrder.Descending)
```

The following image is the output for AutoComplete when "SortOrder" is configured.

AutoComplete PopUp sorted in descending order

Distinct List items

AutoComplete widget provides an option to extract repeating items in the PopUp list. By setting EnableDistinct property to 'true', you can prevent the duplicate items in the suggestions list.

Steps to enable distinct items

The following steps explain you how to enable this property.

1. In the View page, define the AutoComplete control and configure the EnableDistinct property.

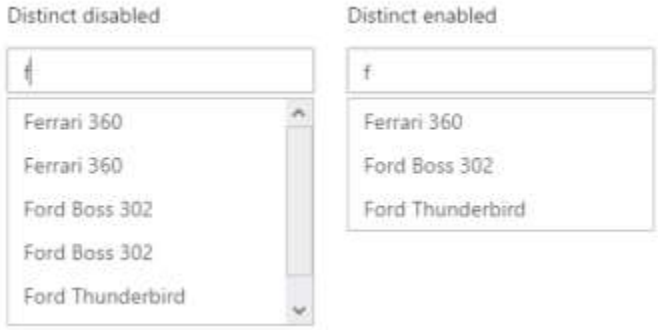
ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
<div style="width: 400px">
<div style="float: left;">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<h6><span style="font-style: italic; font-weight: normal; position:
absolute; margin-top: -30px;">
Distinct disabled</span></h6>
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.EnableDistinct(false)
</div>
<div id="binding" style="float: right;">
<h6><span style="font-style: italic; font-weight: normal; position:
absolute; margin-top: -30px;">
Distinct enabled</span></h6>
@Html.EJ().Autocomplete("autocompleteDistinct")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.EnableDistinct(true)
</div>
</div>
```

The following images are the outputs for AutoComplete when EnableDistinct is set to “true” and “false”.



AutoComplete PopUp items with Distinct property disabled and enabled

Show Popup button

Show Popup button property provides you with an option to display an icon, to show the popup list in the AutoComplete widget.

Enabling Popup button

The following steps explains you how to configure the Popup button for an AutoComplete textbox.

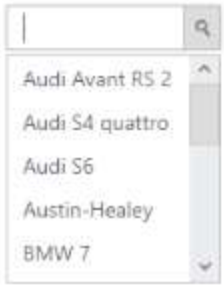
1. In the View page, define the AutoComplete control and enable ShowPopupButton property.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.ShowPopupButton(true)
```

The following image is the output for AutoComplete when ShowPopupButton is enabled.

Copyright © 2001 - 2020 Syncfusion Inc.



AutoComplete with popup icon

Restrict editing

AutoComplete textbox widget provides ReadOnly property to disable editing in the control, so that the value set to AutoComplete can only be read and cannot be modified by the user. The value property allows you to set the default value for AutoComplete widget, when it is created.

Configure AutoComplete textbox to restrict editing

The following steps help you to disable editing in an AutoComplete textbox.

1. In the View page, define the AutoComplete control and configure Readonly property.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.Readonly(true).Value("BMW 7")
.ShowPopupButton(true)
```

The following image is the output for the AutoComplete textbox configured to restrict editing.

AutoComplete with readOnly property

Empty Result settings

The AutoComplete widget allows you to configure the display message when the list doesn't return any values. By default, ShowEmptyResultText is set to 'true' and EmptyResultText is set to the string value "No suggestions".

Configure Empty result setting

The following steps allow you to set text for empty results of an AutoComplete textbox.

1. In the View page, define the AutoComplete control and set the desired text message to be shown in EmptyResultText.

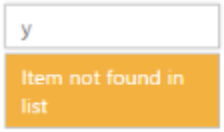
ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.ShowEmptyResultText(true).EmptyResultText("Item not found in list")
```

The following image is the output of the AutoComplete textbox when the list doesn't return any value.



AutoComplete with customized EmptyResultText

Search Customization

HighlightSearch

AutoComplete widget allows you to highlight the search text in the AutoComplete suggestions list using the HighlightSearch property. When this property is set to 'true', the suggestions list appear with the search text it contains is highlighted.

Enabling highlightSearch option

The following steps explain how you can enable the HighlightSearch property for an AutoComplete textbox.

1. In the View page, define the AutoComplete control and enable the HighlightSearch property.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.HighlightSearch(true).FilterType(FilterOperatorType.Contains)
.MinCharacter(2)
```

The following image is the output for AutoComplete when HighlightSearch is set to 'true'.

AutoComplete with highlightSearch enabled

Case-sensitive Search

AutoComplete allows you to enable case sensitivity to filter the suggest list items based on the entered text casing. This property enables strict filtering of list items based on entered text. To enable it, set CaseSensitiveSearch value to 'true'. It is false, by default.

Copyright © 2001 - 2020 Syncfusion Inc.

Configure case sensitivity for AutoComplete

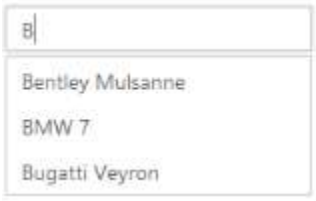
The following steps explain you how to enable the CaseSensitiveSearch property for an AutoComplete textbox.

1. In the View page, define the AutoComplete control and enable the CaseSensitiveSearch property.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.CaseSensitiveSearch(true)
```

The following image is the output for AutoComplete when CaseSensitiveSearch is set to ‘true’.



AutoComplete textbox with caseSensitiveSearch

MultiSelection modes

AutoComplete widget allows you to select multiple values from the suggestions list using the MultiSelectMode property. Multiple values are selected when MultiSelectMode value is set to VisualMode or Delimiter.

Delimiter mode separates multiple items using a separator character defined. When the delimiter mode is set, you can define the delimiter character using DelimiterChar. It takes a single character and it is a symbol.

VisualMode selects multiple items by enclosing the item in a rounded rectangle with a close icon to remove item from the selection.

Configuring MultiSelection Mode

The following steps explain the configuration of the MultiSelectMode for an AutoComplete textbox.

1. In the View page, define the AutoComplete control and configure multiple selection mode.

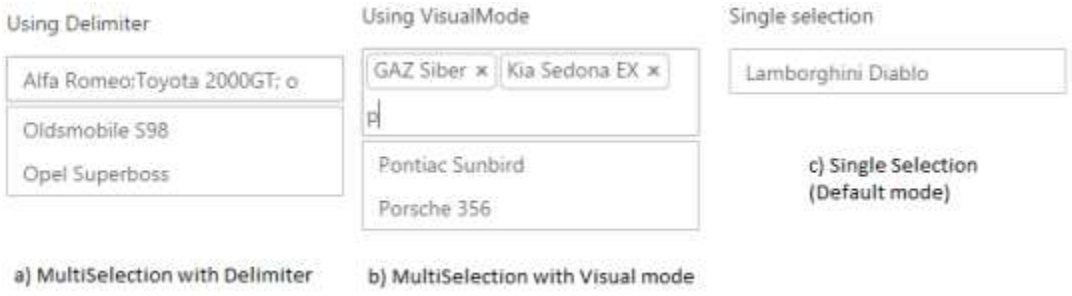
ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
<div style="width: 600px">
<div style="display:inline-block; float:left; margin-right:25px">
<span style="display:block; margin-bottom:12px">Using Delimiter</span>
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.MultiSelectMode(MultiSelectModeTypes.Delimiter).Delimiter(";")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</div>
<div style="display:inline-block; float:left; margin-right:25px">
<span style="display:block; margin-bottom:12px">Using VisualMode</span>
@Html.EJ().Autocomplete("autocompleteVisual")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.MultiSelectMode(MultiSelectModeTypes.VisualMode)
</div>
<div style="display:inline-block; float:left;">
<span style="display:block; margin-bottom:12px">Single selection</span>
@Html.EJ().Autocomplete("autocompleteSingle")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field => field.Key("UniqueKey").Text("Text"))
.MultiSelectMode(MultiSelectModeTypes.None)
</div>
</div>
```

The following image is the output for AutoComplete control with configured multiple selection.



AutoComplete with MultiSelection

Multiple Columns

The Autocomplete allows list of data to be displayed in several columns and column collection can be defined and customized through the **MultiColumnSettings** property.

In AutoComplete Multiple Column search is based on **searchColumnIndices** property which allows user to search text for any number of fields in the suggestion list without modifying the selected text format.

In AutoComplete Multiple Column searched value is updated to autocomplete input box based on **StringFormat** property which specifies values to updated.

Note: StringFormat as “{0} ({1}) ({2})” means search based on 0, 1 and 2 columns data.

Name	Description
Enable	Allow list of data to be displayed in several columns.
ShowHeader	Allow header text to be displayed in corresponding columns.
StringFormat	Displayed selected value and autocomplete search based on mentioned column value specified in that format.
Columns	Field and Header Text collections can be defined and customized through this field.

Copyright © 2001 - 2020 Syncfusion Inc.

Field	Get or set a value that indicates to display the columns in the autocomplete mapping with column name of the dataSource.
HeaderText	Get or set a value that indicates to display the title of that particular column.

Configuring Multiple Columns

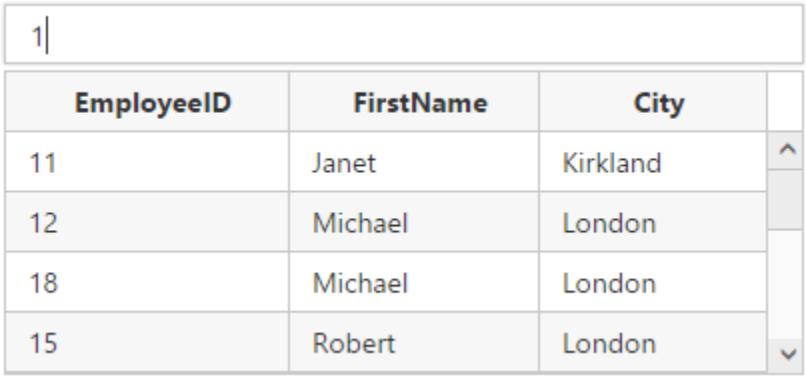
The following steps explain the configuration of the Multiple Columns for an AutoComplete textbox.

1. In the View page, define the AutoComplete control and configure multicolumn.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
<div style="width: 600px">
<div style="display:inline-block; float:left; margin-right:25px">
<span style="display:block; margin-bottom:12px">Using Delimiter</span>
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.MultiColumnSettings(obj => obj.Enable(true).Columns(obj1 =>
{
obj1.Field("EmployeeID").HeaderText("EmployeeID").Add();
obj1.Field("FirstName").HeaderText("FirstName").Add();
obj1.Field("City").HeaderText("City").Add();
}).ShowHeader(true).SearchColumnIndices(new List<int> { 0,1,2
}).StringFormat("{0}"))
</div>
</div>
```

The following image is the output for AutoComplete control with configured multiple column.



AutoComplete with MultiColumn

Grouping

AutoComplete widget provides Grouping support for the suggestions list based on the category specified in the dataSource. By default AllowGrouping is set to ‘false’. To enable Grouping for your AutoComplete widget, set the value to ‘true’.

Configuring Grouping for AutoComplete

The following steps explain you how to configure Grouping for an AutoComplete textbox.

Copyright © 2001 - 2020 Syncfusion Inc.

1. In the Controller page, define the data list with Key, Text, and Category field for grouping.

CSHARP

```
public class CarsList
{
public int UniqueKey { get; set; }
public string Text { get; set; }
public string Category { get; set; }
}
public partial class AutocompleteController : Controller
{
List<CarsList> cars = new List<CarsList>();
public ActionResult AutocompleteFeatures()
{
cars.Add(new CarsList { UniqueKey = 1, Text = "Audi S6", Category = "Audi"
});
cars.Add(new CarsList { UniqueKey = 2, Text = "Austin-Healey", Category =
"Austin" });
cars.Add(new CarsList { UniqueKey = 3, Text = "BMW 7", Category = "BMW" });
cars.Add(new CarsList { UniqueKey = 4, Text = "Chevrolet Camaro", Category =
"Chevrolet" });
cars.Add(new CarsList { UniqueKey = 5, Text = "Mercedes-Benz", Category =
"Mercedes" });
cars.Add(new CarsList { UniqueKey = 6, Text = "Toyota 2000GT", Category =
"Toyota" });
cars.Add(new CarsList { UniqueKey = 7, Text = "Volvo P1800", Category =
"Volvo" });
cars.Add(new CarsList { UniqueKey = 8, Text = "Audi Avant RS 2", Category =
"Audi" });
cars.Add(new CarsList { UniqueKey = 9, Text = "Audi S4 quattro", Category =
"Audi" });
cars.Add(new CarsList { UniqueKey = 10, Text = "BMW M Roadster E85",
Category = "BMW" });
cars.Add(new CarsList { UniqueKey = 11, Text = "Mercedes-Benz Sprinter",
Category = "Mercedes" });
cars.Add(new CarsList { UniqueKey = 12, Text = "Corvette", Category =
"Chevrolet" });
cars.Add(new CarsList { UniqueKey = 13, Text = "Volvo P1800", Category =
"Volvo" });
ViewBag.datasource = cars;
return View();
}
}
```

2. In the View page, define the AutoComplete control and then give the Category filed for GroupBy field property.

HTML

```
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource).Width("205")
.AutocompleteFields(field =>
field.Key("UniqueKey").Text("Text").GroupBy("Category"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following image is the output for AutoComplete control that provides Grouping.

AutoComplete popup panel with grouping

State Persistence

AutoComplete widget can store the model value in the browser's cookies. Every time after initial rendering, the control gets the model from the cookie only. Using EnablePersistence property you can store the model value in cookies. So when any changes are made dynamically, the values are updated in the cookie. On refreshing the page, the previous state of the AutoComplete control is maintained in the cookie and the control is rendered from it.

Configure state persistence of AutoComplete

The following steps explain you how to enable state maintenance for AutoComplete.

1. In the View page, define the AutoComplete control and configure state persistence by using EnablePersistence property.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field =>
field.Key("UniqueKey").Text("Text").GroupBy("Category"))
.EnablePersistence(true)
```

The following image is the output for AutoComplete when EnablePersistence is set to 'true'.

1. Autocomplete during value selection

2. Autocomplete after page refresh

AutoComplete with State maintenance

Templates

You can provide a Template for customizing the appearance of the AutoComplete textbox suggestions. This is achieved by assigning a string template to the Template property.

Configuring Templates

The following steps explain you how to define a Template to display a text and image for an AutoComplete textbox.

1. Define DataSource elements with required template fields by using the Sprite CSS class names.

CSHARP

```
public partial class AutocompleteController : Controller
{
List<Flags> flags = new List<Flags>();
public ActionResult AutocompleteFeatures()
{
flags.Add(new Flags { Text = "Algeria", Sprite = "flag-algeria" });
flags.Add(new Flags { Text = "Armenia", Sprite = "flag-am" });
flags.Add(new Flags { Text = "Brazil", Sprite = "flag-br" });
flags.Add(new Flags { Text = "Bangladesh", Sprite = "flag-bangladesh" });
flags.Add(new Flags { Text = "Canada", Sprite = "flag-ca" });
flags.Add(new Flags { Text = "Cuba", Sprite = "flag-cu" });
flags.Add(new Flags { Text = "China", Sprite = "flag-china" });
flags.Add(new Flags { Text = "Denmark", Sprite = "flag-denmark" });
flags.Add(new Flags { Text = "Estonia", Sprite = "flag-estonia" });
flags.Add(new Flags { Text = "Egypt", Sprite = "flag-eg" });
flags.Add(new Flags { Text = "France", Sprite = "flag-fr" });
flags.Add(new Flags { Text = "Finland", Sprite = "flag-fi" });
flags.Add(new Flags { Text = "Greenland", Sprite = "flag-gl" });
flags.Add(new Flags { Text = "India", Sprite = "flag-in" });
flags.Add(new Flags { Text = "Indonesia", Sprite = "flag-id" });
flags.Add(new Flags { Text = "Malaysia", Sprite = "flag-my" });
flags.Add(new Flags { Text = "Mexico", Sprite = "flag-mexico" });
flags.Add(new Flags { Text = "New Zealand", Sprite = "flag-new-zealand" });
flags.Add(new Flags { Text = "Netherlands", Sprite = "flag-nl" });
flags.Add(new Flags { Text = "Norway", Sprite = "flag-no" });
flags.Add(new Flags { Text = "Portugal", Sprite = "flag-pt" });
flags.Add(new Flags { Text = "Poland", Sprite = "flag-pl" });
flags.Add(new Flags { Text = "Qatar", Sprite = "flag-qatar" });
flags.Add(new Flags { Text = "Romania", Sprite = "flag-ro" });
flags.Add(new Flags { Text = "Spain", Sprite = "flag-es" });
flags.Add(new Flags { Text = "Singapore", Sprite = "flag-singapore" });
flags.Add(new Flags { Text = "Saudi Arabia", Sprite = "flag-sa" });
flags.Add(new Flags { Text = "Thailand", Sprite = "flag-th" });
flags.Add(new Flags { Text = "Turkey", Sprite = "flag-tr" });
flags.Add(new Flags { Text = "Ukraine", Sprite = "flag-ukraine" });
flags.Add(new Flags { Text = "United States", Sprite = "flag-us" });
flags.Add(new Flags { Text = "Uruguay", Sprite = "flag-uruguay" });
flags.Add(new Flags { Text = "Viet Nam", Sprite = "flag-viet-nam" });
ViewBag.datasource = flags;
return View();
}
}
public class Flags
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
public string Text { get; set; }
public string Sprite { get; set; }
}
```

2. Configure template structure for AutoComplete control as follows, including a

   element with image and text in every row of the popup panel. Assign the corresponding variable name within ${} to map them into the list.

ASPX-CS

```
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<Flags>)ViewBag.datasource)
.AutocompleteFields(fields => fields.Text("Text"))
.Template("<div class='flag ${Sprite}'></div><div class='txt'> ${_Text_}
</div>")
```

3. Define the CSS classes for the sprite images. You can find the images in the following location:

[Installed Drive]:\Users\[user name]\AppData\Local\Syncfusion\EssentialStudio\X.X.X.X\MVC\Samples\web\Images\autocomplete\flags.png

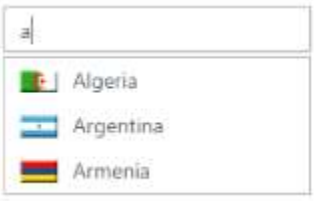
S

```
<style type="text/s">
/* Sprite s for country flags */
.flag
{
background: url("Styles/flags.png") no-repeat;
float: left;
height: 15px;
margin-right: 10px;
margin-top: 3px;
width: 25px;
}
.flag.flag-am {background-position: -25px 0}
.flag.flag-ar {background-position: -50px 0}
.flag.flag-bangladesh {background-position: -75px 0}
.flag.flag-br {background-position: -100px 0}
.flag.flag-ca {background-position: -125px 0}
.flag.flag-china {background-position: 0 -15px}
.flag.flag-cu {background-position: -25px -15px}
.flag.flag-denmark {background-position: -50px -15px}
.flag.flag-algeria {background-position: -75px -15px}
.flag.flag-estonia {background-position: -100px -15px}
.flag.flag-eg {background-position: -125px -15px}
.flag.flag-es {background-position: 0 -30px}
.flag.flag-fi {background-position: -25px -30px}
.flag.flag-fr {background-position: -50px -30px}
.flag.flag-gl {background-position: -75px -30px}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.flag.flag-id {background-position: -100px -30px}
.flag.flag-in {background-position: -125px -30px}
.flag.flag-mexico {background-position: 0 -45px}
.flag.flag-my {background-position: -25px -45px}
.flag.flag-nl {background-position: -50px -45px}
.flag.flag-no {background-position: -75px -45px}
.flag.flag-new-zealand {background-position: -100px -45px}
.flag.flag-pl {background-position: -125px -45px}
.flag.flag-pt {background-position: 0 -60px}
.flag.flag-qatar {background-position: -25px -60px}
.flag.flag-ro {background-position: -50px -60px}
.flag.flag-sa {background-position: -75px -60px}
.flag.flag-singapore {background-position: -100px -60px}
.flag.flag-th {background-position: -125px -60px}
.flag.flag-tr {background-position: 0 -75px}
.flag.flag-ukraine {background-position: -25px -75px}
.flag.flag-us {background-position: -50px -75px}
.flag.flag-uruguay {background-position: -75px -75px}
.flag.flag-viet-nam {background-position: -100px -75px}
.flag.flag-ye {background-position: -125px -75px}
.txt {
display: table-cell;
height: 20px;
vertical-align: middle;
}
</style>
```

The following image is the output for AutoComplete widget with Template support.



AutoComplete with Custom template

Appearance and Styling

Adjusting AutoComplete size

AutoComplete widget allows you to set the height and width of the textbox element in AutoComplete. The Height and Width properties take pixel values to set the dimension accordingly.

Define height and width for AutoComplete textbox

The following steps explain the dimensional properties of an AutoComplete textbox.

1. In the View page, define the AutoComplete control and set values for Height and Width property.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.AutocompleteFields(field =>
field.Key("UniqueKey").Text("Text").GroupBy("Category"))
.Height("50px").Width("250px")
.MultiSelectMode(MultiSelectModeTypes.Delimiter)
```

The following image is the output for AutoComplete textbox with customized dimensions.

AutoComplete with Customized dimensions

Rounded corner

By enabling the ShowRoundedCorner property, you can customize the shape of the AutoComplete widget from a regular rectangular shape to a rounded rectangle shape that is set to 'false' by default.

Enabling Rounded corner

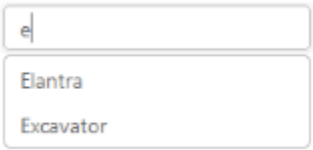
The following steps explain enabling the ShowRoundedCorner property for an AutoComplete textbox.

1. In the View page, define the AutoComplete control and enable the ShowRoundedCorner property.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field =>
field.Key("UniqueKey").Text("Text").GroupBy("Category"))
.ShowRoundedCorner(true)
```

The following image is the output for AutoComplete when ShowRoundedCorner is set to "true".



AutoComplete with Rounded corners

Watermark text

WatermarkText property provides you with an option to display a faded text in the AutoComplete textbox when the textbox is empty.

Copyright © 2001 - 2020 Syncfusion Inc.

Defining Watermark text

The following steps explain you how to configure WatermarkText property for an AutoComplete textbox.

1. In the View page, define the AutoComplete control and enable the WatermarkText property.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field =>
field.Key("UniqueKey").Text("Text").GroupBy("Category"))
.Width("250px").WatermarkText("Select an item")
```

The following image is the output for AutoComplete when WatermarkText is defined.

AutoComplete loaded with watermark text

Adjusting Suggestion list size

AutoComplete widget provides you with a property to define the dimensions of the popup panel that holds the suggestions list items. The PopupHeight and PopupWidth properties allow you to set the maximum height and width of the popup element for use when the content exceeds the default dimensions.

Configure dimensions of PopUp panel

The following steps help you set height and width of the popup panel of an AutoComplete textbox.

1. In the View page, define the AutoComplete control and configure the Popup panel height and width properties.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field =>
field.Key("UniqueKey").Text("Text").GroupBy("Category"))
.Width("250px").PopupHeight("80px").PopupWidth("350px")
```

The following image is the output for AutoComplete, after configuring the height and width of the popup panel.

Copyright © 2001 - 2020 Syncfusion Inc.

AutoComplete PopUp panel with configured dimensions

PopUp Time Delay

AutoComplete widget allows you to set the time delay to fetch the list items. The value of DelaySuggestionTimeout is set in milliseconds, so that data search time can be configured. This enhances the turnaround time to populate the list items.

Configure Time delay of PopUp panel

The following steps are used to set the time delay to load the popup panel of an AutoComplete textbox.

1. In the View page, add an Autocomplete helper and configure it.

2. Configure the delay time for popup panel in AutoComplete control as follows.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field =>
field.Key("UniqueKey").Text("Text").GroupBy("Category"))
.Width("250px").DelaySuggestionTimeout(1000)
```

This takes 1000ms to display the popup panel list items.

Theme

AutoComplete control's style and appearance are controlled based on CSS classes. In order to apply styles to the AutoComplete control, you can refer 2 files namely, ej.widgets.core.min.s and ej.theme.min.s. When the file ej.widgets.all.min.s is referred, then it is not necessary to include the files ej.widgets.core.min.s and ej.theme.min.s in your project, as ej.widgets.all.min.s is the combination of these two.

By default, there are 12 theme supports available for AutoComplete control namely:

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

CSS Class

CSS class is used to customize the AutoComplete control's appearance. Define CSS class as per requirement and assign the class name to CssClass property.

Copyright © 2001 - 2020 Syncfusion Inc.

Configure AutoComplete textbox using CSS class

The following steps allow you to configure CssClass for an AutoComplete textbox.

1. Define CSS class for customizing the AutoComplete control.

S

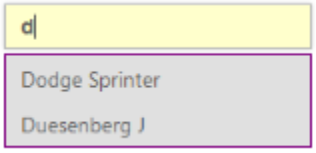
```
<style type="text/s" class="sStyles">
/* Customize the PopUp panel */
.customCss
{
border-color:Purple;
background-color: #E0E0E0;
}
/* Customize the AutoComplete input textbox */
.customCss .e-autocomplete
{
background-color: #FFFFCC;
font-weight:bold;
font-family: sans-serif;
}
</style>
```

2. In the View page, define the AutoComplete control and assign the class name to CssClass property.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field =>
field.Key("UniqueKey").Text("Text").Category("Category"))
.Width("250px").CssClass("customCss")
```

The following image is of an AutoComplete textbox configured based on CSS class.



AutoComplete widget configured with CSS class

RTL support

This feature allows you to change the alignment of the AutoComplete textbox widget from left-to-right to right-to-left (RTL). The custom template AutoComplete textbox also supports RTL.

Enabling RTL Support

The following steps explain how you can enable the right-to-left property for an AutoComplete textbox.

Copyright © 2001 - 2020 Syncfusion Inc.

1. In the View page, define the AutoComplete control and enable the RTL property.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@Html.EJ().Autocomplete("autocomplete")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.AutocompleteFields(field =>
field.Key("UniqueKey").Text("Text").GroupBy("Category"))
.Width("250px").EnableRTL(true)
```

The following image is the output for AutoComplete when EnableRTL is set to “true”.

AutoComplete template with RTL support

Keyboard Interaction

You can use keyboard shortcut keys as an alternative to the mouse while using the AutoComplete widget. The AutoComplete widget allows you to perform all kinds of actions using keyboard shortcuts.

Keyboard shortcut keys

Shortcut Key	Description
Access keyÂ + j	Focuses into the AutoComplete text box
Up	Moves to previous item in pop up
Down	Moves to next item in pop up
Enter	Selects the focused item
Esc	Closes the popup

Configure Keyboard Interaction

The following steps explain how you can enable keyboard interaction for an AutoComplete textbox.

1. In the View page, define the AutoComplete control.

ASPX-CS

```
@*Refer to the DataSource defined in Local Data binding Step 1 *@
@{IDictionary<string, object> htmlAttribute = new Dictionary<string,
object>();
htmlAttribute.Add("accesskey", "j");
}
@(Html.EJ().Autocomplete("autocomplete").HtmlAttributes(htmlAttribute)
.Datasource((IEnumerable<CarsList>
```

```
)ViewBag.datasource)
.AutocompleteFields(field =>
field.Key("UniqueKey").Text("Text").GroupBy("Category"))
.Width("200px"))
```

2. Run the sample, press Access Key + J to focus in the AutoComplete widget and you can navigate using the arrow keys. Use the Escape key to close the popup.

AutoComplete focused with keyboard shortcut

How to

Render Autocomplete from Code behind

Autocomplete can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of Autocomplete properties in the controller.

C#

```
//Namespace to get the JavaScript (Autocomplete) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class AutocompleteController : Controller
{
// GET: Autocomplete
public ActionResult AutocompleteFeatures()
{
//Initializing the Autocomplete model
AutocompleteProperties AutoObj = new AutocompleteProperties();
//Initializing the datasource and other properties
AutoObj.DataSource =
"http://js.syncfusion.com/ejServices/wcf/NorthWind.svc/";
AutoObj.Query = "ej.Query().from('Suppliers').select('SupplierID',
'ContactName')";
AutoObj.AutocompleteFields.Text = "ContactName";
AutoObj.AutocompleteFields.Key = "SupplierID";
AutoObj.Width = "500px";
AutoObj.ShowPopupButton = true;
AutoObj.ShowLoadingIcon = true;
//Passing Autocomplete properties using the ViewData
ViewData["AutoModel"] = AutoObj;
return View();
}
}
}
```

Binding the Autocomplete properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@{
Html.EJ().Autocomplete("searchCustomer",(Syncfusion.JavaScript.Models.Autoco
mpleteProperties)ViewData["AutoModel"]).Render();
}
```

How to set autocomplete default value

You can set a value into autocomplete at initial rendering using

Value property. It is used to select a single value from the autocomplete widget at initial rendering state.

Refer to the following code.

RAZOR

```
@Html.EJ().Autocomplete("selectState").Datasource((IEnumerable<states>)ViewB
ag.datasource).AutocompleteFields(field =>
field.Key("index").Text("countryName")).Value("Arizona")
```

C#

```
public partial class AutocompleteController : Controller{
List<states> state = new List<states>();
public ActionResult AutocompleteFeatures()
{
state.Add(new states { index = "s1", countryName = "Alabama" });
state.Add(new states { index = "s2", countryName = "Alaska" });
state.Add(new states { index = "s3", countryName = "Arizona" });
ViewBag.datasource = state;
return View();
}
}
public class states
{
public string index { get; set; }
public string countryName { get; set; }
}
```

The following output is displayed as a result of the previous code example.

![howto](how-to_images/howto1.png)

If you set autocomplete Value property as a string that is present in the data source, the hidden input value holds the corresponding Key value. This is used for validation purpose in the autocomplete. For example, ‘Arizona’ text holds the key value of ‘s3’. The autocomplete default value ‘Arizona’ is present in the ‘countryName’ of data source and also this field is mapped for autocomplete

Copyright © 2001 - 2020 Syncfusion Inc.

```
<span id="selectState_wrapper" class="e-atc e-widget" style="width: 100%;">
  <span class="e-in-wrap e-box">
    <input id="selectState_hidden" type="hidden" name="selectState" value="s3"> == $0
    <input type="text" id="selectState" class="e-autocomplete e-js e-input" role="combobox" aria-label="Autocomplete textbox" aria-
    expanded="false" aria-autocomplete="list" tabindex="0" autocomplete="off" name="selectState" placeholder="Select a state" aria-owns=
    "selectState_suggestion">
  </span>
</span>
```

Text property. So, hidden input value holds the ‘s3’ value.

The following screenshot illustrates the previous hidden input state of code.

If you set autocomplete

```
<span id="selectState_wrapper" class="e-atc e-widget" style="width: 100%;">
  <span class="e-in-wrap e-box">
    <input id="selectState_hidden" type="hidden" name="selectState" value="New York"> == $0
    <input type="text" id="selectState" class="e-autocomplete e-js e-input" role="combobox" aria-label="Autocomplete textbox" aria-
    expanded="false" aria-autocomplete="list" tabindex="0" autocomplete="off" name="selectState" placeholder="Select a state" aria-owns=
    "selectState_suggestion">
  </span>
</span>
```

Value property as a string that is not present in the data source, the hidden input value holds the autocomplete value. For example, if autocomplete default value is ‘New York’ and not present in the ‘countryName’ of data source, the hidden input value holds the ‘New York’string.

Refer to the following code sample.

RAZOR

```
@Html.EJ().Autocomplete("selectState").Datasource((IEnumerable<states>)ViewB
ag.datasource).AutocompleteFields(field =>
field.Key("index").Text("countryName")).Value("New York")
```

The following screenshot illustrates the previous hidden input state of code.

Remote data

The remote data also allows you to set the default value into autocomplete using Value property.

Refer to the following code sample.

RAZOR

```
@Html.EJ().Autocomplete("selectCar").Datasource(dataSource =>
dataSource.URL(Url.Action("GetOutletsForAutocomplete",
"Autocomplete")).Adaptor(AdaptorType.UrlAdaptor)).AutocompleteFields(field
=> field.Text("Name").Key("Id")).Value("Two")
```

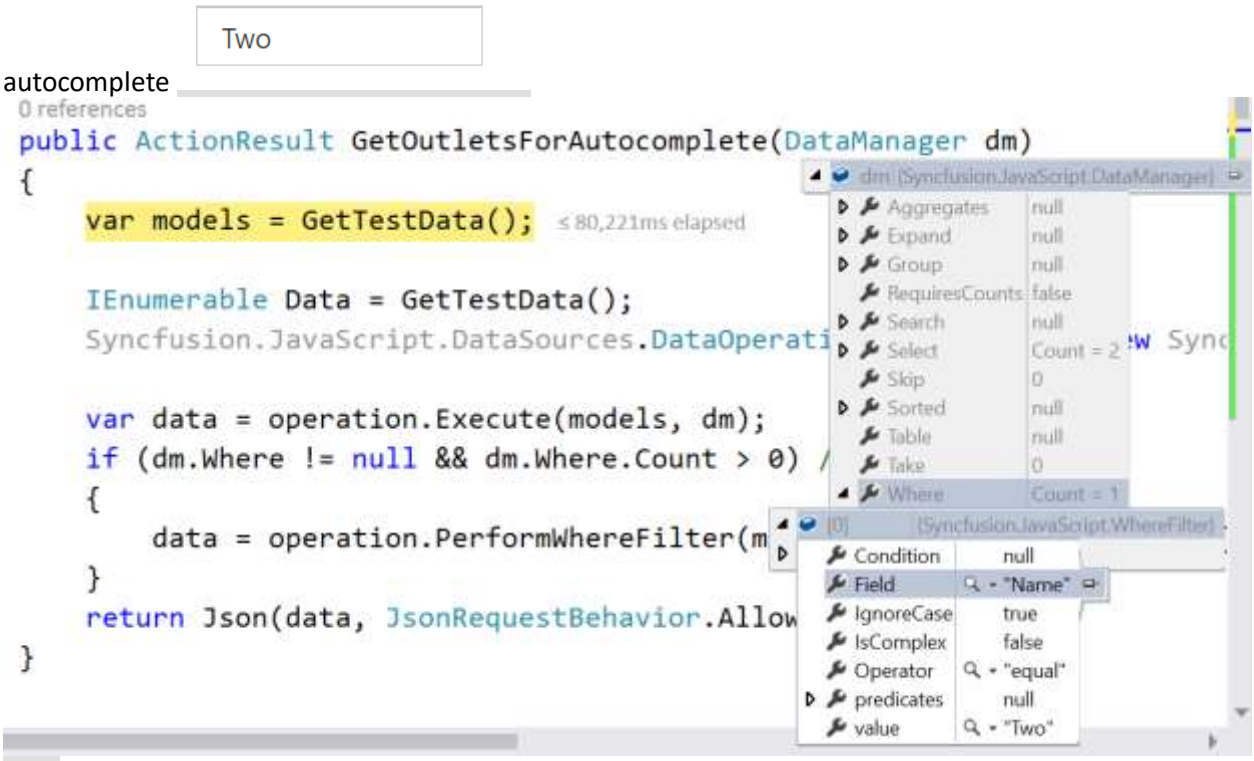
C#

```
public ActionResult GetOutletsForAutocomplete(DataManager dm)
{
var models = GetTestData();
IEnumerable Data = GetTestData();
Syncfusion.JavaScript.DataSources.DataOperations operation = new
Syncfusion.JavaScript.DataSources.DataOperations();
var data = operation.Execute(models, dm);
if (dm.Where != null && dm.Where.Count > 0) //Filtering
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
data = operation.PerformWhereFilter(models, dm.Where, dm.Where[0].Operator);
}
return Json(data, JsonRequestBehavior.AllowGet);
}
public class AutocompleteModel
{
[Display(Name = "Id")]
public string Id { get; set; }
[Display(Name = "Name")]
public string Name { get; set; }
}
private List<AutocompleteModel> GetTestData()
{
var list = new List<AutocompleteModel>();
list.Add(new AutocompleteModel(){ Id = "1", Name = "One"});
list.Add(new AutocompleteModel(){ Id = "2", Name = "Two"});
list.Add(new AutocompleteModel(){ Id = "3", Name = "Three"});
return list;
}
```

The autocomplete Value property triggers a server-side post when using remote data in the autocomplete. The server side data manger holds where query which contains field name as



Text property.

Find the following screenshot for the data manager where query.

![howto](how-to_images/howto6.png)

Find the following output for the previous code.

![howto](how-to_images/howto7.png)

Copyright © 2001 - 2020 Syncfusion Inc.

How to show text on autocomplete using key value

You can set the value of autocomplete text box based on a given key value. The SelectValueByKey property is used to select autocomplete value based on the specified key value.

Refer to the following code sample.

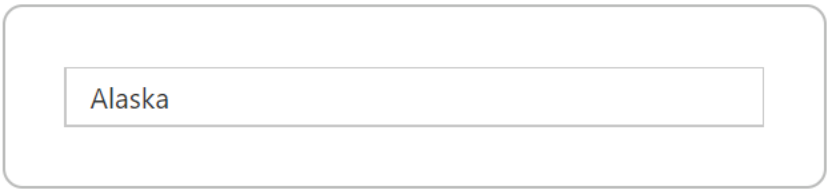
RAZOR

```
@Html.EJ().Autocomplete("selectState").Datasource((IEnumerable<states>)ViewB
ag.datasource).AutocompleteFields(field =>
field.Key("index").Text("countryName")).SelectValueByKey("s2")
```

C#

```
public partial class AutocompleteController : Controller{
List<states> state = new List<states>();
public ActionResult AutocompleteFeatures()
{
state.Add(new states { index = "s1", countryName = "Alabama" });
state.Add(new states { index = "s2", countryName = "Alaska" });
state.Add(new states { index = "s3", countryName = "Arizona" });
ViewBag.datasource = state;
return View();
}
}
public class states
{
public string index { get; set; }
public string countryName { get; set; }
}
```

For example, If SelectValueByKey property specified the value as ‘s2’, the corresponding Text value



Alaska is shown in the autocomplete text.

The following output is displayed as a result of the previous code example.

SelectValueByKey property into autocomplete control, the hidden input value holds a specified key value.

Refer to the following screenshot.

![howto](how-to_images/howto5.png)

Remote data

The remote data also allows you to set the default value into autocomplete based on a given key value using the SelectValueByKey property.

Refer to the following code snippet.

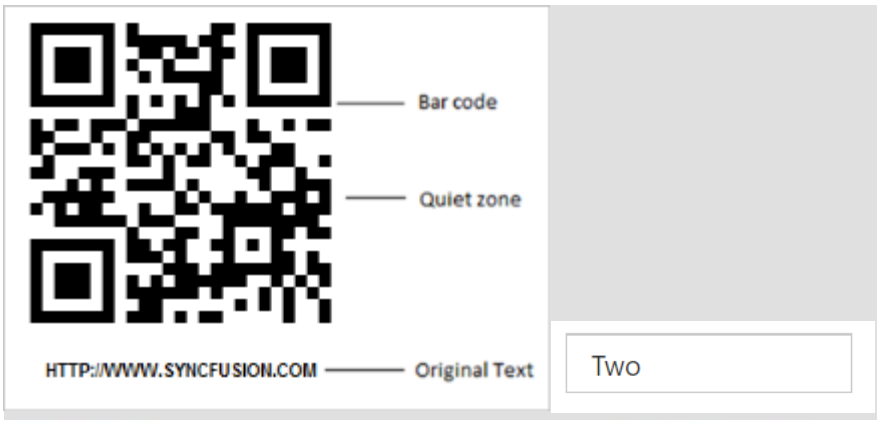
RAZOR

```
@Html.EJ().Autocomplete("selectCar").Datasource(dataSource =>
dataSource.URL(Url.Action("GetOutletsForAutocomplete",
"Autocomplete")).Adaptor(AdaptorType.UrlAdaptor)).AutocompleteFields(field
=> field.Text("Name").Key("Id")).SelectValueByKey("2")
```

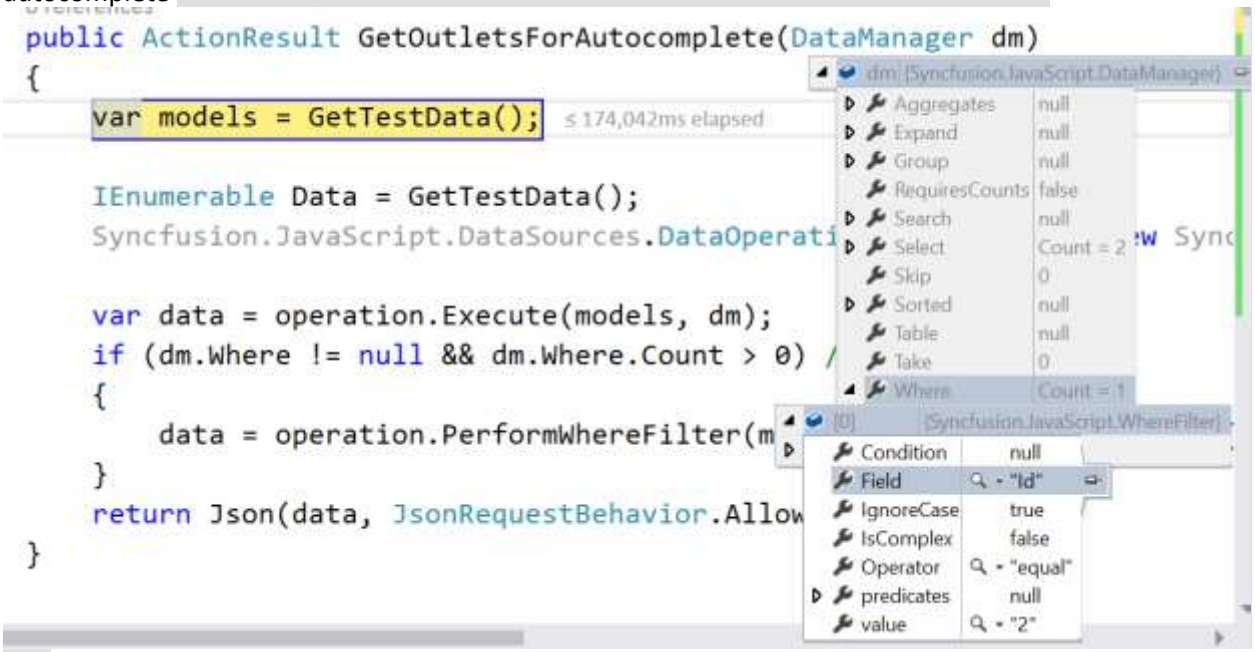
C#

```
public ActionResult GetOutletsForAutocomplete(DataManager dm)
{
var models = GetTestData();
IEnumerable Data = GetTestData();
Syncfusion.JavaScript.DataSources.DataOperations operation = new
Syncfusion.JavaScript.DataSources.DataOperations();
var data = operation.Execute(models, dm);
if (dm.Where != null && dm.Where.Count > 0) //Filtering
{
data = operation.PerformWhereFilter(models, dm.Where, dm.Where[0].Operator);
}
return Json(data, JsonRequestBehavior.AllowGet);
}
public class AutocompleteModel
{
[Display(Name = "Id")]
public string Id { get; set; }
[Display(Name = "Name")]
public string Name { get; set; }
}
private List<AutocompleteModel> GetTestData()
{
var list = new List<AutocompleteModel>();
list.Add(new AutocompleteModel(){ Id = "1", Name = "One"});
list.Add(new AutocompleteModel(){ Id = "2", Name = "Two"});
list.Add(new AutocompleteModel(){ Id = "3", Name = "Three"});
return list;
}
```

The autocomplete SelectValueByKey property triggers a server-side post when using remote data on autocomplete. The server side data manger holds where query which contains field name as



autocomplete



Key property.

Find the following screenshot for the data manager where query.

![howto](how-to_images/howto8.png)

Find the output for the previously given code as follows.

![howto](how-to_images/howto9.png)

Barcode

Barcode

The Barcode control enables rendering of one dimension and two dimension Barcodes in web page. Barcode provides you a simple and inexpensive method of encoding text information that can be easily read by inexpensive electronic readers.

Key Features

- Supports 10 one-dimensional Barcodes including Code 39 and Code 32 barcodes.
- Supports 2 two-dimensional Barcodes such as QR and DataMatrix barcodes.

Copyright © 2001 - 2020 Syncfusion Inc.

Getting Started

This section explains you briefly on how to create a Barcode in your application with ASP.NET MVC.

Control Structure

Control structure

Create your first Barcode in MVC

The ASP.NET MVC Barcode provides you support to encode data and display it in your web page; it takes text and symbology as input and renders the encoded text as Barcode.

The following guideline explains you on how to create a QR Barcode for a real time scenario of encoding a URL. The following screenshot demonstrates a two dimensional barcode encoding the value “HTTP://WWW.SYNCFUSION.COM”.

QR Barcode for the URL “HTTP://WWW.SYNCFUSION.COM”

By default, ASP.NET MVC Barcode renders gray scale colors with predefined Quiet zone. Quiet zone is the blank margin on the side(s) that denotes the reader with the start and stop of the Barcode. It also provides flexible API’s to customize the appearance of the Barcode.

Refer Assemblies

You can create a MVC Project, add necessary assemblies and Scripts. Refer MVC-Getting Started Documentation.

Add the following assemblies in your MVC application for using Barcode control:

- Syncfusion.Core.dll
- Syncfusion.EJ.dll
- Syncfusion.EJ.MVC.dll

These Syncfusion assemblies can either be referenced from Global Assembly Cache (GAC) or from the installed folder.

[Installed Drive]:\Program Files (x86)\Syncfusion\Essential Studio\X.X.X.X\precompiledassemblies\X.X.X.X

Configure Web.Config

Web.config file is configured according to the referenced assemblies. The steps to configure the file are as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

- On the Solution Explorer, double-click the Web.config file in the root folder. The Web.config page appears.
- Add the following assemblies in the Web.config page under the tag:
- Syncfusion.Core
- Syncfusion.EJ
- Syncfusion.EJ.MVC

XML

```
<system.web>
<compilation>
<assemblies>
<add assembly="Syncfusion.Core, Version=x.x.x.x, Culture=neutral,
PublicKeyToken=632609b4d040f6b4"/>
<add assembly="Syncfusion.EJ, Version=x.x.x.x, Culture=neutral,
PublicKeyToken=3d67ed1f87d44c89"/>
<add assembly="Syncfusion.EJ.Mvc, Version=x.x.x.x, Culture=neutral,
PublicKeyToken=3d67ed1f87d44c89"/>
</assemblies>
</compilation>
</system.web>
```

Note: X.X.X.X in the above code corresponds to the correct version number of the Essential Studio version that you are currently using.

- Add the following namespaces under the tag.
- Syncfusion.JavaScript
- Syncfusion.JavaScript.DataVisualization
- Syncfusion.Mvc.EJ

XML

```
<system.web>
<pages>
<namespaces>
<add namespace="Syncfusion.JavaScript"/>
<add namespace="Syncfusion.JavaScript.DataVisualization"/>
<add namespace="Syncfusion.MVC.EJ"/>
</namespaces>
</pages>
</system.web>
```

- Open the Index.cshtml file under Views->Home folder. Add the following code in the cshtml file for Barcode rendering.

ASPX-CS

```
<div>
<div>
@Html.EJ().Barcode("barcode")
.Text("HTTP://WWW.SYNCFUSION.COM")
.SymbologyType(BarcodeSymbolType.QRBarcode)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Render()
</div>
</div>
```

- Run the project. Refer the following screenshot for output.

QR Barcode generated in ASP.NET

Barcode types and supported characters

The following table contains the supported types and associated valid characters.

Table of Barcode types and supported character

Symbol	Enum Value	Supported characters	Length
QR Barcode	QRBarcode	0,1,2,3,4,5,6,7,8,90â€“9, Aâ€“Z (upper-case only), space, $, %, *, +, -,., /, :Shift JIS characters	variable
DataMatrix	DataMatrix	All ASCII characters	
Code 39	Code39	0-9, A-Z,a dash(-),a dot(.),$,/,+,%, SPACE	variable
Code 39 Extended	Code39Extended	0-9 A-Z a-z	variable
Code 11	Code11	0-9, a dash(-)	variable
Codabar	Codabar	0-9,-,$,:,/,a dot(.),+	variable
Code 32	Code32	0 1 2 3 4 5 6 7 8 9Text length should be 8	8

Code 128 C	Code128C	0 1 2 3 4 5 6 7 8 9	variable

Two Dimensional Barcodes

QR Barcode

A QR Barcode is a two-dimensional Barcode that consists of a grid of dark and light dots or blocks that form a square. The data encoded in the Barcode can be numeric, alphanumeric, or Shift Japanese Industrial Standards (JIS8) characters. The QR Barcode uses version from 1 to 40. Version 1 measures 21 modules x 21 modules, Version 2 measures 25 modules x 25 modules, and so on. The number of modules increases in steps of 4 modules per side up to Version 40 that measures 177 modules x 177 modules. Each version has its own capacity. By default, the Barcode control automatically set the version according to the length of the input text. The QR Barcodes are designed for industrial uses and also commonly used in consumer advertising.

Here is the code snippet to create a QR Barcode:

ASPX-CS

```
<div>
<div>
@*Sets the following properties:
Text – Text to encode
SymbologyType - Barcode Type (Default: QRBarcode)
XDimension - Size of each block (Optional, Default: 4)
QuietZone – Sets quiet zone on all sides (Optional, Default: All->1)
*@
@Html.EJ().Barcode("barcode")
.Text("B5330E8278BC4C797C49DD3ED5AD9715")
.XDimension(8)
.SymbologyType(BarcodeSymbolType.QRBarcode)
.QuietZone(qz => { qz.All(30); })
.Render()
</div>
</div>
```

DataMatrix

DataMatrix Barcode is a two dimensional Barcode that consists of a grid of dark and light dots or blocks forming square or rectangular symbol. The data encoded in the Barcode can either be numbers or alphanumeric. They are widely used in printed media such as labels and letters. You can read it easily with the help of a Barcode reader and mobile phones.

Copyright © 2001 - 2020 Syncfusion Inc.

One Dimensional Barcodes

Code 39

The Code 39 character set includes the digits 0-9, the letters A-Z (upper case only), and the following symbols: space, minus (-), plus (+), period (.), dollar sign ($), slash (/), and percent (%). A special start / stop character is placed at the beginning and ending of each Barcode. The Barcode can be of any length; even more than 25 characters begin to push the bounds. Code 39 is the only type of Barcode that does not require a checksum for common use.

Here is the code example to create Code 39 barcode:

HTML

```
<div>
<div>
@*Sets the following properties:
Text - Text to encode
SymbologyType - Barcode Type (Default: QRBarcode)
DisplayText - If original text should be displayed (Optional, Default: true)
QuietZone - Quiet zone on all sides (Optional, Default: All->1)
BarcodeToTextGapHeight - Height between barcode and text (Optional, Default:
10)
BarHeight - Height of bar (Optional, Default: 150)
DarkBarColor - Color of dark bar (Optional, Default: black)
EncodeStartStopSymbol - If start stop symbol should be encoded (Mandatory
for some types, Default: true)
LightBarColor - Color of light bar (Optional, Default: white)
NarrowBarWidth - Width of the narrow bar (Optional, 1)
TextColor - Color of the display text (Optional, black)
WideBarWidth - Width of the wide bar (Optional, 3)
*@
@Html.EJ().Barcode("barcode")
.Text("SYNCFUSION")
.SymbologyType(BarcodeSymbolType.Code39)
.DisplayText(true)
.QuietZone(qz => { qz.All(30);})
.BarcodeToTextGapHeight(10)
.BarHeight(150)
.DarkBarColor("black")
.EncodeStartStopSymbol(true)
.LightBarColor("white")
.NarrowBarWidth(1)
.TextColor("red")
.WideBarWidth(3)
.Render()
</div>
</div>
```

Code 39 Extended

Code 39 Extended is an extended version of Code 39 that supports ASCII character set. In Code 39 Extended, you can also code 26 lower letters (a-z) and the special characters in the keyboard.

Code 11

Code 11 is used primarily for labeling the telecommunication equipment's. The character set includes the digits 0 to 9, a dash (-), and a start / stop code.

Copyright © 2001 - 2020 Syncfusion Inc.

Codabar

Codabar is a variable length symbol that encodes the following 20 characters:

0123456789-$:/.+ABCD

The characters, A, B, C and D are used as start and stop characters. Codabar is used in libraries, blood banks, the package delivery industry and a variety of other information processing applications.

Code 32

It is mainly used for coding pharmaceuticals, cosmetics and dietetics. Code 32 is often used to encode Italian Pharmacode that has the following structure:

- 'A' character (ASCII 65), that is not really encoded
- 8 digits for Pharmacode (It generally begins with / and prefixed with 0)
- 1 digit for Checksum module 10, that is automatically calculated by Barcode

The value to be encoded must be8 digits Pharmacode (prefix it with '0' if necessary) and the 9th digit (the checksum) is automatically calculated by Barcode.

Code 93

Code 93 was designed to complement and improve upon Code 39. It can represent the entire ASCII character set by using combinations of 2 characters. Code 93 is a continuous, variable-length symbology and produces denser code.

- The Standard Mode (default implementation) can encode uppercase letters (A-Z), digits (0-9), and special characters like *, -, $, %, (Space), ., /, and +.

Code 93 Extended

The Code 93 ExtendedBarcode symbology is continuous, variable length, and self-checking. It is based on Code 93 Barcode. The Extended Version can encode all 128 ASCII characters.

Code 128

Code 128 is a variable length, high density, alphanumeric, linear bar code symbology, capable of encoding the full 128-character ASCII character set and extended character sets. This symbology includes a checksum digit for verification and the barcode can also be verified character-by-character by verifying the parity of each data byte.

Code 128 Code Sets

- Code Set A (or Chars Set A) includes all of the standard upper case U.S. alphanumeric keyboard characters and punctuation characters along with the control characters, (namely, characters with ASCII values from 0 to 95 inclusive), and seven special characters.
- Code Set B (or Chars Set B) includes all of the standard upper case alphanumeric keyboard characters and punctuation characters along with the lower case alphabetic characters (namely, characters with ASCII values from 32 to 127 inclusive), and seven special characters.
- Code Set C (or Chars Set C) includes the set of 100 digit pairs from 00 to 99 inclusive along with three special characters. This allows numeric data to be encoded as two data digits per symbol character, at effectively twice the density of standard data.

Copyright © 2001 - 2020 Syncfusion Inc.

Code 128 Special characters

The last seven characters of Code Sets A and B (character values 96 - 102) and the last three characters of Code Set C (character values 100 - 102) are special non-data characters with no ASCII character equivalents that have a particular significance to the Barcode reading device.

Customizing the appearance

A page or printed media with Barcode often appears colorful in the background and surrounding region with other contents. In such cases the Barcode can also be customized to suit the needs. You can achieve this by changing the darkBarColor property.

Note: This color customization is possible only for one dimensional barcodes and it is not supported for two dimensional barcodes.

ASPX-CS

```
<div>
<div
@Html.EJ().Barcode("barcode")
.Text("B5330E8278BC4C797C49DD3ED5AD9715")
.SymbologyType(BarcodeSymbolType.Code39)
.DisplayText(true)
.QuietZone(qz => { qz.All(30);})
.BarcodeToTextGapHeight(10)
.BarHeight(150)
.DarkBarColor("blue")
.EncodeStartStopSymbol(true)
.LightBarColor("white")
.NarrowBarWidth(1)
.TextColor("red")
.WideBarWidth(3)
.Render()
</div>
</div>
```

Execute the above code to render the following output.

Customized Barcode

The height of the barcode can be changed using the BarHeight property. The equivalent property to change the block size for two dimensional barcode is XDimension.

ASPX-CS

```
<div>
<div
@Html.EJ().Barcode("barcode")
.Text("B5330E8278BC4C797C49DD3ED5AD9715")
.SymbologyType(BarcodeSymbolType.Code39)
.DisplayText(false)
.BarcodeToTextGapHeight(10)
.BarHeight(45)
.DarkBarColor("#990099")
.Render()
</div>
</div>
```

Execute the above code to render the following output.

Barcode with customized height

BulletGraph

BulletGraph

BulletGraphs are easy to interpret and also it conveys much more information to the user by visualizing the data in a small amount of space. It is generally used to compare a primary measure to one or more other measures in the context of qualitative ranges of performance. Occasionally, the BulletGraphs are also used to compare the same measure across multiple categories.

Key Features

- Data sources: Bind the BulletGraph control with an array of JSON objects or ej.DataManager.
- Tooltip with template: Template for tooltip support has been included to customize the tooltip.
- FlowDirection: The control can be rendered either in a “forward” or “backward” direction.
- Orientation: The control can be oriented either in “horizontal” or “Vertical” mode.
- Binding Range Stroke to ticks and labels: The Range colors can be bound to its underlying ticks and labels when the properties “applyRangeStrokeToLabels” and “applyRangeStrokeToTicks” are enabled.
- Multiple Measures: Provided support to render multiple feature measure bars as well as multiple comparative measure symbols.
- Animation: Animation support provided for the feature measure bars and the comparative measure symbols.

Getting Started

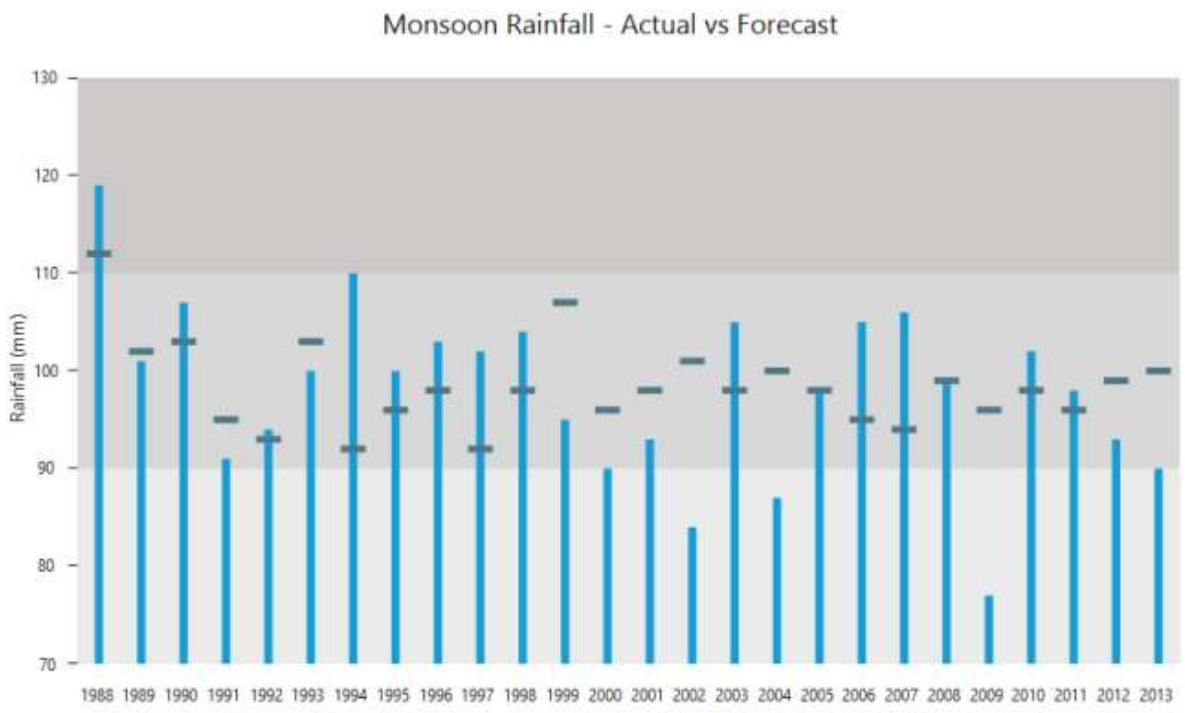
This section explains briefly about how to create a **BulletGraph** in your ASP.NET MVC application.

Create your first BulletGraph in MVC

This section encompasses the details on how to configure the **BulletGraph** control in your application. It also allows you to learn how to pass the required data to it and customize its various options according to your requirements.

Copyright © 2001 - 2020 Syncfusion Inc.

In the following screenshot, a **BulletGraph** is used to compare the actual monsoon rainfall received in a state versus its forecasted values for the years ranging from 1988 to 2013.



Bullet Graph

1. Create a

   tag.

HTML

```
<div>
</div>
```

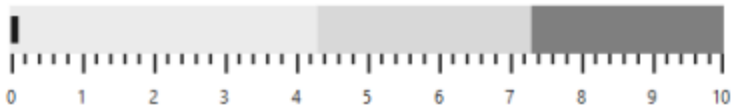
2. Add the following code in the index.cshtml file to create the BulletGraph control in the View page.

JAVASCRIPT

```
<div>
@(Html.EJ().BulletGraph("Bullet").Render())
</div>
```

3. Execute the above code to display the BulletGraph. To customize the measure bars in the BulletGraph, you can pass the data either locally or remotely.

Copyright © 2001 - 2020 Syncfusion Inc.



BulletGraph

Provide Required Data

You can customize the values of feature and comparative measure bars in a **BulletGraph**, either locally or remotely. The category data is optional, and it is used to display label values parallel to the measure bars.

Assign the data in BulletLocalDataBind variable to the DataSource property of BulletGraph as illustrated in the following code example.

C#

```
publicActionResult LocalDataBinding()
{
localDataBind.Add(newBulletLocalDataBind { category = "2013", value = "90",
comparativeMeasureValue = "100" });
localDataBind.Add(newBulletLocalDataBind { category = "2012", value = "93",
comparativeMeasureValue = "99" });
localDataBind.Add(newBulletLocalDataBind { category = "2011", value = "98",
comparativeMeasureValue = "96" });
localDataBind.Add(newBulletLocalDataBind { category = "2010", value = "102",
comparativeMeasureValue = "98" });
localDataBind.Add(newBulletLocalDataBind { category = "2009", value = "77",
comparativeMeasureValue = "96" });
localDataBind.Add(newBulletLocalDataBind { category = "2008", value = "99",
comparativeMeasureValue = "99" });
localDataBind.Add(newBulletLocalDataBind { category = "2007", value = "106",
comparativeMeasureValue = "94" });
localDataBind.Add(newBulletLocalDataBind { category = "2006", value = "105",
comparativeMeasureValue = "95" });
localDataBind.Add(newBulletLocalDataBind { category = "2005", value = "98",
comparativeMeasureValue = "98" });
localDataBind.Add(newBulletLocalDataBind { category = "2004", value = "87",
comparativeMeasureValue = "100" });
localDataBind.Add(newBulletLocalDataBind { category = "2003", value = "105",
comparativeMeasureValue = "98" });
localDataBind.Add(newBulletLocalDataBind { category = "2002", value = "84",
comparativeMeasureValue = "100" });
localDataBind.Add(newBulletLocalDataBind { category = "2001", value = "93",
comparativeMeasureValue = "98" });
localDataBind.Add(newBulletLocalDataBind { category = "2000", value = "96",
comparativeMeasureValue = "101" });
localDataBind.Add(newBulletLocalDataBind { category = "1999", value = "107",
comparativeMeasureValue = "98" });
localDataBind.Add(newBulletLocalDataBind { category = "1998", value = "98",
comparativeMeasureValue = "101" });
localDataBind.Add(newBulletLocalDataBind { category = "1997", value = "92",
comparativeMeasureValue = "98" });
localDataBind.Add(newBulletLocalDataBind { category = "1996", value = "98",
comparativeMeasureValue = "96" });
localDataBind.Add(newBulletLocalDataBind { category = "1995", value = "96",
comparativeMeasureValue = "107" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
localDataBind.Add(newBulletLocalDataBind { category = "1994", value = "92",
comparativeMeasureValue = "98" });
localDataBind.Add(newBulletLocalDataBind { category = "1993", value = "103",
comparativeMeasureValue = "92" });
localDataBind.Add(newBulletLocalDataBind { category = "1993", value = "93",
comparativeMeasureValue = "98" });
localDataBind.Add(newBulletLocalDataBind { category = "1991", value = "95",
comparativeMeasureValue = "96" });
localDataBind.Add(newBulletLocalDataBind { category = "1990", value = "103",
comparativeMeasureValue = "92" });
localDataBind.Add(newBulletLocalDataBind { category = "1989", value = "102",
comparativeMeasureValue = "103" });
localDataBind.Add(newBulletLocalDataBind { category = "1988", value = "112",
comparativeMeasureValue = "93" });
ViewBag.datasource = localDataBind;
return View();
}
```

Once the **DataSource** property is assigned with the required values, you can bind the variable names used in the **JSON** data to the corresponding fields of the **BulletGraph** as shown in the following code example.

ASPX-CS

```
@(Html.EJ().BulletGraph("Bullet")
.Fields(fie =>
{
fie.Datasource((IEnumerable<BulletLocalDataBind>)ViewBag.datasource)
.Category("category").ComparativeMeasure("comparativeMeasureValue")
.FeatureMeasure("value");
})
.Render())
```

Set Default and Scale Values

You can plot any number of measure bars within the **BulletGraph** by increasing the height and width of the control to locate all the measure bars within the graph. Set the QualitativeRangeSize and QuantitativeScaleLength properties according to the following code example.

By default, the **BulletGraph** is rendered in the horizontal orientation with its flow direction set to **Forward**. In this example, to achieve the desired output, change the horizontal orientation to vertical orientation with the flow direction set to **Backward**.

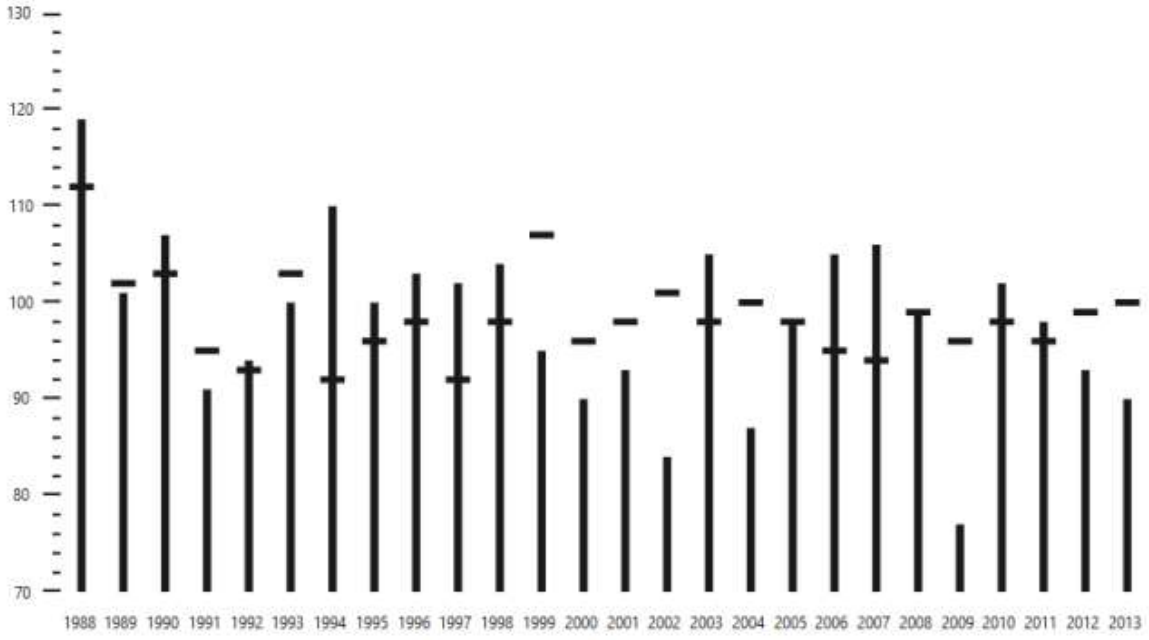
Minimum, Maximum and Interval values for the QuantitativeScale of the BulletGraph are set, as illustrated in the following code example. The ticks and labels within the scale are also positioned.

JS

```
@(Html.EJ().BulletGraph("Bullet").Width(850).Height(540)
.QualitativeRangeSize(800).QuantitativeScaleLength(425)
.Orientation(Orientation.Vertical).FlowDirection(FlowDirection.Backward)
.QuantitativeScaleSettings(scale=>scale.Minimum(70).Maximum(130).Interval(10
)
.TickPosition(TickPosition.Above)
.LabelSettings(lb=>lb.Position(LabelPosition.Above)))
.Fields(fie =>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
fie.Datasource((IEnumerable<BulletLocalDataBind>)ViewBag.datasource)
.Category("category").ComparativeMeasure("comparativeMeasureValue")
.FeatureMeasure("value");
})
.Render())
```



BulletGraph

The above image illustrates the BulletGraph without any ranges displayed in the background.

Add Qualitative Ranges

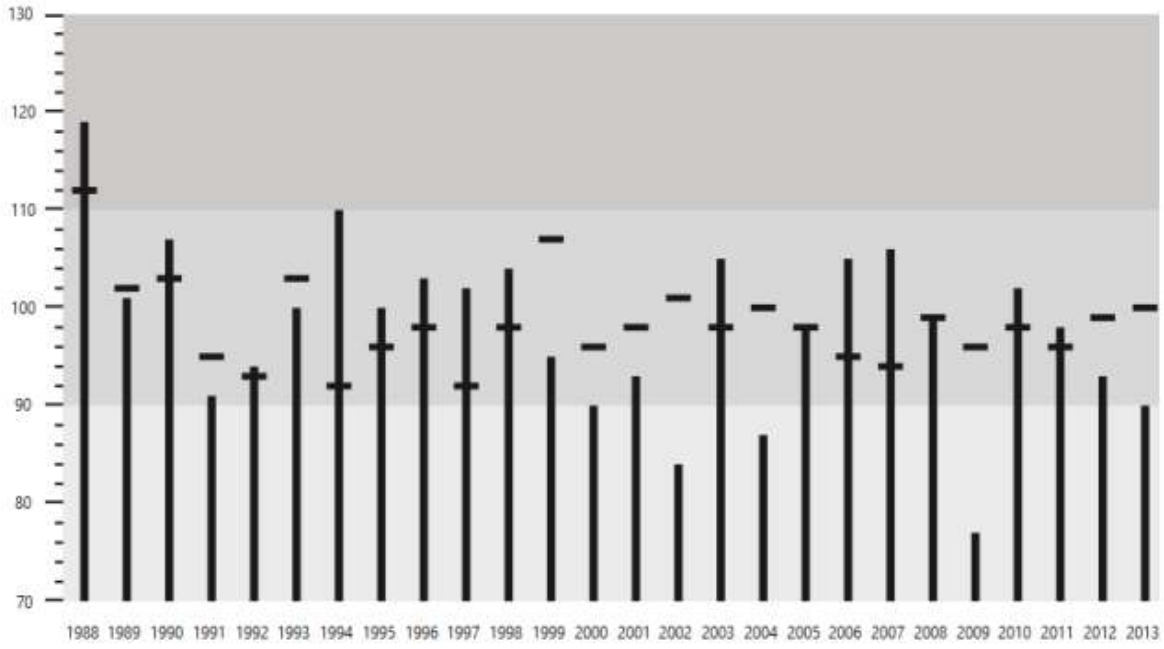
By default, 3 ranges are displayed in the **BulletGraph** control during the initial rendering of the control with its default values. To customize it, you can set appropriate values for the RangeEnd and RangeStroke properties. Any number of QualitativeRanges can be added to the control.

JS

```
@(Html.EJ().BulletGraph("Bullet").Width(850).Height(540)
.QualitativeRangeSize(800).QuantitativeScaleLength(425)
.Orientation(Orientation.Vertical).FlowDirection(FlowDirection.Backward)
.QuantitativeScaleSettings(scale=>scale.Minimum(70).Maximum(130).Interval(10
)
.TickPosition(TickPosition.Above)
.LabelSetting(lb=>lb.LabelPosition(LabelPosition.Above)))
.Fields(fie =>
{
fie.Datasource((IEnumerable<BulletLocalDataBind>)ViewBag.datasource)
.Category("category").ComparativeMeasure("comparativeMeasureValue")
.FeatureMeasure("value");
})
.QualitativeRanges(range =>
```

```
{
range.RangeEnd(90).Add();
range.RangeEnd(110).Add();
range.RangeEnd(130).RangeStroke(System.Drawing.Color.DarkBlue).Add();
})
.Render())
```

After adding **QualitativeRanges** to the **BulletGraph**, the control appears as follows.



BulletGraph

Ticks and Measure Bars Customization

You can do the following code changes in the quantitative scale to customize the tick size, the color of the feature bar and the comparative measure symbols.

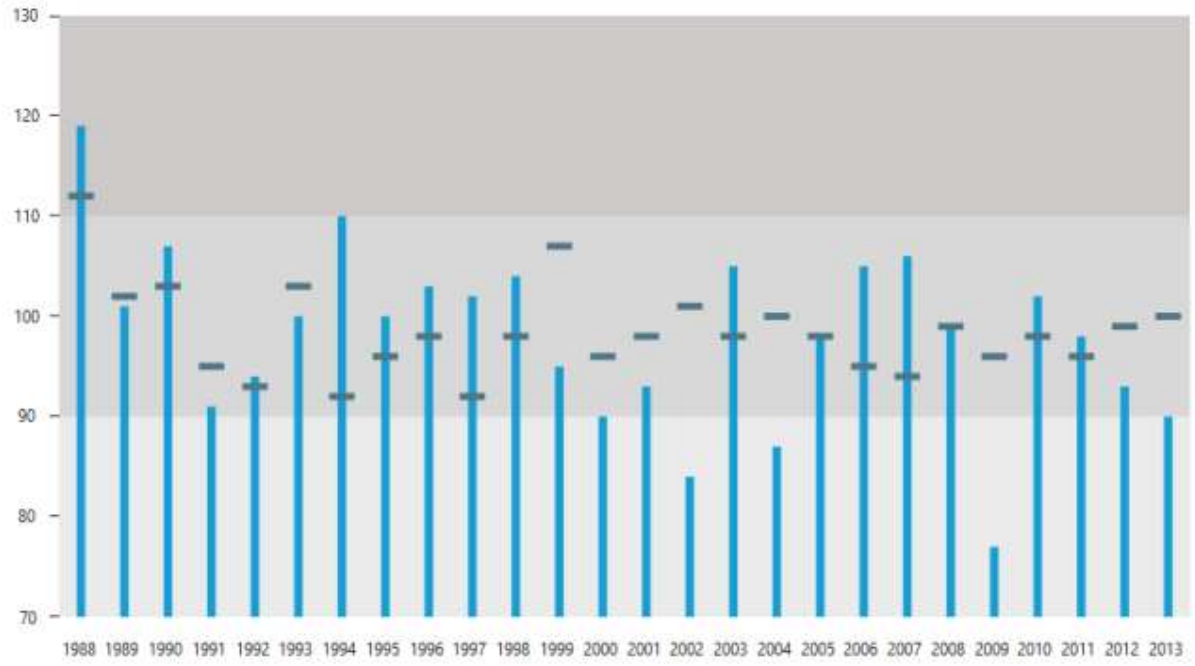
JS

```
@(Html.EJ().BulletGraph("Bullet").Width(850).Height(540)
.QualitativeRangeSize(800).QuantitativeScaleLength(425)
.Orientation(Orientation.Vertical).FlowDirection(FlowDirection.Backward)
.QuantitativeScaleSettings(scale=>scale.Minimum(70).Maximum(130).Interval(10
)
.TickPosition(TickPosition.Above)
.LabelSettings(lb=>lb.Position(LabelPosition.Above))
.MinorTickSettings(tick => tick. Width(1))
.MajorTickSettings(mat=> mat.Size(7).Width(1))
.ComparativeMeasureSettings(cm=>cm.Color(System.Drawing.Color.Blue))
.FeaturedMeasureSettings(measure=>measure.Color(System.Drawing.Color.CadetBl
ue)))
.Fields(fie =>
{
fie.Datasource((IEnumerable<BulletLocalDataBind>)ViewBag.datasource)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Category("category").ComparativeMeasure("comparativeMeasureValue")
.FeatureMeasure("value");
})
.QualitativeRanges(range =>
{
range.RangeEnd(90).Add();
range.RangeEnd(110).Add();
range.RangeEnd(130).RangeStroke(System.Drawing.Color.DarkBlue).Add();
})
.Render())
```

When you customize the ticks and measure bar, the **BulletGraph** appears as follows.



BulletGraph

Add Caption and Subtitle

You can add the following code example to display an appropriate Caption and Subtitle to the **BulletGraph**.

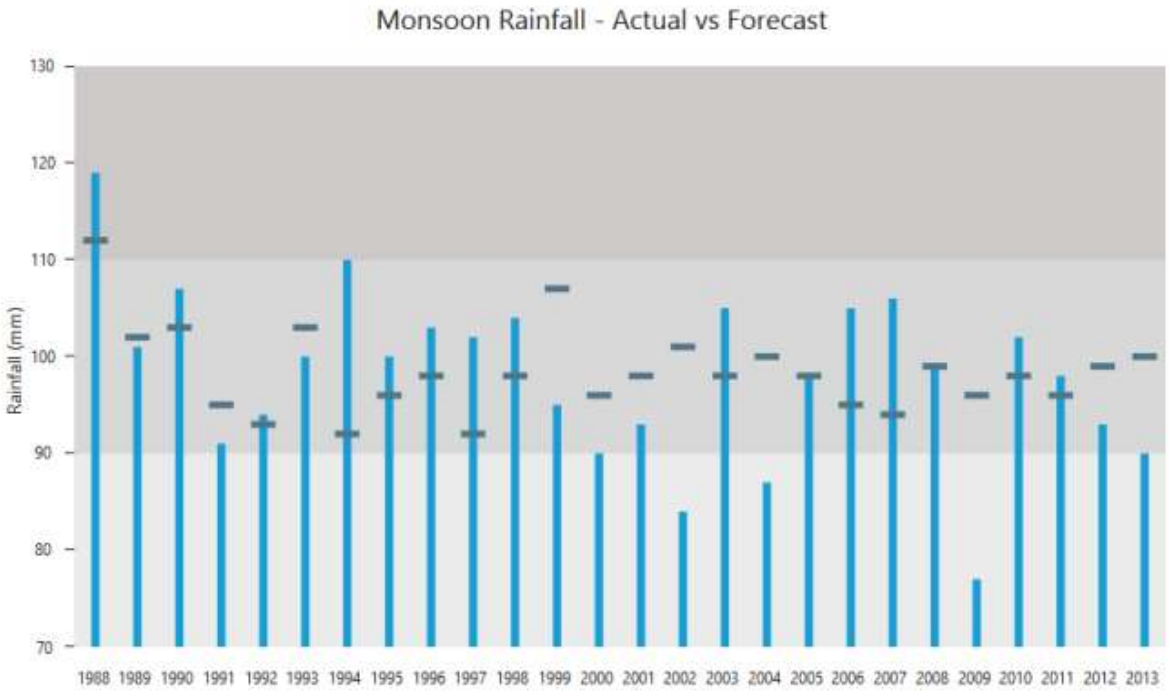
JS

```
@(Html.EJ().BulletGraph("Bullet").Width(850).Height(540)
.QualitativeRangeSize(800).QuantitativeScaleLength(425)
.Orientation(Orientation.Vertical).FlowDirection(FlowDirection.Backward)
.QuantitativeScaleSettings(scale=>scale.Minimum(70).Maximum(130).Interval(10
)
.TickPosition(TickPosition.Above)
.LabelSettings(lb=>lb.Position(LabelPosition.Above))
.MinorTickSettings(tick => tick.Width(1))
.MajorTickSettings(mat=> mat.Size(7).Width(1))
.ComparativeMeasureSettings(cm=>cm.Color(System.Drawing.Color.Blue))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.FeaturedMeasureSettings(measure=>measure.Color(System.Drawing.Color.CadetBl
ue)))
.Fields(fie =>
{
fie.Datasource((IEnumerable<BulletLocalDataBind>)ViewBag.datasource)
.Category("category").ComparativeMeasure("comparativeMeasureValue")
.FeatureMeasure("value");
})
.QualitativeRanges(range =>
{
range.RangeEnd(90).Add();
range.RangeEnd(110).Add();
range.RangeEnd(130).RangeStroke(System.Drawing.Color.DarkBlue).Add();
})
.CaptionSettings(ca=>ca.TextAngle(90).Location(location=>location.x(470).y(2
70))
.Text("Monsoon Rainfall - Actual vs Forecast")
.Font(font=>font.FontFamily("Segoe UI")
.FontSize("20px").FontWeight("regular").Opacity(1))
.SubTitle(title=>title.TextAngle(0).Text("Rainfall (mm)")
.Location(location=>location.x(180).y(4))
.Font(font=>font.FontFamily("Segoe UI")
.FontSize("14px").FontWeight("regular").Opacity(1))))
.Render())
```

The following screenshot displays a **BulletGraph** with a Caption and Subtitle.



BulletGraph with Caption and Subtitle

Show Tooltip

You can use a Tooltip in your application to display the values of forecasted rainfall, actual rainfall received in millimeter and also the appropriate year. The Tooltip Visible property is set to **true** to enable the Tooltip option. To set the template Tooltip, you can pass the template id to it as illustrated in the following code example.

JS

```
@(Html.EJ().BulletGraph("Bullet").Width(850).Height(540)
.TooltipSettings(t=>t.Visible(true).template("Tooltip"))
.QualitativeRangeSize(800).QuantitativeScaleLength(425)
.Orientation(Orientation.Vertical).FlowDirection(FlowDirection.Backward)
.QuantitativeScaleSettings(scale=>scale.Minimum(70).Maximum(130).Interval(10
)
.TickPosition(TickPosition.Above)
.LabelSettings(lb=>lb.Position(LabelPosition.Above))
.MinorTickSettings(tick => tick.Width(1))
.MajorTickSettings(mat=> mat.Size(7).Width(1))
.ComparativeMeasureSettings(cm=>cm.Color(System.Drawing.Color.Blue))
.FeaturedMeasureSettings(measure=>measure.Color(System.Drawing.Color.CadetBl
ue)))
.Fields(fie =>
{
fie.Datasource((IEnumerable<BulletLocalDataBind>)ViewBag.datasource)
.Category("category").ComparativeMeasure("comparativeMeasureValue")
.FeatureMeasure("value");
})
.QualitativeRanges(range =>
{
range.RangeEnd(90).Add();
range.RangeEnd(110).Add();
range.RangeEnd(130).RangeStroke(System.Drawing.Color.DarkBlue).Add();
})
.CaptionSettings(ca=>ca.TextAngle(90).Location(location=>location.x(470).y(2
70))
.Text("Monsoon Rainfall - Actual vs Forecast")
.Font(font=>font.FontFamily("Segoe UI")
.FontSize("20px").FontWeight("regular").Opacity(1))
.SubTitle(title=>title.TextAngle(0).Text("Rainfall (mm)")
.Location(location=>location.x(180).y(4))
.Font(font=>font.FontFamily("Segoe UI")
.FontSize("14px").FontWeight("regular").Opacity(1))))
.Render())
```

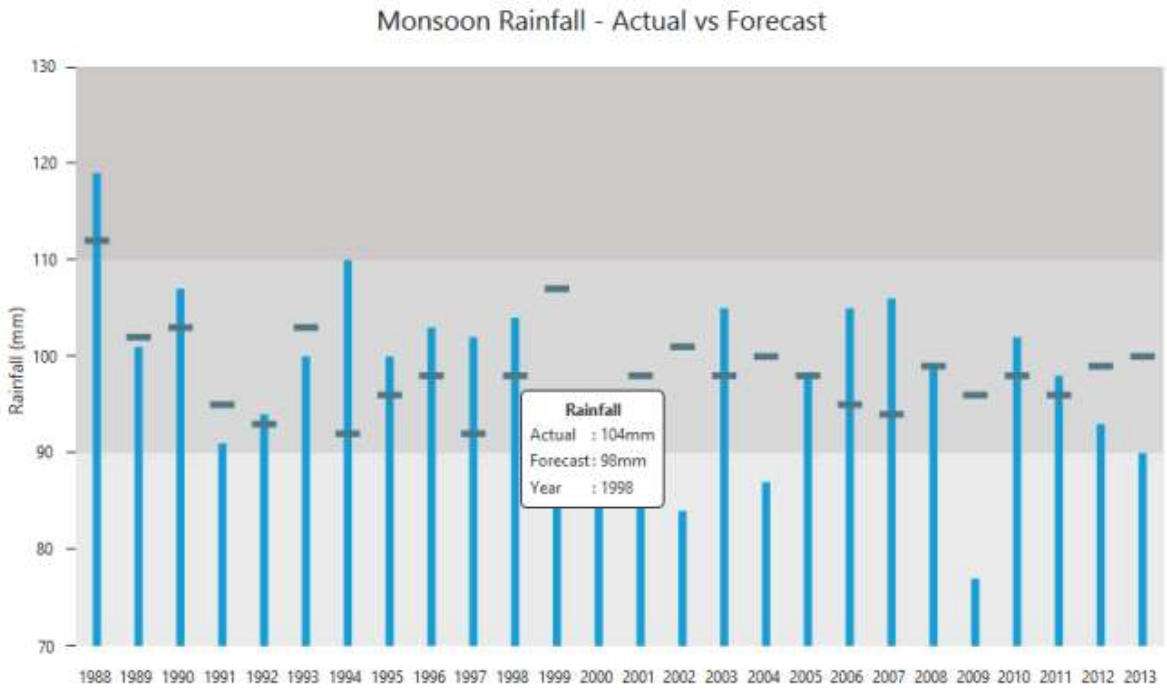
XML

```
<divid="Tooltip"style="display:none; width:125px;padding-top: 10px;padding-
bottom:10px">
<divalign="center"style="font-weight:bold">
Rainfall </div>
<table>
<tr><td>Actual</td>
<td>: {{:currentValue}}mm</td></tr>
<tr><td>Forecast</td>
<td>: {{:targetValue}}mm</td></tr>
<tr><td>Year</td>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<td>: {{:category}}</td></tr>
</table>
</div>
```

The following screenshot displays a customized BulletGraph.

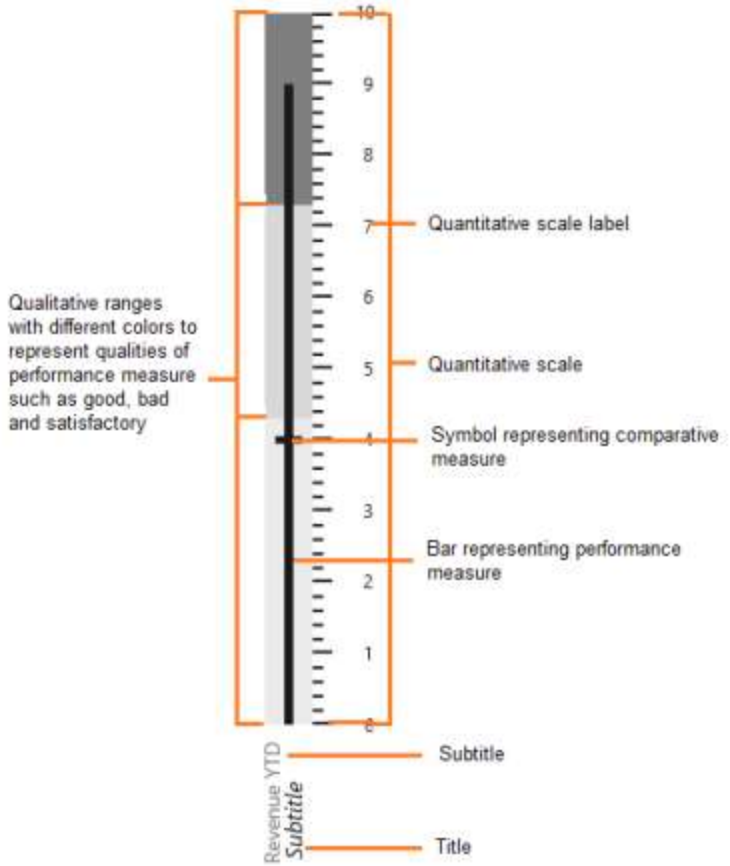


Customized BulletGraph

Bullet Graph Elements

Bullet Graph is composed of elements such as title, quantitative scale, qualitative range, etc. The following screenshot illustrates the element of BulletGraph

Copyright © 2001 - 2020 Syncfusion Inc.



Elements of the Bullet Graph

Bullet Graph Dimensions

This section explains you on how to change the dimensions of the **Bullet Graph**. You can change various dimensions and properties of Bullet Graph like width, height, quantitative scale length, qualitative range size etc. By default, Bullet Graph uses 595 pixel width and 90 pixel height. You can customize width and height of a Bullet Graph using Width and Height properties of Bullet Graph respectively.

Size

JS

```
@(Html.EJ().BulletGraph("Bullets").Width(500).Height(100))
```

In the above code example, width is set as 500 pixel and height is set as 100 pixel. The output of the above code example with dimension 500 * 100 is as follows.

Bullet Graph

Copyright © 2001 - 2020 Syncfusion Inc.

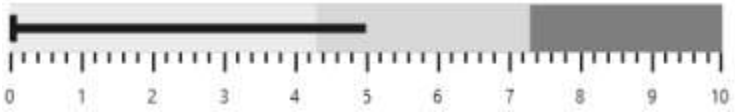
Value for performance bar

The feature measure bar value is customized using the Value property. Default value of this property is 0.

JS

```
@(Html.EJ().BulletGraph("Bullets").Value(5))
```

The following screenshot displays **Bullet Graph** with a performance measure value of 5



Bullet Graph with performance measure

Comparative measure value

The **Comparative measure value** is set using ComparativeMeasureValue property. The default value of this property is 0.

JS

```
@(Html.EJ().BulletGraph("Bullets").ComparativeMeasureValue(5))
```

The following screenshot displays **Bullet Graph** with comparative measure value of 5

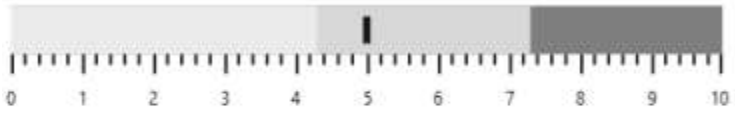


Figure: Bullet Graph with comparative measue

Bullet Graph with comparative symbol

Theme

Bullet Graph Theme is customized using Theme property. Default value is flatlight. **Bullet Graph** supports flatlight and flatdark themes. Flatdark theme improves **Bullet Graph** appearance when background of **Bullet Graph** container uses dark color like black.

JS

```
@(Html.EJ().BulletGraph("Bullets").Theme("flatdark”))
```

The following screenshot displays **Bullet Graph** with flatdark theme

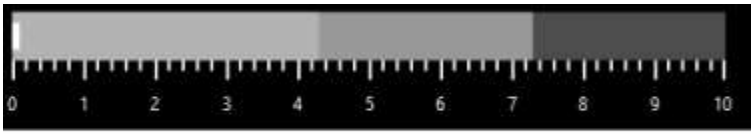

Figure: Bullet graph with flat dark theme

Bullet Graph with theme

Copyright © 2001 - 2020 Syncfusion Inc.

Orientation

Bullet Graph is oriented either horizontally or vertically using Orientation property. Default value of this property is Horizontal.

JS

```
@(Html.EJ().BulletGraph("Bullets").Orientation(Orientation.Vertical)
.Width(100)
.Height(550).FlowDirection(FlowDirection.Backward))
```

Flow direction

The Flow direction of Bullet Graph is customized using FlowDirection property. Default value of this property is Forward. Setting Forward renders Bullet Graph left to right and Backward renders from right to left.

JS

```
@(Html.EJ().BulletGraph("Bullets").ComparativeMeasureValue(2).FlowDirection(
FlowDirection.Backward))
```

The following screenshot displays **Bullet Graph** in a backward direction.

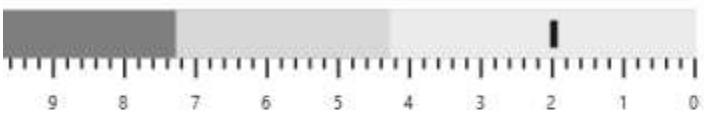

Figure: Bullet graph with backward flow (Right-to-left)

Bullet Graph in backward flow

Qualitative range size

Size of the qualitative range is customized using QualitativeRangeSize property. Default value of this property is 32.

JS

```
@(Html.EJ().BulletGraph("Bullets").QualitativeRangeSize(50))
```

The following screenshot displays **Bullet Graph** with Qualitative range of size 50

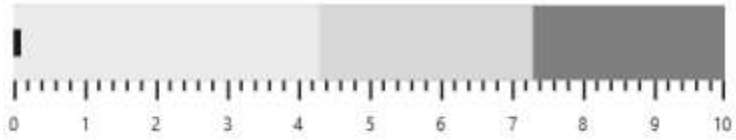

Figure: Bullet graph with qualitative range size of 50

Bullet Graph with customized qualitative range height

Quantitative scale length

Length of the quantitative scale is customized using QuantitativeScaleLength property. Default value of this property is 475.

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleLength(500))
```

The following screenshot displays **Bullet Graph** with Quantitative scale length of 500

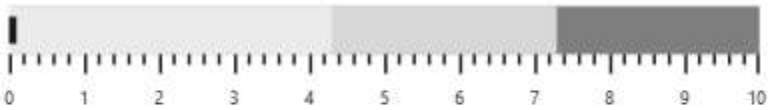

Figure: Bullet graph with quantitative scale length of 500

Bullet Graph with quantitative scale of length 500 pixels

Bullet Graph Caption

Bullet Graph supports title and subtitle to convey what is represented in **Bullet Graph**. They are customized using CaptionSettings property.

Title

Title is set to **Bullet Graph** using Text property in CaptionSettings. Caption settings also include properties like Location, Font, and TextAngle for customizing the caption of Bullet Graph.

Location

Using location option, you can set the X and Y position of caption text.

Font

Using font property, you can customize font color, font family, font style, font weight, opacity, size options.

ASPX-CS

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.Location( loc=> loc.x(110).y(200))
.Minimum(0)
.Maximum(5)
.Interval(1)
.FeatureMeasure(measure=>measure.Value(4).ComparativeMeasureValue(3.5)))
.Height(700)
.Width(600)
.CaptionSettings(cs=>
cs.Text("Revenue YTD")
.Location(loc=>loc.y(220))
.Font(font=>font.FontStyle("bold").FontColor(System.Drawing.Color.Gray).Font
Size("14px")))
)
```

The following screenshot displays a **Bullet Graph** with customized caption using the above code

Copyright © 2001 - 2020 Syncfusion Inc.

Figure: Bullet graph with title

Bullet Graph with title

Subtitle

Subtitle is added to **Bullet Graph** using Text property of Subtitle in CaptionSettings. Subtitle also provides properties like Location, TextAngle and Font to customize subtitle similar to caption.

Location

Using location option, you can set the X and Y position of caption text.

Font

Using font property, you can customize font color, font family, font style, font weight, opacity, size options.

ASPX-CS

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.Location( loc=> loc.x(110).y(200))
.Minimum(0)
.Maximum(5)
.Interval(1)
.FeatureMeasure(measure=>measure.Value(4).ComparativeMeasureValue(3.5)))
.Height(700)
.Width(600)
.CaptionSettings(cs=>
cs.SubTitle(subtitle=>
subtitle.Text("Subtitle")
.Location(loc=>loc.x(20).y(225))
.Font(font=>font.FontStyle("italic").FontSize("16px")))
.Text("Revenue YTD")
.Location(loc=>loc.y(210))
.Font(font=>font.FontStyle("bold").FontColor(System.Drawing.Color.Gray).Font
Size("14px")))
)
```

The following screenshot displays **Bullet Graph** with a subtitle

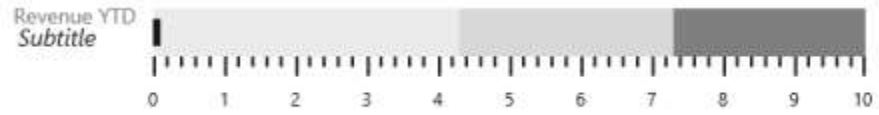

Figure: Bullet graph with subtitle

Bullet Graph with subtitle

Copyright © 2001 - 2020 Syncfusion Inc.

Indicator

You can add **Indicator** to bullet graph by enabling Visible and setting Text properties of Indicator in **CaptionSettings**. Indicator is used to represent whether target is achieved or not with text and symbol by comparing current and target values in bullet graph.

Indicator displays a symbol along with text which is different from caption and subtitle. Images like logos can be used in indicator instead of symbols. Indicator has properties such as Symbol, Text, TextSpacing, TextAngle, Location and Font.

Location

Using location option, you can set the X and Y position of caption text.

Font

Using font property, you can customize font color, font family, font style, font weight, opacity, size options.

Symbol

- Using symbol settings, you can customize the following symbol properties.
- You can customize the symbol border properties border color and border width using border

settings.

- You can specify the color of the symbol using color property.
- You can set the shape of the symbol using shape property.
- Instead of setting shape for symbol, you can use image also. To use image as symbol, you need to set image url for symbol.
- You can customize the size of the indicator symbol using width and height properties of

indicator's symbol size settings.

- To customize the opacity of the indicator symbol, you can use the opacity property of the

symbol.

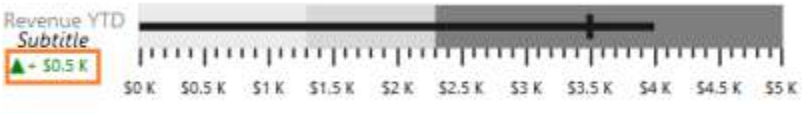
ASPX-CS

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.Location( loc=> loc.x(110).y(200))
.Minimum(0)
.Maximum(5)
.Interval(1)
.LabelSettings(ls=>ls.LabelPrefix("$").LabelSuffix("K"))
.FeatureMeasure(measure=>measure.Value(4).ComparativeMeasureValue(3.5)))
.Height(700)
.Width(600)
.CaptionSettings(cs=>
cs.Indicator(indicator=>
indicator.Visible(true)
.Text("+ $0.5 K")
.Location(loc=>loc.x(15).y(240))
.Symbol(symbol=>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
symbol.Shape(SymbolShape.Triangle)
.Color("green")
.Border(border=>border.Width(1).Color("green")
)))
.SubTitle(subtitle=>
subtitle.Text("Subtitle")
.Location(loc=>loc.x(20).y(225))
.Font(font=>font.FontStyle("italic").FontSize("16px")))
.Text("Revenue YTD")
.Location(loc=>loc.y(210))
.Font(font=>font.FontStyle("bold").FontColor(System.Drawing.Color.Gray).Font
Size("14px")))
)
```

The following screenshot displays a **bullet graph** with indicator.



Bullet Graph with indicator

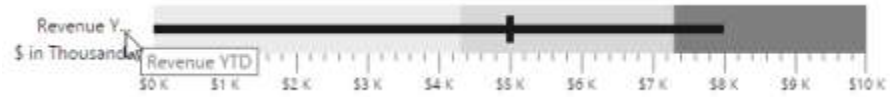
Trim

The title, subtitle and indicator text can be overlapped to the scale group. You can avoid the overlapped text by using the EnableTrim property of the CaptionSettings. The default value of the EnableTrim is true.

HTML

```
@(Html.EJ().BulletGraph("BulletGraph1")
.CaptionSettings(title=>title.Text("Bullet Graph Title").EnableTrim (true))
)
```

The following screenshot displays the BulletGraph with Trim.



BulletGraph with trim

Text Placement

All the caption group elements (caption, subtitle, and indicator) in the **Bullet Graph** support text positioning by using the property **TextPosition** available in all caption group elements. The properties, **TextAlignment** and **TextAnchor** are used to customize text placement further.

Text Position

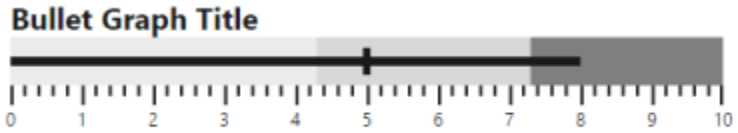
The property TextPosition, is used to position the text at the top, bottom, left, and right side of the quantitative scale. The default value of this property is **Float**. By default, text can be placed at any desired location by using the Location property.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().BulletGraph("BulletGraph1").Width(650).Height(150).Value(8).Comp
arativeMeasureValue(5)
.CaptionSettings(title=>title.Text("Bullet Graph Title")
.TextPosition(BulletTextPosition.Top)
.Font(font=>
font.FontSize("20px")
.FontWeight("bold")
))
.QuantitativeScaleSettings(scale=>scale.Location(loc=>loc.x(120).y(40)))
)
```

The following screenshot displays the **Bullet Graph** with the title positioned above.



Bullet Graph with title automatically positioned above the scale

Text Alignment

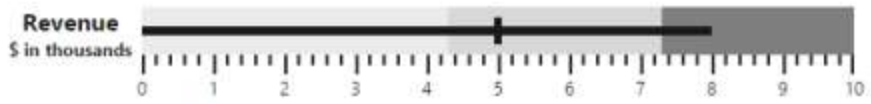
Alignment of text at different positions with respect to scale can be customized by using the TextAlignment property. Text can be aligned in the near, center, and far locations of the scale. Text alignment depends upon TextPosition property and is not applicable when the value of the TextPosition property is **Float**. The default value of the TextAlignment property is **Near**.

ASPX-CS

```
@(Html.EJ().BulletGraph("BulletGraph1").Width(650).Height(150).Value(8).Comp
arativeMeasureValue(5)
.CaptionSettings(title=>title.Text("Revenue")
.TextPosition(BulletTextPosition.Left)
.TextAnchor(BulletTextAnchor.Middle)
.Font(font=>
font.FontSize("16px")
.FontWeight("bold")
)
.SubTitle(subtitle=>subtitle.Text("$ in thousands")
.TextPosition(BulletTextPosition.Left)
.TextAlignment(BulletTextAlignment.Center)
.Font(font=>
font.FontSize("12px")
.FontWeight("bold")
)))
.QuantitativeScaleSettings(scale=>scale.Location(loc=>loc.x(120).y(40)))
)
```

The following screenshot displays the Bullet Graph with the title and subtitle at different alignments.

Copyright © 2001 - 2020 Syncfusion Inc.



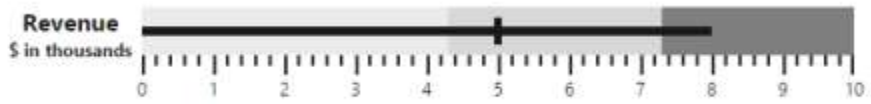
Bullet graph with the title aligned at near and sub title aligned at center positions

Text Anchor

Text elements aligned at the same position are anchored by using the TextAnchor property. These can be anchored at the Start, Middle, and End. The default value of this property is Start and applicable only when two or more text elements are aligned at the same position.

ASPX-CS

```
@(Html.EJ().BulletGraph("BulletGraph1").Width(650).Height(150).Value(8).Comp
arativeMeasureValue(5)
.CaptionSettings(title=>title.Text("Revenue")
.TextPosition(BulletTextPosition.Left)
.TextAnchor(BulletTextAnchor.Middle)
.Font(font=>
font.FontSize("16px")
.FontWeight("bold")
)
.SubTitle(subtitle=>subtitle.Text("$ in thousands")
.TextPosition(BulletTextPosition.Left)
.TextAlignment(BulletTextAlignment.Center)
.Font(font=>
font.FontSize("12px")
.FontWeight("bold")
)))
.QuantitativeScaleSettings(scale=>scale.Location(loc=>loc.x(120).y(40)))
)
```



Bullet Graph with title text anchored at the center with respect to subtitle text

Padding

The space required between text and quantitative scale is customized by using the Padding property. The default value of this property is 5 and not applicable when the value of the TextPosition property is Float.

ASPX-CS

```
@(Html.EJ().BulletGraph("BulletGraph1").Width(650).Height(150).Value(8).Comp
arativeMeasureValue(5)
.CaptionSettings(title=>title.Text("Profit in %")
.TextPosition(BulletTextPosition.Left)
.TextAlignment(BulletTextAlignment.Center)
.Padding(10)
.Font(font=>
font.FontSize("16px")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.FontWeight("bold")
))
.QuantitativeScaleSettings(scale=>scale.Location(loc=>loc.x(120).y(40)))
)
```

Bullet graph with 10 pixel padding between the title text and quantitative scale

Data Binding

Bullet Graph supports binding JSON data from a remote server or data created in client-side. You can use the Fields property to customize the data bound with **Bullet Graph**.

Local Data

Data available in client-side (local data) can be bound with **Bullet Graph** using Fields property. This property provides option to specify data source, fields representing progress measure bar value, comparative measure value and category value.

C#

```
public class BulletData
{
public double BulletValue
{ get; set; }
public double ComparisonValue
{ get; set; }
public string Category
{ get; set; }
}
List<BulletData> data = new List<BulletData>();
data.Add(new BulletData() { BulletValue=9.5, ComparisonValue=7.5,
Category="2001"  });
data.Add(new BulletData() { BulletValue = 9.5, ComparisonValue = 5, Category
= "2002" });
ViewBag.DataSource = data;
```

ASPX-CS

```
@(Html.EJ().BulletGraph("Bullets").QualitativeRangeSize(60).QuantitativeScal
eSettings( scale=>
scale.Location( loc=> loc.x(50).y(20))
.Interval(1))
.Height(120)
.Fields(field=>field.Category("Category").ComparativeMeasure("ComparisonValu
e")
.FeatureMeasure("BulletValue").Datasource(ViewBag.DataSource))
)
```

The following screenshot displays Bullet Graph with local data generated using JavaScript

Copyright © 2001 - 2020 Syncfusion Inc.

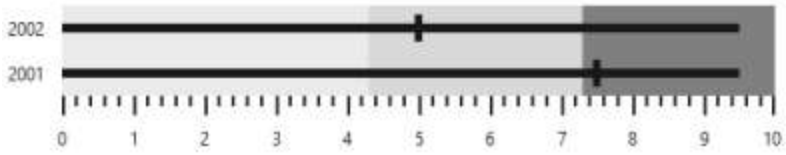


Figure: Bullet graph bound with local data

Bullet Graph bounded to JSON data

Remote Data

Bullet Graph provides option to bind data from a remote server using **ejDataManager** as data source in fields property. A query object should also be passed to query property when using data manager as data source.

JAVASCRIPT

```
@(Html.EJ().BulletGraph("Bullets").QualitativeRangeSize(60)
.QuantitativeScaleSettings(scale=>
scale.Location(loc=>loc.x(50).y(20))
.Minimum(5)
.Maximum(45)
.Interval(10))
.QualitativeRanges( qr=>
{
qr.RangeEnd(25).Add();
qr.RangeEnd(37).Add();
qr.RangeEnd(45).Add();
})
.Fields(fields=>
fields.Category("ProductID")
.ComparativeMeasure("Quantity")
.FeatureMeasure("UnitPrice"))
)
<script type="text/javascript">
//Creating data manager instance
var dataManger = new ej.DataManager({
url: "http://mvc.syncfusion.com/Services/Northwnd.svc/"
});
// Query creation
var query = ej.Query().from("Order_Details").take(3).where("UnitPrice",
ej.FilterOperators.greaterThan, 18, false)
.where("UnitPrice", ej.FilterOperators.lessThanOrEqual, 40, false)
.where("Quantity", ej.FilterOperators.greaterThan, 5, false)
.where("Quantity", ej.FilterOperators.lessThanOrEqual, 45, false);
dataManger.executeQuery(query).done(function (e) {
$("#Bullets").ejBulletGraph("option", "fields", {
dataSource: dataManger,
query: query,
});
});
</script>
```

The following screenshot displays a Bullet Graph bounded with data from a remote server

Copyright © 2001 - 2020 Syncfusion Inc.

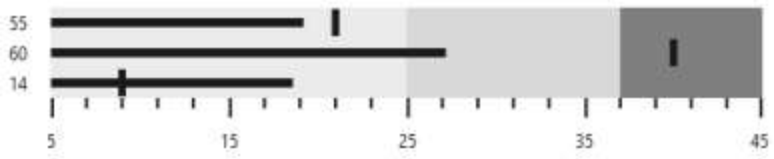

Figure: Bullet graph with data from remote server

Bullet Graph bounded to data from server

Quantitative Scale

The **Quantitative Scale** appearance is customized using QuantitativeScaleSettings property. It has properties to customize labels, major ticks, minor ticks, comparative measure and performance measure of the bullet graph

Range for Quantitative Scale

Quantitative Scale range is set using the properties Minimum, Maximum and Interval of **QuantitativeScaleSettings** property. **Minimum** specifies the start range of the scale, **Maximum** specifies the end range of scale and interval specifies the number of intervals between start and end range. Default values of Minimum, Maximum and Interval are 0, 10 and 1 respectively. The number of minor ticks (ticks between intervals) are specified using MinorTicksPerInterval property.

HTML

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.Minimum(0)
.Maximum(10))
)
```

The following screenshot displays a **Bullet Graph** with start range 0, end range 10 and interval 1 with 4 minor ticks per interval

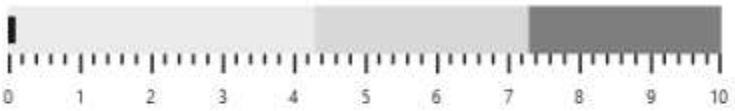

Figure: Bullet graph with default range in quantitative scale

Bullet Graph quantitative scale with customized range

Quantitative scale location

Bullet Graph does not position quantitative scale automatically based on its size or space required for caption text, etc. By default Quantitative scale is positioned at 10 pixels from left and 10 pixels from top. Quantitative scale location is customized as per the requirement using the Location property available in QuantitativeScaleSettings.

HTML

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.Location(loc=>loc.x(20).y(20))
)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot displays Bullet Graph with Quantitative scale at 20 pixels from left and 20 pixels from top

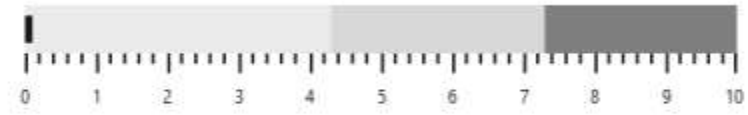

Figure: Bullet graph with customized quantitative scale location

Bullet Graph quantitative scale in a specified location

Major ticks

Color, size and width of **Major tick** lines are customized using MajorTickSettings property in **QuantitativeScaleSettings**. Default value of Size and Width properties are 13 and 2 respectively. Ticks are drawn in black color by default. The property Size represents the height of tick lines and Width represents the width of tick lines and ticks color are customized using Stroke property.

HTML

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.MajorTickSettings(mt=>
mt.Size(15).Width(3).Stroke(System.Drawing.Color.Gray))
)
)
```

The following screenshot displays **Major ticks** in **gray** color with a width of 3 pixels and height 15 pixels

Figure: Bullet graph with customized major ticks

Bullet Graph quantitative scale with customized major ticks

Minor ticks

Minor ticks can also be customized similar to major ticks. The properties Stroke, Width and Size of MinorTickSettings are used to customize Minor ticks in quantitative scale. Stroke specifies the color of ticks, Width specifies the width of ticks and Size specifies the height of the ticks.

HTML

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.MinorTickSettings(tick=>
tick.Size(7).Width(3).Stroke(System.Drawing.Color.Gray))
)
)
```

The following screenshot displays **Bullet Graph** with customized **Minor ticks** in quantitative scale

Copyright © 2001 - 2020 Syncfusion Inc.

Figure: Bullet graph with customized minor tick settings in quantitative scale

Bullet Graph quantitative scale with customized minor ticks

Tick position

Ticks are positioned below, above or inside the quantitative scale. By default ticks are positioned below the quantitative scale. The **TickPosition** property is used to customize the position of ticks in quantitative scale. Ticks can be placed inside the quantitative scale by setting **TickPosition** to **Cross**.

HTML

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.TickPosition(TickPosition.Above)
)
)
```

The following screenshot displays **Bullet Graph** with ticks positioned above quantitative scale

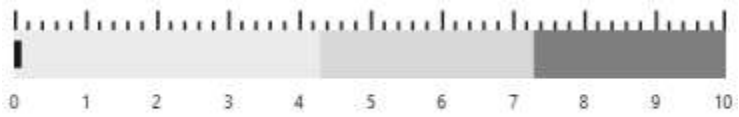

Figure: Bullet graph with ticks positioned above quantitative scale

Bullet Graph quantitative scale with ticks positioned above

Tick Placement

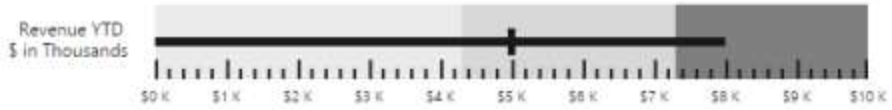
Quantitative scale ticks can be placed either inside or outside the scale using “TickPlacement” property. By default ticks are placed outside the scale.

HTML

```
@(Html.EJ().BulletGraph("Bullets") .QualitativeRangeSize(50)
.QuantitativeScaleSettings(scale =>
{
scale.Location(location => location.x(108).y(10))
.LabelSettings(ls=> ls.Offset(0).Size(10))
.TickPlacement(Syncfusion.JavaScript.DataVisualization.BulletTickPlacement.I
nside)
.FeatureMeasure(measure =>
{measure.ComparativeMeasureValue(6).Value(8).Add();});
})
.CaptionSettings(cs => cs.TextAngle(0).Text("Revenue YTD").Location(ls =>
ls.x(17).y(28))
.SubTitle(so => so.TextAngle(0).Text("$ in Thousands").Location(l =>
l.x(10).y(42))))
)
```

The following screenshot displays **Bullet Graph** ticks inside Quantitative Scale

Copyright © 2001 - 2020 Syncfusion Inc.



Bullet Graph with ticks inside quantitative scale

Quantitative scale labels

Quantitative scale labels are customized with prefix, suffix, font, color and size using **LabelSettings** property. By default, label text is displayed in black color with 12 pixel 'Segoe UI' font and there is a padding of 20 pixels space between quantitative scale and labels.

HTML

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings(scale=>
scale.LabelSettings(label=>
label.Stroke(System.Drawing.Color.Blue)
.LabelPrefix("$")
.LabelSuffix("K")
.Size(12)
.Offset(15)
.Font(font=>
font.FontFamily("Segoe UI")
.FontStyle("bold")
.FontWeight("regular")
.Opacity(0.8)
)
)
)
)
```

The following screenshot displays **Bullet Graph** labels in blue color

Figure: Bullet graph with customized labels

Bullet Graph quantitative scale with customized labels

Label Placement

Quantitative scale labels can be placed either inside or outside the scale using "LabelPlacement" property. By default labels are placed 15 pixels outside the scale.

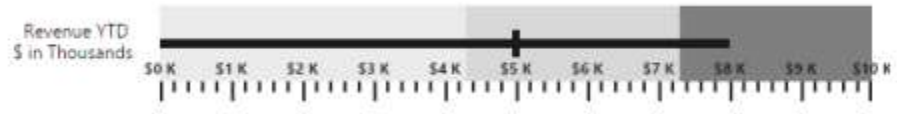
JS

```
@(Html.EJ().BulletGraph("Bullets").QualitativeRangeSize(50)
.QuantitativeScaleSettings(scale =>
{
scale.Location(loc => loc.x(108).y(10))
.LabelSettings(ls=> ls.Offset(0).Size(10)
.LabelPlacement(Syncfusion.JavaScript.DataVisualization.BulletLabelPlacement
.Inside))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.FeatureMeasure(measure =>
{measure.ComparativeMeasureValue(6).Value(8).Add();});
})
.CaptionSettings(cs => cs.TextAngle(0).Text("Revenue YTD").Location(ls =>
ls.x(17).y(28))
.SubTitle(so => so.TextAngle(0).Text("$ in Thousands").Location(l =>
l.x(10).y(42))))
)
```

The following screenshot displays **Bullet Graph** labels inside **Quantitative Scale**



Bullet Graph with labels inside quantitative scale

Performance measure bar

Performance measure bar is customized using FeaturedMeasureSettings in QuantitativeScaleSettings property. Color of the bar is customized using Stroke property and width using Width property. By default bar is drawn in black color with 6 pixels of width.

JS

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.FeaturedMeasureSettings(measure=>
measure.Stroke(System.Drawing.Color.Blue).Width(4))
).Value(5))
```

The following screenshot displays **Bullet Graph** with customized **Performance measure bar**.

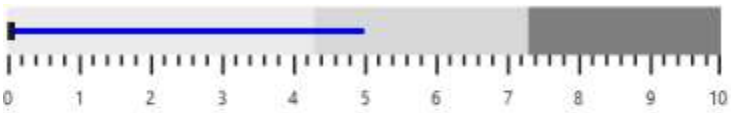


Figure: Bullet graph with customized performance measure bar

Bullet Graph quantitative scale with customized performance measure bar

Comparative measure symbol

Comparative symbol color and width are customized using ComparativeMeasureSettings through QuantitativeScaleSettings property. Color of the symbol is customized using Stroke property and width using Width property. By default Comparative measure symbol is displayed in black color with a width of 5 pixels.

JS

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.ComparativeMeasureSettings(measure=>
measure.Stroke(System.Drawing.Color.Blue).Width(4))
).ComparativeMeasureValue(5)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot displays **Bullet Graph** with customized **Comparative measure value**.

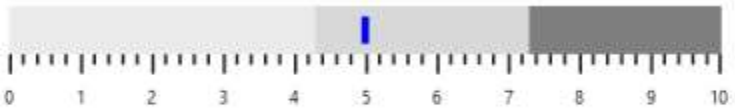

Figure: Bullet graph with customized comparative measure value

Bullet Graph with customized comparative symbol

Multiple performance measures comparison

Bullet Graph supports comparing more than one performance at a time, given that all the comparisons are related using FeatureMeasure in **QuantitativeScaleSettings** property.

JS

```
@(Html.EJ().BulletGraph("Bullets").QuantitativeScaleSettings( scale=>
scale.FeatureMeasure(measure=>
{
measure.Value(6).ComparativeMeasureValue(3).Category("2010").Add();
measure.Value(9).ComparativeMeasureValue(6).Category("2011").Add();
measure.Value(5).ComparativeMeasureValue(5).Category("2012").Add();
})
.Location(loc=>
loc.x(50).y(10))
).QualitativeRangeSize(60).Height(120)
)
```

The following screenshot displays **Bullet Graph** that compares 3 related performance measures.

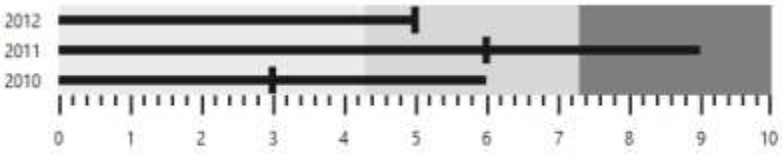

Figure: Bullet graph with multiple performance measures

Bullet Graph with multiple performance measures

Qualitative Range

Qualitative Range represents the quality of a specific range in quantitative scale like good, bad and satisfactory. Color for each qualitative range is customized using RangeStroke property. The RangeEnd property specifies the ending point of the qualitative range. Minimum value of quantitative scale is considered as the starting point of first qualitative range and previous end points are considered as starting point for other qualitative ranges.

JS

```
@(Html.EJ().BulletGraph("Bullets").QualitativeRanges(qr =>
{
qr.RangeEnd(35).RangeStroke(System.Drawing.Color.DarkRed).RangeOpacity(0.5).
Add();
qr.RangeEnd(50).RangeStroke(System.Drawing.Color.Red).RangeOpacity(1).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
qr.RangeEnd(75).RangeStroke(System.Drawing.Color.Blue).RangeOpacity(0.7).Add
();
qr.RangeEnd(90).RangeStroke(System.Drawing.Color.LightGreen).RangeOpacity(1)
.Add();
qr.RangeEnd(100).RangeStroke(System.Drawing.Color.Green).RangeOpacity(1).Add
();
}).QualitativeRangeSize(80)
.QuantitativeScaleSettings(scale =>
scale.FeatureMeasure(measure =>
{
measure.Value(55).ComparativeMeasureValue(75).Category("Year 1").Add();
measure.Value(65).ComparativeMeasureValue(70).Category("Year 2").Add();
measure.Value(80).ComparativeMeasureValue(65).Category("Year 3").Add();
})
.Location(loc =>
loc.x(50).y(20))
.Minimum(0)
.Maximum(100)
.Interval(10)
).QualitativeRangeSize(60).Height(120)
)
```

The following screenshot displays **Bullet Graph** with different qualitative ranges in different colors. In this image, range 0 to 35 represents bad performance, 35 to 50 represents average performance, 50 to 75 represents that the performance is above average, 75 to 90 represents good performance and above 90 represents excellent performance.

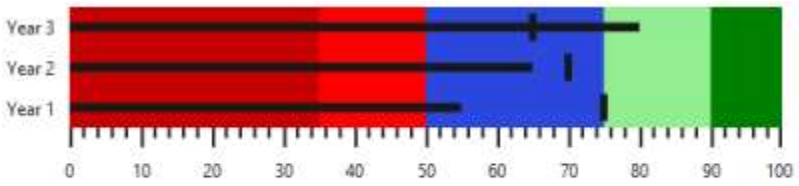

Figure: Bullet graph with different ranges to represent qualities of performance measure such as bad, average, above average, good and excellent

Bullet Graph with customized qualitative ranges

User Interaction

Animation

Bullet Graph supports animation that makes the performance measure bar to animate when rendering the **Bullet Graph**. **Animation** is enabled or disabled using EnableAnimation property. By default, **Animation** is enabled in **Bullet Graph**.

JS

```
@(Html.EJ().BulletGraph("Bullets").EnableAnimation(true).Value(8).Comparativ
eMeasureValue(5))
```

Responsiveness during browser resize

Bullet Graph is made responsive when resizing the browser by using IsResponsive property. By default the value of this property is **true** in **Bullet Graph**.

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
@(Html.EJ().BulletGraph("Bullets").IsResponsive(true).Value(8).ComparativeMe
asureValue(5))
```

Applying same color to all ticks and labels in a range

Background color for qualitative range is applied to major ticks and minor ticks of the **Bullet Graph** using ApplyRangeStrokeToTicks property. The range colors are applied to labels using ApplyRangeStrokeToLabels property. By default same colors are not applied to a qualitative range and its corresponding ticks or labels.

JS

```
@(Html.EJ().BulletGraph("Bullets").ApplyRangeStrokeToLabels(true).ApplyRange
StrokeToTicks(true)
.QualitativeRanges(qr =>
{
qr.RangeEnd(3.5).RangeStroke(System.Drawing.Color.DarkRed).RangeOpacity(0.5)
.Add();
qr.RangeEnd(5.0).RangeStroke(System.Drawing.Color.Red).RangeOpacity(1).Add()
;
qr.RangeEnd(7.5).RangeStroke(System.Drawing.Color.Blue).RangeOpacity(0.7).Ad
d();
qr.RangeEnd(9.0).RangeStroke(System.Drawing.Color.LightGreen).RangeOpacity(1
).Add();
qr.RangeEnd(10.0).RangeStroke(System.Drawing.Color.Green).RangeOpacity(1).Ad
d();
})
.Value(8).ComparativeMeasureValue(5))
```

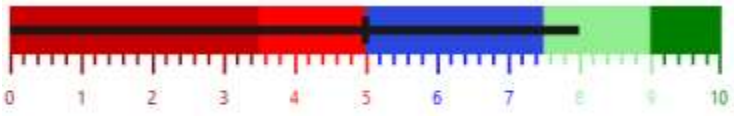

Figure: Bullet graph with same color for qualitative range, ticks and labels

Tooltip

By default **Bullet Graph** displays **Tooltip** when mouse is hovered over feature measure bar. **Tooltip** is enabled or disabled using Visible property in TooltipSettings.

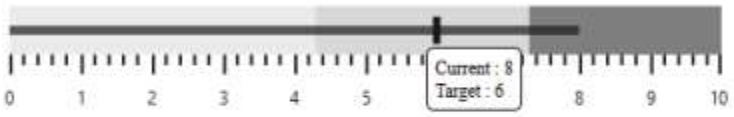

Figure: Bullet graph with default tooltip

Bullet Graph with tooltip

Bullet Graph supports Tooltip template instead of defaultTooltip to customize the appearance and contents of Tooltip. The Tooltip template should be a element with display set to ‘none’, so it is displayed only when mouse is placed on feature measure bar. The id value of the element should be provided as value to the Template property in TooltipSettings of Bullet Graph to display the

customized element as Tooltip instead of default Tooltip. The values displayed in default Tooltip such as current value, target value and category are accessed in template element by using {{currentValue}}, {{targetValue}} and {{category}} respectively.

JS

```
@(Html.EJ().BulletGraph("Bullets").Value(8).ComparativeMeasureValue(6).Height(150)
.TooltipSettings(ts=>
ts.Template("BulletGraphTooltip"))
)
```

The following screenshot displays Bullet Graph with a customized Tooltip including a header and contents such as current value and target value in different colors.

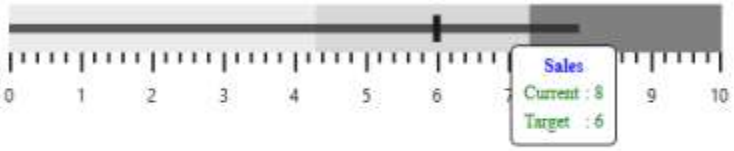

Figure: Bullet graph with customized tooltip using a template

Bullet Graph using a tooltip template

Methods

destroy ()

To destroy the bullet graph

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1"))
```

JS

```
var bullet = $("#bullet1").data("ejBulletGraph");
bullet.destroy();
```

redraw()

To redraw the bullet graph

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1"))
```

JS

```
var bullet = $("#bullet1").data("ejBulletGraph");
bullet.redraw();
```

setComparativeMeasureSymbol()

To set the value for comparative measure in bullet graph.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().BulletGraph("bullet1"))
```

JS

```
var bullet = $("#bullet1").data("ejBulletGraph");
bullet.setComparativeMeasureSymbol();
```

setFeatureMeasureBarValue()

To set the value for feature measure bar.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1"))
```

JS

```
var bullet = $("#bullet1").data("ejBulletGraph");
bullet.setFeatureMeasureBarValue();
```

Events

DrawCaption

Fires on rendering the caption of bullet graph.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.DrawCaption("drawCaption")
)
```

JS

```
function drawCaption(){
// Do Something
}
```

DrawCategory

Fires on rendering the category.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.DrawCategory("drawCategory")
)
```

JS

```
function drawCategory(){
// Do Something
}
```

DrawComparativeMeasureSymbol

Fires on rendering the comparative measure symbol.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.DrawComparativeMeasureSymbol("drawComparativeMeasureSymbol")
)
```

JS

```
function drawComparativeMeasureSymbol(){
// Do Something
}
```

DrawFeatureMeasureBar

Fires on rendering the feature measure bar.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.DrawFeatureMeasureBar("drawFeatureMeasureBar")
)
```

JS

```
function drawFeatureMeasureBar(){
// Do Something
}
```

DrawIndicator

Fires on rendering the indicator of bullet graph.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.DrawIndicator("drawIndicator")
)
```

JS

```
function drawIndicator(){
// Do Something
}
```

DrawLabels

Fires on rendering the labels.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.DrawLabels("drawLabels")
)
```

JS

```
function drawLabels(){
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
// Do Something
}
```

DrawTicks

Fires on rendering the ticks.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.DrawTicks("drawTicks")
)
```

JS

```
function drawTicks(){
// Do Something
}
```

DrawQualitativeRanges

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.DrawQualitativeRanges("drawQualitativeRanges")
)
```

JS

```
function drawQualitativeRanges(){
// Do Something
}
```

Load

Fires on loading bullet graph.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.Load("load")
)
```

JS

```
function load(){
// Do Something
}
```

Click

Click event fires on clicking the bullet graph.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.Click("click")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

JS

```
function click(){
// Do Something
}
```

DoubleClick

DoubleClick event fires on double clicking the bullet graph.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.DoubleClick("doubleClick")
)
```

JS

```
function doubleClick(){
// Do Something
}
```

RightClick

RightClick event fires on right clicking the bullet graph.

ASPX-CS

```
@(Html.EJ().BulletGraph("bullet1")
.RightClick("rightClick")
)
```

JS

```
function rightClick(){
// Do Something
}
```

Button

Button

The Essential ASP.NET MVCButton control allows you to perform an action by clicking on it. The Button control has the feature of displaying both text and images. When the Button is clicked, it looks as if it is being pushed in and released. The Text property is used to display the Text content in Button. The Button control displays images using the sprite CSS and Image Position properties. The Buttons control has theme support. While using input type submit, reset and button to be render as button, has text only support.

Key Features

- Trendy Look: Rich Appearance with Theme Support

- RTL: Supports for Right to Left alignment
- Repeat-Button: Supports the rising of click event Repeatedly
- Text and Image: Supports both text and image as Button content
- Built-in Icon: Supports the built-in icon libraries
- Easy Customization: The customization of Button control to any form is made simple

Getting Started

This section explains you briefly on how to create a Button in your application with ASP.NET MVC.

Create your first Button in MVC

Essential ASP.NET MVC Button provides support to display a Button control within your web page and allows you to Click, Toggle Click, Reset, and Submit. Using the following guidelines, you can customize Button for a real-time Multimedia player scenario. This allows you to Play, Pause, Stop, Mute, Un-mute a music player.

The following screenshot illustrates the functionality of Button in Multimedia player control.

Multimedia Player

Create Button Control in MVC

Essential ASP.NET MVC Button control contains built-in features like Click and different display option. You can easily create the Button control by using HTML helper as follows.

1. You can create an MVC Project and add necessary assemblies, styles and scripts to it. Refer MVC-Getting Started.
2. Add the following code example to the corresponding view page to render Button.

HTML

```
<table>
<tr>
<td>
@Html.EJ().ToggleButton("playPause").Size(ButtonSize.Large).ShowRoundedCorne
r(true)
.ContentType(ContentType.TextAndImage).ToggleState(true).DefaultPrefixIcon("
e-icon e-mediaplay")
.ActivePrefixIcon("e-icon e-
mediapause").DefaultText("Play").ActiveText("Pause")
</td>
<td>
@Html.EJ().Button("mute").Size(ButtonSize.Large).ShowRoundedCorner(true).Tex
t("Mute")
</td>
<td>
@Html.EJ().Button("unmute").Size(ButtonSize.Large).ShowRoundedCorner(true).T
ext("unmute")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</td>
<td>
@Html.EJ().Button("stop").Size(ButtonSize.Large).ShowRoundedCorner(true).Tex
t("top")
</td>
</tr>
</table>
```

Create Multimedia Player

1. Add the Action Result for Audio control in HomeController.cs file.

CSHARP

```
public ActionResult MyAudio()
{
var file = Server.MapPath("../song.mp3");
return File(file, "audio/mp3");
}
```

2. Add the following code example to your view page to display Audio control and render the Button.

HTML

```
<div class="audiodiv">
<audio controls>
<source src="@Url.Action("MyAudio","Home")" type="audio/mp3" />
<p>Your browser does not support HTML 5 audio element</p>
</audio>
</div>
<div>
<table>
<tr>
<td>
@Html.EJ().ToggleButton("playPause").Size(ButtonSize.Large).ShowRoundedCorne
r(true)
.ContentType(ContentType.TextAndImage).ToggleState(true).ClientSideEvents(e
=> e.Create("play").Click("pause")
.Change("play")).DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-
mediapause").DefaultText("Play").ActiveText("Pause")
</td>
<td>
@Html.EJ().Button("mute").Size(ButtonSize.Large).ShowRoundedCorner(true).Cli
entSideEvents(e => e.Click("mute")).Text("Mute")
</td>
<td>
@Html.EJ().Button("unmute").Size(ButtonSize.Large).ShowRoundedCorner(true).C
lientSideEvents(e => e.Click("unmute")).Text("unmute")
</td>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<td>
@Html.EJ().Button("stop").Size(ButtonSize.Large).ShowRoundedCorner(true).Cli
entSideEvents(e => e.Click("stop")).Text("stop")
</td>
</tr>
</table>
</div>
```

3. Add the following event function to script section in your view page to use Button control feature as the Multimedia player control.

JS

```
<script type="text/javascript">
//getting audio control access and stored in variable v
var v = document.getElementsByTagName("audio")[0];
//trigger the audio control using variable v
function play(e) {
if (e.isChecked) {
v.play();
}
else {
v.pause();
}
}
function start() {
v.play();
}
function stop() {
v.pause();
}
function mute()
{
v.volume = 0;
}
function unmute()
{
v.volume = 1;
}
</script>
```

4. The following screenshot displays Multimedia player control.

Multimedia Player Control

Create Office Ribbon

In this section, you can learn how to create a Microsoft Office Ribbon used to change the style of the selected text. You can achieve this by using ASP.NET MVC Toggle Button control. You can change the styles by toggling the Button. Add the following code example to your view page to display OfficeRibbon control and render the Button.

HTML

```
<table>
<tr>
<td>
@Html.EJ().ToggleButton("Bold").Size(ButtonSize.Mini).ShowRoundedCorner(true
).DefaultText("<b>B</b>").ActiveText("B").ClientSideEvents(e =>
e.Click("bold"))
</td>
<td>
@Html.EJ().ToggleButton("italic").Size(ButtonSize.Mini).ShowRoundedCorner(tr
ue).DefaultText("I").ActiveText("<li>I</li>").ClientSideEvents(e =>
e.Click("italic"))
</td>
<td>
@Html.EJ().ToggleButton("underline").Size(ButtonSize.Mini).ShowRoundedCorner
(true).DefaultText("U").ActiveText("<u>U</u>").ClientSideEvents(e =>
e.Click("underline"))
</td>
</tr>
</table>
```

1. Add the following code example in your view page for sample text.

HTML

```
<div class="sample">
<span id="sampletext">Hi Welcome!</span>
</div>
```

2. Add the following event function to the script section in your view page to use Button control feature as the Multimedia player control.

JAVASCRIPT

```
<script type="text/javascript">
function bold(e) {
if (e.isChecked) {
$(".sample span").wrap("<b></b>");
} else {
$(".sample span").unwrap("<b></b>");
}
}
function italic(e) {
if (e.isChecked) {
$(".sample span").wrap("<i></i>");
} else {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$(".sample span").unwrap("<i></i>");
}
}
function underline(e) {
if (e.isChecked) {
$(".sample span").wrap("<u></u>");
} else {
$(".sample span").unwrap("<u></u>");
}
}
</script>
```

3. The following screenshots display Office Ribbon control.

Office Ribbon before applying the styles

Office Ribbon after applying the styles

Easy Customization

Button is used in all applications. Button size, content and content location is varied according to each application. Here you can see some customizable option for button that can perform easily.

Button Size

You can render the button in different sizes. Here, you have some predefined size options for rendering a button with different sizes in easiest way. Each size option has different height and width. Mainly it avoids the complexity in rendering button with complex CSS class.

List of predefined button size

Normal	Creates button with content size.
Mini	Creates button with Built-in mini size height, width specified.
Small	Creates button with Built-in small size height, width specified.
Medium	Creates button with Built-in medium size height, with specified.
Large	Creates button with Built-in large size height, width specified.

Copyright © 2001 - 2020 Syncfusion Inc.

Apart from the above mentioned predefined size option, you can set your own width and height for button using Height and Width property.

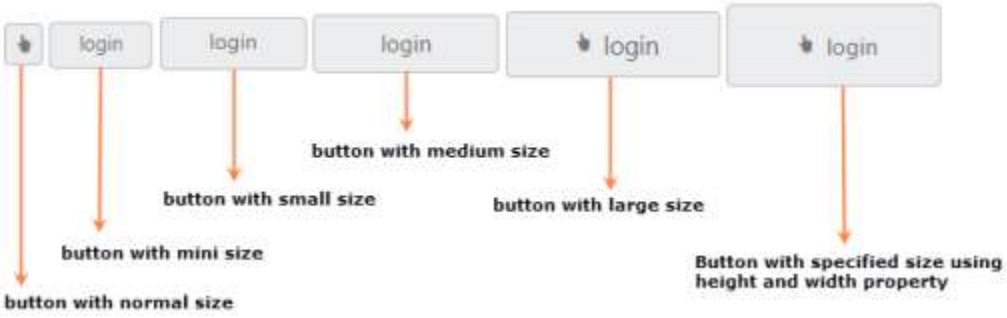
The following steps explains you the details about rendering the button with different size options.

1. In the CSHTML page, configure the button widget as follows.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@*Set the different size types for button control as follows.*@
<div class="control">
@Html.EJ().Button("button_normal").Text("login").Size(ButtonSize.Normal).Sho
wRoundedCorner(true).ContentType(ContentType.ImageOnly).PrefixIcon("e-icon
e-handup")
@Html.EJ().Button("button_mini").Text("login").ShowRoundedCorner(true).Size(
ButtonSize.Mini)
@Html.EJ().Button("button_small").Text("login").ShowRoundedCorner(true).Size
(ButtonSize.Small)
@Html.EJ().Button("button_medium").Text("login").ShowRoundedCorner(true).Siz
e(ButtonSize.Medium)
@Html.EJ().Button("button_large").Text("login").ShowRoundedCorner(true).Size
(ButtonSize.Large).ContentType(ContentType.TextAndImage).PrefixIcon("e-icon
e-handup")
@Html.EJ().Button("button_customSize").Text("login").ShowRoundedCorner(true)
.ContentType(ContentType.TextAndImage).PrefixIcon("e-icon e-
handup").Height("50").Width("150")
</div>
```

Execute the above code to render the following output.



Button with different sizes

Content Type

The content of the Button is mainly text and images. Instead of using complex CSS classes to render Button with different content types, you can use some predefined content type options provided for button control. Using this content types you can easily add different types of content for button. Button supports the following content types.

List of content types for button

TextOnly	Supports only for text content only.
ImageOnly	Supports only for image content only

ImageBoth	Supports image for both ends of the button.
TextAndImage	Supports image with the text content.
ImageTextImage	Supports image with both ends and middle in text.

Prefix and Suffix icons

Icons inside the Button is added easily using PrefixIcon and SuffixIcon property. Location of the icon in button is a necessary thing and you can easily customize it using the following mentioned options.

Button control also supports the Built-in icon libraries. The ej.widgets.core.minCSS contains definitions for important icons that can be used in buttons. Simply you can use these Built-in icons by mentioning the icon class name as value in PrefixIcon and SuffixIcon property. You can use any font icons that are defined in ej.widgets.core.minCSS. It avoids the complexity in specifying icon using sprite image and CSS.

For example the following mentioned Built-in CSS class are used to show the font icons that is used by media player.

e-mediaback

e-mediaforward

e-medianext

e-mediaprev

e-mediaeject

e-mediaclose

e-mediapause

e-mediaplay

Prefix Icon

It inserts the icon at the starting position of button. After this prefix icon, you can use text or suffix icon.

Suffix Icon

It inserts the icon at the ending position of button. Before this suffix icon, you can use text or prefix icon.

The following steps explains you the details about rendering the Button with above mentioned content type, prefix and suffix icon options

1. In the CSHTML page, configure the Button widget as follows.

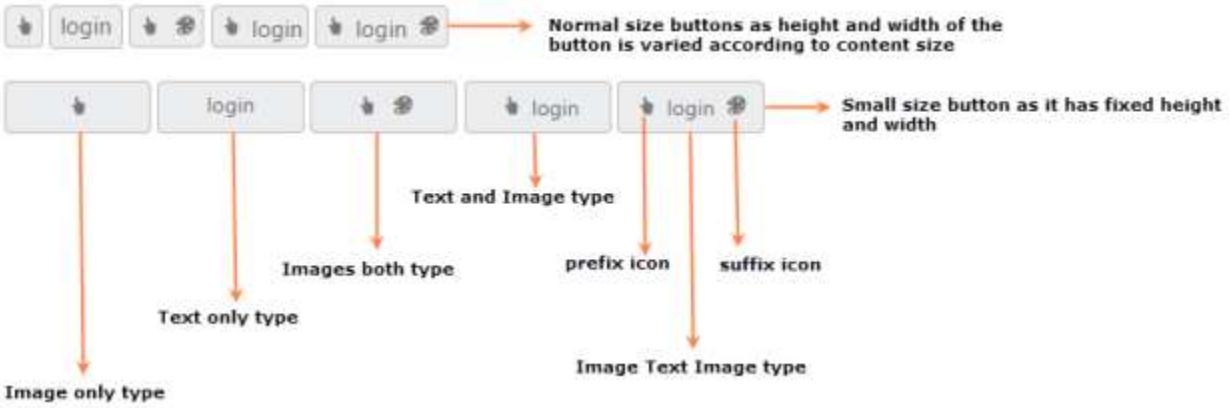
ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* Set the different content types and use the necessary built-in icons for
button control as follows.*@
<div class="control">
@Html.EJ().Button("button_imageOnly").Text("login").ShowRoundedCorner(true).
ContentType(ContentType.ImageOnly).PrefixIcon("e-icon e-handup")
@Html.EJ().Button("button_textOnly").Text("login").ShowRoundedCorner(true).C
ontentType(ContentType.TextOnly)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().Button("button_imageBoth").Text("login").ShowRoundedCorner(true).
ContentType(ContentType.ImageBoth).PrefixIcon("e-icon e-
handup").SuffixIcon("e-icon e-palette")
@Html.EJ().Button("button_textAndImage").Text("login").ShowRoundedCorner(tru
e).ContentType(ContentType.TextAndImage).PrefixIcon("e-icon e-handup")
@Html.EJ().Button("button_imageTextImage").Text("login").ShowRoundedCorner(t
rue).ContentType(ContentType.ImageTextImage).PrefixIcon("e-icon e-
handup").SuffixIcon("e-icon e-palette")
<br />
<br />
@Html.EJ().Button("button_small_imageOnly").Text("login").Size(ButtonSize.Sm
all).ShowRoundedCorner(true).ContentType(ContentType.ImageOnly).PrefixIcon("
e-icon e-handup")
@Html.EJ().Button("button_small_textOnly").Text("login").ShowRoundedCorner(t
rue).Size(ButtonSize.Small).ContentType(ContentType.TextOnly)
@Html.EJ().Button("button_small_imageBoth").Text("login").ShowRoundedCorner(
true).Size(ButtonSize.Small).ContentType(ContentType.ImageBoth).PrefixIcon("
e-icon e-handup").SuffixIcon("e-icon e-palette")
@Html.EJ().Button("button_small_textAndImage").Text("login").ShowRoundedCorn
er(true).Size(ButtonSize.Small).ContentType(ContentType.TextAndImage).Prefix
Icon("e-icon e-handup")
@Html.EJ().Button("button_small_imageTextImage").Text("login").ShowRoundedCo
rner(true).Size(ButtonSize.Small).ContentType(ContentType.ImageTextImage).Pr
efixIcon("e-icon e-handup").SuffixIcon("e-icon e-palette")
</div>
```

Execute the above code to render the following output.



Button with different content types

Image Position

To provide the best look and feel for Button, position of button images is an important customizable option. With ImagePosition property you can easily customize the position of images inside button without using any complex CSS. ImagePosition property is applicable only with the TextAndImageContentType property. This property supports the following values.

List of values supported by ContentType property

ImageLeft	Support for aligning text in right and image in left.
ImageRight	Support for aligning text in left and image in right.

Copyright © 2001 - 2020 Syncfusion Inc.

ImageTop	Support for aligning text in bottom and image in top.
ImageBottom	Support for aligning text in top and image in bottom.

The following steps explains you the details about rendering the Button with the above mentioned image Position options.

2. In the CSHTML page, configure the Button widget as follows.

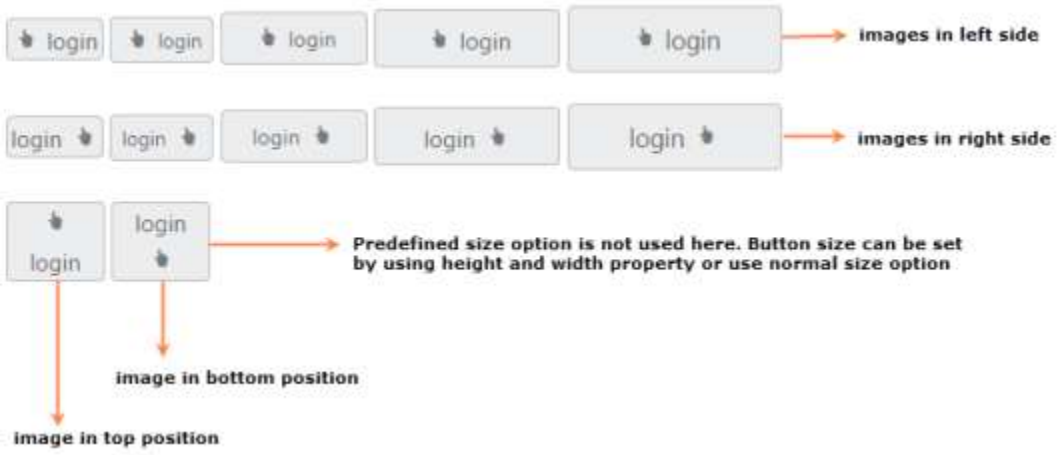
ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* Set the different image position for button control as follows.*@
<div class="control">
@Html.EJ().Button("button_normal_imageLeft").Text("login").ShowRoundedCorner
(true).Size(ButtonSize.Normal).ContentType(ContentType.TextAndImage).PrefixI
con("e-icon e-handup").ImagePosition(ImagePosition.ImageLeft)
@Html.EJ().Button("button_mini_imageLeft").Text("login").ShowRoundedCorner(t
rue).Size(ButtonSize.Mini).ContentType(ContentType.TextAndImage).PrefixIcon(
"e-icon e-handup").ImagePosition(ImagePosition.ImageLeft)
@Html.EJ().Button("button_small_imageLeft").Text("login").ShowRoundedCorner(
true).Size(ButtonSize.Small).ContentType(ContentType.TextAndImage).PrefixIco
n("e-icon e-handup").ImagePosition(ImagePosition.ImageLeft)
@Html.EJ().Button("button_medium_imageLeft").Text("login").ShowRoundedCorner
(true).Size(ButtonSize.Medium).ContentType(ContentType.TextAndImage).PrefixI
con("e-icon e-handup").ImagePosition(ImagePosition.ImageLeft)
@Html.EJ().Button("button_large_imageLeft").Text("login").ShowRoundedCorner(
true).Size(ButtonSize.Large).ContentType(ContentType.TextAndImage).PrefixIco
n("e-icon e-handup").ImagePosition(ImagePosition.ImageLeft)
<br />
<br />
@Html.EJ().Button("button_normal_imageRight").Text("login").ShowRoundedCorne
r(true).Size(ButtonSize.Normal).ContentType(ContentType.TextAndImage).Prefix
Icon("e-icon e-handup").ImagePosition(ImagePosition.ImageRight)
@Html.EJ().Button("button_mini_imageRight").Text("login").ShowRoundedCorner(
true).Size(ButtonSize.Mini).ContentType(ContentType.TextAndImage).PrefixIcon
("e-icon e-handup").ImagePosition(ImagePosition.ImageRight)
@Html.EJ().Button("button_small_imageRight").Text("login").ShowRoundedCorner
(true).Size(ButtonSize.Small).ContentType(ContentType.TextAndImage).PrefixIc
on("e-icon e-handup").ImagePosition(ImagePosition.ImageRight)
@Html.EJ().Button("button_medium_imageRight").Text("login").ShowRoundedCorne
r(true).Size(ButtonSize.Medium).ContentType(ContentType.TextAndImage).Prefix
Icon("e-icon e-handup").ImagePosition(ImagePosition.ImageRight)
@Html.EJ().Button("button_large_imageRight").Text("login").ShowRoundedCorner
(true).Size(ButtonSize.Large).ContentType(ContentType.TextAndImage).PrefixIc
on("e-icon e-handup").ImagePosition(ImagePosition.ImageRight)
<br />
<br />
@Html.EJ().Button("button_imageTop").Text("login").ShowRoundedCorner(true).C
ontentType(ContentType.TextAndImage).PrefixIcon("e-icon e-
handup").ImagePosition(ImagePosition.ImageTop).Width("60")
@Html.EJ().Button("button_imageBottom").Text("login").ShowRoundedCorner(true
).ContentType(ContentType.TextAndImage).PrefixIcon("e-icon e-
handup").ImagePosition(ImagePosition.ImageBottom).Width("60")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</div>
```

Execute the above code to render the following output.



Button with different image positions

Theme support

You can control the style and appearance of Button control based on CSS classes. In order to apply styles to the Button control, you can refer two files namely, ej.widgets.core.min.css and ej.theme.min.css. When you refer the ej.widgets.all.min.css file, then it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these two.

By default, there are 12 themes support available for Button control.

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

Custom CSS

You can customize the appearance of Button control using CSS class. Define a CSS class as per requirement and assign the class name to CssClass property.

The following steps explains you the details about rendering the Button with custom CSS.

3. In the CSHTML page, configure the Button widget as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* Set Custom CSS class for button control as follows.*@
<div class="control">
@Html.EJ().Button("button_customCss1").Text("login").ShowRoundedCorner(true)
.Size(ButtonSize.Small).ContentType(ContentType.TextAndImage).PrefixIcon("e-
icon e-
handup").ImagePosition(ImagePosition.ImageLeft).CssClass("customCss1")
@Html.EJ().Button("button_customCss2").Text("login").ShowRoundedCorner(true)
.Size(ButtonSize.Small).ContentType(ContentType.TextAndImage).PrefixIcon("e-
icon e-
handup").ImagePosition(ImagePosition.ImageLeft).CssClass("customCss2")
@Html.EJ().Button("button_customCss3").Text("login").ShowRoundedCorner(true)
.Size(ButtonSize.Small).ContentType(ContentType.TextAndImage).PrefixIcon("e-
icon e-
handup").ImagePosition(ImagePosition.ImageLeft).CssClass("customCss3")
@Html.EJ().Button("button_customCss4").Text("login").ShowRoundedCorner(true)
.Size(ButtonSize.Small).ContentType(ContentType.TextAndImage).PrefixIcon("e-
icon e-
handup").ImagePosition(ImagePosition.ImageLeft).CssClass("customCss4")
@Html.EJ().Button("button_customCss5").Text("login").ShowRoundedCorner(true)
.Size(ButtonSize.Small).ContentType(ContentType.TextAndImage).PrefixIcon("e-
icon e-
handup").ImagePosition(ImagePosition.ImageLeft).CssClass("customCss5")
</div>
```

4. Configure the CSS styles to apply on buttons.

CSS

```
<style type="text/css" class="cssStyles">
/* Customize the button background */
.e-button.customCss1 {
background-color: #121111;
}
.e-button.customCss2 {
background-color: #94bbd5;
}
.e-button.customCss3 {
background-color: #f3533c;
}
.e-button.customCss4 {
background-color: #d1eeed;
}
.e-button.customCss5 {
background-color: #deb66e;
}
/* Customize the button image & text color */
.e-button.customCss1.e-btn.e-select .e-icon, .e-button.customCss1.e-btn.e-
select .e-btntxt {
color: #94bbd5;
}
.e-button.customCss2.e-btn.e-select .e-icon, .e-button.customCss2.e-btn.e-
select .e-btntxt {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
color: #121111;
}
.e-button.customCss3.e-btn.e-select .e-icon, .e-button.customCss3.e-btn.e-
select .e-btntxt {
color: #cef6f7;
}
.e-button.customCss5.e-btn.e-select .e-icon, .e-button.customCss5.e-btn.e-
select .e-btntxt {
color: #534f4f;
}
</style>
```

Execute the above code to render the following output.

Button with Custom CSS

Button Type

Button is used as normal click able button, submitting form data, resetting the form data to its initial value. According to the usage of button, you can render the button in three types. Using the Type property, you can easily render the button in following types.

List of Button types

Button	The button is a click able button
Submit	The button is a submit button (submits form-data)
Reset	The button is a reset button (resets the form-data to its initial values)

The following steps explains you the details about rendering the Button with above mentioned button types.

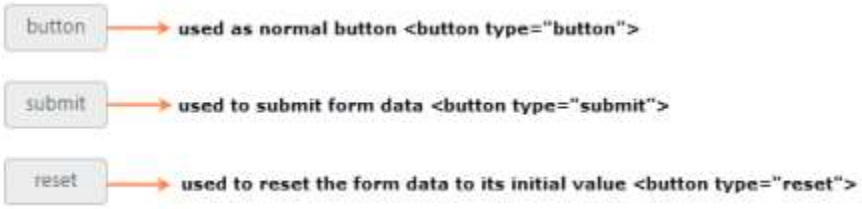
1. In the CSHTML page, configure the Button widget as follows.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* Set the different types for button control as follows.*@
<div class="control">
@Html.EJ().Button("button_button").Text("button").ShowRoundedCorner(true).Si
ze(ButtonSize.Mini).Type(ButtonType.Button)
<br />
<br />
@Html.EJ().Button("button_submit").Text("submit").ShowRoundedCorner(true).Si
ze(ButtonSize.Mini).Type(ButtonType.Submit)
<br />
<br />
@Html.EJ().Button("button_reset").Text("reset").ShowRoundedCorner(true).Size
(ButtonSize.Mini).Type(ButtonType.Reset)
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Execute the above code to render the following output.



Different button types

Repeat Button

When you press button continuously, click event is raised at each specific time interval. This type of button is called Repeat Button. This functionality repeatedly raises the click event of button in both button click and from button in pressed state to the released state. TimeInterval property is used to specify the time Interval for triggering click event, when the button is in pressed state. RepeatButton property is used to set the button in repeat mode.

The following steps explains you the details about rendering the Repeat Button.

1. In the CSHTML page, configure the Button widget as follows.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* Enable the button in repeat action mode and specifies time interval.*@
<div class="control">
<div class="align">
@Html.EJ().Button("repeatButton").Text("click").ShowRoundedCorner(true).Size
(ButtonSize.Mini).RepeatButton(true).TimeInterval("200").ClientSideEvents(e
=> e.Click("btnClick"))
</div>
<div class="align">
<div><b>Event Trace</b></div>
<div class="eventTrace"></div>
</div>
</div>
```

JAVASCRIPT

```
//Add this script section that is used to handle the click event
<script type="text/javascript">
function btnClick(e) {
$(".eventTrace").html("click event has been triggered..</br>" +
$(".eventTrace").html());
}
</script>
</table>
```

2. Configure the CSS styles to apply on button

CSS

Copyright © 2001 - 2020 Syncfusion Inc.

```
<style>
.align {
display: table-cell;
padding-left: 50px;
}
</style>
```

Execute the above code to render the following output.

Output for repeat button

RTL Support

In some cases you can use right to left alignment. Here, RTL support is provided using EnableRTL property. In RTL mode when you have more than one content (image/text, image/image) in button, then these content are aligned in right to left format. For example, when text is in left and image is in right position, after applying right to left alignment these position are interchanged.

The following steps explains the details about rendering the button with Right to left alignment support.

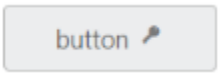
1. In the CSHTML page, configure the Button widget as follows.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* Enable the alignment format for button control as follows.*@
<div class="control">
@Html.EJ().Button("button_rtl").Text("button").ShowRoundedCorner(true).Size(
ButtonSize.Large).ContentType(ContentType.TextAndImage).PrefixIcon("e-icon
e-login").EnableRTL(true)
</div>
```

In above mentioned code example PrefixIcon property is used and the icon that is to be on left side, (before text) is rendered on right side as EnableRTL property is used with PrefixIcon. Consequently, the alignment is changed in right to left order.

Execute the above code to render the following output.



Button in Right to left format

Icons

The Essential Studio for ASP.NET MVC provide icons library that contains the number of in-built icons that can be applied for CSS class names to elements and refer “ej.widgets.all.core.min.css” file. Use the following syntax to apply class names.

Copyright © 2001 - 2020 Syncfusion Inc.

Syntax: .e-icon .e-[icon description]

.e-icon .e-search

Adding icon in Button

For example, you can render the desired icon in the button by using the following table that contains the listed icons' CSS class names in the "PrefixIcon" property of button component. Also, use "ContentType" property to display the icon in the button. In the following code example, specify the "ContentType" of the button as ImageOnly.

Refer to the following link to know what are the values passed in the "ContentType" property

http://help.syncfusion.com/aspnetmvc/button/icons

Also in the button sample, you can use the icon class names as follows,

ASPX-CS

```
@Html.EJ().Button("button").Size(ButtonSize.Small).ContentType(ContentType.I
mageOnly).PrefixIcon("e-icon e-handup")
@Html.EJ().SplitButton("splitbutton").ContentType(ContentType.ImageOnly).Pre
fixIcon("e-icon e-calender")
@Html.EJ().ToggleButton("toggleButton").Size(ButtonSize.Small).ContentType(C
ontentType.ImageOnly).DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-mediapause")
```

Execute the above code to render the following output.

List of Icons

The complete list of icons is listed in the following table.

Miscellaneous

Text

You can display the user defined text for Button. Using Text property, you can easily set text content for button. This text property overwrites the text that is provided on input button element.

The following steps explains you the details about rendering the button with specified text.

1. In the CSHTML page, configure the Button widget as follows.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* Set the text for button control as follows.*@
<div class="control">
@Html.EJ().Button("button_text").Text("Enter").Size(ButtonSize.Mini)
</div>
```

In the above code, the content of button “button” is replaced by the text value “Enter” that is given using text property.

Execute the above code to render the following output.

Button with new text

Show Rounded Corner

Specifies the corner of button in round shape. By default button doesn’t have rounded corner. To set rounded corner, you can enable ShowRoundedCorner property.

The following steps explains you the details about rendering the button with rounded corner.

2. In the CSHTML page, configure the Button widget as follows.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* Enable the rounded corner for button control as follows.*@
<div class="control">
@Html.EJ().Button("button_roundedCorner").Text("button").Size(ButtonSize.Min
i).ShowRoundedCorner(true)
</div>
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Button with rounded corner

How to?

Render Button from Code behind

Button can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of Button properties in the controller.

C#

```
//Namespace to get the JavaScript (Button) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class ButtonController : Controller
{
// GET: Button
public ActionResult ButtonFeatures()
{
//Initializing the Button model
ButtonProperties BtnObj = new ButtonProperties();
//Initializing the datasource and other properties
BtnObj.Text = "Button";
BtnObj.ShowRoundedCorner = true;
//Passing Button properties using the ViewData
ViewData["BtnModel"] = BtnObj;
return View();
}
}
}
```

Binding the Button properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().Button("searchCustomer",(Syncfusion.JavaScript.Models.ButtonProper
ties)ViewData["BtnModel"]).Render();
}
```

Captcha

Captcha

Captcha is a popular technique that is used to prevent computer programs from sending automated requests and is used for meta-searching search engines, performing dictionary attacks in login pages, or sending spam using mail servers. Captcha is validated at the time of form submission.

Key Features

- Auto validation - It compares the input field with captcha image and thrown validation message. Also it prevents submission of forms when validation gets fail.
- Case sensitive text - It checks for case sensitive (Upper case and lower case) at the time of validation.
- Maximum length - It limits the captcha characters when exceeds the maximum limit.
- Minimum length - Sets minimum number of captcha characters to display.
- Customizable character set - You can customize the captcha characters.
- Image Refresh - When captcha is not readable you can use refresh to get new captcha.
- Audio Captcha - Captcha in the form of audio
- RTL - It provides audio and refresh button in left side of captcha

Getting Started

Create your first Captcha in ASP.NET MVC

This section enables you to configure the Captcha control in your ASP.NET MVC application and also in learning how to use captcha with auto validation in Web Forms.

Captcha control with AutoValidation

Create Captcha Control

The Captcha is one of the way to prevent dictionary attacks, it basically comes with the random text. The following steps are used to create Captcha control.

1. You can create an MVC Project and add necessary assembly and script with the given MVC-Getting Started Documentation.
2. Add the following code to the corresponding view page for Captcha rendering.

ASPX-CS

```
<div>
@Html.EJ().Captcha("SignUpCaptcha")
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

3. Add the following handler codes to the web.config file for Captcha image rendering.

HTML

```
<!--add the following code in <system.web>-->
<system.web>
<httpHandlers>
<add verb="*" path="captimage.axd" type="Syncfusion.JavaScript.ImageHandler,
Syncfusion.EJ, Version=XX.XXXX.X.XX, Culture=neutral,
PublicKeyToken=3D67ED1F87D44C89" />
</httpHandlers>
</system.web>
<!--add the following code in <system.webserver>-->
<system.webserver>
<handlers>
<add verb="*" path="captimage.axd" name="syncfusion_generatetools"
type="Syncfusion.JavaScript.ImageHandler, Syncfusion.EJ,
Version=XX.XXXX.X.XX, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
</handlers>
</system.webserver>
```

Note: Version=XX.XXXX.X.X - It will vary depend up on .NET Framework version and Essential Studio version you have using. If you are using Essential Studio version as-12.3.0.36 and .NET Framework is 4.5 use like following Version=12.3450.0.36

The following screen shot displays the output of the above codes.

Captcha control with initial render

Enable Audio and Refresh

The Captcha control supports captcha in the form of audio and when you click the audio button it readouts the captcha characters. You can achieve this by setting “EnableAudio” property to true. Enable refresh is used to refresh or change the captcha image without full page refresh. This is achieved by adding “EnableRefreshImage” property to true. Also include RequestMapper for refresh support.

1. Add the following code example to view page to render captcha with Audio and Refresh.

ASPX-CS

```
<div>
@Html.EJ().Captcha("SignUpCaptcha").EnableAudio(true).EnableRefreshImage(tru
e).RequestMapper("Refresh")
</div>
```

2. Add the following code example to corresponding controller page to render captcha with Audio and Refresh.

CSHARP

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult Refresh(CaptchaParams parameters)
{
return parameters.CaptchaActions();
}
```

The following screenshot displays the output of the above codes.

Captcha control with refresh and audio support

Auto Validation

The Captcha supports automatic validation by enabling the property EnableAutoValidation. When you set this property to true, captcha validation is done automatically. When the validation fails, CustomErrorMessage property supports to display the customized error message.

1. Add the following code example to view page for auto validation.

ASPX-CS

```
( CaptchaFeatures)
@using (Html.BeginForm("CaptchaFeatures", "Captcha", FormMethod.Post))
{
<div class="frame" style="width: 500px">
<div class="control" style="width: 560px;">
<table class="tableprop">
<tr>
<td>
<h2 style="text-align:center">
Sign Up</h2>
<br>
</td>
</tr>
<tr>
<td>
<span class="NodeText">Enter Your Name</span>
</td>
<td>
<input type="text" name="username" />
@if (!(bool)ViewBag.NameStatus)
{<span style="color: red">Invalid Value</span>}
</td>
</tr>
<tr>
<td>
<span class="NodeText">Email</span>
</td>
<td>
<input type="text" name="email" />
@if (!(bool)ViewBag.EmailStatus)
{<span style="color: red">Invalid Value</span>}
</td>
</tr>
```

```
<tr>
<td>
<span class="NodeText">Enter Your Password</span>
</td>
<td>
<input type="password" name="password" />
@if (!(bool)ViewBag.PasswordStatus)
{<span style="color: red">Invalid Password</span>}
</td>
</tr>
<tr>
<td>
<span class="NodeText">Re-Enter Your Password</span>
</td>
<td>
<input type="password" name="repassword" />
</td>
</tr>
<tr>
<td>
</td>
<td>
<div>
@Html.EJ().Captcha("myCaptcha").EnableRefreshImage(true).EnableAudio(true).E
nableAutoValidation(true).RequestMapper("Refresh").CustomErrorMessage("Inval
id captcha code entered. Please try again.").TargetButton("submit")
</div>
<br />
<br />
</td>
</tr>
<tr>
<td>
</td>
<td>
@Html.EJ().Button("submit").Size(ButtonSize.Large).Text("Submit").Type(Butto
nType.Submit)
</td>
</tr>
</table>
</div>
</div>
}
( CaptchaSuccess)
<div class="frame" style="height: 300px; width: 500px; border: 1px solid
gray; padding: 10px;
background: #f9f9f9">
<div class="control">
<table>
<tr>
<td style="padding: 50px;">
<br>
<br>
<h2>
Thank you for registering.</h2>
<br>
</td>
```

Copyright © 2001 - 2020 Syncfusion Inc.

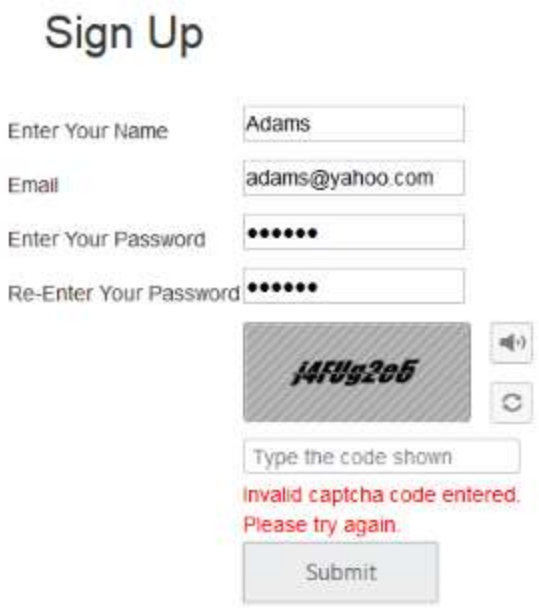
```
</tr>
</table>
</div>
</div>
```

2. Add the following code example to corresponding controller page for captcha with Auto-Validation support.

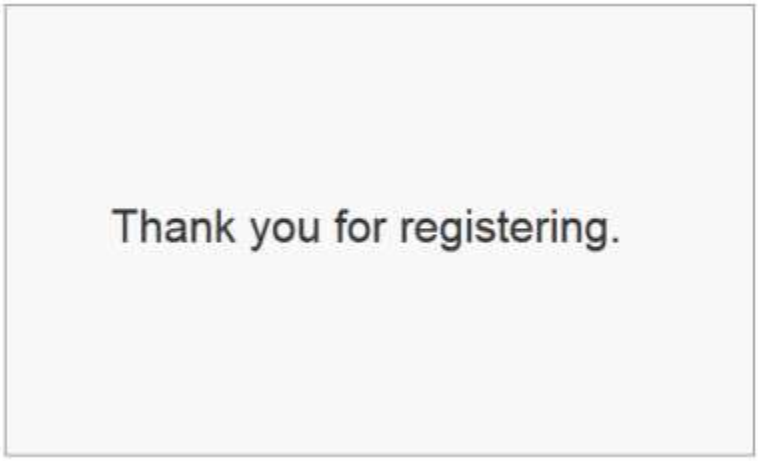
CSHARP

```
public ActionResult CaptchaFeatures()
{
ViewBag.NameStatus = true;
ViewBag.PasswordStatus = true;
ViewBag.EmailStatus = true;
return View();
}
public ActionResult CaptchaFeatures(FormCollection Values)
{
if (!string.IsNullOrEmpty(Values["username"].ToString()) &&
(Values["username"].ToString().Length > 3))
ViewBag.NameStatus = true;
else
ViewBag.NameStatus = false;
if (!string.IsNullOrEmpty(Values["email"].ToString()) &&
(Values["email"].ToString().Length > 3))
ViewBag.EmailStatus = true;
else
ViewBag.EmailStatus = false;
if ((!string.IsNullOrEmpty(Values["password"].ToString())) &&
(Values["password"].ToString().Length > 3) &&
(Values["password"].ToString().Equals(Values["repassword"].ToString())))
ViewBag.PasswordStatus = true;
else
ViewBag.PasswordStatus = false;
if ((bool)ViewBag.NameStatus && (bool)ViewBag.PasswordStatus &&
(bool)ViewBag.EmailStatus)
return View("CaptchaSuccess");
else
return View();
}
public ActionResult Refresh(CaptchaParams parameters)
{
return parameters.CaptchaActions();
}
public ActionResult CaptchaSuccess()
{
return View();
}
```

The following screenshot is the output for the above code example.



Captcha control with failed Auto Validation



Captcha control with successful AutoValidation

Behavior Settings

Regenerate Captcha

Captcha control supports regeneration of captcha image without full page refresh. You can achieve this by clicking refresh button. By default Captcha renders without refresh button. You can add the refresh button by setting EnableRefreshImage property to true.

Note: To refresh the Captcha image, include “RequestMapper”. It enables you to get or set name for the post action function.

The following code example is used to render the Captcha with Refresh support.

1. Add the following code example to the corresponding CSHTML page to render Captcha with Refresh button.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@Html.EJ().Captcha("captcha").EnableRefreshImage(true).RequestMapper("Refres
h")
```

CSHARP

```
// Add the following code in controller page for Captcha with refresh image
public ActionResult Refresh(CaptchaParams parameters)
{
return parameters.CaptchaActions();
}
```

2. The following screenshot illustrates the Captcha with Refresh button.

Captcha with Refresh button

Audio Accessibility

Sometimes, Captcha characters are too hard to identify. In this case Captcha with audio helps to understand the Captcha character. Captcha supports captcha with audio. You can achieve this by enabling EnableAudio property to true. When this property is set true, captcha renders with audio button and when you click the audio button it readouts the captcha characters. By default Captcha renders without audio button.

The following code example is used to render the Captcha with Audio.

1. Add the following code example to the corresponding CSHTML page to render Captcha with audio button.

ASPX-CS

```
@Html.EJ().Captcha("captcha").EnableAudio(true)
```

2. The following screenshot illustrates the Captcha with audio button.

Captcha with Audio support

Enabling Validation

Auto Validation

You can validate the Captcha characters by default when you click the submit button without adding any validation code. You can achieve this by enabling EnableAutoValidation property to true. By default, this

property is set as false. When this property is set as true Captcha renders with textbox. Here, you can also customize the error message by using CustomErrorMessage property that accepts the string value.

Next, define the target button that performs validation. You can achieve this by using TargetButton property. The button id that performs the click action should be assigned in TargetButton.

Note: To validate the Captcha by default, include RequestMapper. It enables to get or set name for the post action function. The post action function is used to process the captcha values internally such as get values from client side for regeneration of captcha image and validation of the captcha.

The following code example is used to render the Captcha with Auto-Validation support.

1. Add the following code example to the corresponding CSHTML page to render Captcha with Auto-Validation support.

ASPX-CS

```
@(Html.EJ().Captcha("captcha").EnableAutoValidation(true).RequestMapper("Ref
resh").CustomErrorMessage("Invalid captcha code entered. Please try
again.").TargetButton ("submit"))<br /><br /><br />
@Html.EJ().Button("submit").Size(ButtonSize.Large).Text("Submit").Type(Butto
nType.Submit)
```

CSHARP

```
// Add the following code in controller page for Captcha with Auto-
Validation support
public ActionResult Refresh(CaptchaParams parameters)
{
return parameters.CaptchaActions();
}
```

2. The following screenshot illustrates the Captcha with Auto-Validation support.

Captcha with auto validation support

Validation by Method

Validation by method is used when EnableAutoValidation is set as false. Here, you can include TargetButton to validate Captcha. CaptchaService.IsValid() method is used to validate the Captcha. It requires three arguments namely as captcha, textbox, case sensitivity.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example is used to render the Captcha with manual validation.

1. Add the following code example to the corresponding CSHTML page to render Captcha with manual validation support.

ASPX-CS

```
@using (Html.BeginForm("Default", "Captcha", FormMethod.Post)){
@Html.EJ().Captcha("captcha").TargetButton("submit")<br />
@Html.TextBox("validateText")
@Html.ValidationMessage("myCaptcha")<br /><br />
@(Html.EJ().Button("submit").Size(ButtonSize.Large).Text("Submit")
.Type(ButtonType.Submit))}
```

CSHARP

```
// Add the following code in Controller page for Captcha with manual
validation support[HttpPost]
public ActionResult Default(FormCollection Values)
{
if (!CaptchaService.IsValid(Values["captcha"], Values["validateText "],
true))
ModelState.AddModelError("myCaptcha", "Invalid characters. Try again!");
return View();
}
```

2. The following screenshot illustrates the Captcha with manual validation support.

Captcha validation by method

Case Sensitive Validation

Captcha supports to check case sensitivity (Upper case and lower case) of the Captcha characters at the time of validation. You can achieve this by enabling EnableCaseSensitivity property to true. By default this value is set as true.

The following code example is used to render the Captcha with Case sensitive validation support.

1. Add the following code example to the corresponding CSHTML page to render Captcha with Case sensitive validation support.

ASPX-CS

```
@(Html.EJ().Captcha("captcha").EnableAutoValidation(true).RequestMapper("Ref
resh").CustomErrorMessage("Invalid captcha code entered. Please try
again.").TargetButton("submit ").EnableCaseSensitivity(true))<br /><br /><br
/>@Html.EJ().Button("submit").Size(ButtonSize.Large).Text("Submit").Type(But
tonType.Submit)
```

CSHARP

```
// Add the following code in controller page for Captcha with case sensitive
validation support
public ActionResult Refresh(CaptchaParams parameters)
{
return parameters.CaptchaActions();
}
```

2. The following screenshot illustrates the Captcha with Case sensitive validation support.

Captcha with Case sensitive validation support

Appearance and Styling

Hatch Styles

You can customize the captcha background styles by HatchStyle property.

The following code example is used to render the Captcha with customized Hatch style.

1. Add the following code example to the corresponding CSHTML page to render Captcha with customized Hatch style.

ASPX-CS

```
@Html.EJ().Captcha("captcha").HatchStyle(HatchStyle.Cross)
```

2. The following screenshot illustrates the Captcha with some of customized Hatch styles.

HatchStyle(HatchStyle.Cross)	
HatchStyle(HatchStyle.Percent90)	
Copyright © 2001 - 2020 Syncfusion Inc.

HatchStyle(HatchStyle.Wave)	HatchStyle(HatchStyle.WideDownwardDiagonal)	
HatchStyle(HatchStyle.HorizontalBrick)	

Captcha with customized Hatch style

Pattern

You can customize the patterns of the Captcha by enabling EnablePattern property to true. When the property is set to true, Captcha characters renders with strikeout. By default the property is set as true.

The following code example is used to render the Captcha with hard visibility mode.

1. Add the following code example to the corresponding CSHTML page to render Captcha with visibility mode.

ASPX-CS

```
@Html.EJ().Captcha("captcha").EnablePattern(false)
```

2. The following screenshot illustrates the Captcha with disabled pattern.

Captcha without pattern

Background and Font color

You can customize the appearance of Captcha control by using the following property. PatternForeColor is used to set background pattern color. PatternBackColor is used to set background color for Captcha. ForeColor is used to set Captcha text color.

The following code example is used to render the Captcha with customized appearance.

1. Add the following code example to the corresponding CSHTML page to render Captcha with customized appearance.

ASPX-CS

```
@Html.EJ().Captcha("captcha").PatternForeColor(System.Drawing.Color.LightGra
y).PatternBackColor(System.Drawing.Color.Snow).ForeColor(System.Drawing.Colo
r.LightSeaGreen)
```

2. The following screenshot illustrates the Captcha with customized appearance.

Copyright © 2001 - 2020 Syncfusion Inc.

Captcha with customized appearance

Adjusting Captcha Size

Height and width Customization

The height of the Captcha widget can be customized using “Height” property that accepts only integer values. The width of the Captcha widget can be customized using “Width” property that also accepts only integer values.

The following code example is used to render the Captcha with customized Height and Width.

1. Add the following code example to the corresponding CSHTML page to render Captcha with customized Height and Width.

ASPX-CS

```
@Html.EJ().Captcha("captcha").Height(50).Width(150)
```

2. The following screenshot illustrates the Captcha with customized Height and Width.

Captcha with customized Height and Width

Theme

You can control the appearance of border color, refresh and audio button styles of the Captcha control based on CSS classes. In order to apply these styles, you can refer to the 2 files, ej.widgets.core.min.css and ej.theme.min.css. When ej.widgets.all.min.css file is referred, it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these two.

By default, there are 12 themes support available for Captcha control.

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

Copyright © 2001 - 2020 Syncfusion Inc.

Appearance for gradient-azure,

Captcha with gradient-azure theme

Appearance for flat-lime,

Captcha with flat-lime theme

Maximum and Minimum length

You can limit the Captcha characters by MinimumLength and MaximumLength property. MaximumLength property is used to define the maximum number of characters to be displayed in the image. MinimumLength sets minimum number of captcha characters need to display.

The following code example is used to render the Captcha with Minimum and Maximum length support.

1. Add the following code example to the corresponding CSHTML page to render Captcha with Minimum and Maximum length support.

ASPX-CS

```
@Html.EJ().Captcha("captcha").MaximumLength(6).MinimumLength(5)
```

2. The following screenshot illustrates the Captcha with Minimum and Maximum length support.

Captcha with Minimum and Maximum length

Character Set Customization

The Captcha characters can be customized by CharacterSet property. Depending on this value, the Captcha characters are generated. This property accepts string values.

The following code example is used to render the Captcha with customized character set.

1. Add the following code example to the corresponding CSHTML page to render Captcha with customized character set.

ASPX-CS

```
@Html.EJ().Captcha("captcha").CharacterSet("qwertyuiop1234")
```

Copyright © 2001 - 2020 Syncfusion Inc.

2. The following screenshot illustrates the Captcha with customized character set.

Captcha with customized character set

Localization

The Captcha provides option to localize the place holder string to a particular local language. By default, the Captcha place holder text will use the US English (en-US) as its language.

Note: The culture name has to be specified in a standard format such as [Language Code]-[County/Region Code].

To localize the Captcha's strings with your own localization, copy the default language informations and localize the strings in the values column. For example, to localize the Captcha in French language (“fr-FR”).

JAVASCRIPT

```
ej.Captcha.Locale["fr-FR"] =  {
placeHolderText: "Entrer le code indiqué",
};
```

Set the locale property of the Captcha to the new language.

HTML

```
@(Html.EJ().Captcha("captcha").EnableAutoValidation(true).RequestMapper("Ref
resh").Locale("fr-FR"))
```

RTL Support

Right to Left alignment of Captcha can be achieved by enabling EnableRTL property to true. When this property is set as true, refresh image and audio button are displayed in left side of captcha and also auto validation text box characters are entered from right to left. To achieve this, enable refresh, audio, and auto validation properties. By default RTL property value is set as false.

The following code example is used to render the Captcha with RTL support.

1. Add the following code example to the corresponding CSHTML page to render Captcha with RTL support.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Captcha("captcha").EnableRTL(true).EnableRefreshImage(true).Enab
leAudio(true).EnableAutoValidation(true))
```

2. The following screenshot illustrates the Captcha with RTL support.

Captcha with RTL support

Chart

Overview

Essential Chart for ASP.NET MVC is a visually stunning Charting component. It includes common Chart types ranging from line Charts to specialized financial Charts.

Some of the key features are,

- Supports highly interactive 28 chart types; 8 charts can be viewed in 3D view.
- Data Binding with local and remote data source.
- Supports multiple axes, and able to plot data with different data types such as numbers, date time and strings.
- Supports interactive features like zooming, panning, crosshair, trackball, tooltip and data point selection.
- Supports 10 types of technical indicators and trend lines.
- Easily customize each and every element of Chart.

Getting Started

This section explains you the steps required to populate the Chart with data, add data labels, tooltips and title to the Chart. This section covers only the minimal features that you need to know to get started with the Chart.

Installation and Deployment

It describes you on how to configure the Syncfusion dependencies in your ASP.NET MVC application to create a Chart.

Referencing Syncfusion Assemblies

The following assemblies need to be referenced in your application for using Essential Chart MVC

1. Syncfusion.EJ.dll
2. Syncfusion.EJ.MVC.dll

Follow the steps given below to deploy the application in the development server by referencing the assembly in

Copyright © 2001 - 2020 Syncfusion Inc.

```
<system.web>
  <compilation debug="true" targetFramework="4.5.1">
    <assemblies>
      <add assembly="Syncfusion.EJ, Version=13.3400.0.7, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
      <add assembly="Syncfusion.EJ.Mvc, Version=13.3400.0.7, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
    </assemblies>
  </compilation>
```

GAC.

- Web.config file should be configured according to the referenced assemblies.
- To deploy your application, you have to ensure that the above referenced assemblies (in your web.config files) are present in the GAC.

![](Getting-Started

```
<system.web.webPages.razor>
  <pages pageBaseType="System.Web.Mvc.WebViewPage">
    <namespaces>
      <add namespace="Syncfusion.JavaScript, Version=13.3400.0.7, Culture=neutral,
                                                PublicKeyToken=3d67ed1f87d44c89" />
      <add namespace="Syncfusion.JavaScript.DataVisualization, Version=13.3400.0.7,
                                                Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
      <add namespace="Syncfusion.MVC.EJ, Version=13.3400.0.7, Culture=neutral,
                                                PublicKeyToken=3d67ed1f87d44c89" />
    </namespaces>
  </pages>
</system.web.webPages.razor>
```

*images/Getting-Started*img1.png)

And, add Syncfusion namespace in the Web.config file of Views folder to generate Chart builder code in View page.

Note: If you are referring Syncfusion dll's manually from bin folder to create MVC Chart, then remove Culture, Version and PublicKeyToken attributes used in all, and nodes.

Adding script reference

Add the below scripts references and Syncfusion **ScriptManager** to execute the script as mentioned in the following code snippet in layout page.

ASPX-CS

```
<!--  jquery script  -->
<script src="http://cdn.syncfusion.com/js/assets/external/jquery-
1.10.2.min.js"></script>
<!-- Essential JS UI widget -->
<script src="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/ej.web.all.min.js"></script>
<!--Add Syncfusion Script Manager -->
@Html.EJ().ScriptManager()
```

Note: If you are using the Essential Studio below 13.4.0.53 version, then you need to refer **jQuery.globalize.js** script file along with the above references to render the Chart control.

To render the MVC Chart in unobtrusive mode refer **ej.unobtrusive.js** script file. Otherwise set false to **UnobtrusiveJavaScriptEnabled** in Web.config file.

Copyright © 2001 - 2020 Syncfusion Inc.

In the above code, ej.web.all.min.js script reference has been added for demonstration purpose. It is not recommended to use this for deployment purpose, as its file size is larger since it contains all the widgets. Instead, you can use CSG utility to generate a custom script file with the required widgets for deployment purpose.

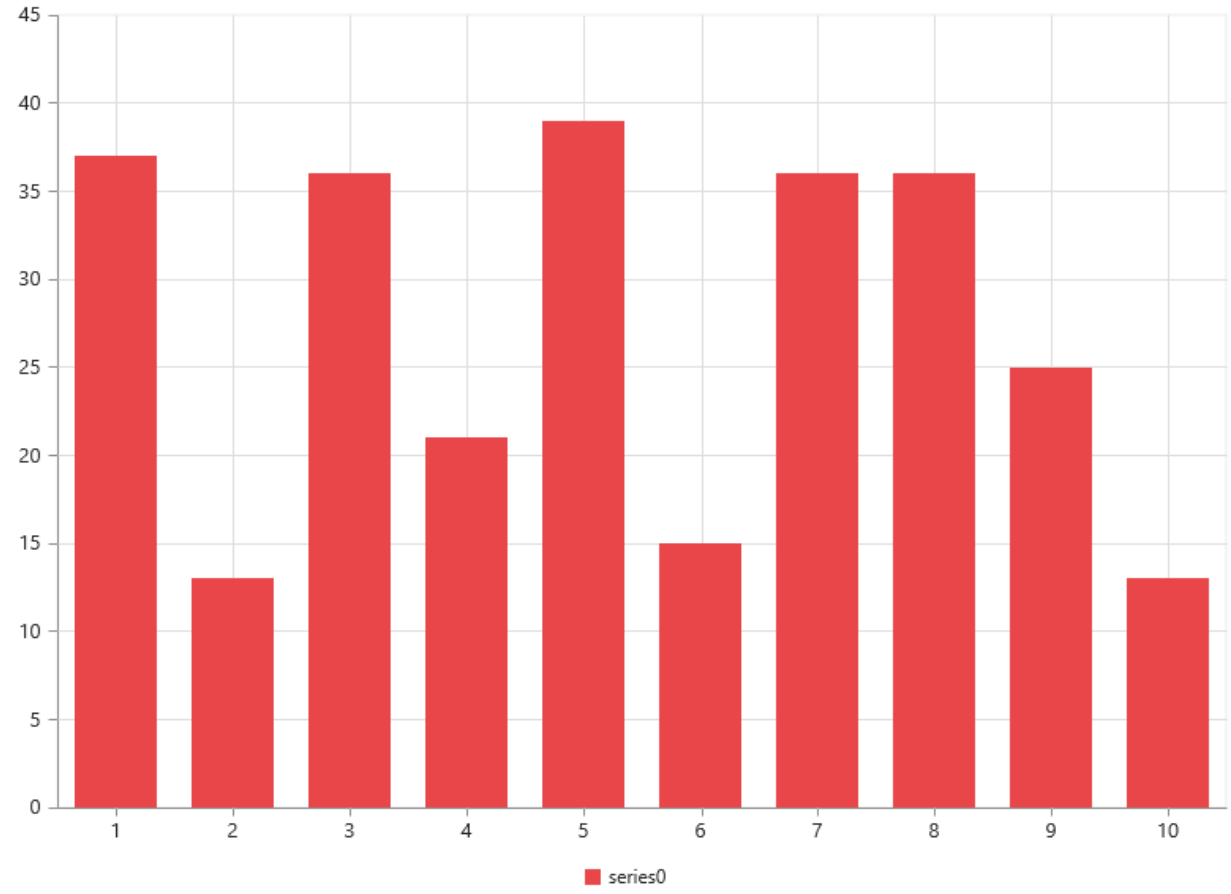
Initialize chart

Add the following code in the index.cshtml file to create the Chart control in View page.

ASPX-CS

```
<div>
@(Html.EJ().Chart("chartContainer"))
</div>
```

Now, the Chart is rendered with some auto-generated random values and with default Column chart type.



Initialize the chart by using the ejChart method. The chart is rendered to the size of its container, by default. You can also customize the chart dimension either by setting the width and height of the container element as in the above code example or by using the **Size** option of the Chart. Refer to the Chart Dimensions to know more about setting the size of the chart.

Populate chart with data

Now, let's see how to plot data source to the Chart. First, let us generate a data source containing following fields in controller– Month and Sales.

Copyright © 2001 - 2020 Syncfusion Inc.

CSHARP

```
public class HomeController : Controller
{
public ActionResult Index()
{
//// Create dataSource to chart
List<ChartData> data = new List<ChartData>();
data.Add(new ChartData("Jan", 35));
data.Add(new ChartData("Feb", 28));
data.Add(new ChartData("Mar", 34));
data.Add(new ChartData("Apr", 32));
data.Add(new ChartData("May", 40));
data.Add(new ChartData("Jun", 32));
data.Add(new ChartData("Jul", 35));
data.Add(new ChartData("Aug", 55));
data.Add(new ChartData("Sep", 38));
data.Add(new ChartData("Oct", 30));
data.Add(new ChartData("Nov", 25));
data.Add(new ChartData("Dec", 32));
///...
ViewBag.ChartData = data;
return View();
}
}
public class ChartData {
public string Month;
public double Sales;
public ChartData(string month, double sales)
{
this.Month = month;
this.Sales = sales;
}
}
```

Add a Series object to the chart using **Series** option and set the chart type as **Line** using **Type** option.

ASPX-CS

```
@using Syncfusion.JavaScript.DataVisualization
<div>
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
//Change series type
sr.Type(SeriesType.Line).Add();
})
)
</div>
```

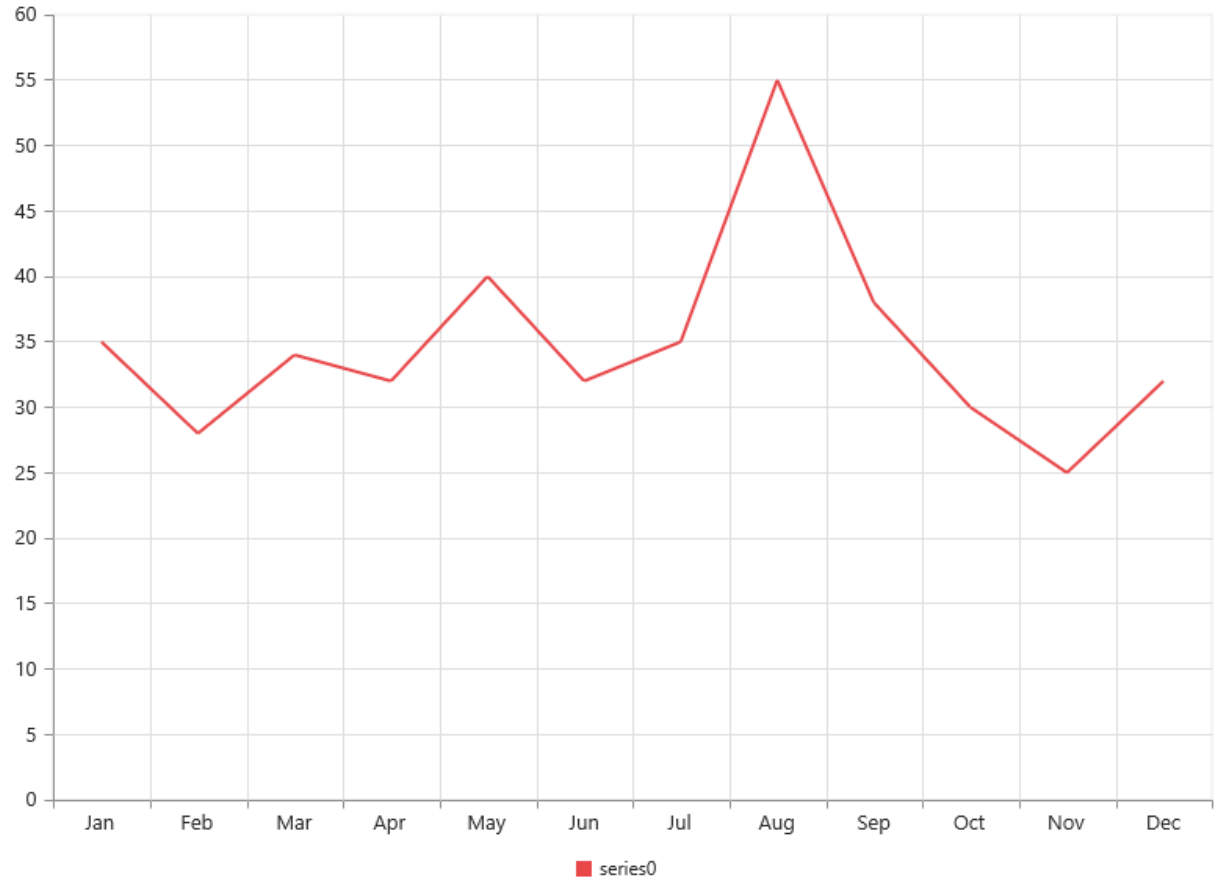
You can also add multiple series objects based on your requirement. Refer Chart Types and Chart Series sections to know more about chart types, how to add multiple series and customize series appearance.

Copyright © 2001 - 2020 Syncfusion Inc.

Next, map the Month and Sales values in the data source to the Line series by setting XName and YName with the field names respectively, and then set the actual data using DataSource option. Refer Data Binding section to know more about binding local and remote data to the chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
sr.DataSource(ViewBag.ChartData)
.Type(SeriesType.Line)
.XName("Month").YName("Sales")
.Add();
})
)
```



Since the data is related to Sales, format the vertical axis labels by adding '$' as a prefix and 'K' as a suffix to each label. This can be achieved by setting the "${value}K" to the **LabelFormat** option of the axis. Here, {value} acts as a placeholder for each axis label, "$" and "K" are the actual prefix and suffix added to each axis label.

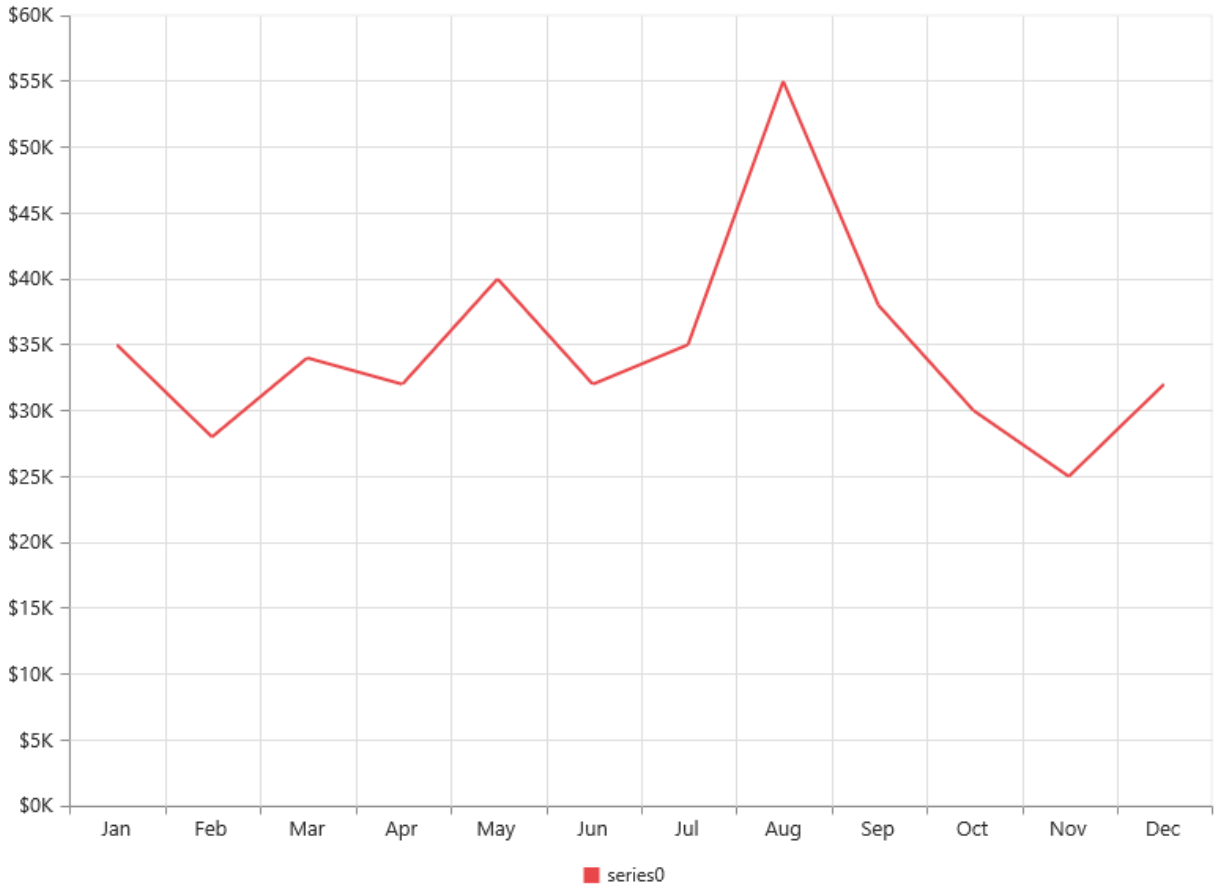
The following code example illustrates this,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Customize the axis label format.
.PrimaryYAxis(pry=>pry.LabelFormat("${value}K"))
//...
)
```



Refer Axis section to know more about axis types, adding multiple axes and other customization options.

Add Data Labels

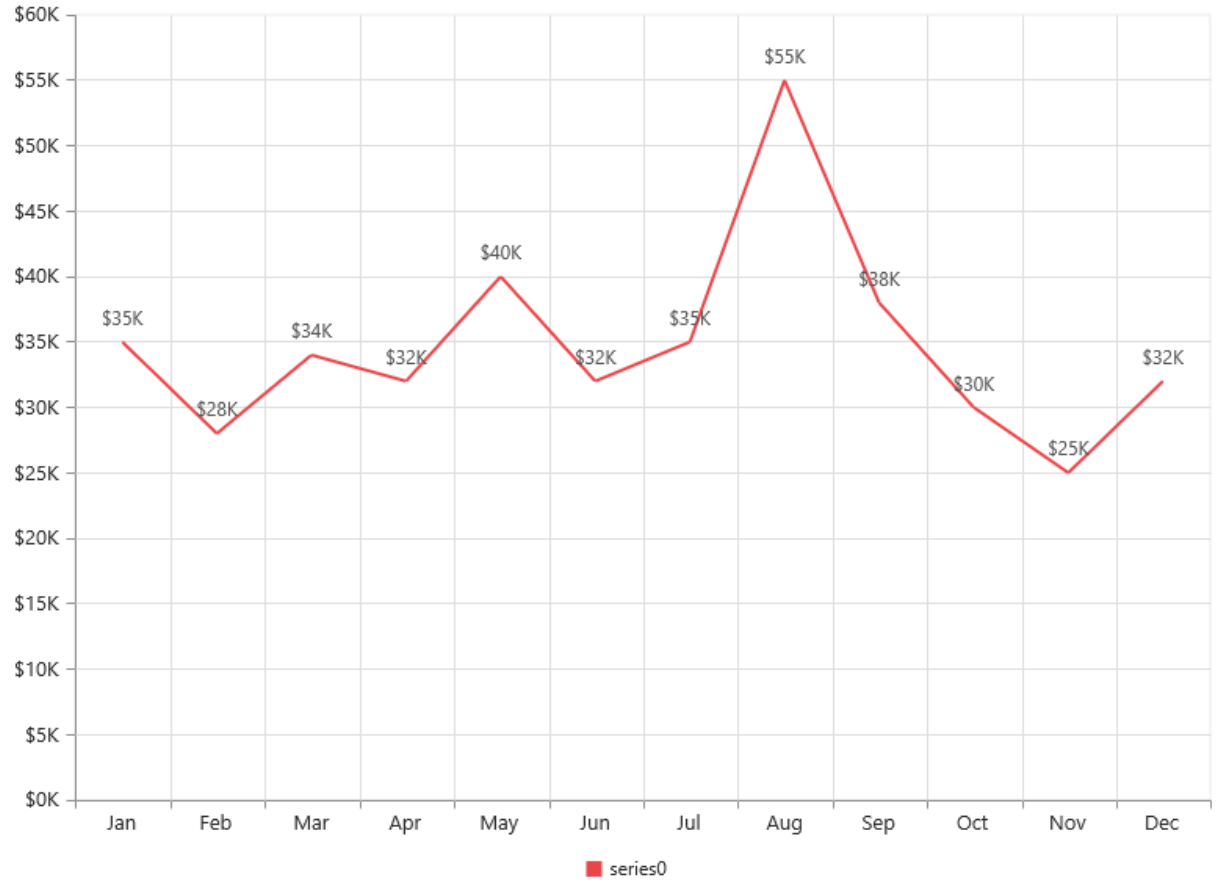
You can add data labels to improve the readability of the chart. This can be achieved by enabling the Visible option in the **DataLabel** option. Now, the data labels are rendered at the top of all the data points.

The following code example illustrates this,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
//Display data label in chart
.Marker(mr=>mr.DataLabel(label=>label.Visible(true)))
//...
.Add();
})
//...
```

```
)
```



There are situations where the default label content is not sufficient to the user. In this case, you can use the **Template** option to format the label content with some additional information.

HTML

```
<!DOCTYPE html>
<html>
<body>
<div id="dataLabelTemplate" style="display:none; padding:3px;background-
color:#B9C5C9; opacity:0.8;">
<div id="point">#point.x#:$#point.y#K</div>
</div>
</body>
</html>
```

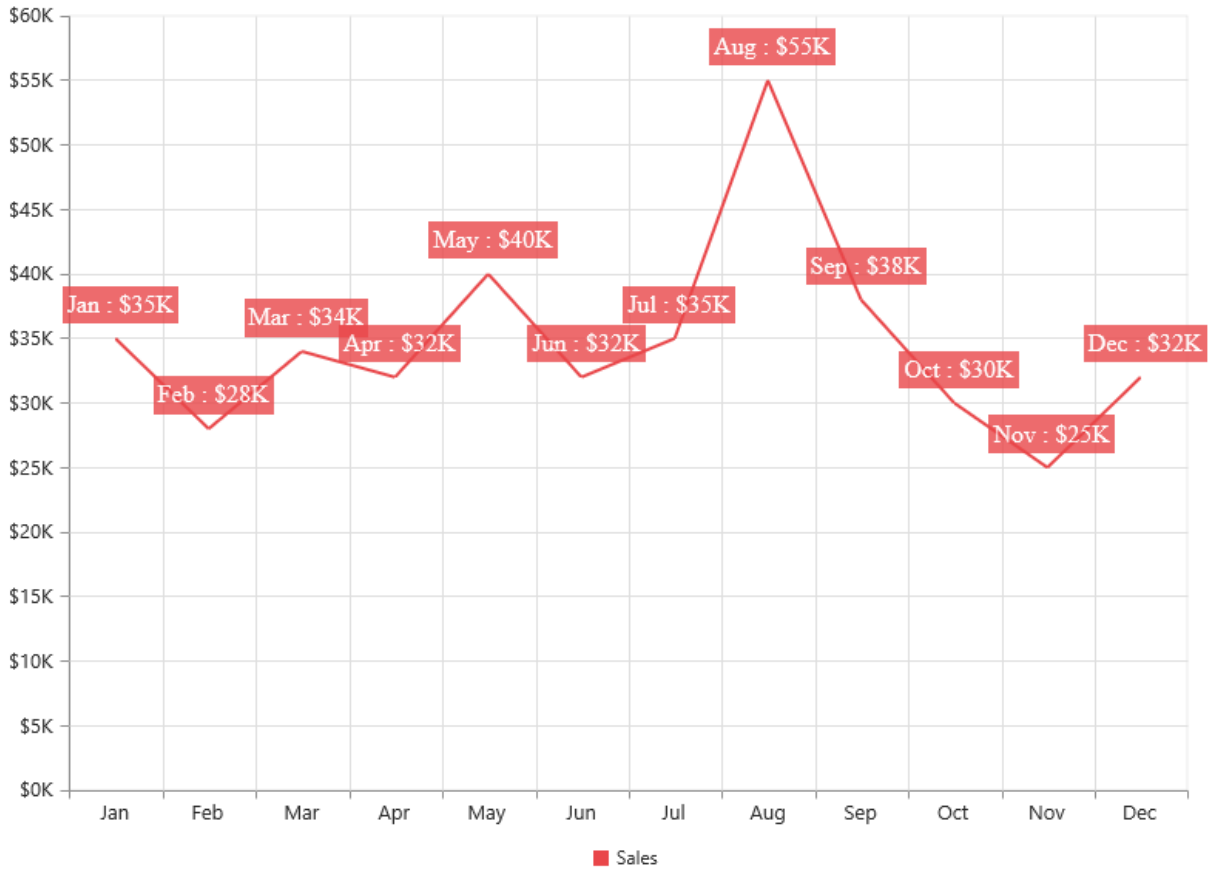
The above HTML template is used as a template for each data label. Here, “point.x” and “point.y” are the placeholder text used to display the corresponding data point’s x & y value.

The following code example shows how to set the id of the above template to Template option,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
```

```
.Series(sr =>
{
//Display data label in chart
.Marker(mr=>mr.DataLabel(label=>label.Visible(true).
//Set the id of HTML template to the chart series
Template("dataLabelTemplate"))
)
//...
.Add();
})
//...
)
```



Refer to the Data Markers section to know more about the options available to customize it.

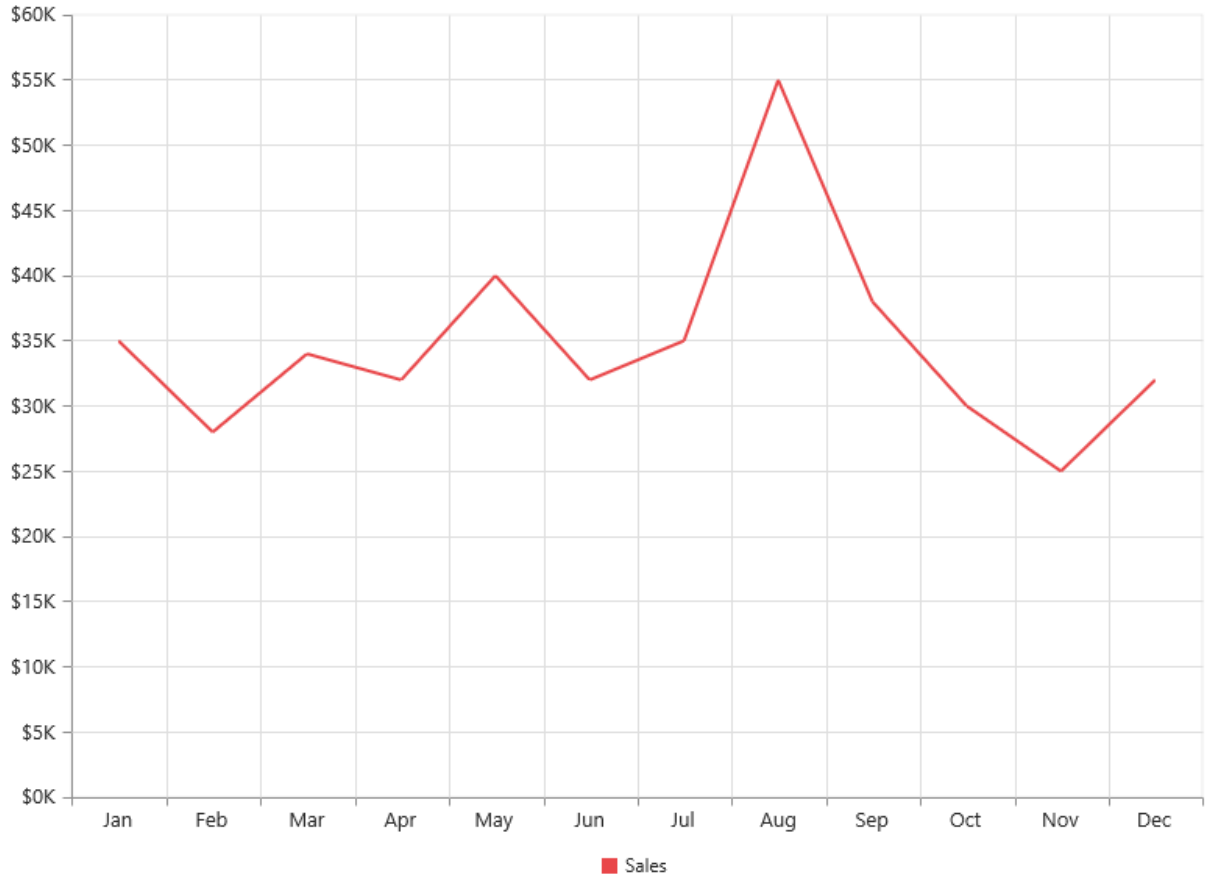
Enable Legend

You can enable or disable the legend by using the Visible option in the **Legend**. It is enabled in the chart, by default.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
//Add series name to display on the legend item
.Name("Sales")
```

```
.Add();
})
//Enable chart legend
.Legend(legend=>legend.Visible(true))
//...
)
```



Refer to the Legend section to know more about how to position legend and customize its appearance.

Enable Tooltip

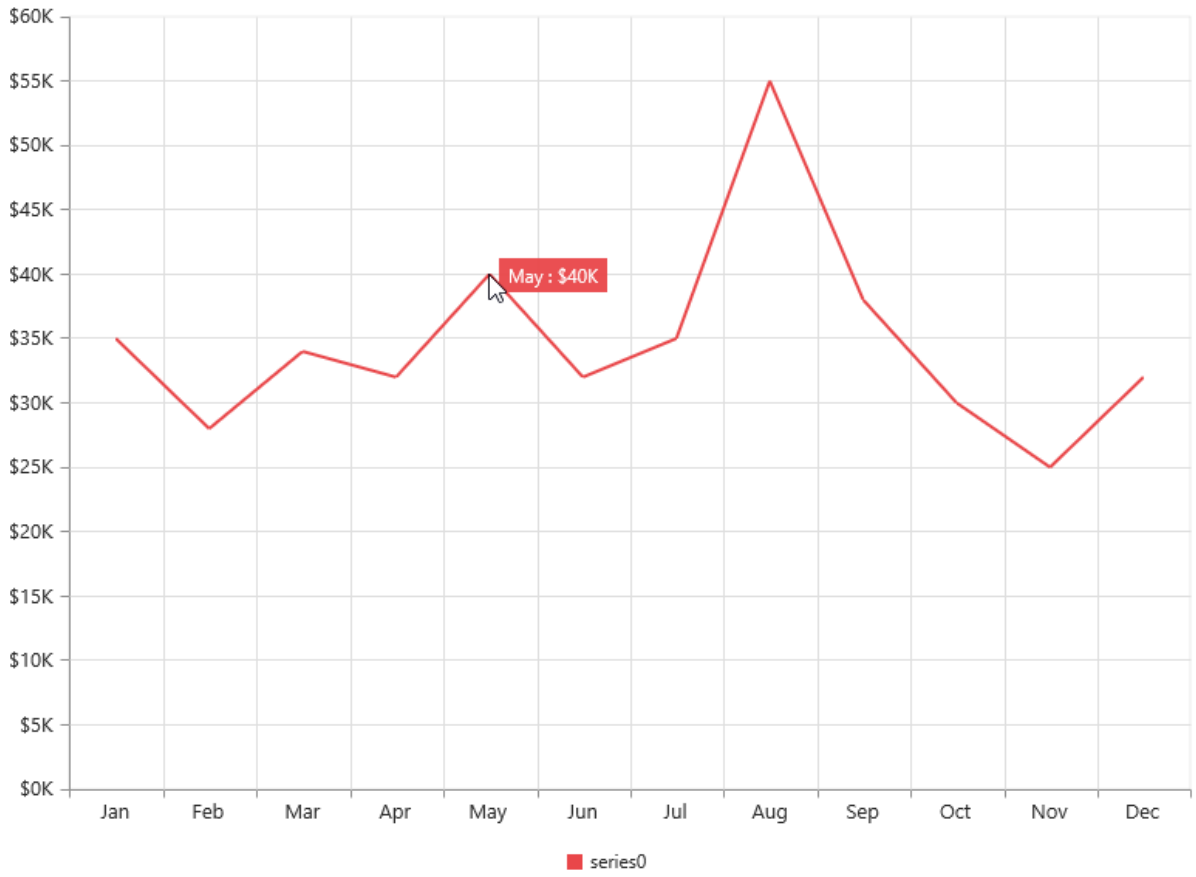
The Tooltip is useful when you cannot display information by using the **DataLabels** due to the space constraints. You can enable tooltip by using the Visible option of the **Tooltip** in the specific series.

The following code example illustrates this,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
//...
//Enable tooltip in chart area
.Tooltip(tooltip=>tooltip.Visible(true))
.Add();
})
//...
```

```
)
```



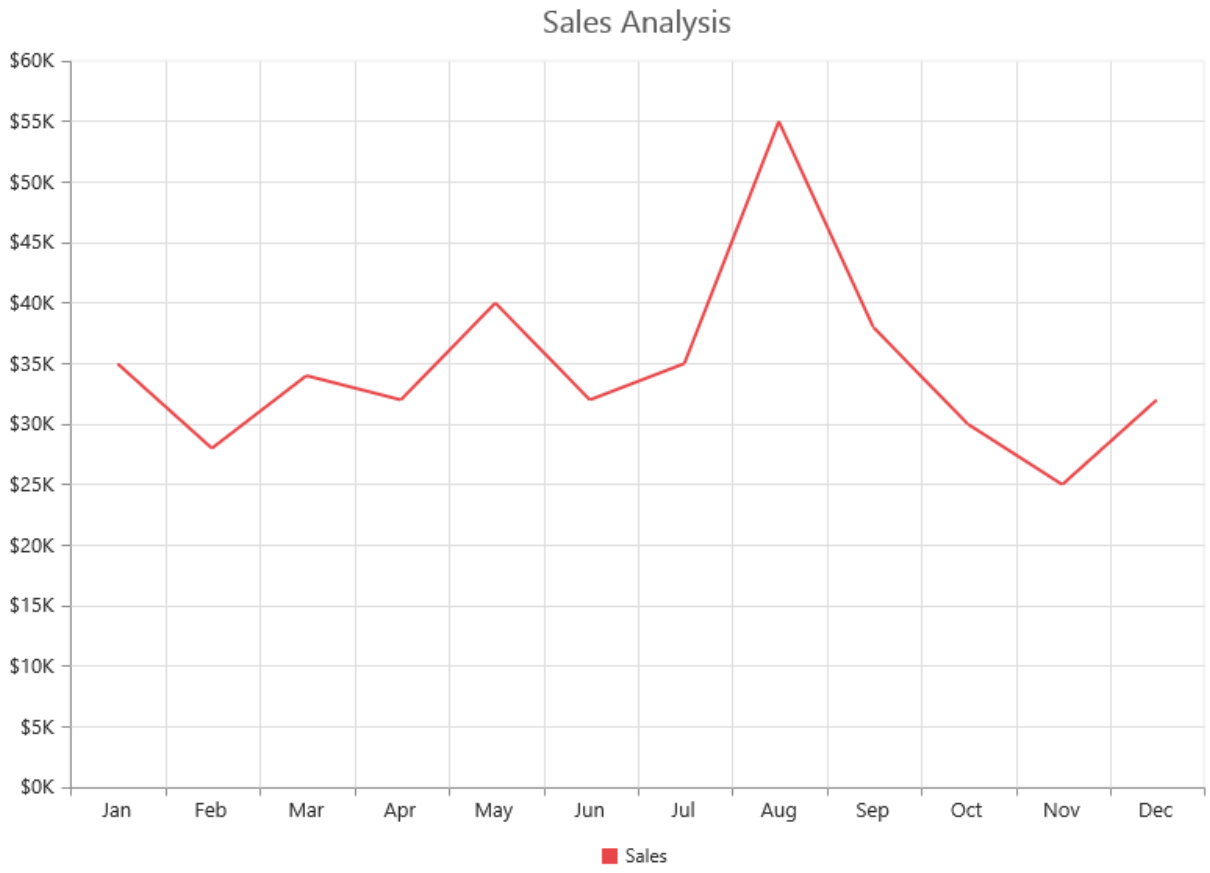
Refer to the Tooltip section to know more about formatting tooltip contents and customizing its appearance.

Add Chart Title

You need to add a title to the chart to provide quick information to the user about the data being plotted in the chart. You can add it by using the Text option of the **Title**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Add chart title
.Title(title=>title.Text("Sales Analysis"))
// ...
)
```



Refer to the Chart Title section to know more about aligning Title, customizing its appearance and adding SubTitle to the chart.

Working with Data

Local Data

There are two ways to provide local data to chart.

1. You can bind the data to the chart by using the **DataSource** property of the series and then you need to map the X and Y value with the *XName* and *YName* properties respectively.

Note: For the **OHLC** type series, you have to map four dataSource fields *High, Low, Open* and *Close* to bind the data source and for the **bubble** series you have to map the *Size* field along with the *XName* and *YName*.

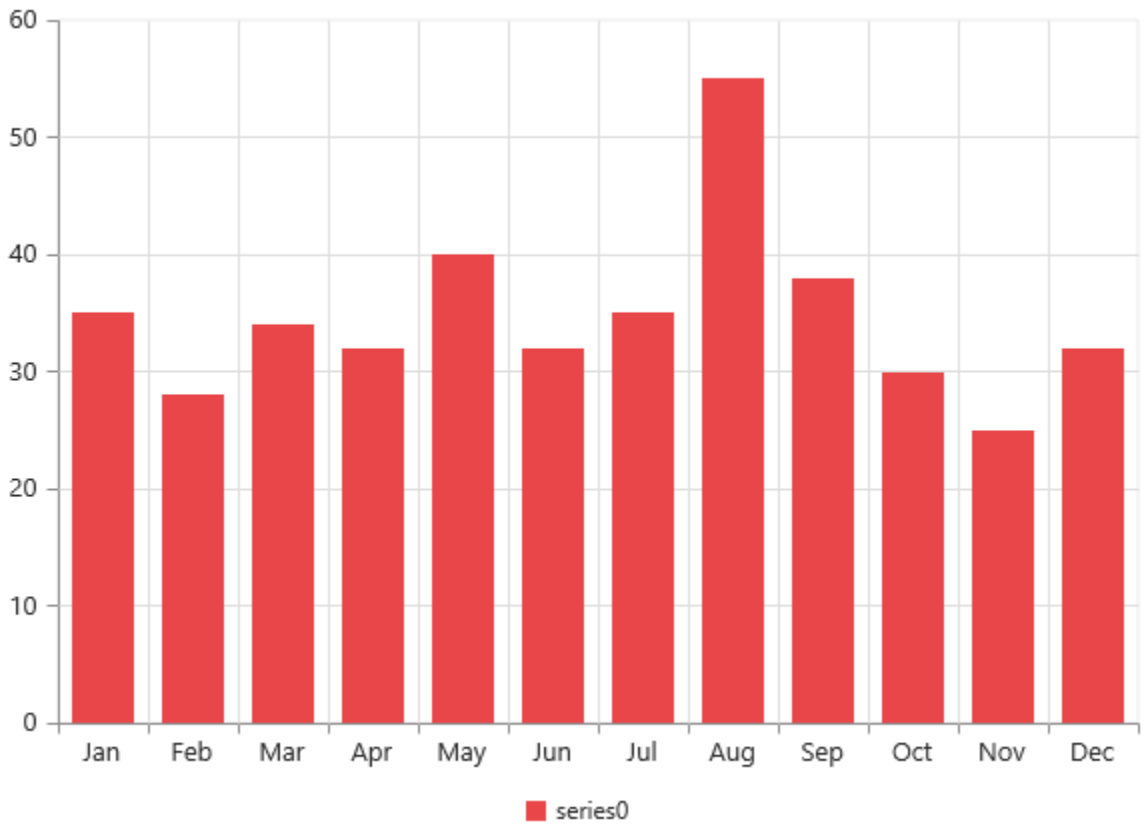
ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
//Add series
sr.Type(SeriesType.Line).Add();
})
.Load("onChartLoad")
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
var chartData = [
{ month: 'Jan', sales: 35 }, { month: 'Feb', sales: 28 },  { month: 'Mar',
sales: 34 },
{ month: 'Apr', sales: 32 },{ month: 'May', sales: 40 },{ month: 'Jun',
sales: 32 },
{ month: 'Jul', sales: 35 },  { month: 'Aug', sales: 55 }, { month: 'Sep',
sales: 38 },
{ month: 'Oct', sales: 30 }, { month: 'Nov', sales: 25 }, { month: 'Dec',
sales: 32 }];
function onChartLoad(sender) {
var data = GetData();
sender.model.series[0].dataSource = chartData;
sender.model.series[0].xName = "month";
sender.model.series[0].yName = "sales";
}
```



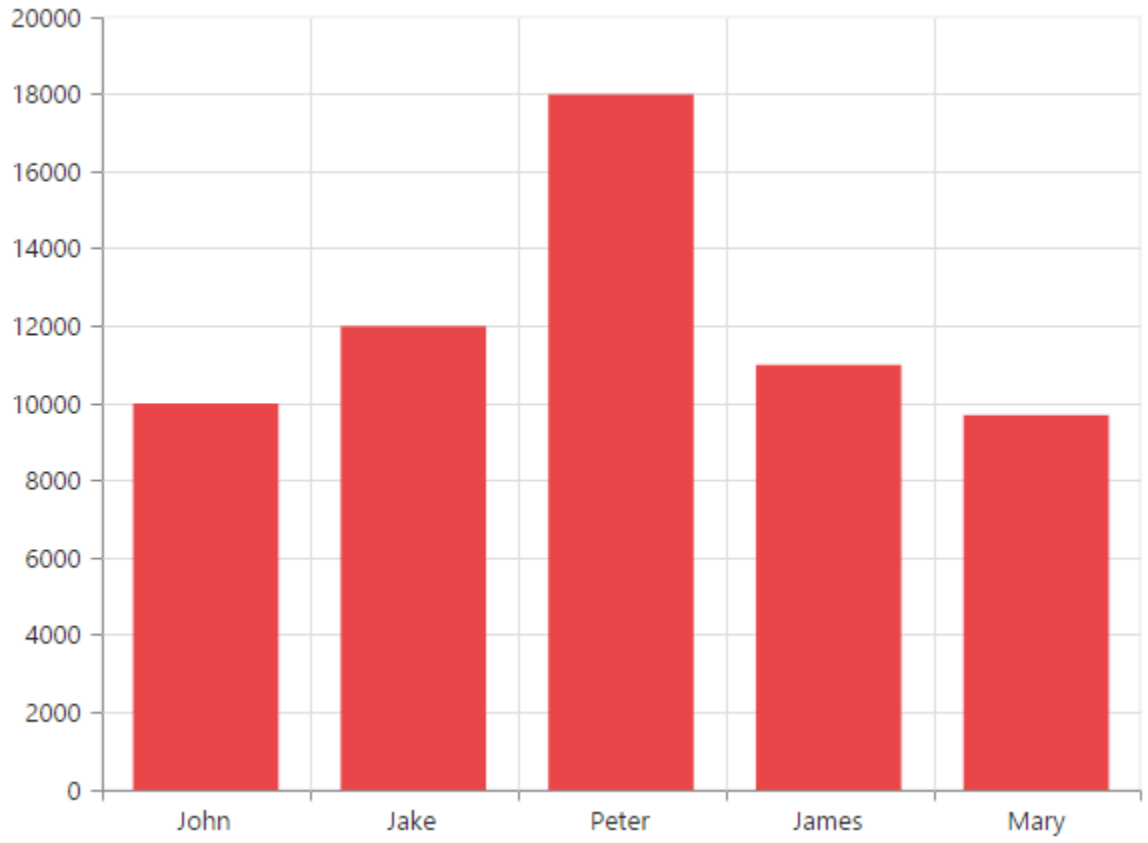
Click here to view the local data binding online demo sample.

2.You can also plot data to chart using **Points** option in the series. Using this property you can customize each and every point in the data.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
sr
//Adding data points using x and y field of points
.Points(pt =>
{
pt.X("John").Y(10000).Add();
pt.X("Jake").Y(12000).Add();
pt.X("Petter").Y(18000).Add();
pt.X("James").Y(11000).Add();
pt.X("Mary").Y(9700).Add();
}).Add();
})
//...
)
```



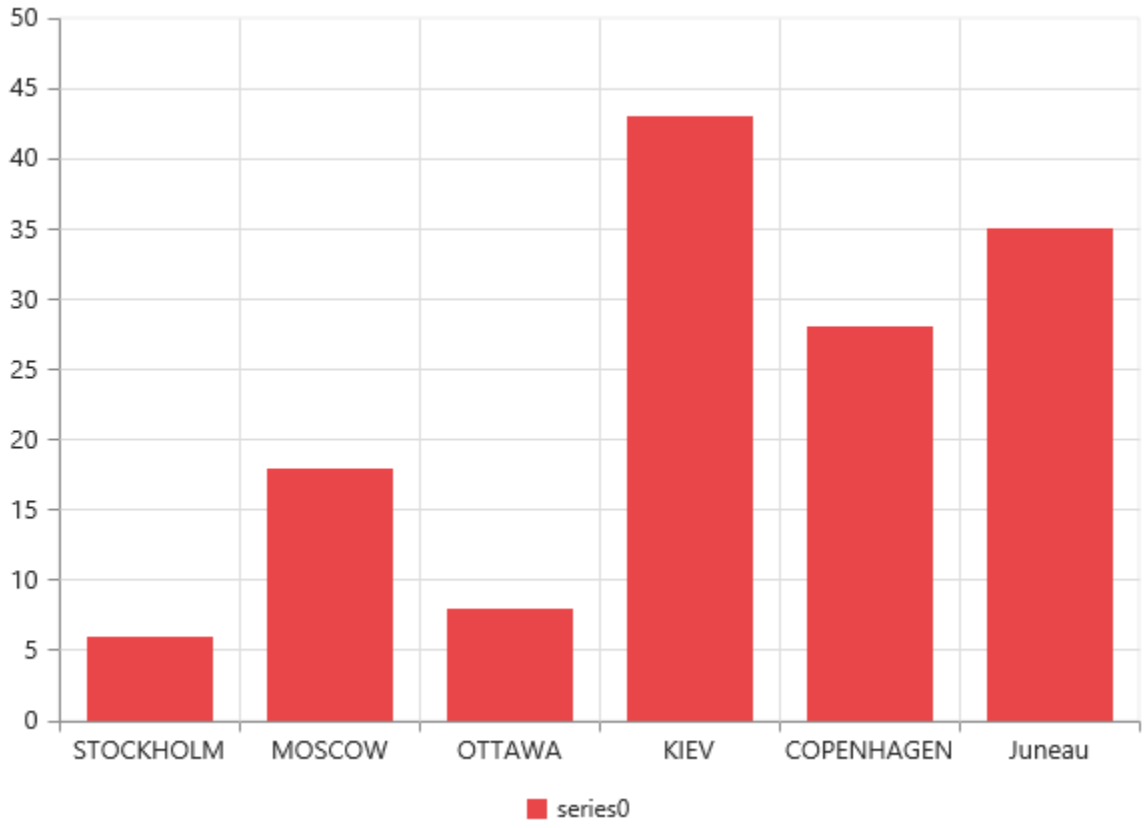
Remote Data

You can bind the remote data to the chart by using the **DataSource** and you can use the **Query** property of the series to filter the data from the dataSource.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
```

```
//...
.Series(ser =>
{
ser.DataSource(service =>
service.URL("http://mvc.syncfusion.com/Services/Northwnd.svc/"));
ser.XName("ShipCity");
ser.YName("Freight");
ser.Query("ej.Query().from('Orders').take(10)").Add();
})
//...
)
```



Click here to view the remote data binding online demo sample.

AngularJS Data Binding

Typically, you will assign data directly to chart using **dataSource** property of the series. In AngularJS, you need to bind the variable, which contains data in the AngularJS scope object, to the dataSource property as illustrated in the following code example,

Information: Essential JS includes AngularJS directives for all controls in the **ej.widget.angular.min.js** script file.

Note: All the properties in EjChart supports one way AngularJS binding except inner array properties like **series.points[]**, **series.trendlines[]**. Click here to know more about Essential AngularJS and the properties which support two way AngularJS binding in chart.

{ "Day": 1, "John": 57, "Hendrik": 43 },
{ "Day": 2, "John": 73, "Hendrik": 27 },
{ "Day": 3, "John": 49, "Hendrik": 51 },
{ "Day": 4, "John": 63, "Hendrik": 37 },
{ "Day": 5, "John": 44, "Hendrik": 56 },
{ "Day": 6, "John": 49, "Hendrik": 51 },
{ "Day": 7, "John": 61, "Hendrik": 39 },
{ "Day": 8, "John": 35, "Hendrik": 65 },
{ "Day": 9, "John": 45, "Hendrik": 55 },
{ "Day": 10, "John": 37, "Hendrik": 63 }
];
angular.module('syncApp', ['ejangular'])
.controller('Chart', function ($scope) {
//Assigning data to the dataSource variable in the $scope object.
$scope.dataSource = obj;
});
```

Click here to view the AngularJS data binding online demo sample.

Copyright © 2001 - 2020 Syncfusion Inc.

Chart Dimensions

You can set the size of the chart directly on the chart or to the container of the chart. When you do not specify the size, it takes 450px as the height and window size as its width, by default.

Set size for the container

You can customize the chart dimension by setting the width and height for the container element.

ASPX-CS

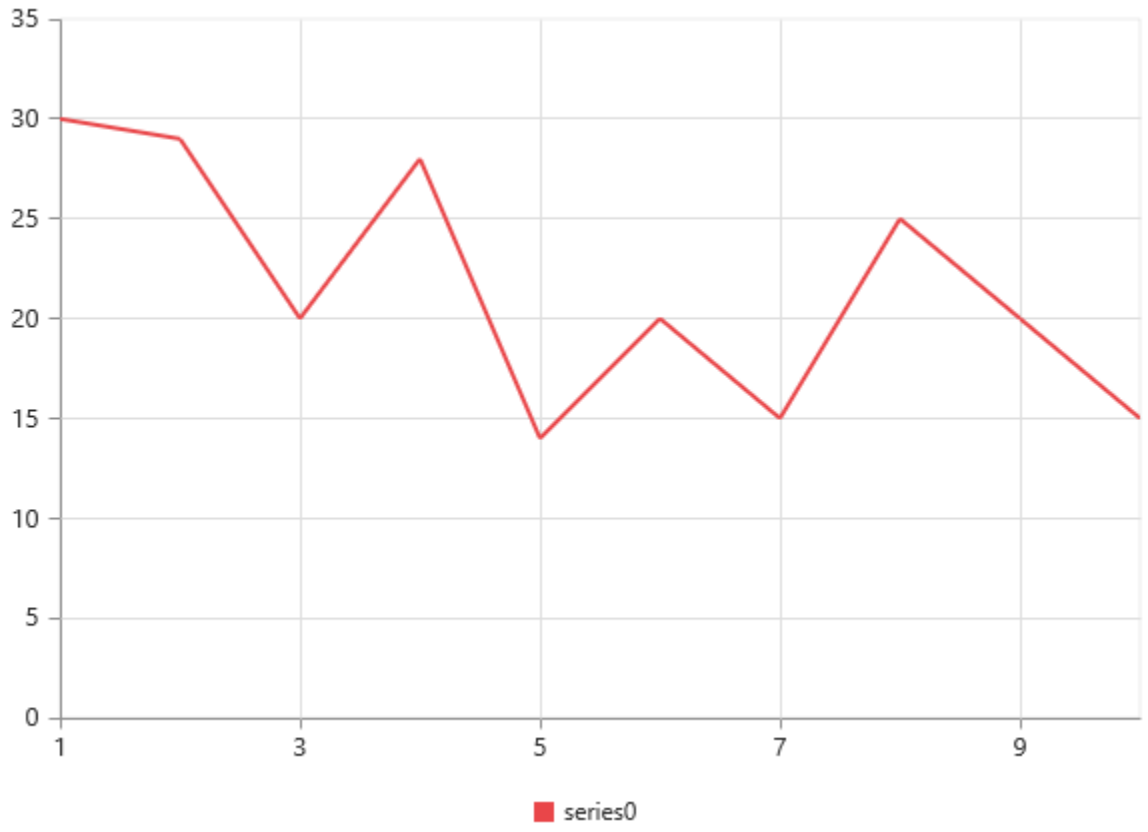
```
<div id="container" style="width:820px; height:500px;">
@(Html.EJ().Chart("chartContainer")
// ...
)
</div>
```

Set size in pixels

You can also set the chart dimension by using the **Size** property of the chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Set size to chart container
.Size(size=>size.Height("450").Width("600"))
)
```



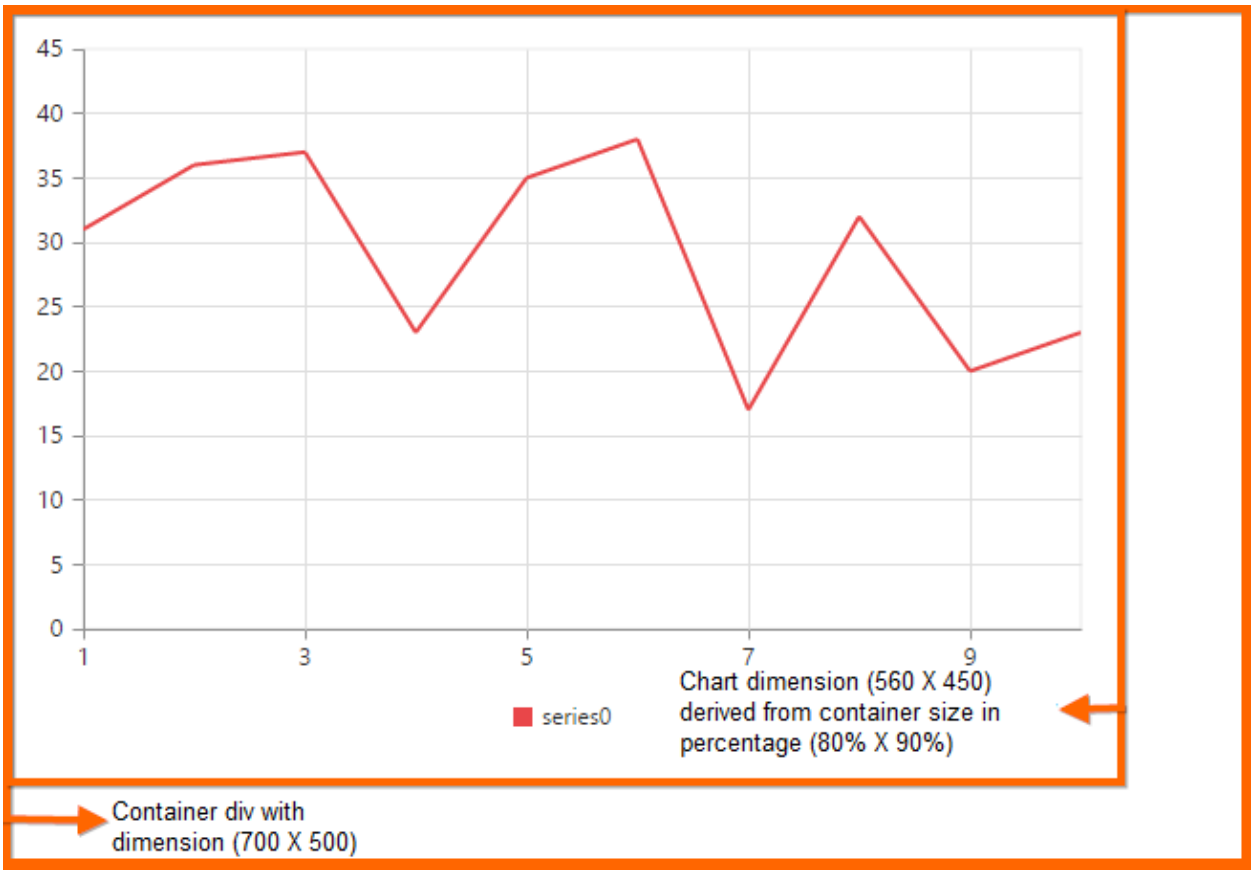
Copyright © 2001 - 2020 Syncfusion Inc.

Setting size relative to the container size

You can specify the chart size in percentage by using the Size property. The chart gets its dimension with respect to its container.

ASPX-CS

```
<div id="container" style="width:700px; height:500px">
@(Html.EJ().Chart("container")
// ...
//Set size to chart container
.Size(size=>size.Height("90%").Width("80%"))
)
</div>
```



Responsive chart

To resize the Chart when the browser or the chart container is resized, set the **IsResponsive** property to **true**, where the chart adapts to the changes in size of the container.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Enable IsResponsive to change the chart size dynamically.
.IsResponsive(true)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Axis

Charts typically have two axes that are used to measure and categorize data: a vertical (y) axis, and a horizontal (x) axis.

Vertical axis always uses numerical or logarithmic scale. Horizontal(x) axis supports the following types of scale:

- Category
- Numeric
- DateTime
- DateTime Category
- Logarithmic

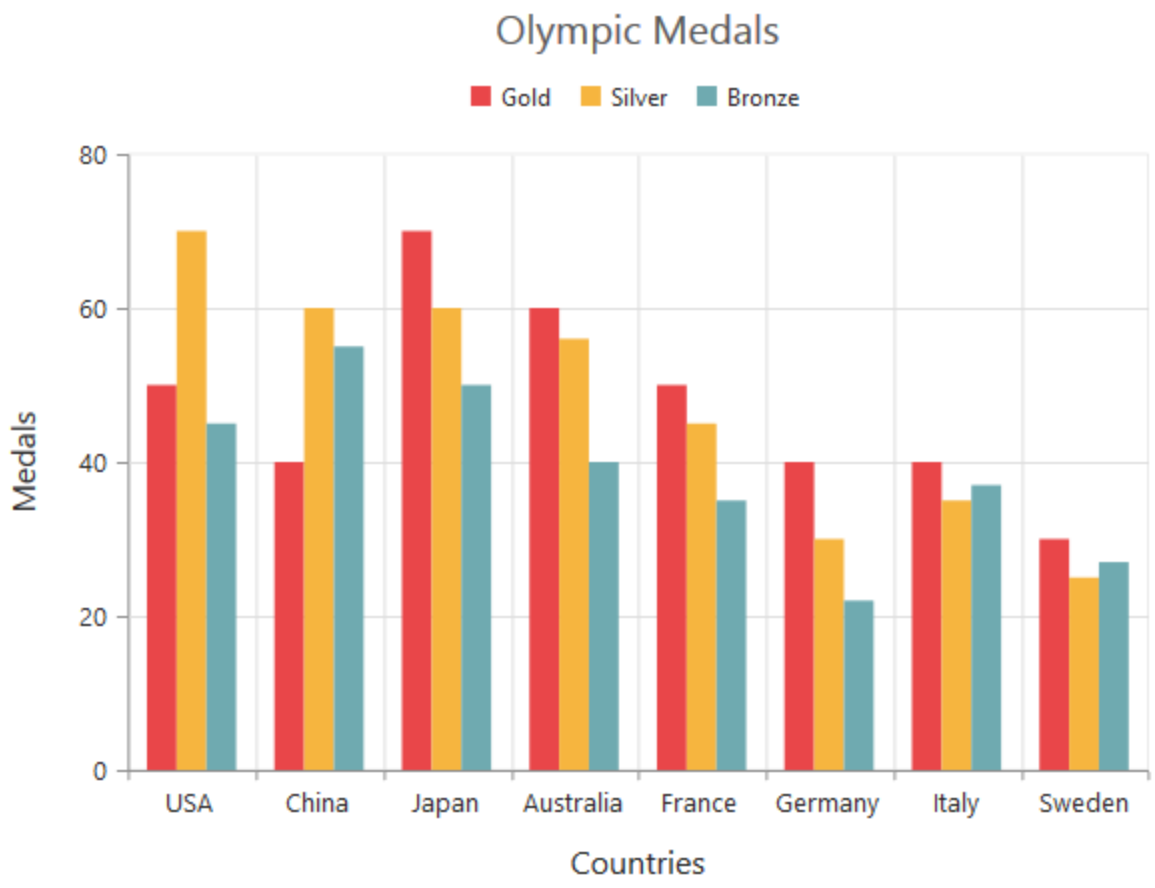
Category Axis

Category axis displays the text labels instead of numbers. To use the categorical axis, you can set the **ValueType** property of the axis to the **Category**. Default value of ValueType is **Double**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Use categorical scale in primary X axis
px=>px.ValueType(AxisValueType.Category)
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view our online demo sample that uses Category axis.

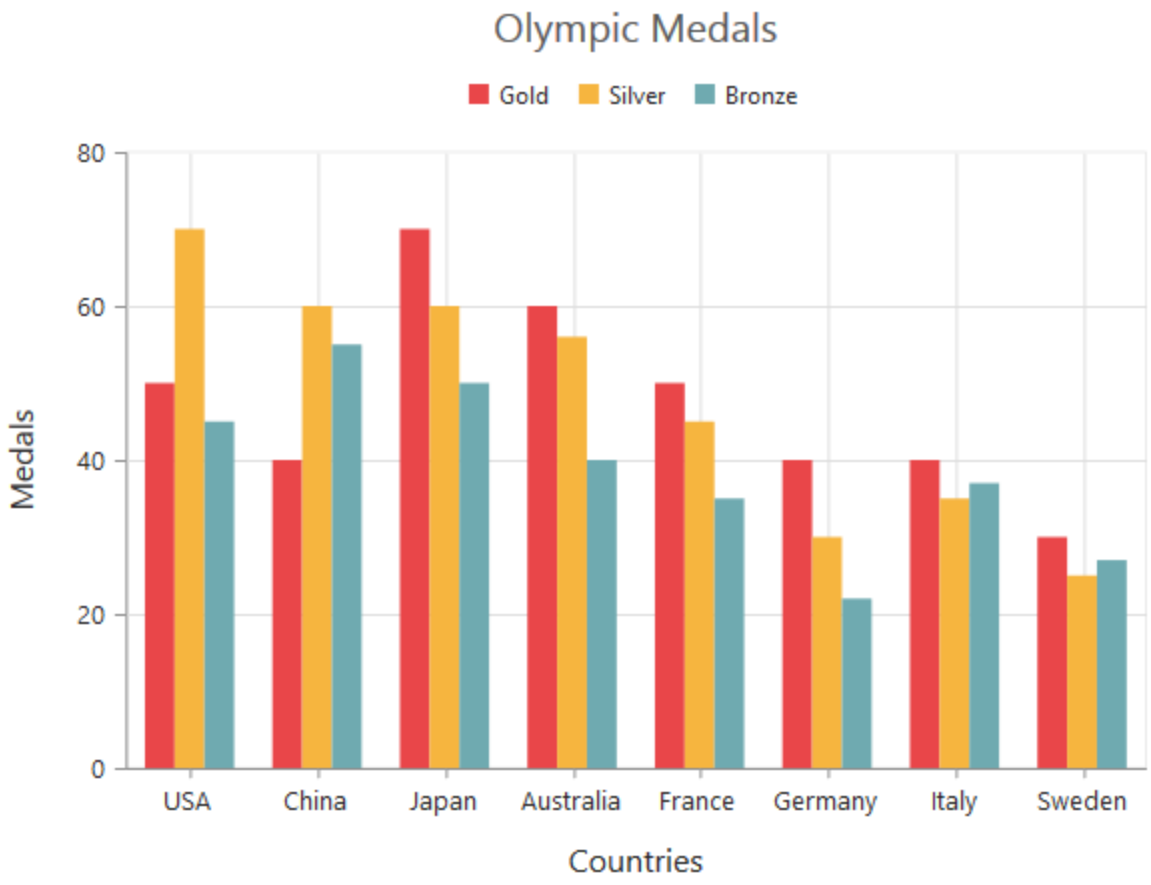
Place labels on ticks

Labels in the category axis can be placed on the ticks by setting the **LabelPlacement** property of axis to the onTicks. The default value of the LabelPlacement property is betweenTicks i.e. labels are placed between the ticks, by default.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Placing X-axis labels on the ticks
px=>px.LabelPlacement("onTicks")
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



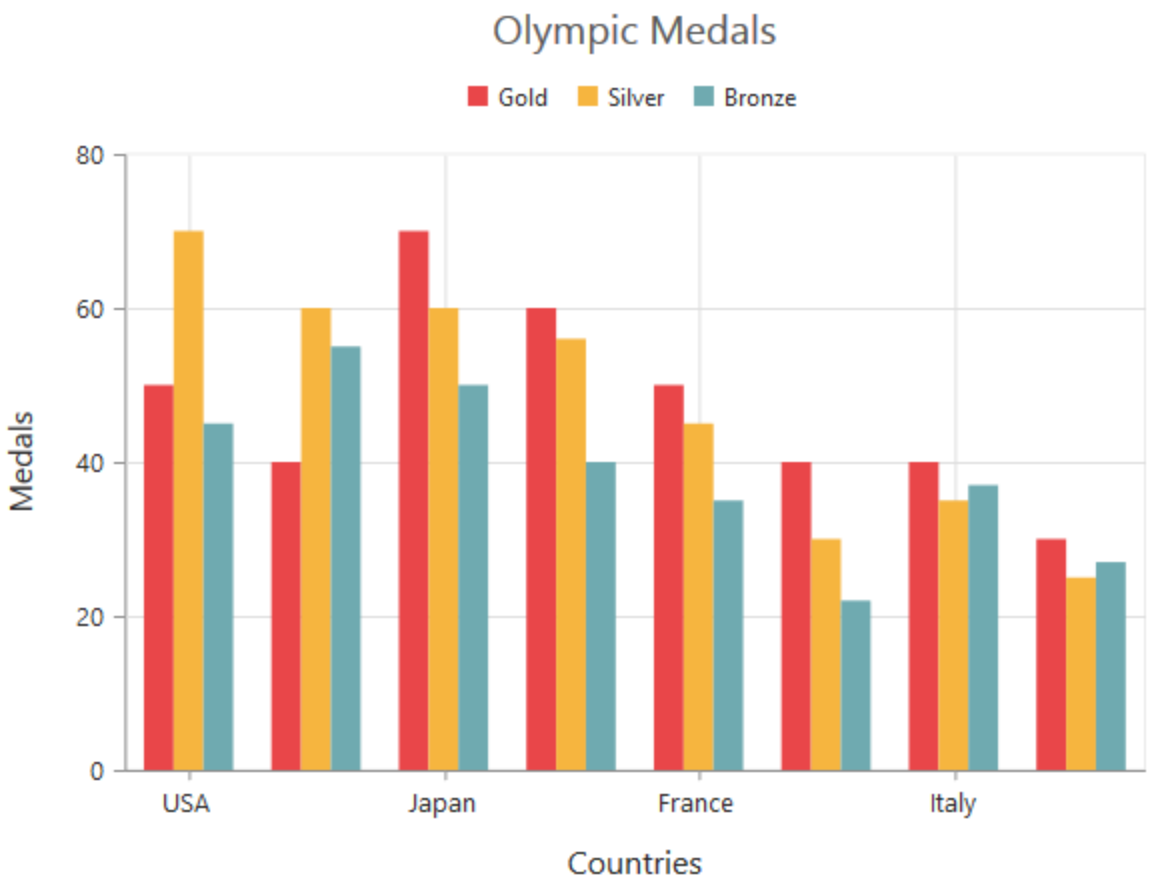
Display labels after a fixed interval

To display the labels after a fixed interval n, you can set the **Interval** property of the axis range as **n**. The default value of the interval is 1 i.e. all the labels are displayed.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Displaying labels after 2 intervals
axis=>axis.Range(range=>range.Interval(2))
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



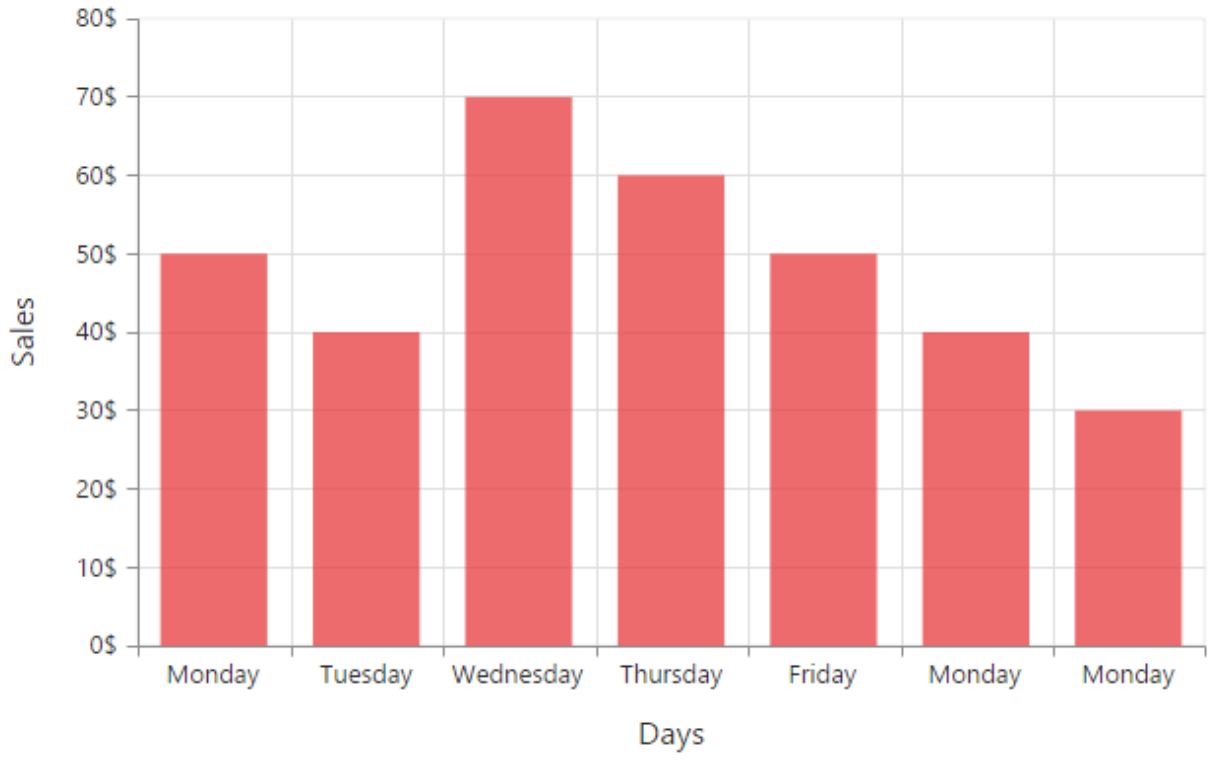
Indexed Category Axis

Category axis can also plot points based on index value of data points. Index based plotting can be enabled by setting **IsIndexed** property to true in the axis.

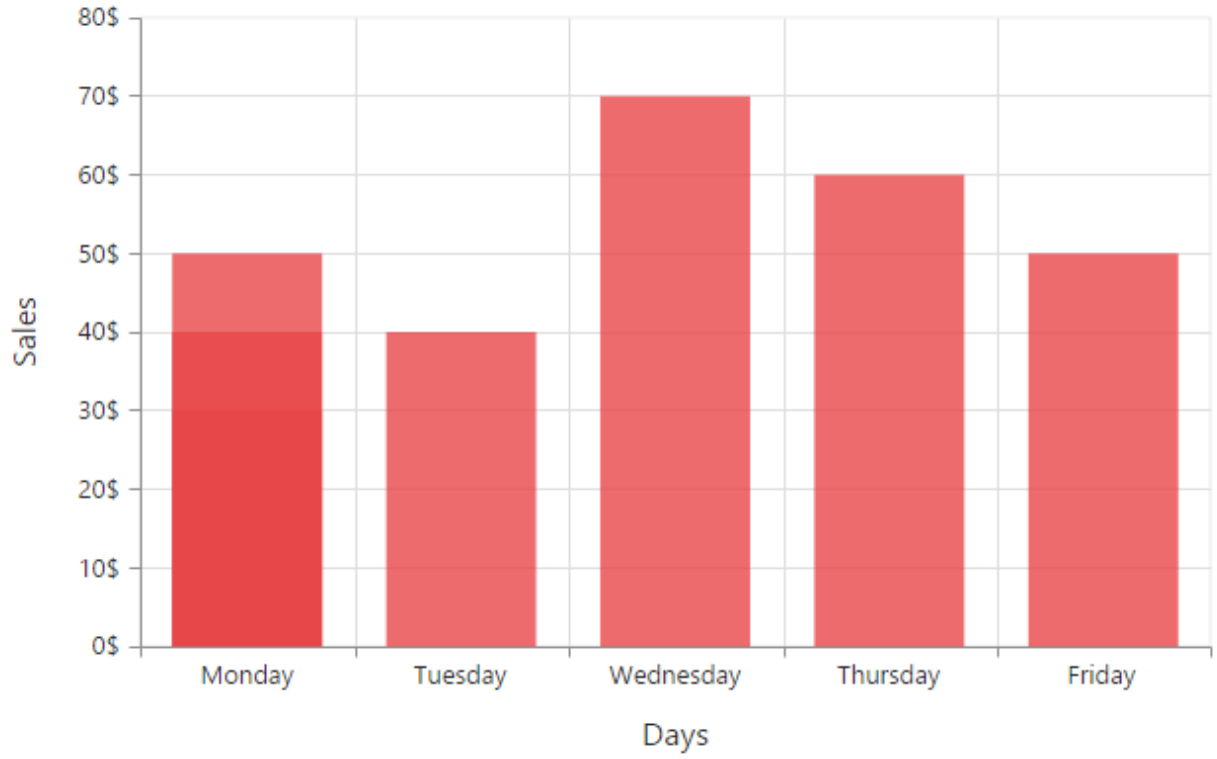
ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.PrimaryXAxis(px=>px.IsIndexed(true))
.Series(sr =>
{
//Adding Candle series
sr.Points(pt=>{
pt.X("Monday").Y(50).Add();
pt.X("Tuesday").Y(40).Add();
pt.X("Wednesday").Y(70).Add();
pt.X("Thursday").Y(60).Add();
pt.X("Friday").Y(50).Add();
pt.X("Monday").Y(40).Add();
pt.X("Monday").Y(30).Add();
}) .Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



While Category axis IsIndexed value false



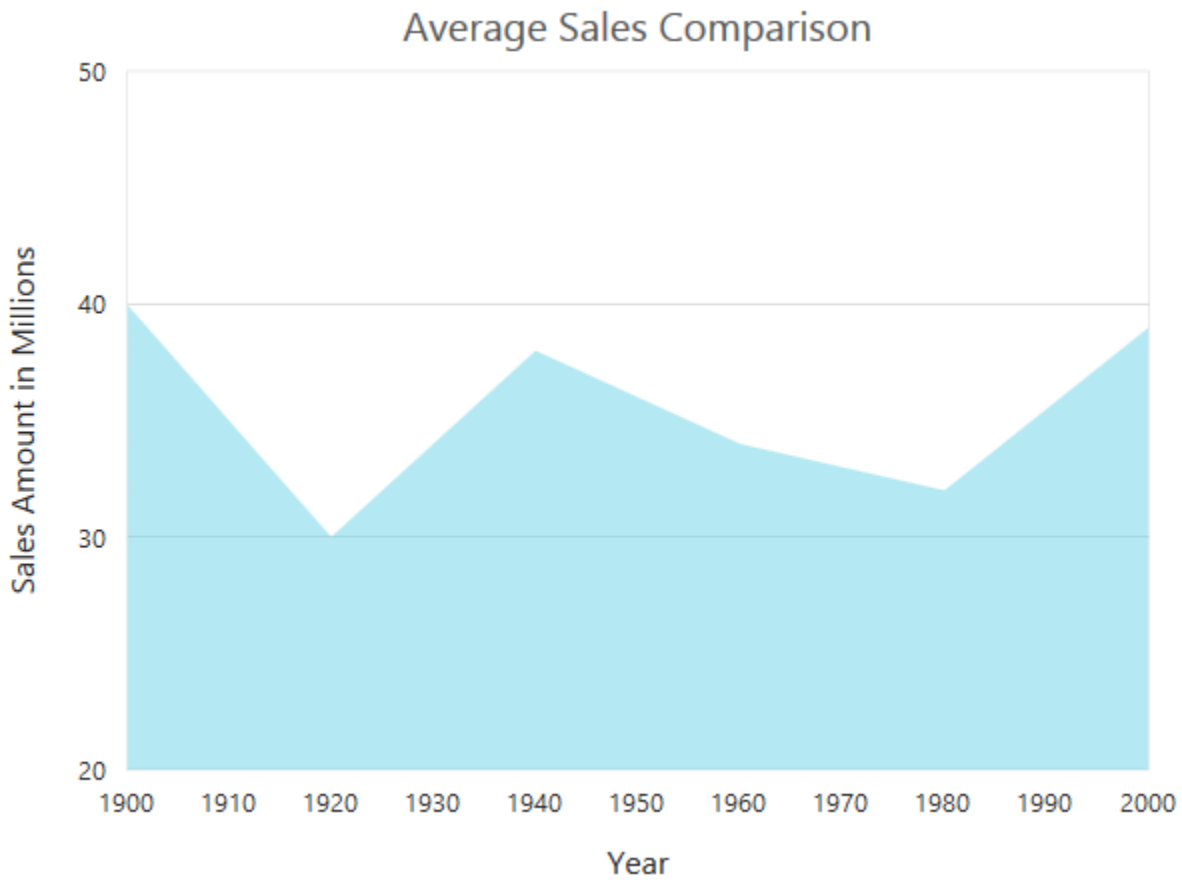
Copyright © 2001 - 2020 Syncfusion Inc.

Numeric Axis

Numeric axis uses numerical scale and displays numbers as labels. To use numeric axis, you can set the **ValueType** property of the axis to **Double**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
//Use numerical scale in primary Y axis
px=>px.ValueType(AxisValueType.Double)
)
// ...
)
```



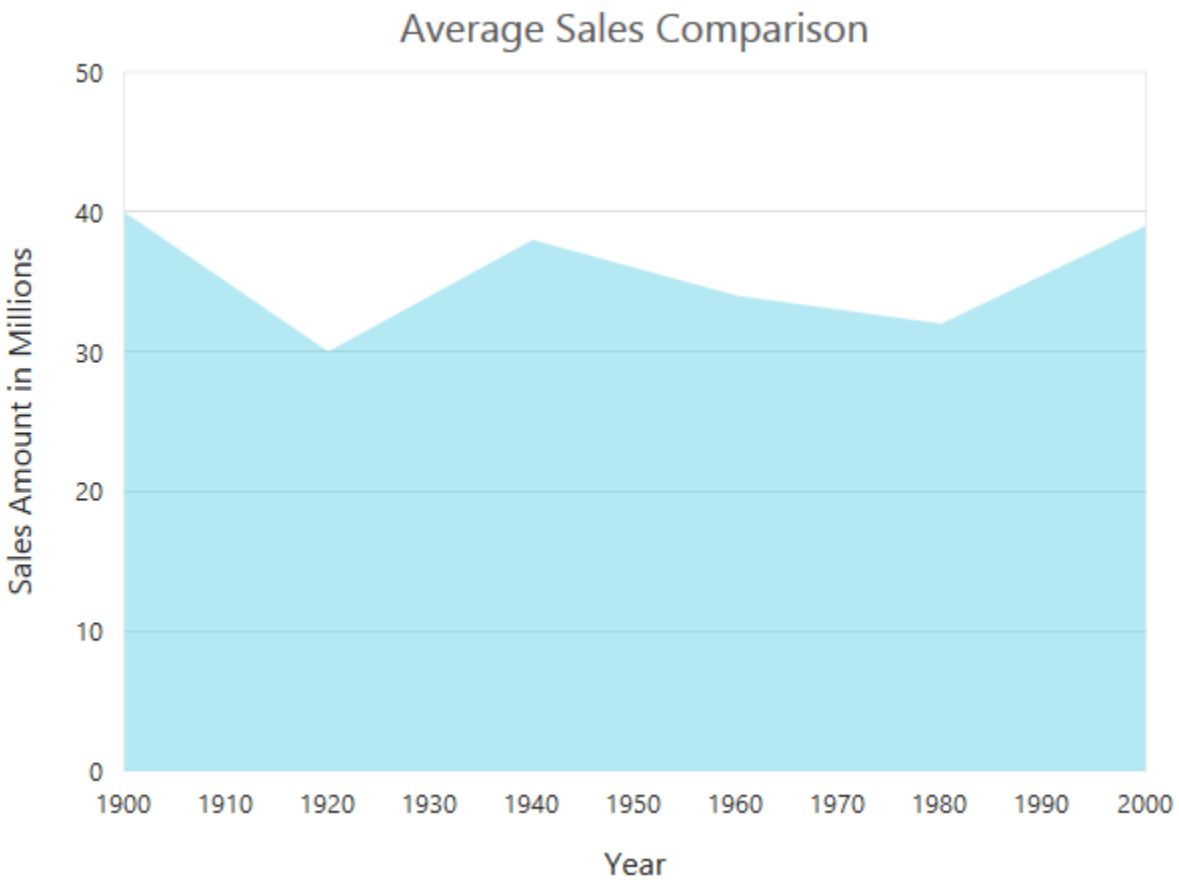
Customize numeric range

To customize the range of an axis, you can use the **Range** property of the axis to set the **Minimum**, **Maximum** and **Interval** values. Nice range is calculated automatically based on the provided data, by default.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
```

```
//Customizing Y-axis range
px=>px.Range(range=>range.Min(0).Max(50))
)
// ...
)
```



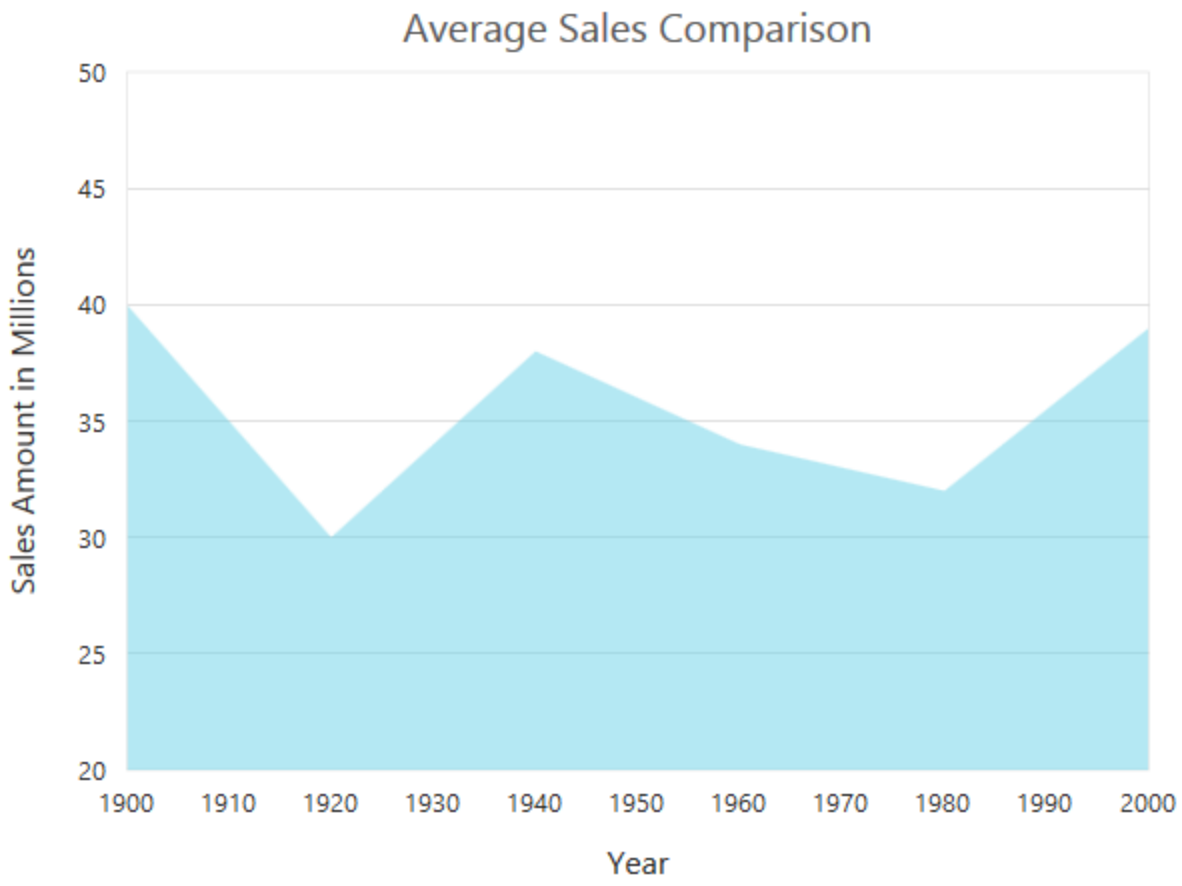
Customizing numeric interval

Axis interval can be customized by using the **Interval** property of the axis range. Nice interval is calculated based on the minimum and maximum value of the provided data, by default.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
//Set interval to PrimaryYAxis
px=>px.Range(range=>range.Interval(5))
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Apply padding to the range

Padding can be applied to the minimum and maximum extremes of the axis range by using the **RangePadding** property. Numeric axis supports the following types of padding

- None
- Round
- Additional
- Normal

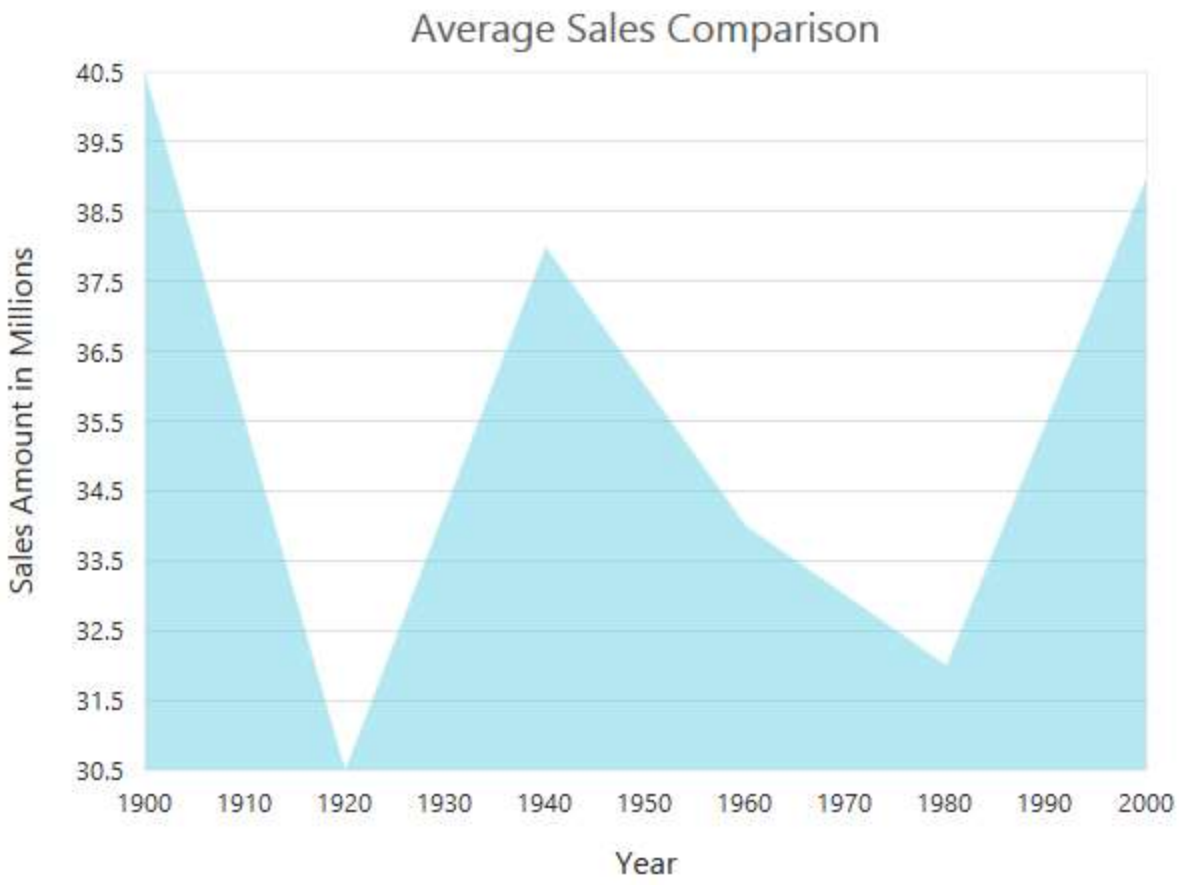
None

When the value of the RangePadding property is **None**, padding can not be applied to the axis. This is also the default value of the rangePadding.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
//Applying none as range padding
px=>px.RangePadding(ChartRangePadding.None)
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Round

When the value of RangePadding property is **Round**, the axis range is rounded to the nearest possible value divided by the interval.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
//Applying round as range padding
px=>px.RangePadding(ChartRangePadding.Round)
)
// ...
)
```

Chart before rounding axis range

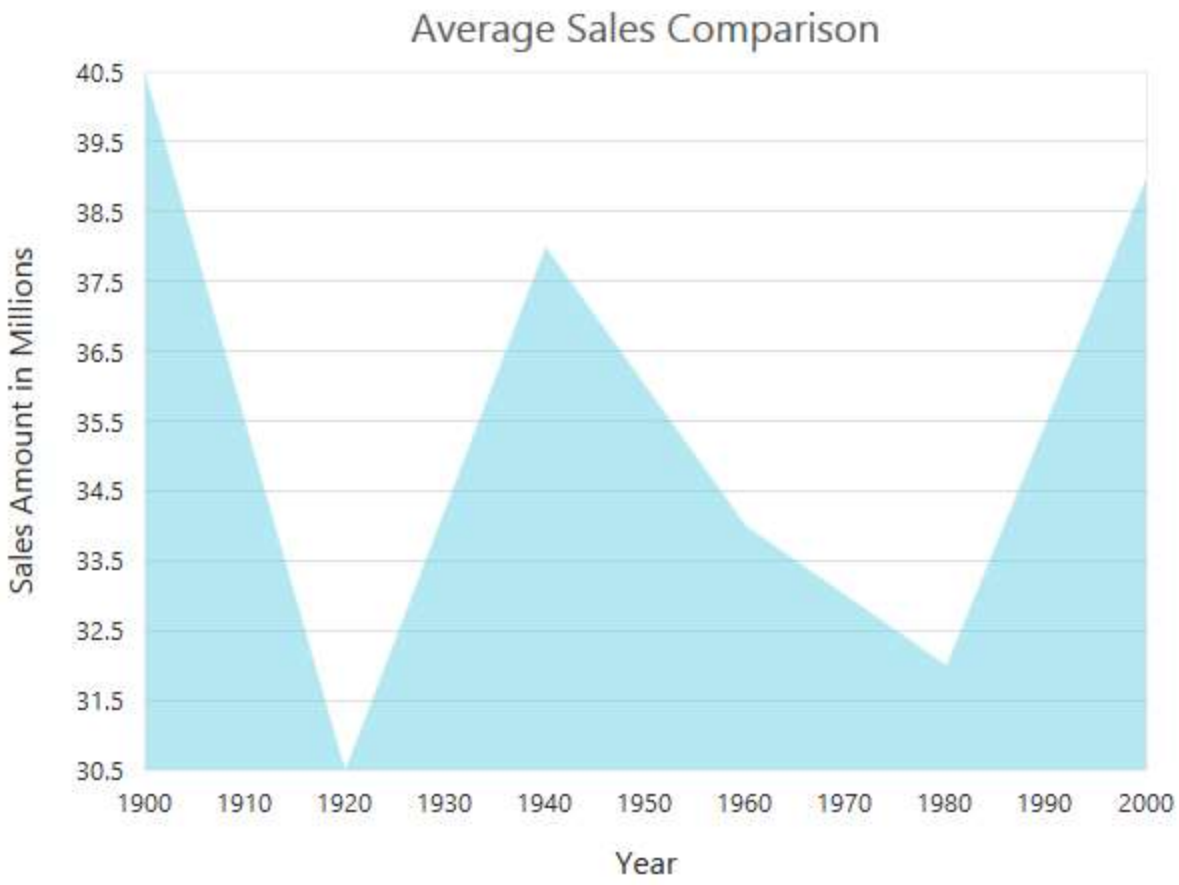


Chart after rounding axis range

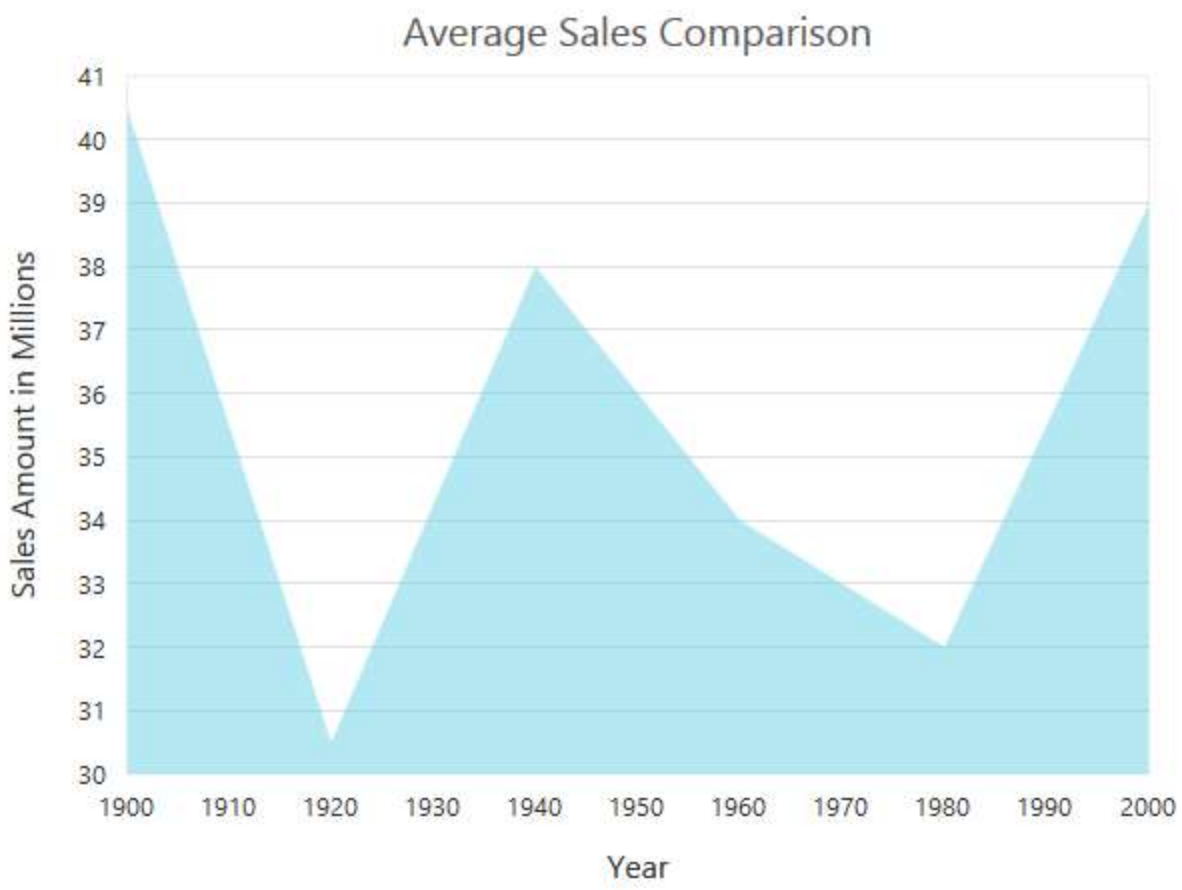


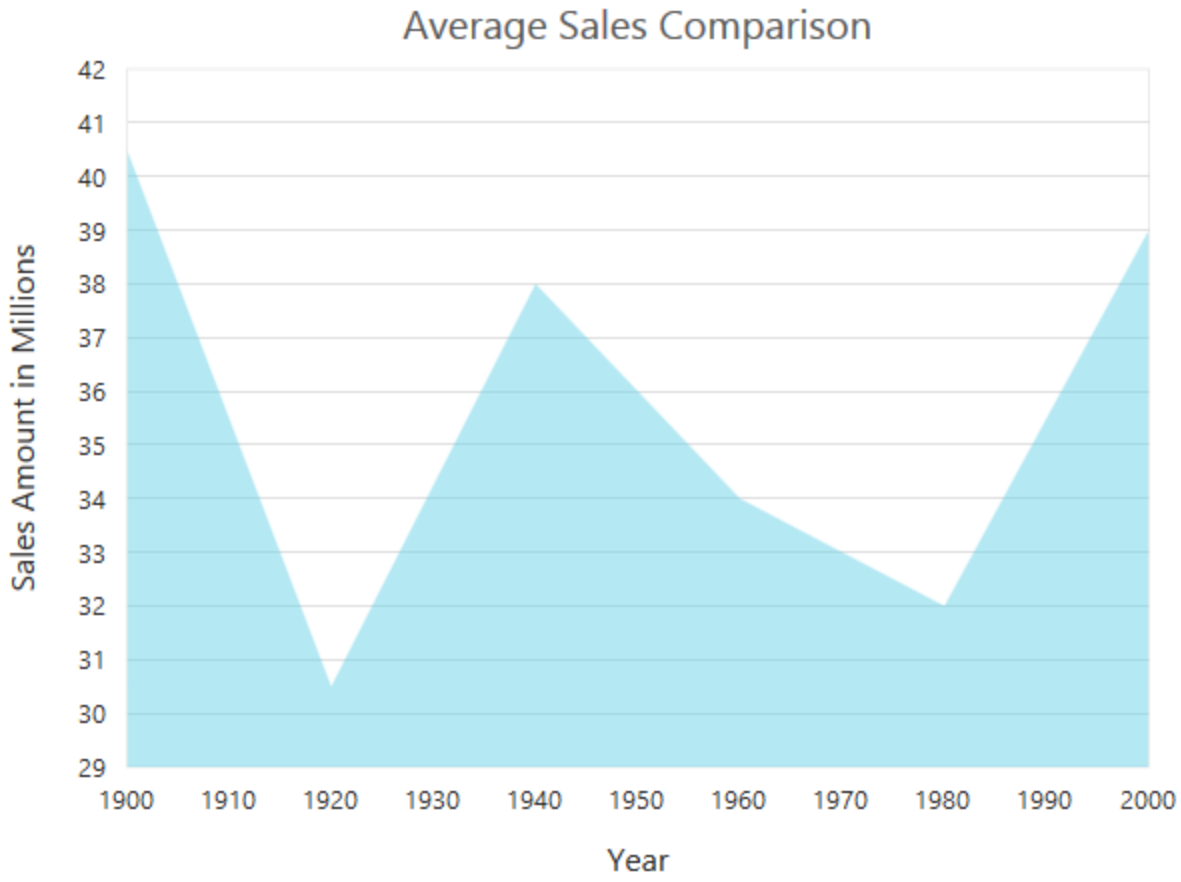
Additional

When the value of the RangePadding property is **Additional**, the axis range is rounded and an interval of the axis is added as padding to the minimum and maximum values of the range.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
//Applying additional range padding
px=>px.RangePadding(ChartRangePadding.Additional)
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

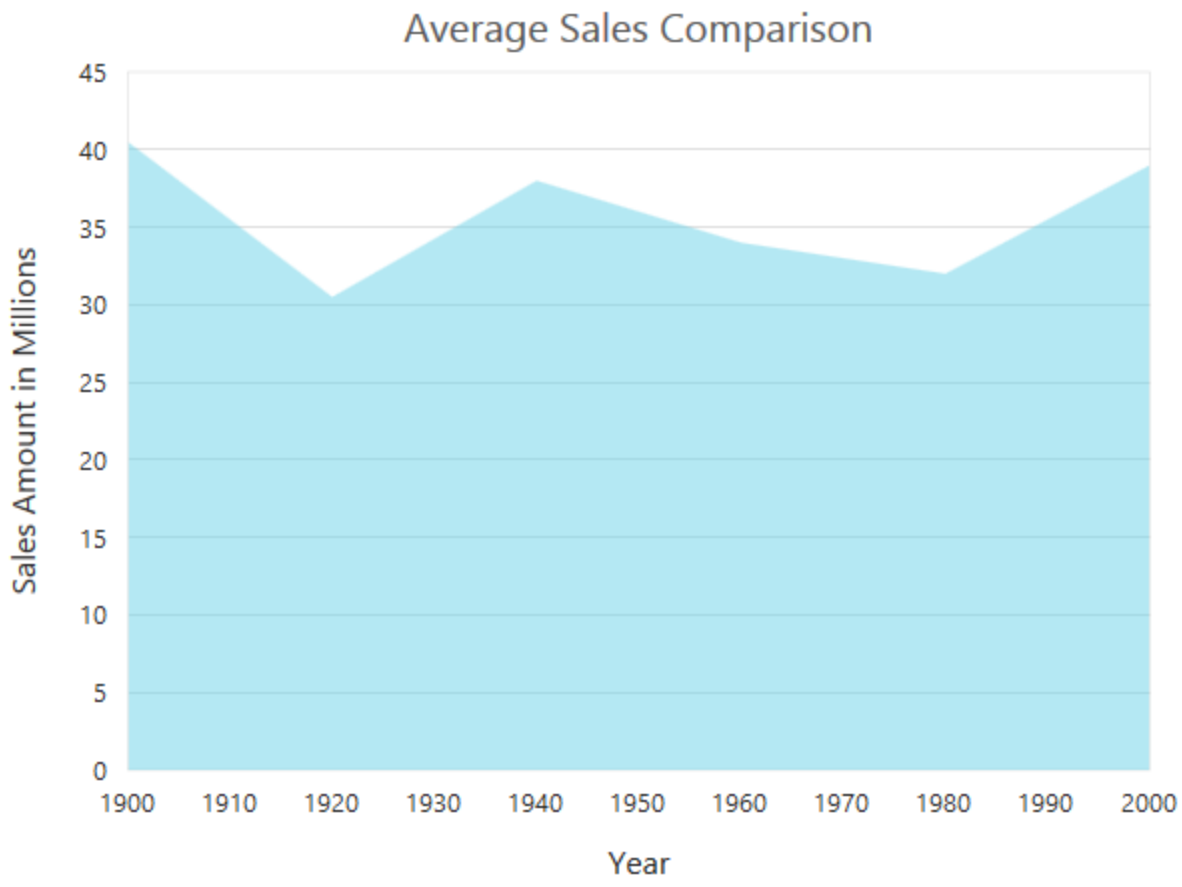


Normal

When the value of the RangePadding property is **Normal**, the padding is applied to the axis based on the range calculation.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
//Applying normal range padding
px=>px.RangePadding(ChartRangePadding.Normal)
)
// ...
)
```



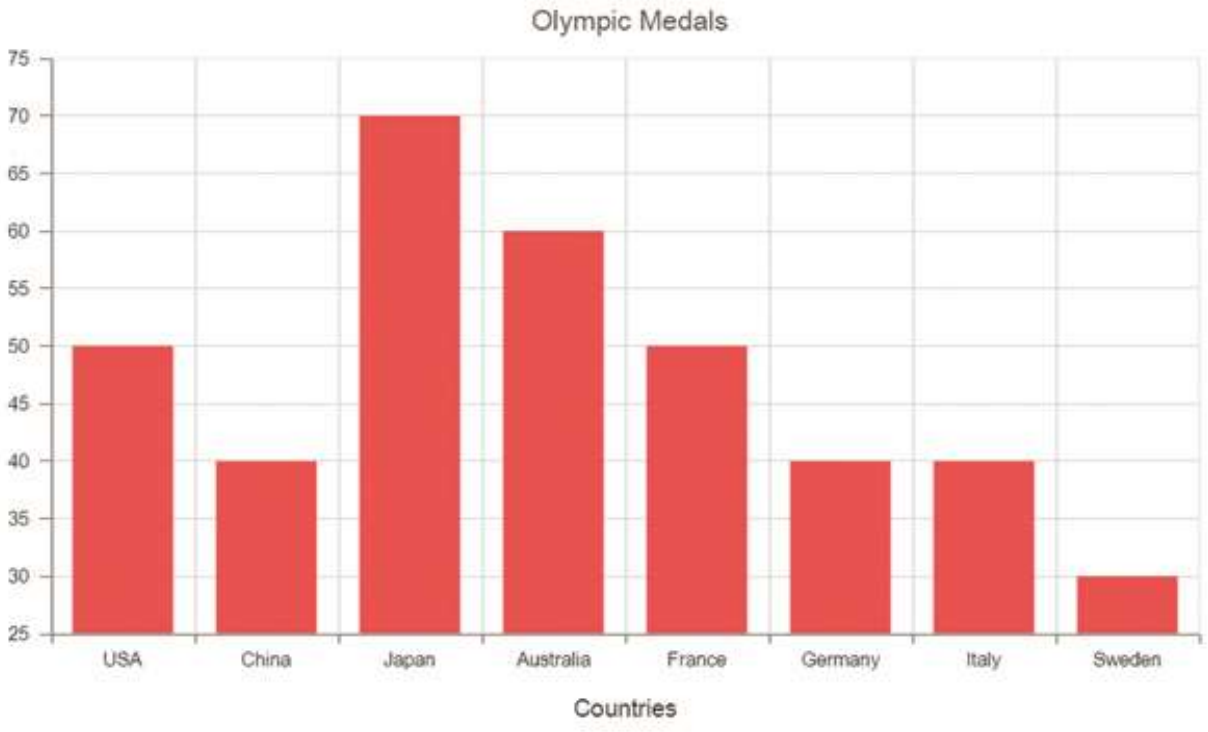
Customizing the starting range of the axis

By default the Y axis will be always calculated from the value 0 for column, bar, stacking column and stacking bar series types. You can modify this behavior by setting false to the property **StartFromZero** in the axis. On setting this the axis minimum value will be calculated based on the value for the data points.

ASPX-CS

```
@(Html.EJ().Chart("container")
.PrimaryYAxis(axis =>
axis.RangePadding(ChartRangePadding.None).StartFromZero(false))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



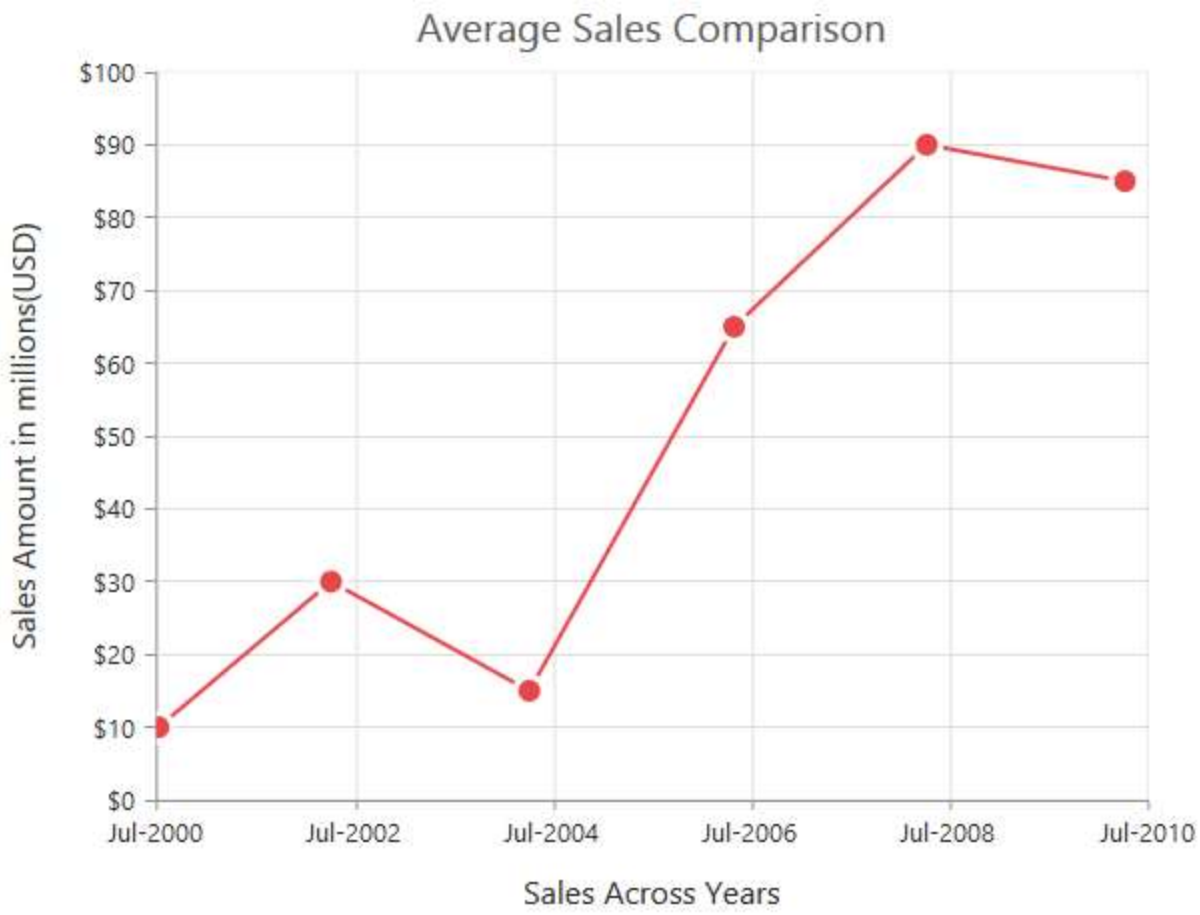
DateTime Axis

Date time axis uses date time scale and displays the date time values as axis labels in the specified format. To use date time axis, set the ValueType property of the axis to **Datetime**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Use date time scale in primary X axis
px=>px.ValueType(AxisValueType.Datetime)
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



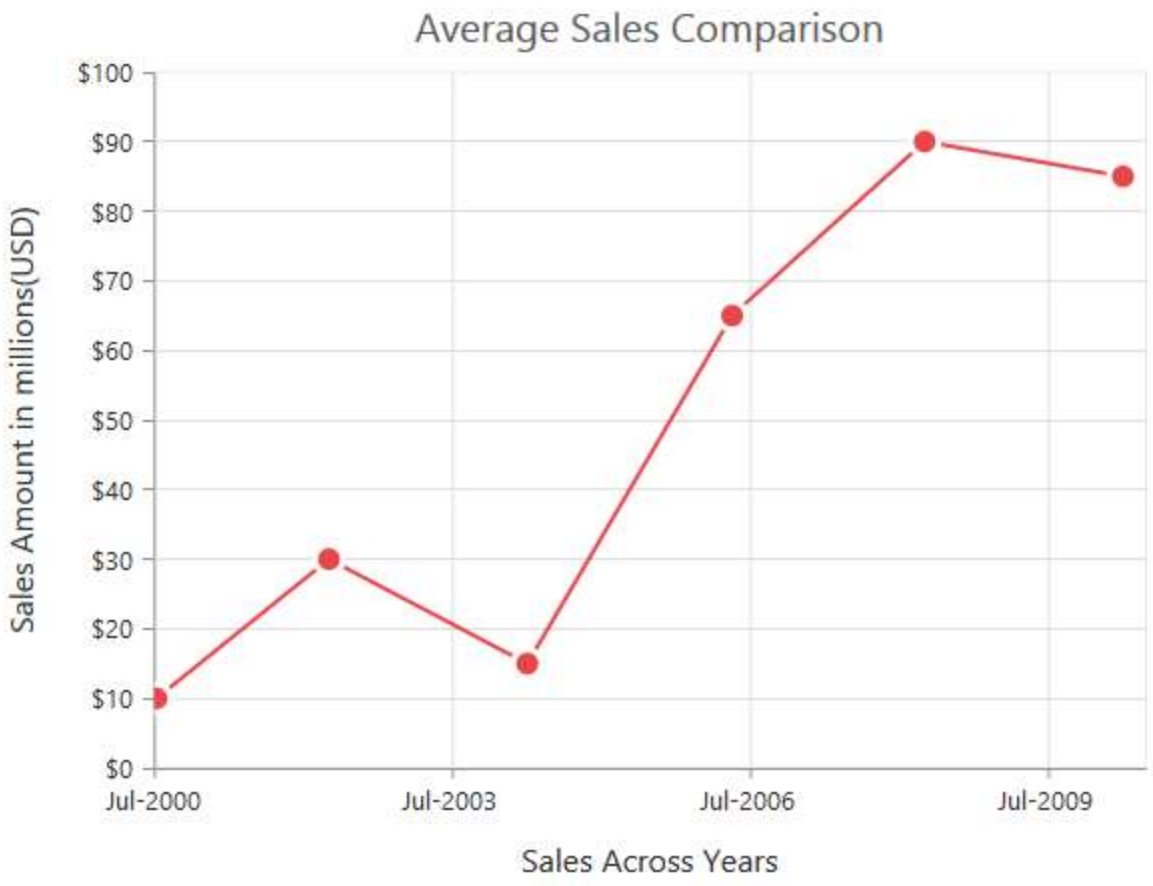
Click here to view our online demo sample for date time axis.

Customizing date time range

Axis range can be customized by using the Range property to set the **Minimum**, **Maximum** and **Interval** values. Nice range is calculated automatically based on the provided data, by default.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Customizing X-axis date time range
axis=>axis.Range(range=>range.Min("2000/6/1").Max("2010/6/1"))
)
// ...
)
```



Date time intervals

Date time intervals can be customized by using the **Interval** and **IntervalType** properties of the axis. For example, when you set Interval as **2** and IntervalType as **Years**, it considers the 2 years as interval.

Essential Chart supports the following types of interval for date time axis.

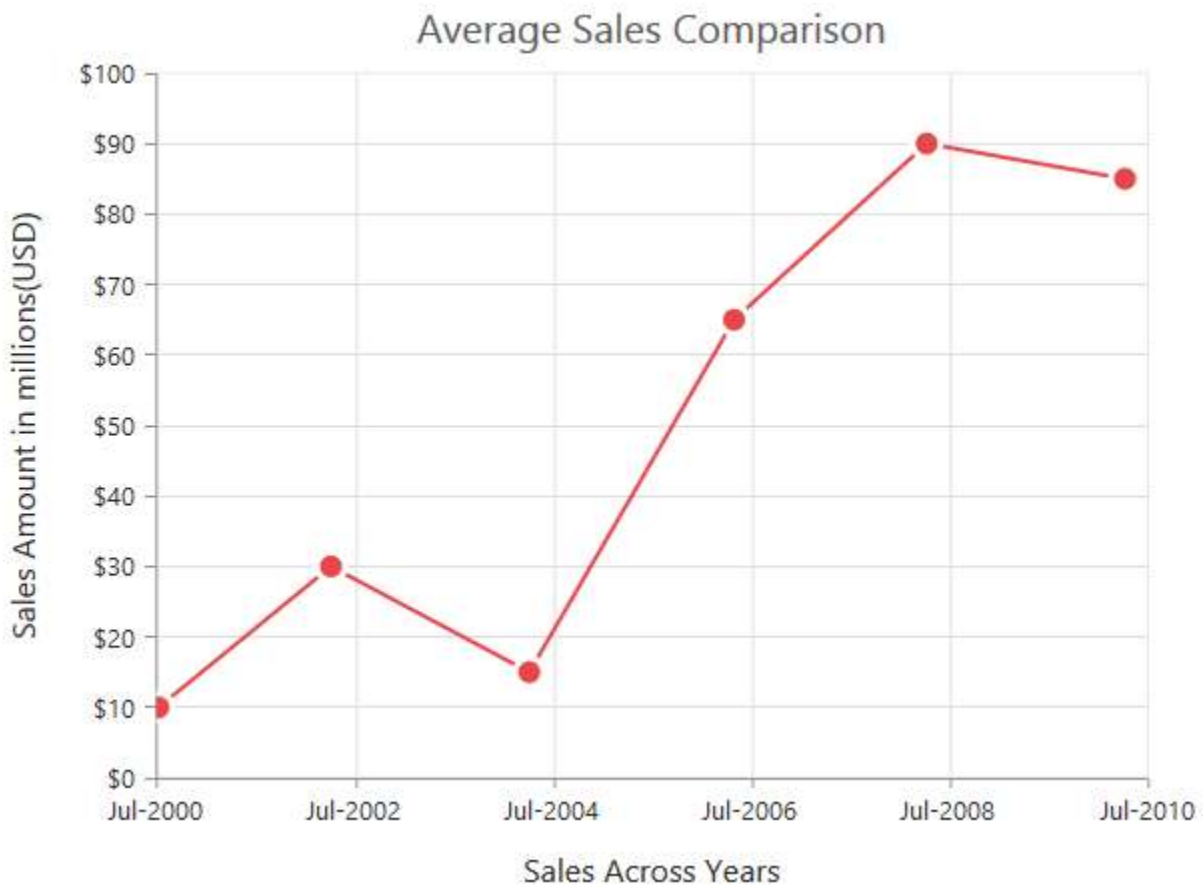
- Days
- Hours
- Milliseconds
- Minutes
- Months
- Seconds
- Years

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Customizing X-axis date time range
axis=>axis.Range(range=>range.Interval(2)).IntervalType(ChartIntervalType.Ye
ars)
)
// ...
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```



Apply padding to the range

Padding can be applied to the minimum and maximum extremes of the range by using the **RangePadding** property. Date time axis supports the following types of padding

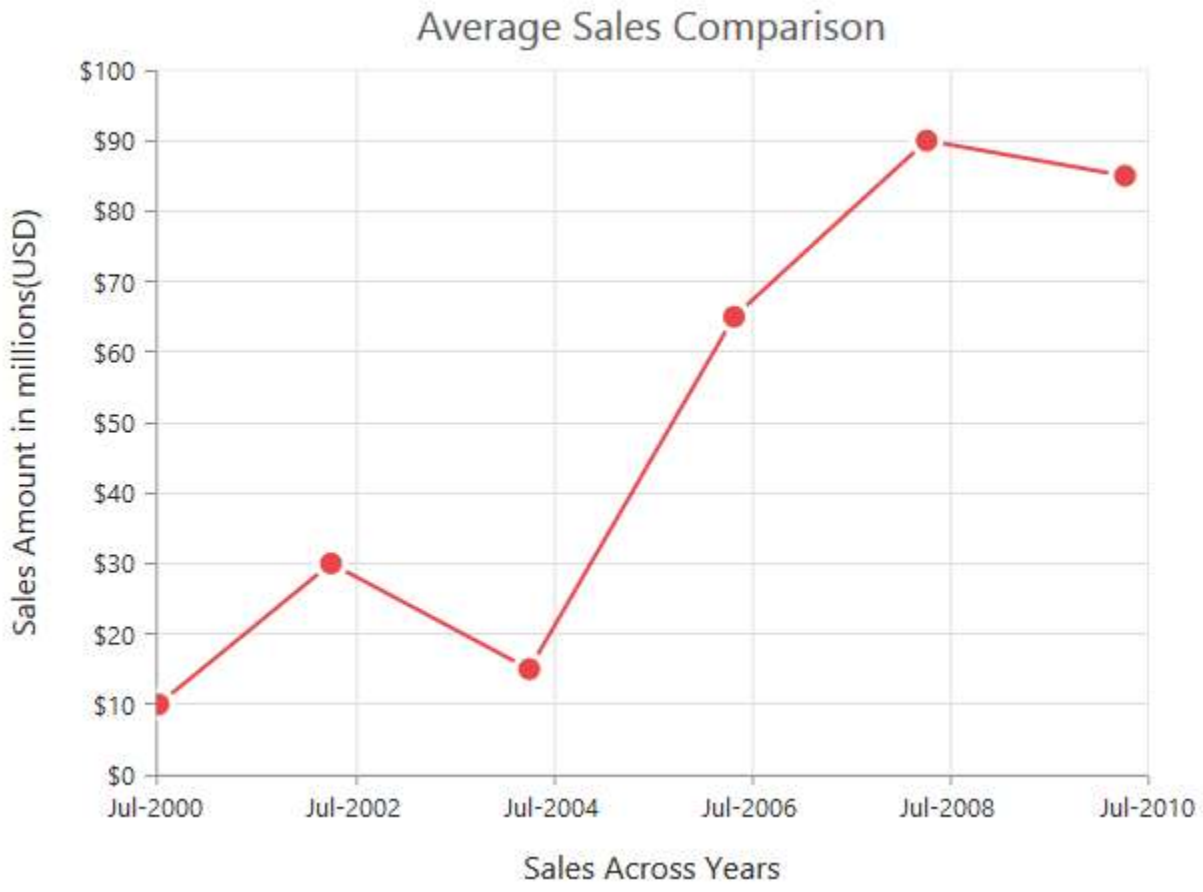
- None
- Round
- Additional

None

When the value of the RangePadding property is **None**, padding is applied to the axis. This is also the default value of the rangePadding.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Applying none as range padding
px=>px.RangePadding(ChartRangePadding.None)
)
// ...
)
```



Round

When the value of the RangePadding property is **Round**, the axis range is rounded to the nearest possible date time value.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Applying round as range padding
px=>px.RangePadding(ChartRangePadding.Round)
)
// ...
)
```

Chart before rounding axis range

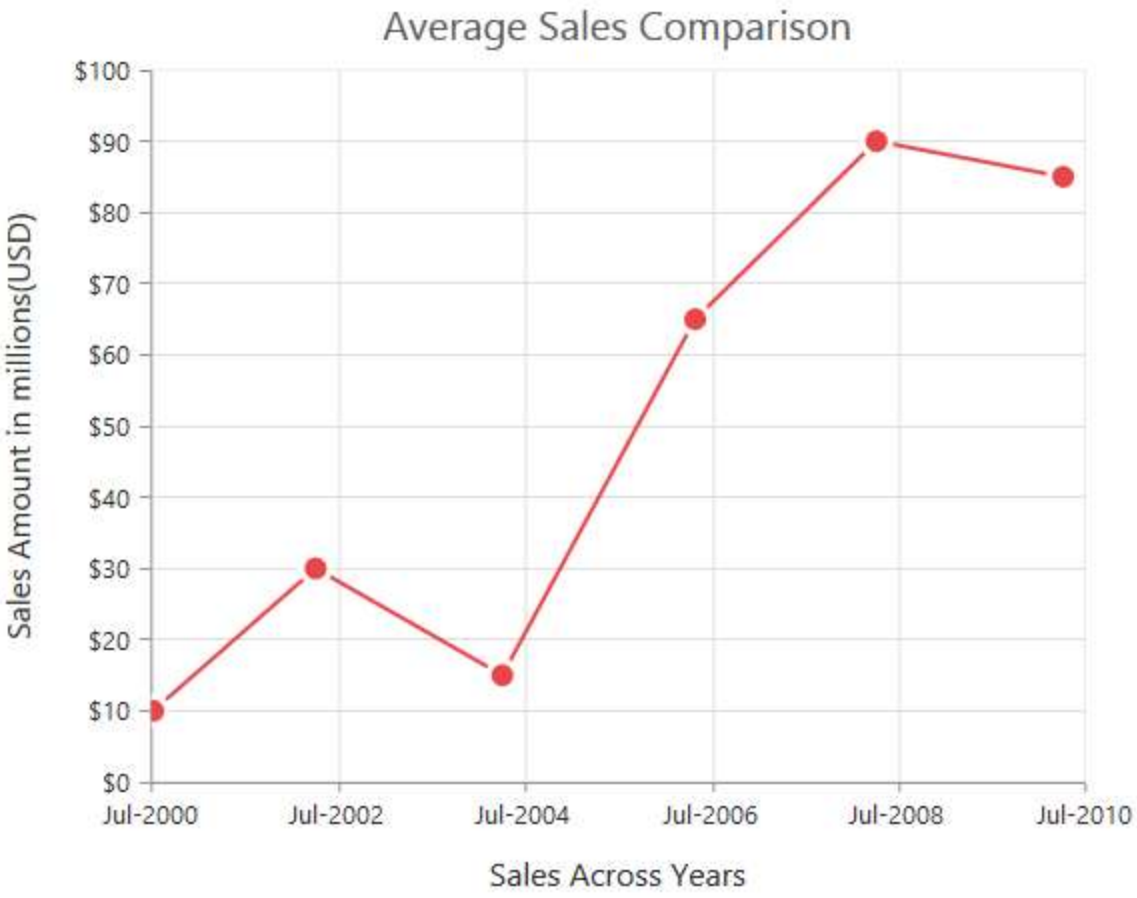


Chart after rounding axis range

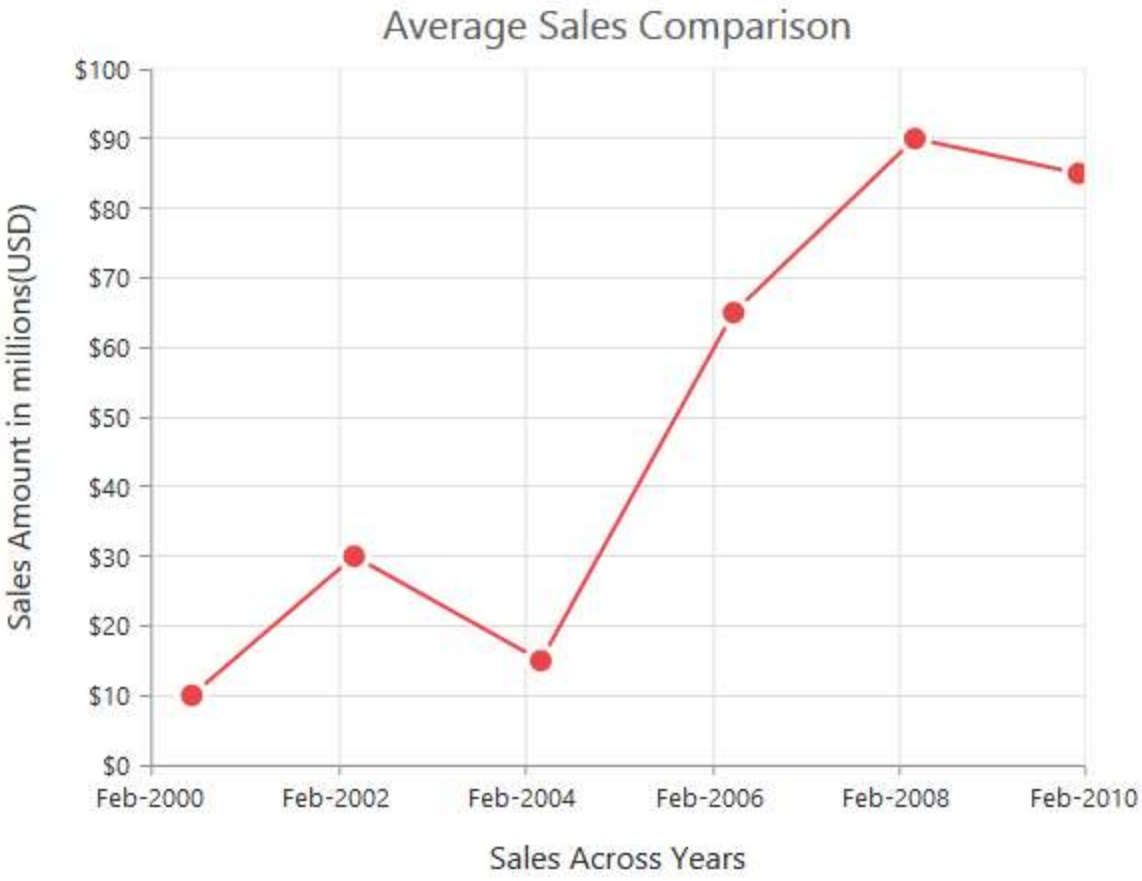
Copyright © 2001 - 2020 Syncfusion Inc.



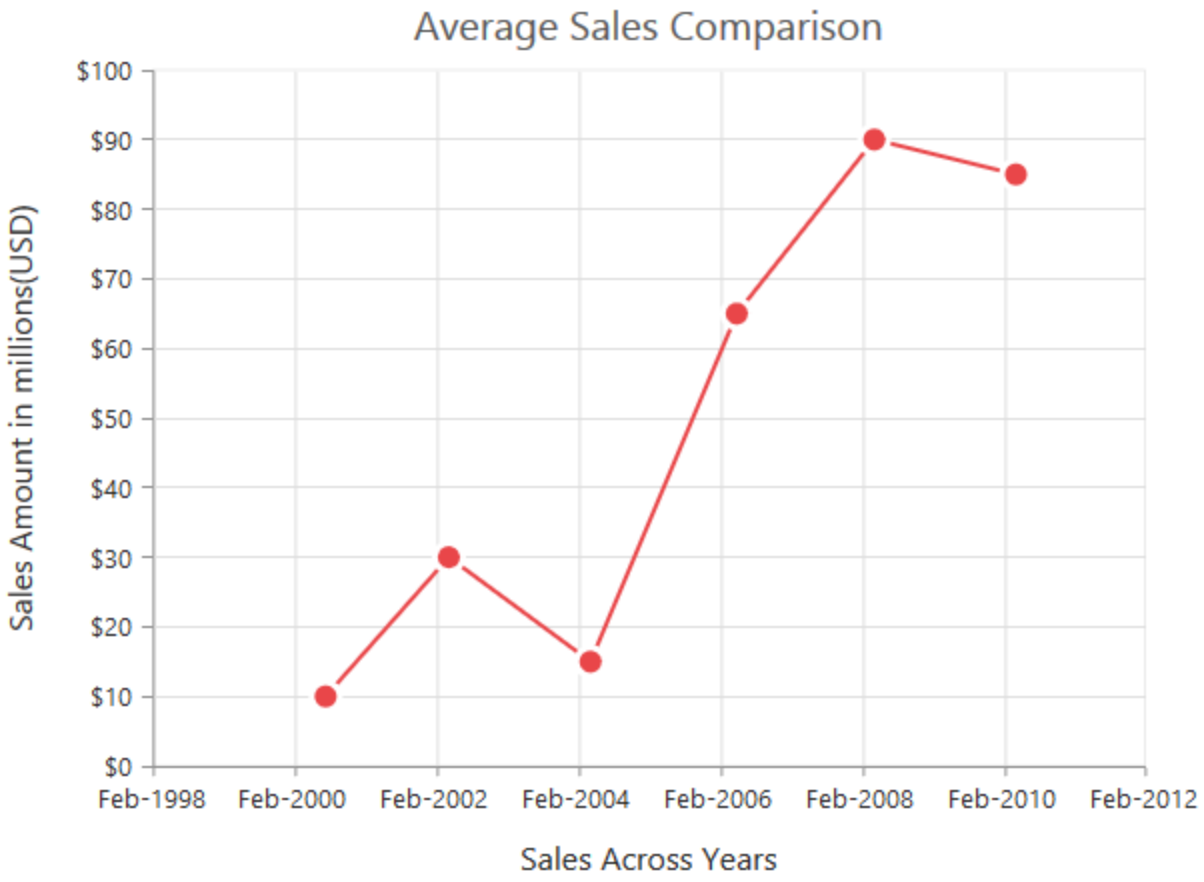
Additional

When the value of the RangePadding property is **Additional**, the range is rounded and date time interval of the axis are added as padding to the minimum and maximum extremes of the range.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Applying additional as range padding
px=>px.RangePadding(ChartRangePadding.Additional)
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



DateTime Category Axis

DateTime category axis takes date time value as input but behaves like category axis. This is used to display the date time values with nonlinear intervals (used to depict the business days by skipping holidays). To use date time axis, set the **ValueType** property of the axis to **DatetimeCategory**.

ASPX-CS

```
@(Html.EJ().Chart("container")
.PrimaryXAxis(axis => axis.ValueType(AxisValueType.DateTimeCategory))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Click here to view our online demo sample for date time axis.

Customizing DateTime Category range

Axis range can be customized by using the *range* property to set the **Minimum**, **Maximum** and **Interval** values. Datetime category axis takes numeric input for minimum and maximum property.

ASPX-CS

```
@(Html.EJ().Chart("container")
.PrimaryXAxis(
//Customizing X axis date time category range
axis => axis.Range(range => range.Min(0).Max(4)))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

DateTime Category intervals

Date time category intervals can be customized by using the **Interval** and **IntervalType** properties of the axis. For example, when you set the intervalType as months, it displays only the first label of all the months from the data.

Essential Chart supports the following types of interval for date time category axis.

- Days
- Hours
- Milliseconds
- Minutes
- Months
- Seconds
- Years
- Auto

ASPX-CS

```
@(Html.EJ().Chart("container")
.PrimaryXAxis(axis => axis.IntervalType(ChartIntervalType.Months))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

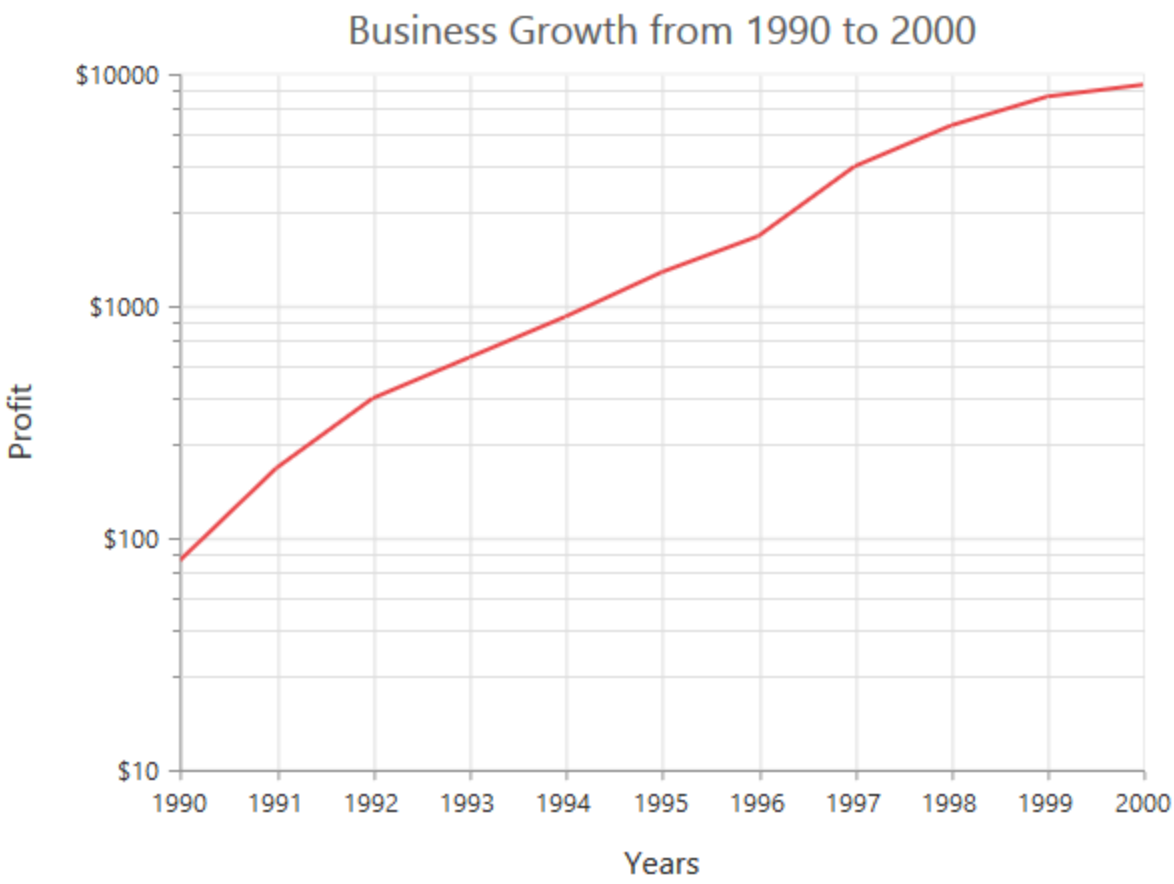
Logarithmic Axis

Logarithmic axis uses logarithmic scale and it is very useful in visualizing when the data has values with both lower order of magnitude **(eg: 10⁻⁶)** and higher order of magnitude **(eg: 10⁶)**. To use logarithmic axis, set the ValueType property of the axis to **Logarithmic**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Use logarithmic scale in primary X axis
px=>px.ValueType(AxisValueType.Logarithmic)
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



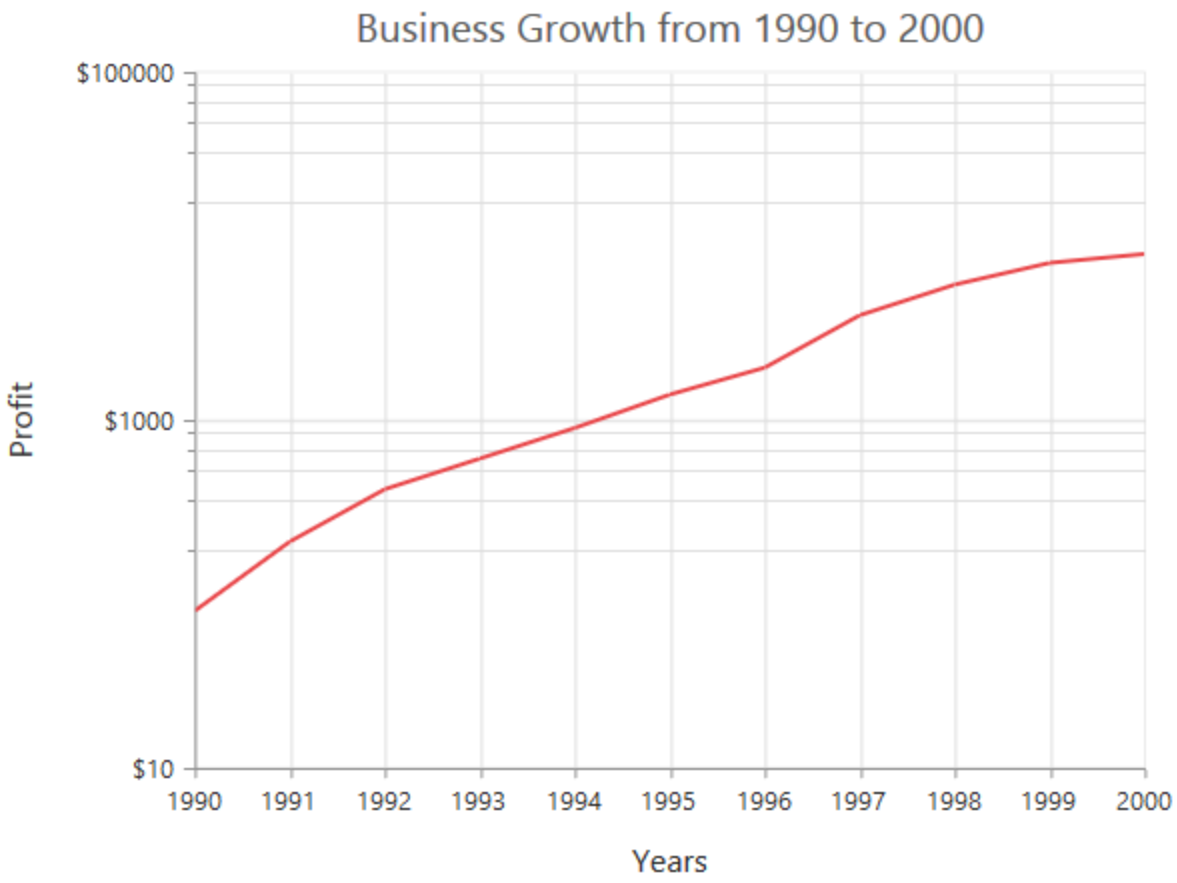
Click here to view our online demo sample link for logarithmic axis.

Customize Logarithmic range

Logarithmic range can be customized by using the Range property of the axis to change the Minimum, Maximum and Interval values. Nice range is calculated automatically based on the provided data, by default.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
//Customizing logarithmic range
px=>px.Range(range=>range.Min(1).Max(5))
)
// ...
)
```



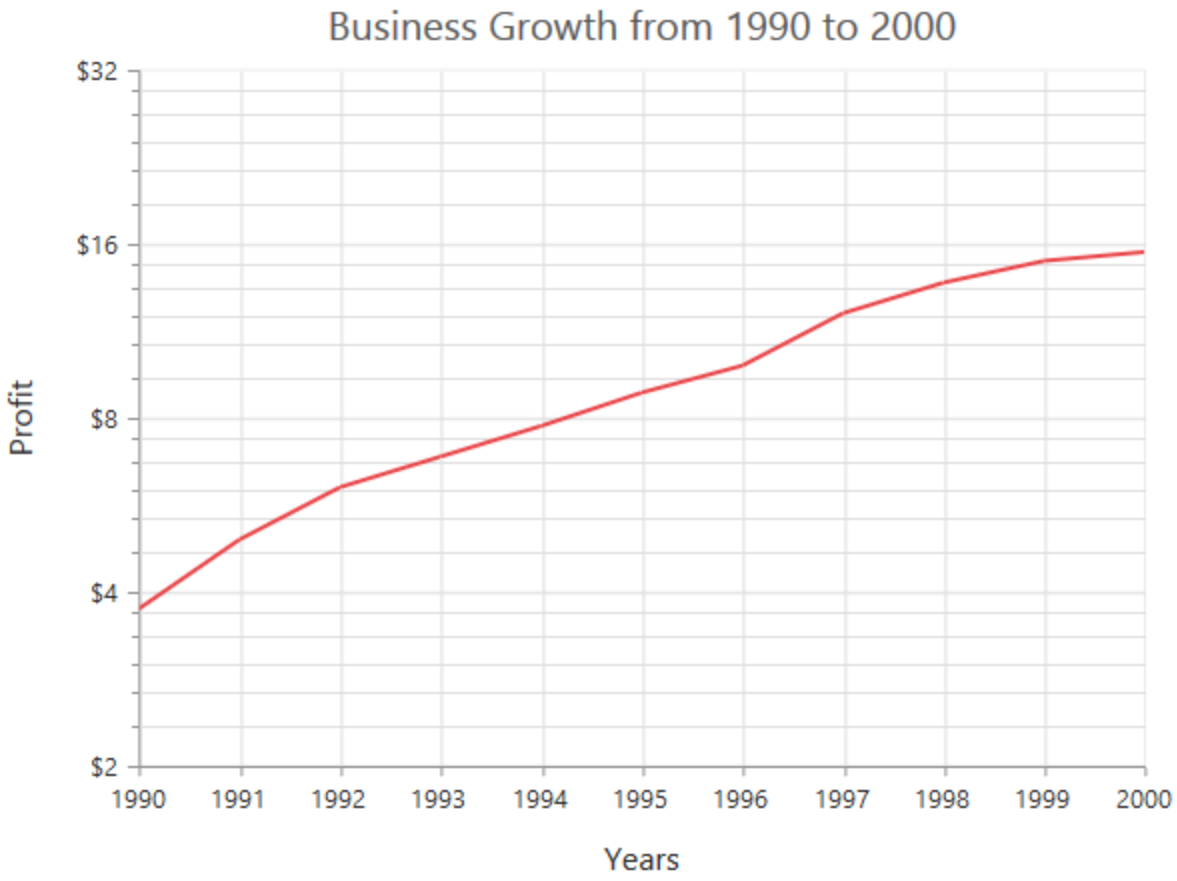
Logarithmic base

Logarithmic base can be customized by using the **LogBase** property of the axis. The default value of the LogBase is **10**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
//Customizing logarithmic base
px=>px.LogBase(2)
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



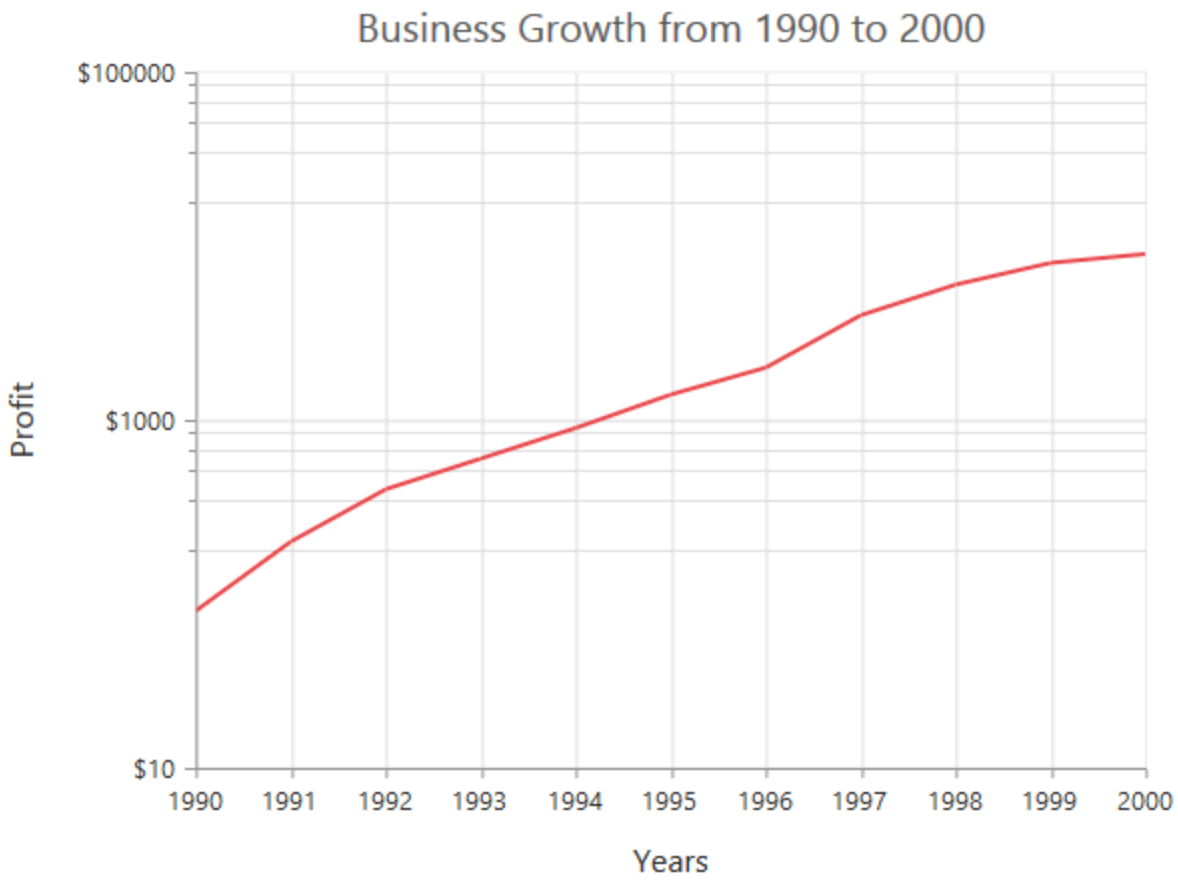
Logarithmic interval

Logarithmic axis interval can be customized by using the Interval property of the axis. When the logarithmic base is 10 and logarithmic interval is 2, then the axis labels are placed at an interval of 10². The default value of the interval is 1.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
//Customizing logarithmic interval
px=>px.Range(range=>range.Interval(2))
//....
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Label Format

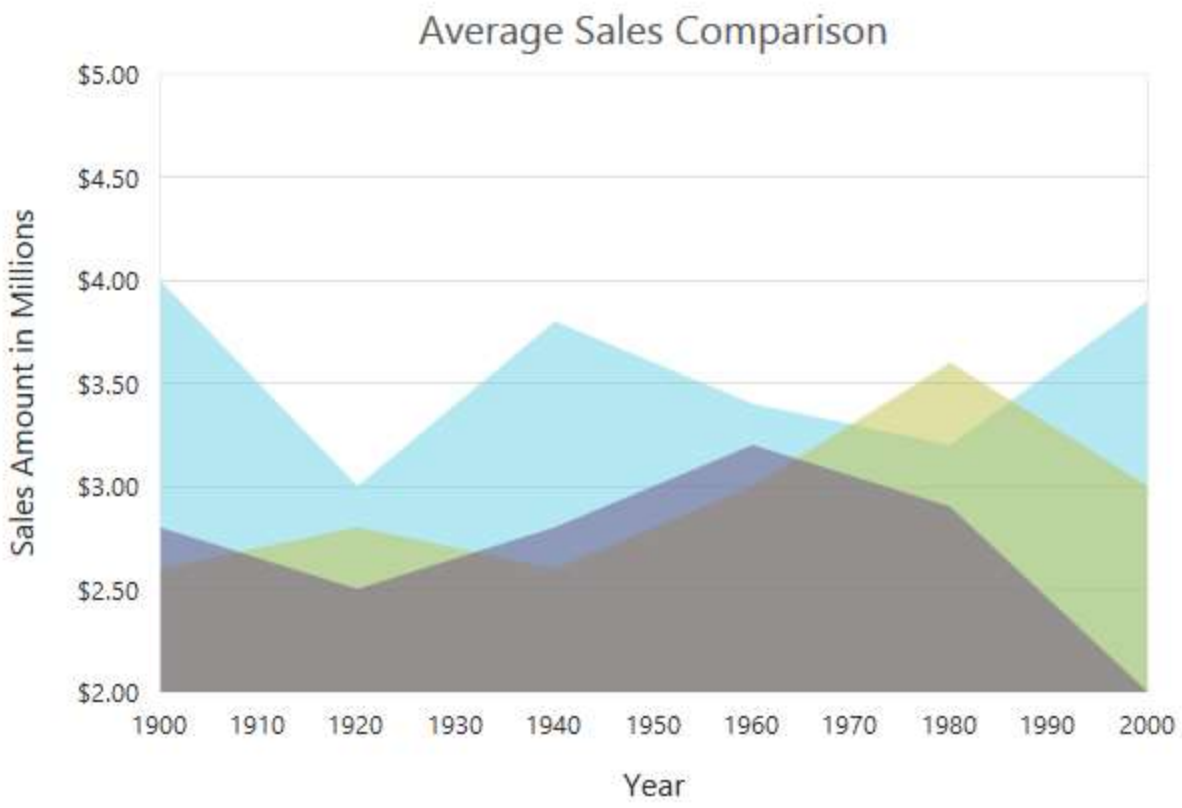
Format numeric labels

Numeric labels can be formatted by using the **LabelFormat** property. Numeric values can be formatted with n (number with decimal points), c (currency) and p (percentage) commands.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Applying currency format to axis labels
px=>px.LabelFormat("c")
//....
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



The following table describes the result of applying some commonly used label formats on numeric values.

Label Value	Label Format property value	Result	Description
1000	n1	1000.0	The Number is rounded to 1 decimal place
1000	n2	1000.00	The Number is rounded to 2 decimal place
1000	n3	1000.000	The Number is rounded to 3 decimal place
0.01	p1	1.0%	The Number is converted to percentage with 1 decimal place
0.01	p2	1.00%	The Number is converted to percentage with 2 decimal place
0.01	p3	1.000%	The Number is converted to percentage with 3 decimal place
1000	c1	$1,000.0	The Currency symbol is appended to number and number is rounded to 1 decimal place
1000	c2	$1,000.00	The Currency symbol is appended to number and number is rounded to 2 decimal place

Copyright © 2001 - 2020 Syncfusion Inc.

Format date time values

Date time labels can be formatted by using the **LabelFormat** property of the axis.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Formatting date time labels in date/Month name/Year format
px=>px.LabelFormat("dd/MMMM/yyyy")
//....
)
// ...
)
```

The following table describes the result of applying some common date time formats to the labelFormat property

Label Value	Label Format Property Value	Result	Description
new Date(2000, 03, 10)	dddd	Monday	The Date is displayed in day format
new Date(2000, 03, 10)	MM/dd/yyyy	04/10/2000	The Date is displayed in month/date/year format

Copyright © 2001 - 2020 Syncfusion Inc.

new Date(2000, 03, 10)	n3	1000.000	The Number is rounded to 3 decimal place
new Date(2000, 03, 10)	MMM	Apr	The Shorthand month for the date is displayed
new Date(2000, 03, 10)	t	12:00 AM	Time of the date value is displayed as label
new Date(2000, 03, 10)	hh:mm:ss	12:00:00	The Label is displayed in hours:minutes:seconds format

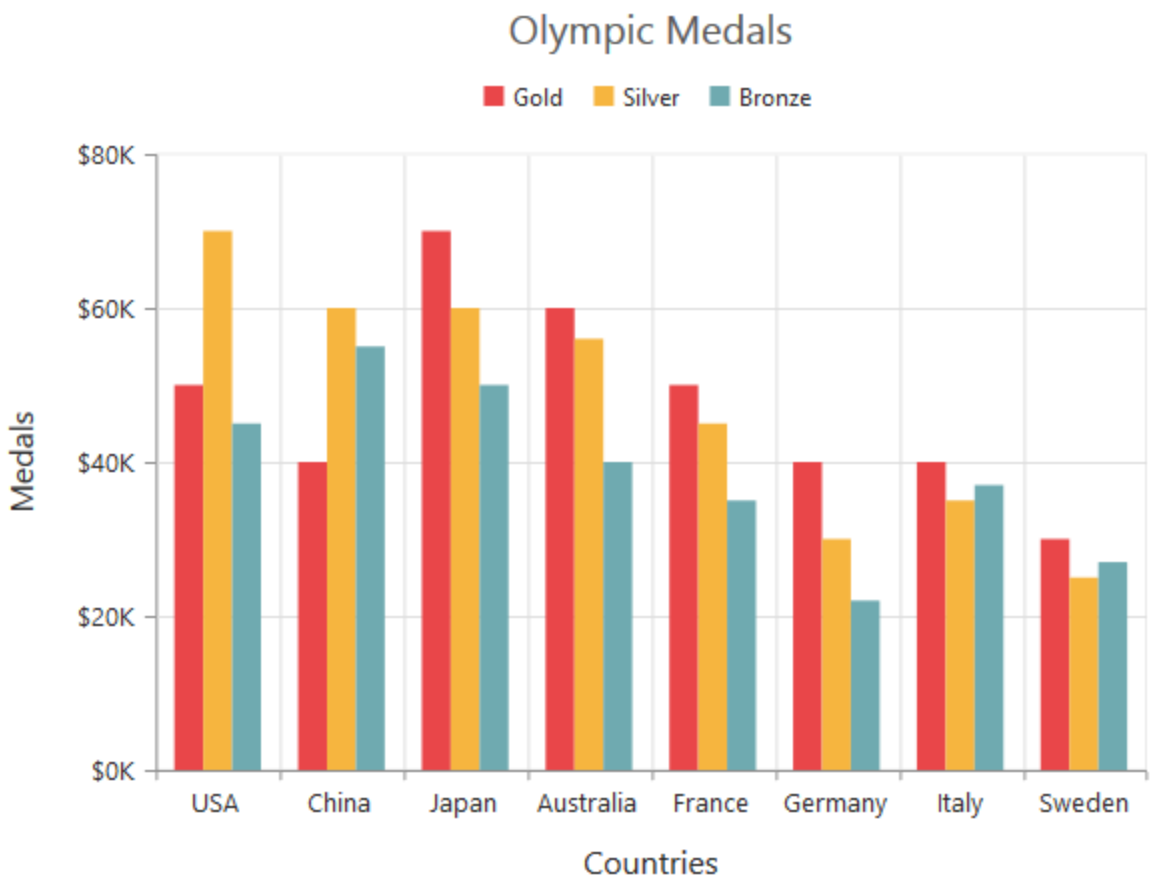
Custom label format

Prefix and suffix can be added to the category labels by using the LabelFormat property. You can use the *{value}* as placeholder text in your custom text, it is replaced with the corresponding axis label at the runtime.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Adding prefix and suffix to axis labels
px=>px.LabelFormat("${value} K")
//....
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Common axis features

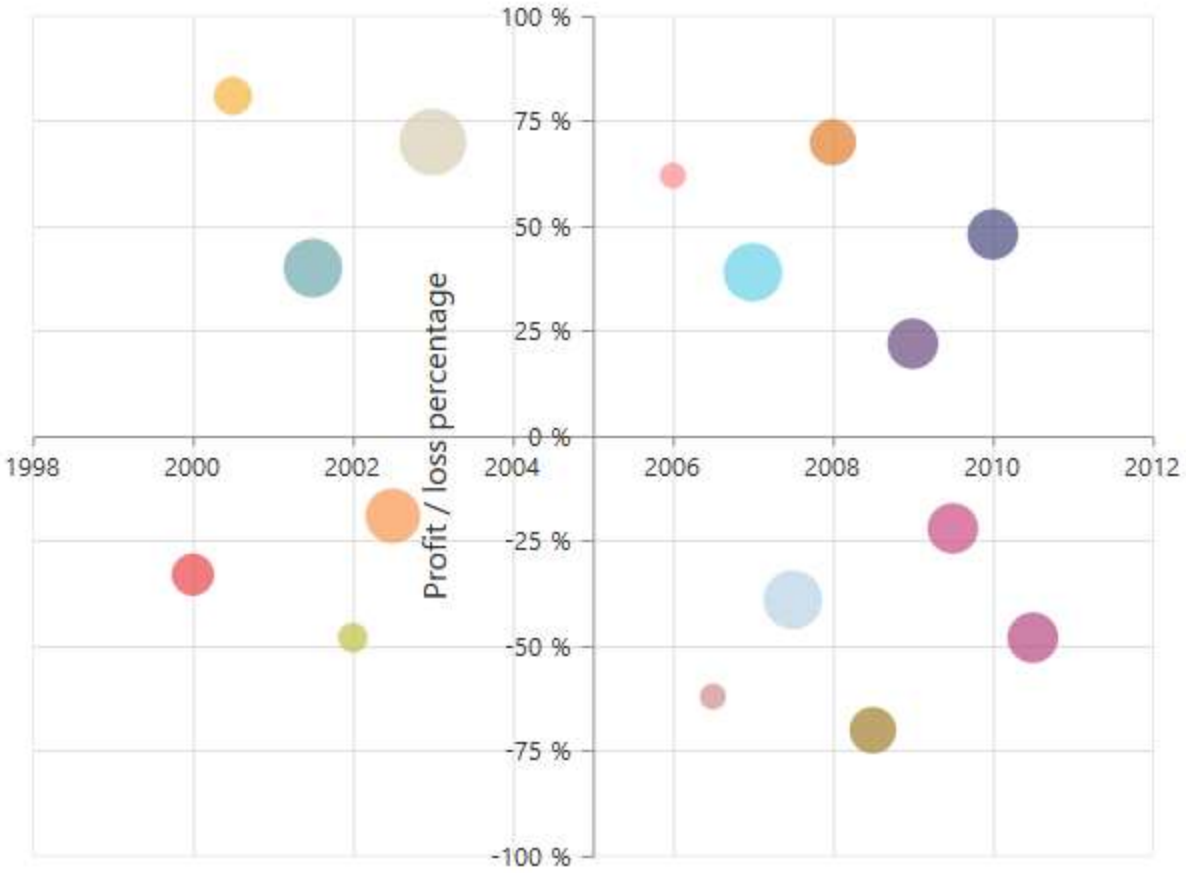
Customization of features such as axis title, labels, grid lines and tick lines are common to all the axis. Each of these features are explained in this section.

Axis Crossing

Axis can be positioned anywhere in chart area using the **CrossesAt** property of axis. This property specifies where the horizontal axis should intersect or cross the vertical axis and vice versa. Default value of *CrossesAt* property is null.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Crosses primary Y axis at 0
px=>px.CrossesAt(0)
//....
)
// ...
)
```



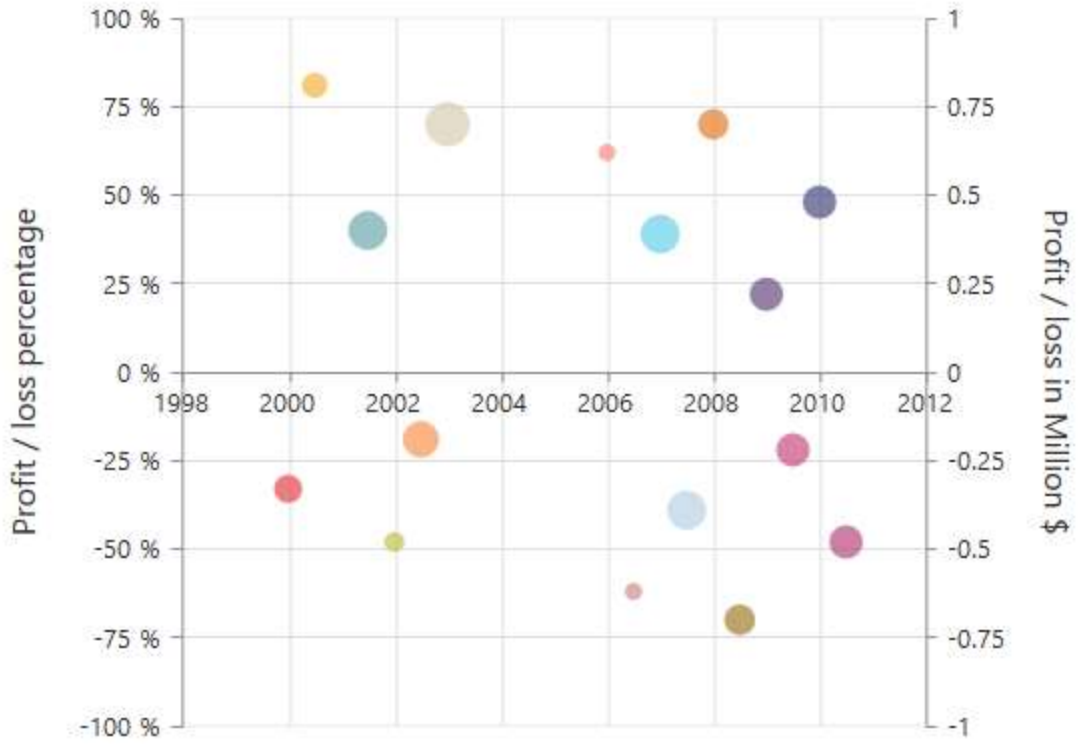
Crossing a specific Axis

The **CrossesInAxis** property takes axis name as input and determines the axis used for crossing. By default all the horizontal axes crosses in primary Y axis and all the vertical axes crosses in primary X axis.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Crosses secondary vertical axis at -0.2
px=>px.CrossesAt(-0.2)
.CrossesInAxis('SecondaryYAxis')
//....
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

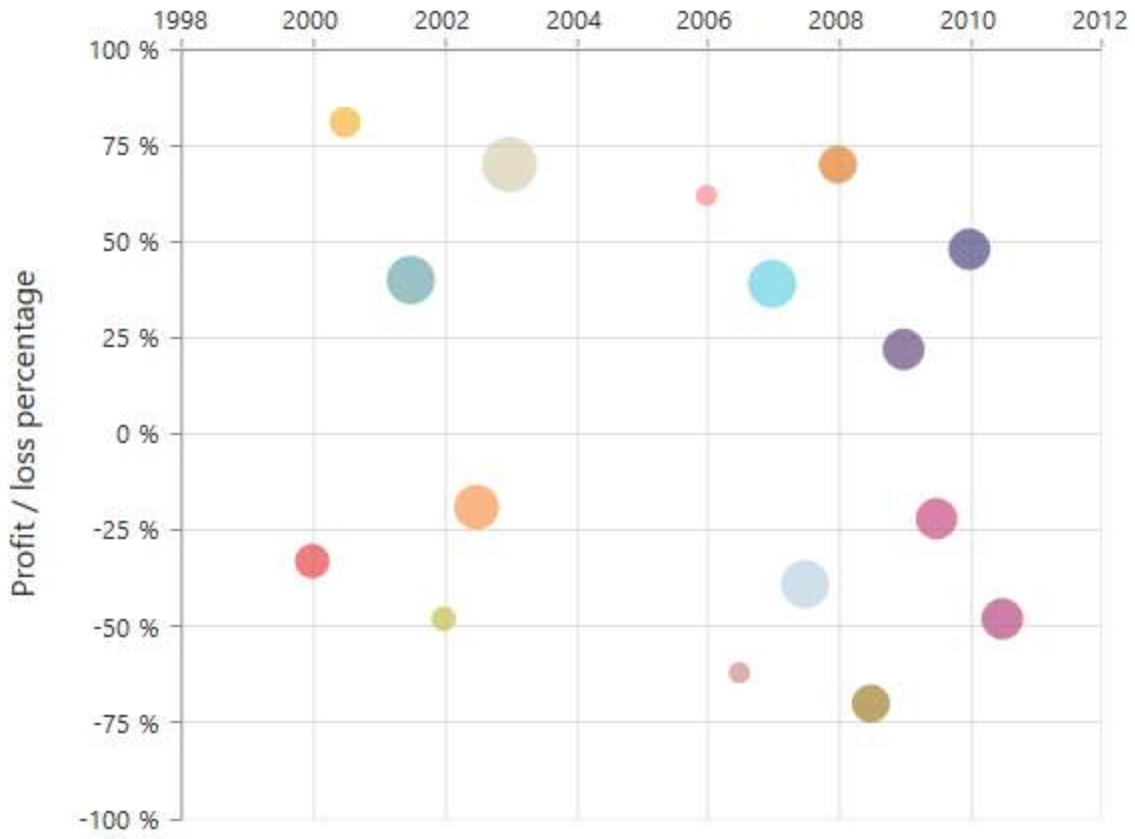


Axis will be placed in the opposite side if value of *CrossesAt* property is greater than the maximum value of crossing axis (axis name provided through *CrossesInAxis* property or primary Y axis for horizontal axis).

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Crosses primary Y axis at 200
px=>px.CrossesAt(200)
//....
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Positioning the axis elements while crossing

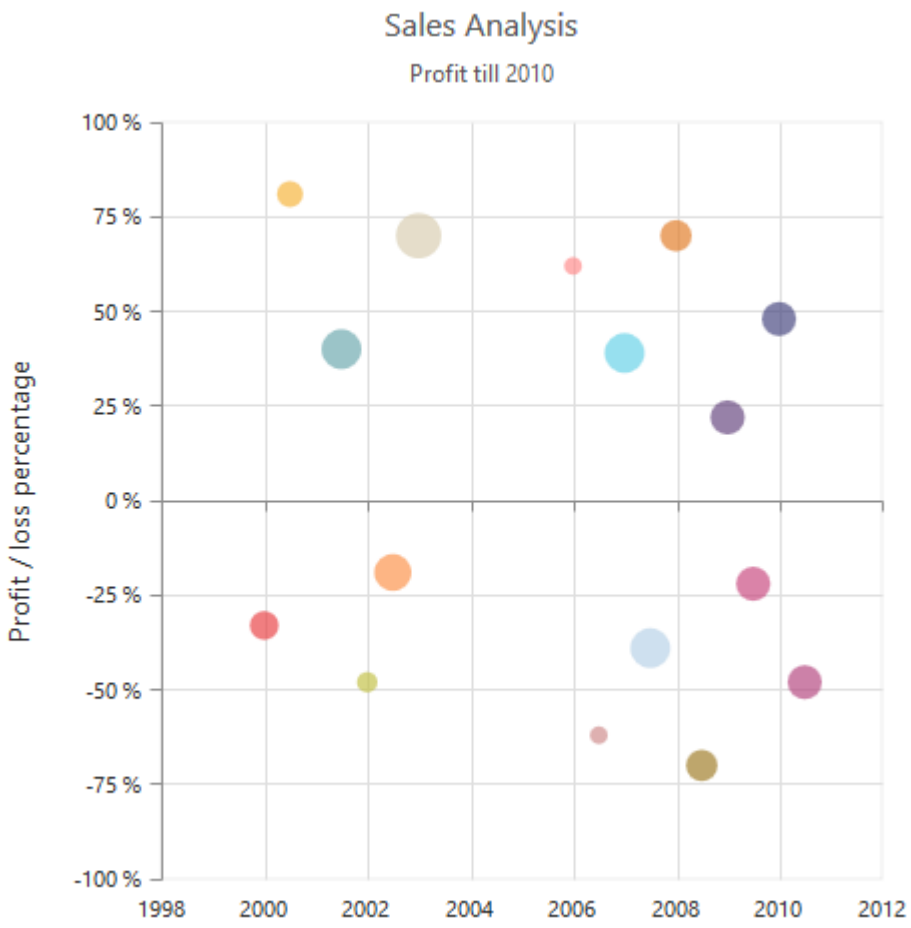
The ShowNextToAxisLine property is used for controlling the axis elements movement along with the axis line while axis crossing is performed. When the showNextToAxisLine is set as false only the axis line and the tick lines are placed at the crossing Value and the axis elements will be placed outside the chart area. The default value of ShowNextToAxisLine is **true**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Crosses primary Y axis at 0
px=>px.CrossesAt(0)
.ShowNextToAxisLine(false)
//....
)
// ...
)
```

The axis is placed at the crossing value without the axis elements

Copyright © 2001 - 2020 Syncfusion Inc.



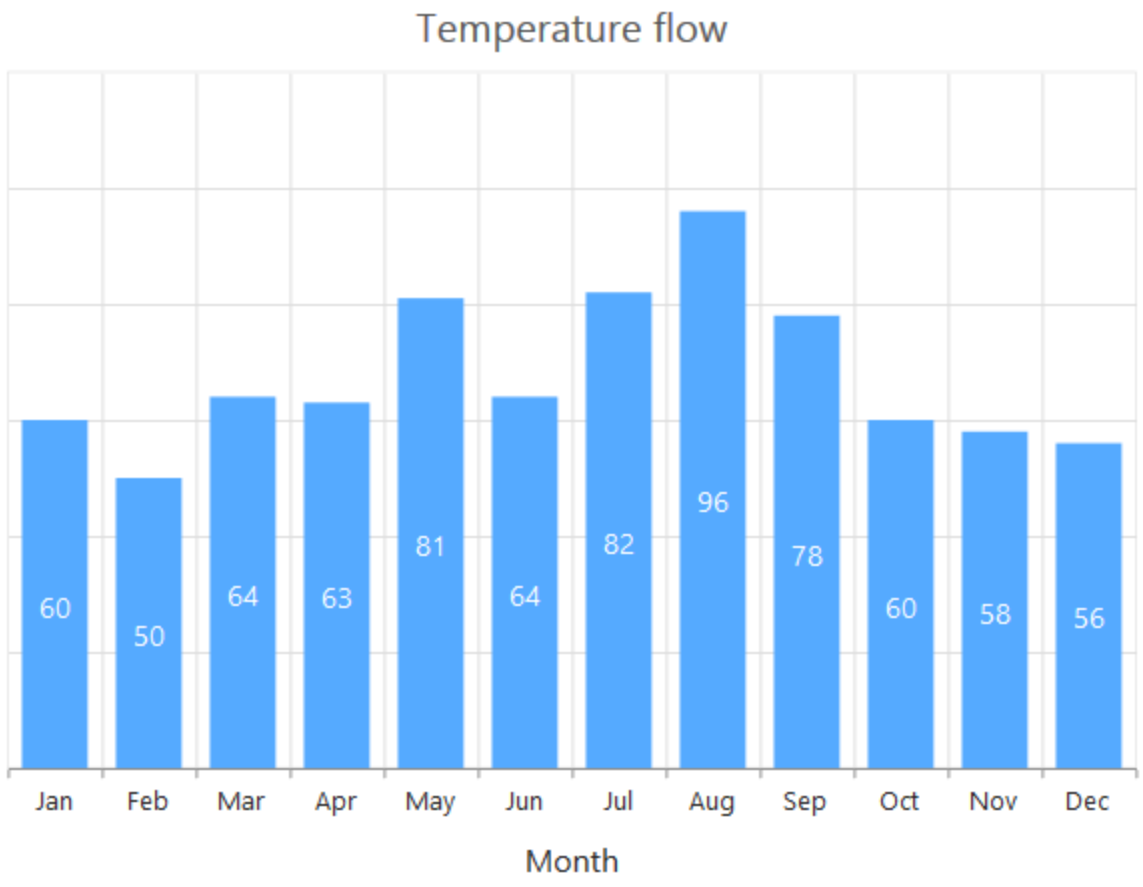
Axis Visibility

Axis visibility can be controlled by using the **Visible** property of the axis. The default value of the Visible property is **true**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(
//Disabling visibility of Y-axis
px=>px.Visible(false)
//....
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



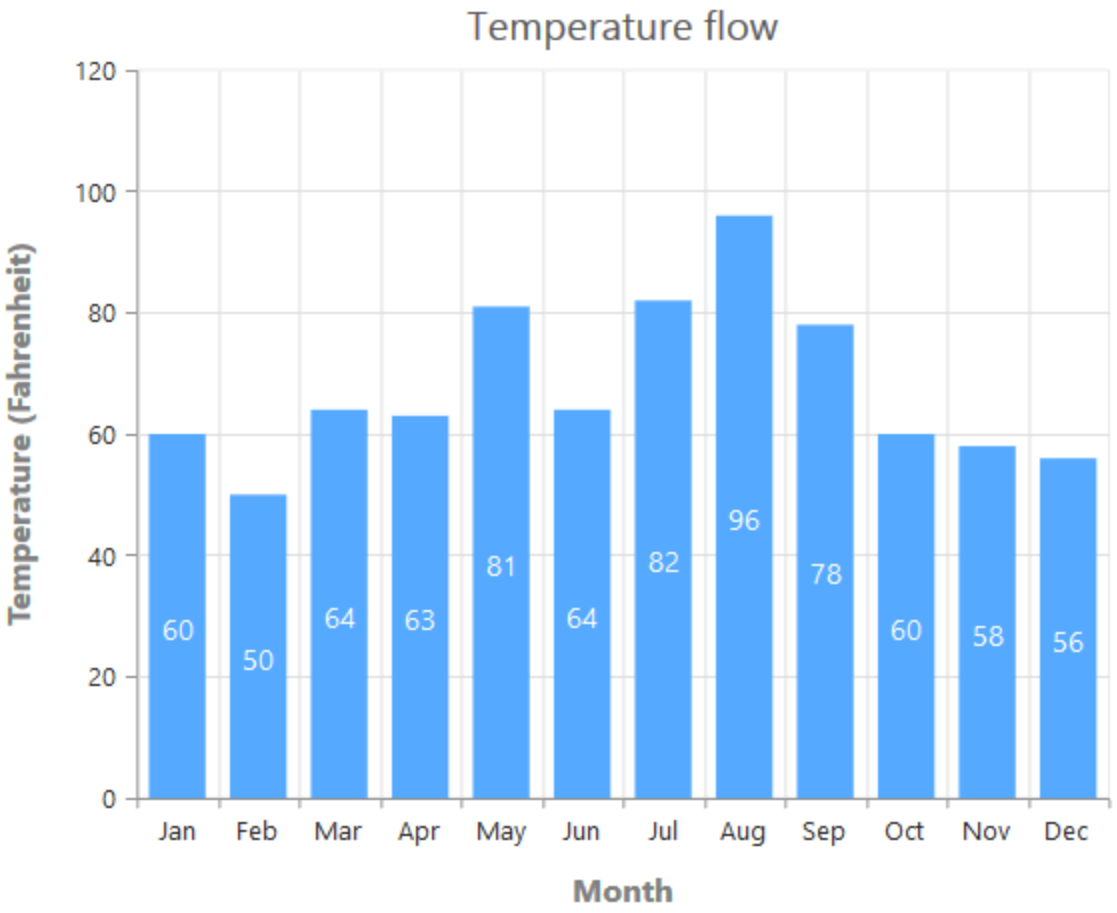
Axis title

The **Title** property in the axis provides options to customize the text and font of the axis title. Axis does not display the title, by default. Title text can also be trimmed based on the title text length or specified length.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Customizing axis title
px=>px.Title(title=>title.EnableTrim(true)
.MaximumTitleWidth(80)
.Text("Month")
.Font(ft=>ft.Color("grey").
FontWeight(ChartFontWeight.Bold)
.FontFamily("Segoe UI")
.Size("16px")))
//....
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

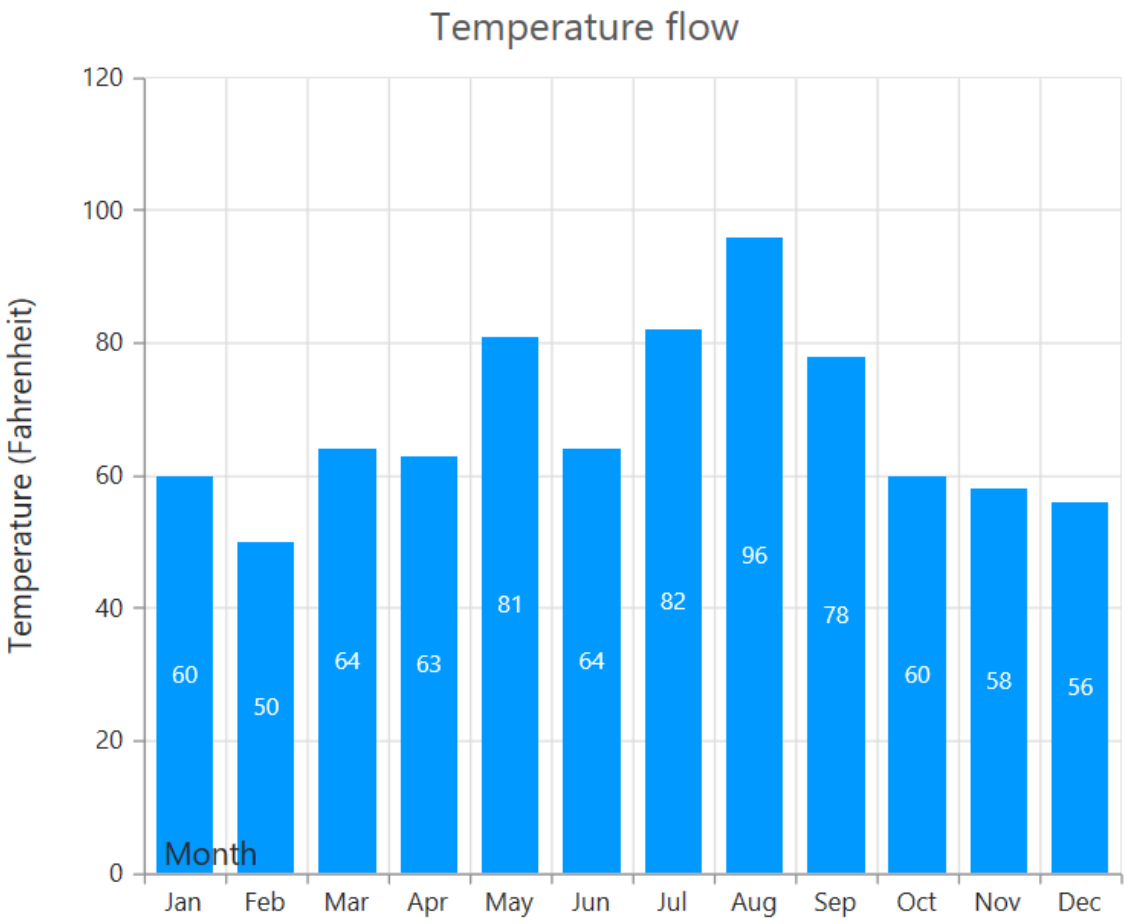


You can modify the position of the axis title either inside or outside the chart area using the property **Position**. By default, it will be placed outside the chart area. In addition, you can also change the alignment of the title to near, far and center by **Alignment** property, using **Offset** property you can change the position with respect to pixels.

ASPX-CS

```
@(Html.EJ().Chart("container")
.PrimaryXAxis(pr => pr.Title(title => title
.AxisTitlePosition(AxisTitlePosition.Inside).Alignment(Alignment.Near).Offse
t(10))
))
```

Copyright © 2001 - 2020 Syncfusion Inc.

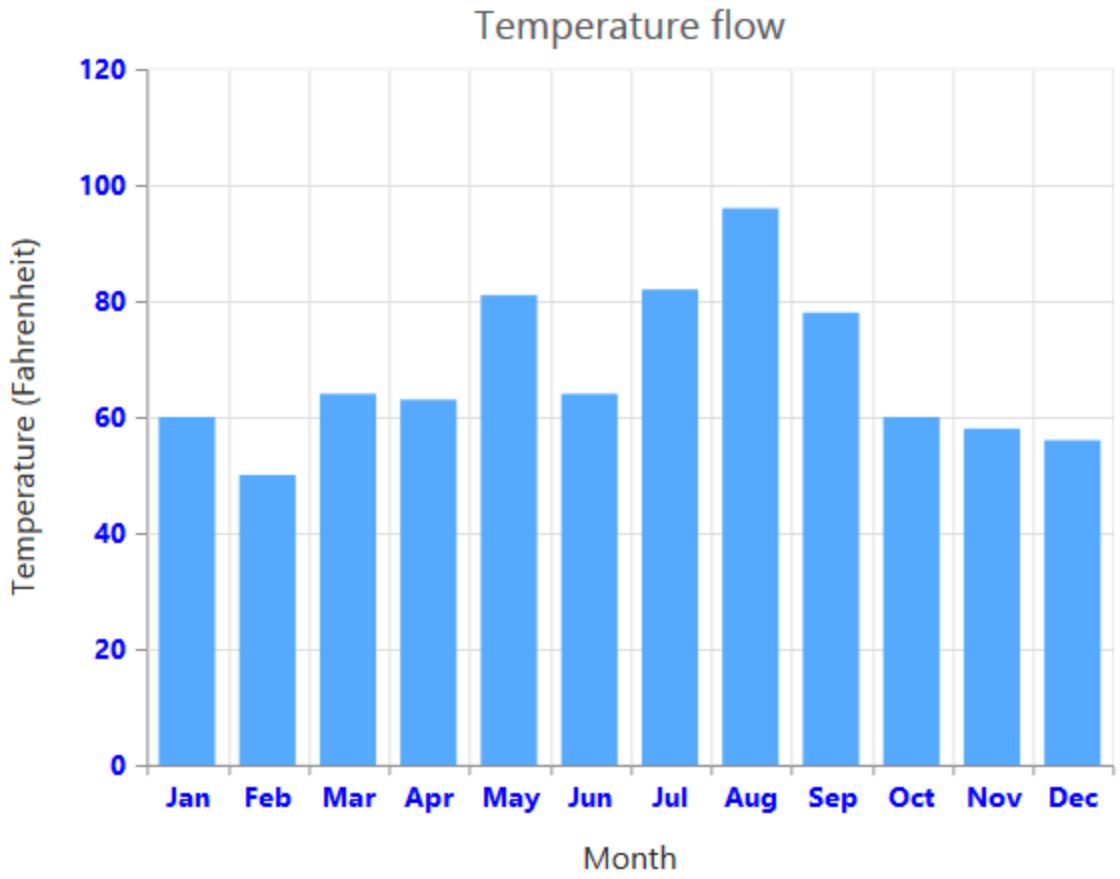


Label customization

The **Font** property of the axis provides options to customize the FontFamily, Color, Opacity, Size and FontWeight of the axis labels.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Customizing label appearance
px=>px.Font(ft=>ft.Color("blue").
FontWeight(ChartFontWeight.Bold)
.FontFamily("Segoe UI")
.Size("14px"))
//....
)
// ...
)
```



Axis Labels Line Break

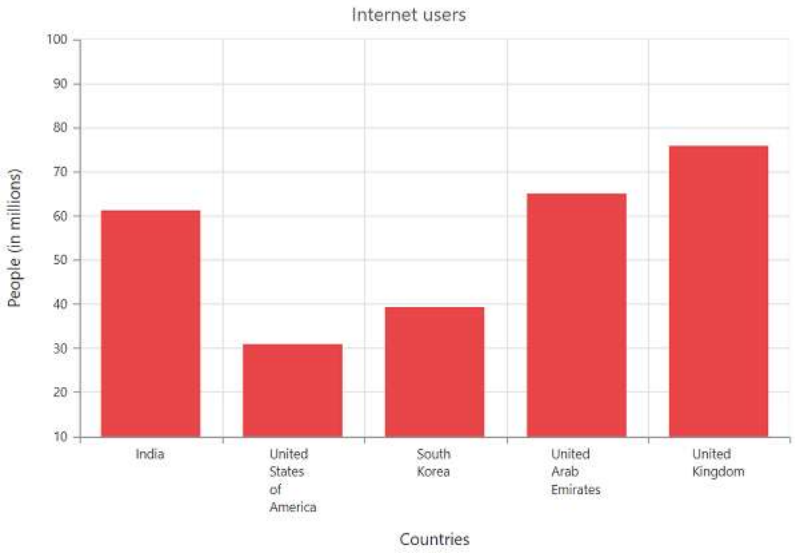
Axis Labels can be placed in multiple lines by specifying **
** for data points x value and in label format.

For category value type, **
** can be specified in x value of data points.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
sr
.Points(pt =>
{
pt.X("India").Y(61.3).Add();
pt.X("United<br>States<br>of<br>America").Y(31).Add();
pt.X("South<br>Korea").Y(39.4).Add();
pt.X("United<br>Arab<br>Emirates").Y(65.1).Add();
pt.X("United<br>Kingdom").Y(75.9).Add();
}).Add();
})
//...
)
```

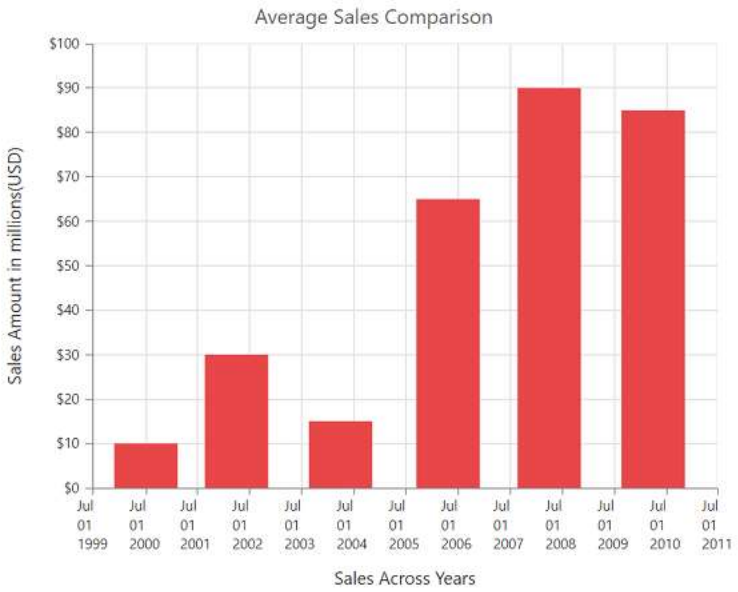
Copyright © 2001 - 2020 Syncfusion Inc.



For numeric, datetime and datetimeCategory value type, **
** can be specified in labelFormat.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
px=>px.LabelFormat("MMM<br>dd<br>yyyy").ValueType(AxisValueType.Datetime)
)
// ...
)
```



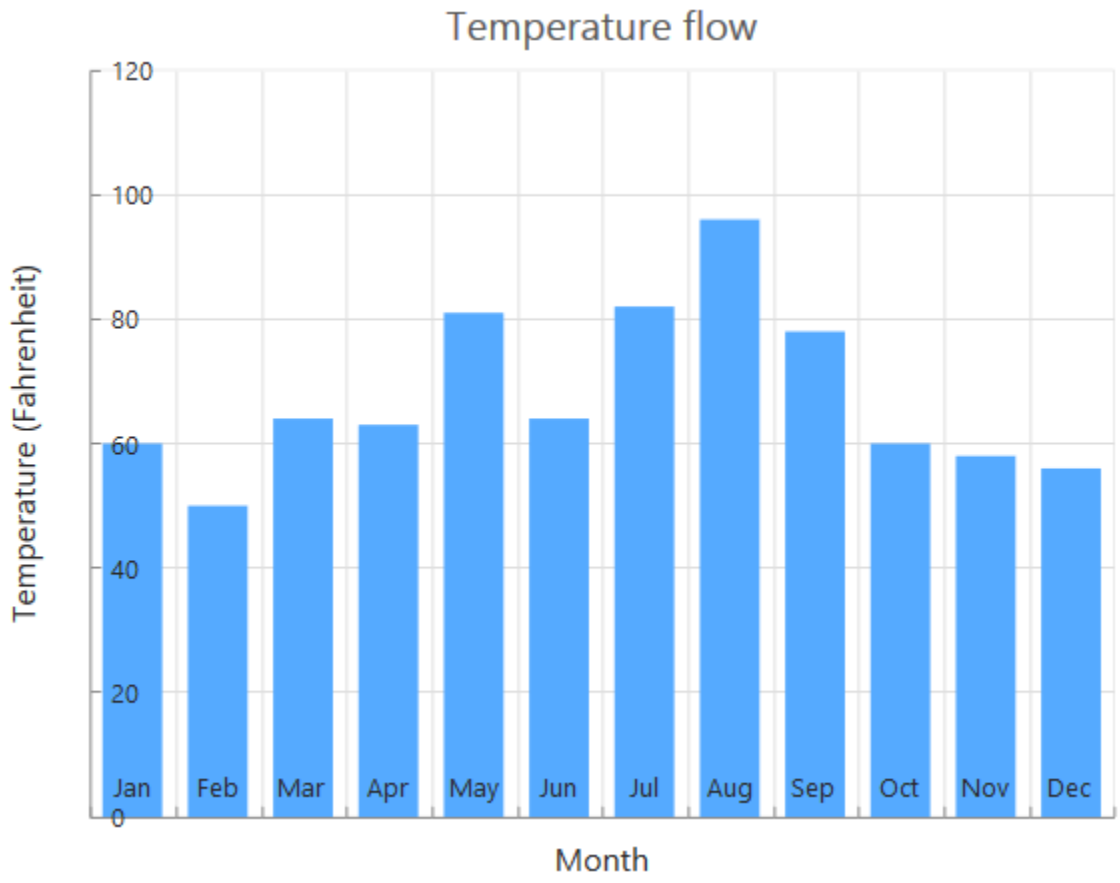
Label and tick positioning

Axis labels and ticks can be positioned inside or outside the chart area by using the **LabelPosition** and **TickPosition** properties. The labels and ticks are positioned outside the chart area, by default.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Customizing label and tick positions
px=>px.AxisLabelPosition(AxisLabelPosition.Inside).TickLinesPosition(TickLin
esPosition.Inside)
//....
)
// ...
)
```



Edge labels placement

Labels with long text at the edges of an axis may appear partially outside the chart. The **EdgeLabelPlacement** property can be used to avoid the partial appearance of the labels at the corners.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Customizing edge label placement
px=>px.EdgeLabelPlacement(EdgeLabelPlacement.Shift)
//....
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
// ...
)
```

Chart before setting edge label placement to X-axis

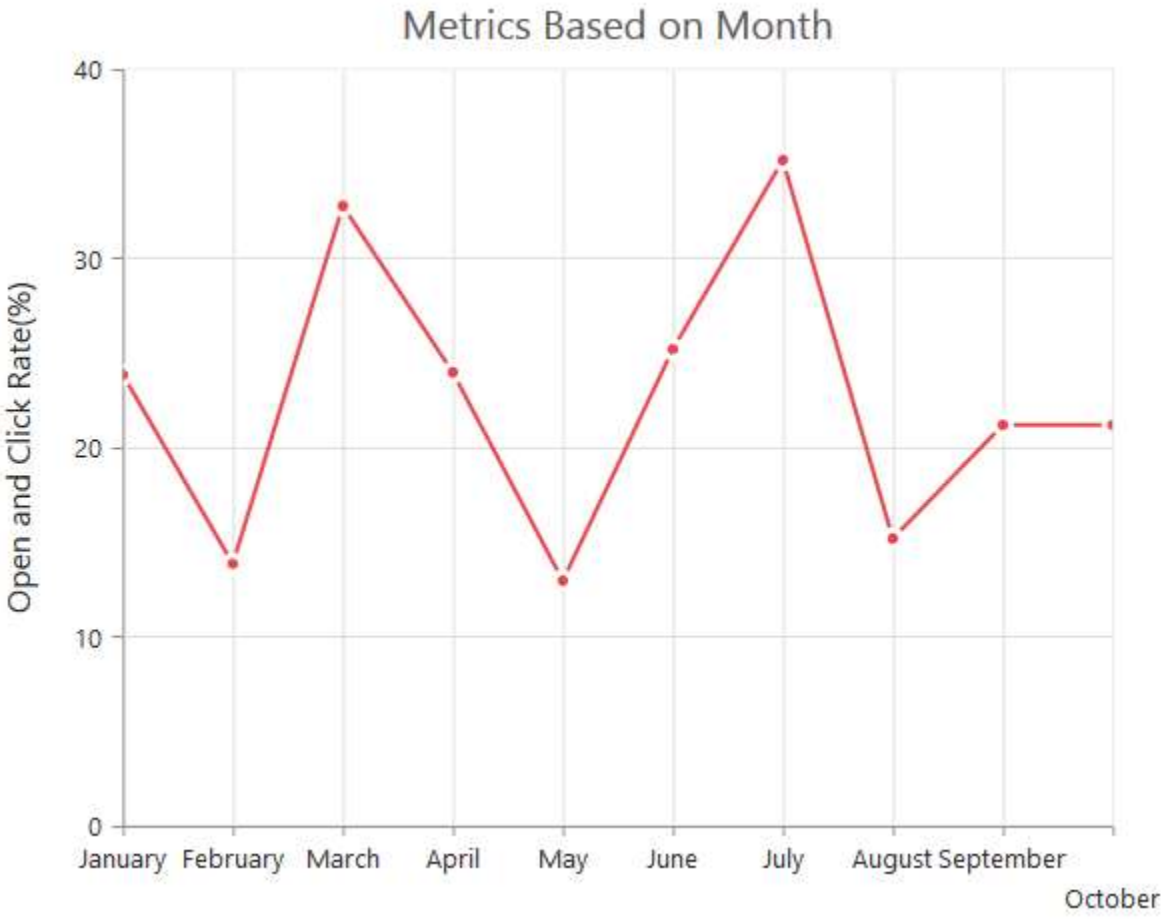


Chart after setting edge label placement to X-axis

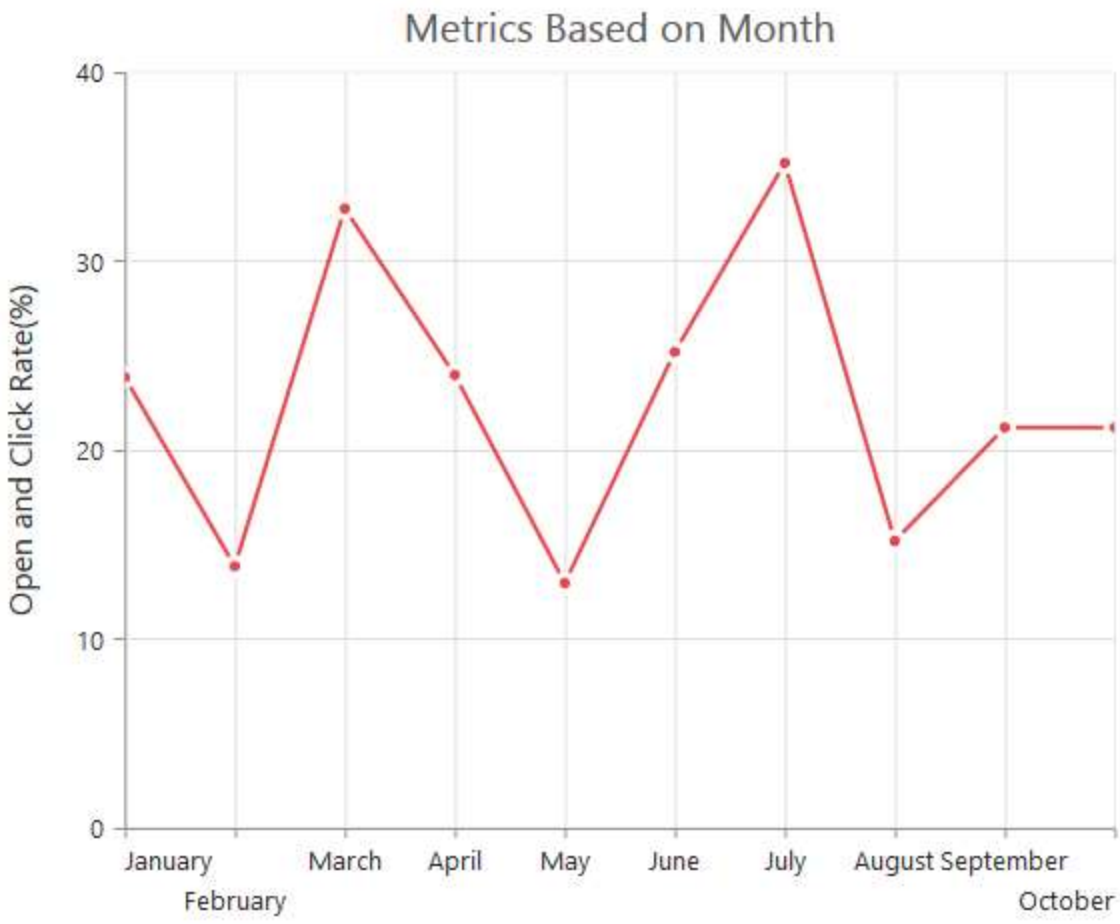


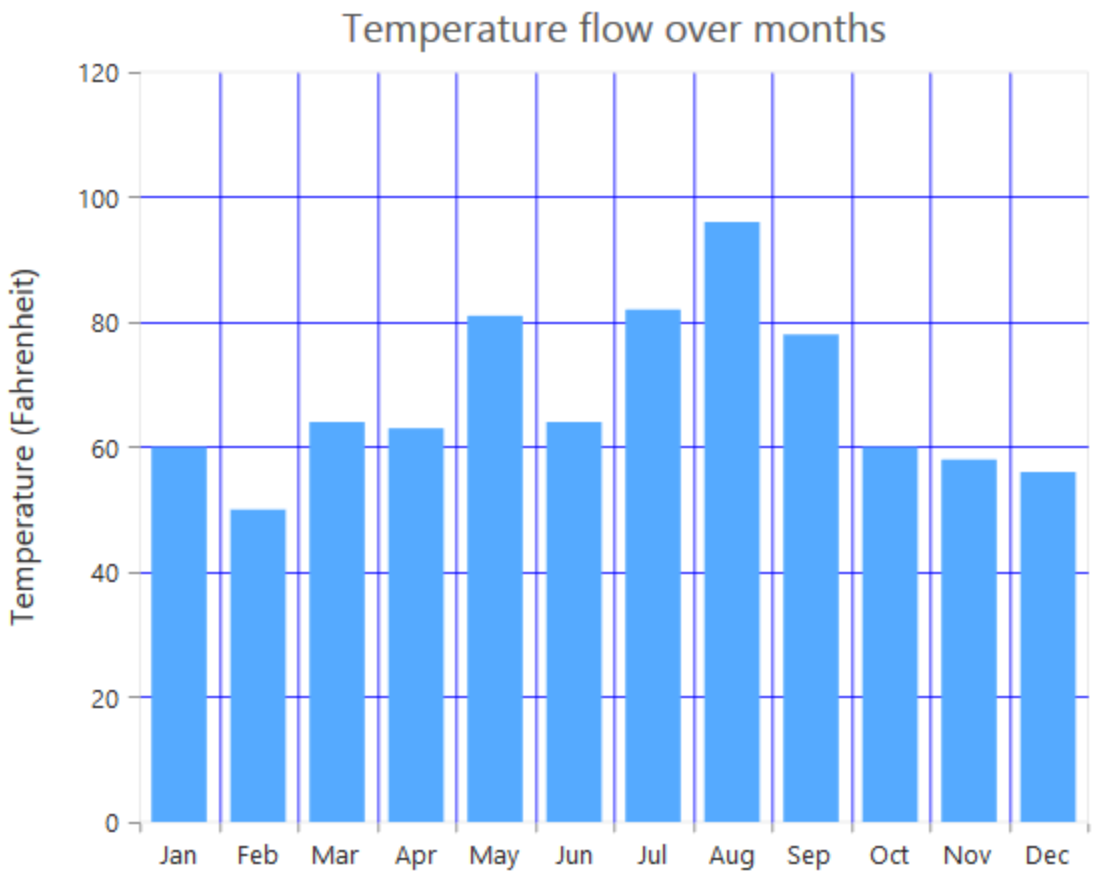
Grid lines customization

The **MajorGridLines** and **MinorGridLines** properties in the axis are used to customize the major grid lines and minor grid lines of an axis. They provide options to change the Width, Color, Visibility and Opacity of the grid lines. The minor grid lines are not visible, by default.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Customizing grid lines
px=>px.MajorGridLines(ma=>ma.Color("blue").Visible(true).Width(1))
.MinorGridLines(mi=>mi.Color("red").Visible(false).Width(1))
.MinorTicksPerInterval(0)
//....
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



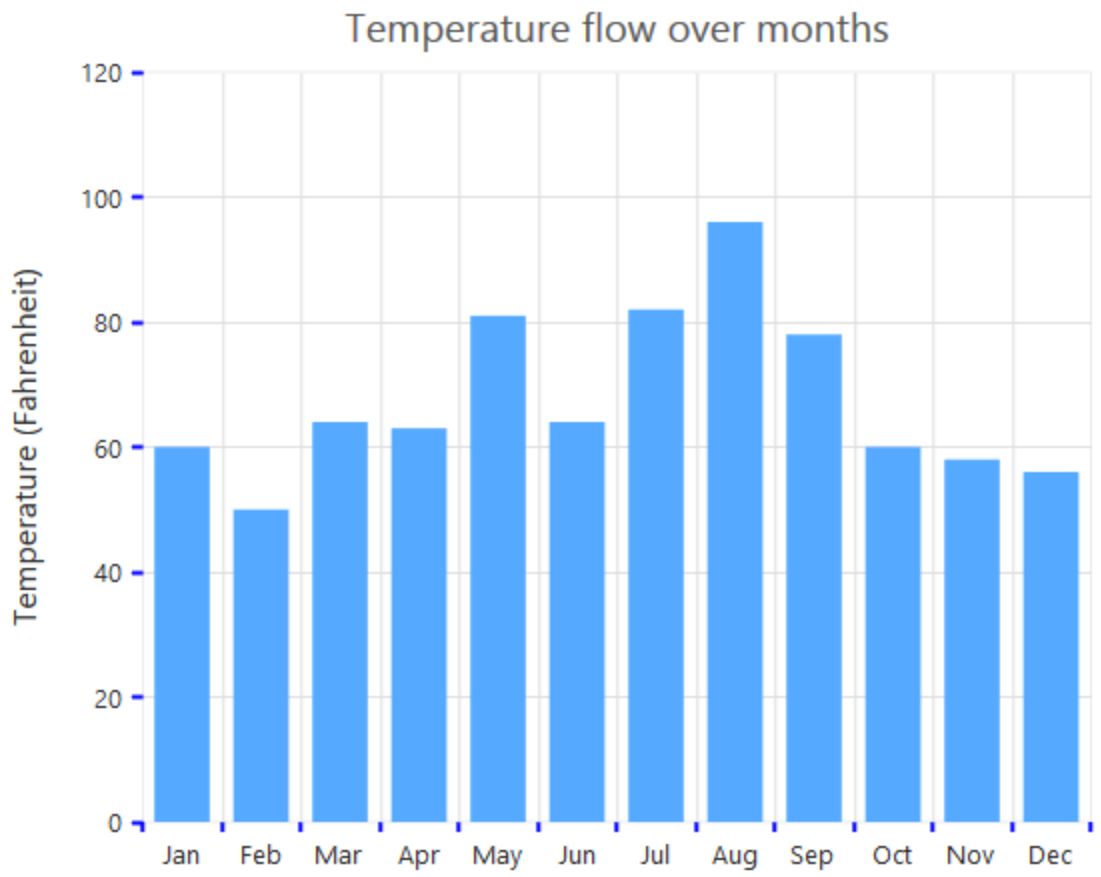
Tick lines customization

The **MajorTickLines** and **MinorTickLines** properties in the axis are used to customize the major tick lines of an axis and minor tick lines of an axis. They provide options to change the Width, Size, Color and Visibility of the grid lines. The minor tick lines are not visible, by default.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Customizing tick lines
px=>px.MajorTickLines(ma=>ma.Color("blue").Visible(true).Width(1).Size(5))
.MinorTickLines(mi=>mi.Color("red").Visible(false).Width(1).Size(5))
.MinorTicksPerInterval(0)
//....
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Inversing axis

Axis can be inversed by using the **IsInversed** property of the axis. The default value of the IsInversed property is **false**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Inversing the X-axis
px=>px.IsInversed(false)
//....
)
// ...
)
```

Chart before inversing the axes

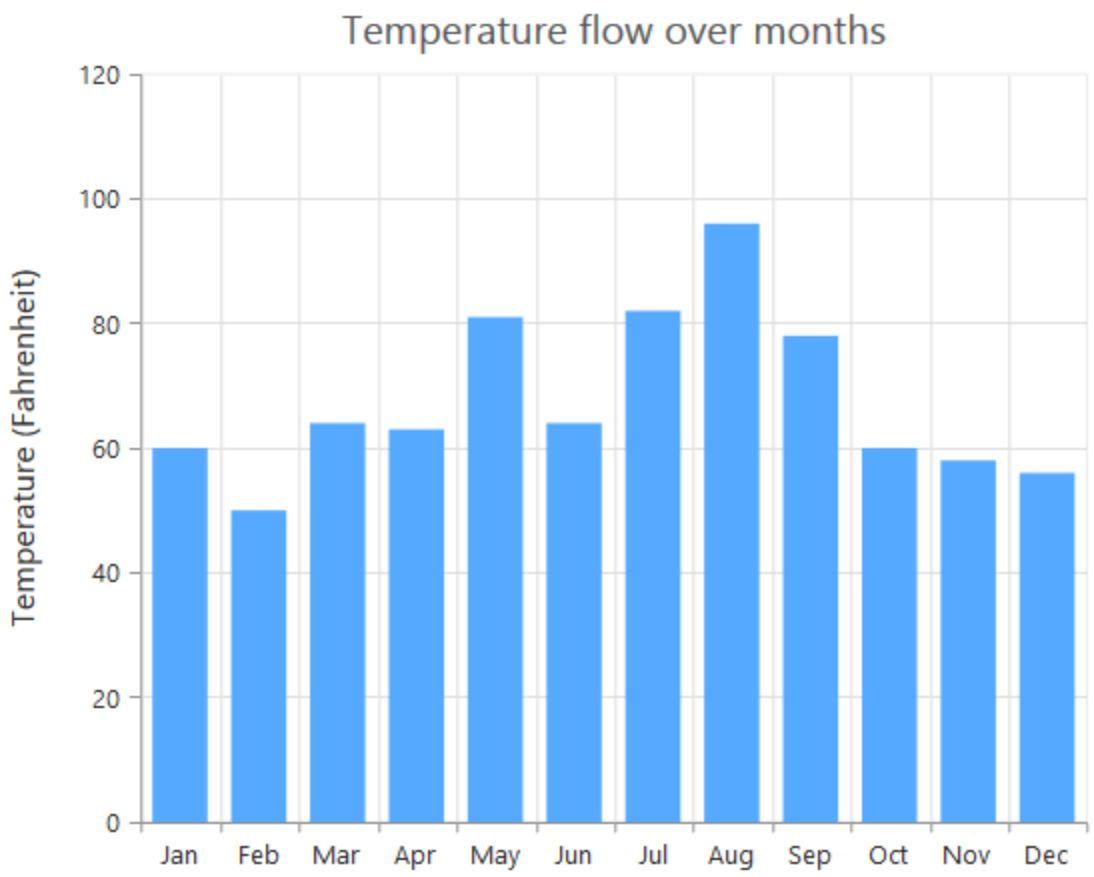


Chart after inversing the axes

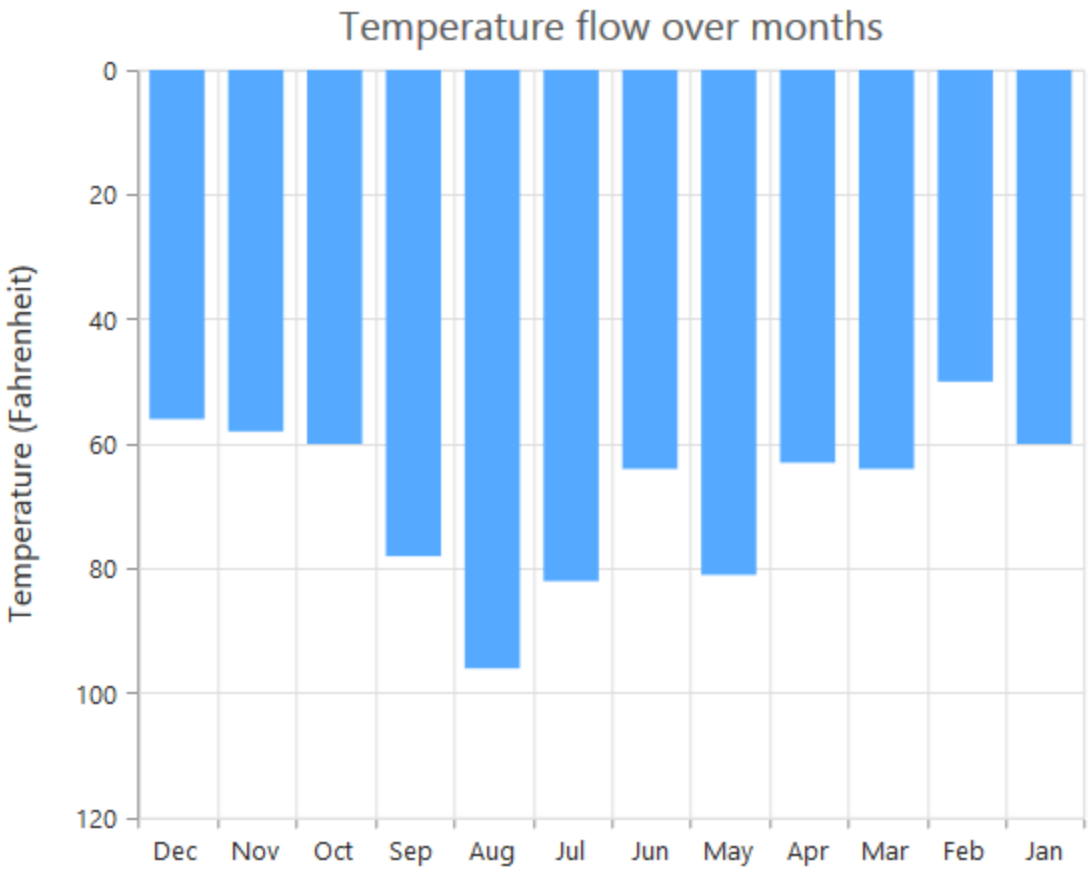
Copyright © 2001 - 2020 Syncfusion Inc.



Place axes at the opposite side

The **OpposedPosition** property of axis can be used to place the axis at the opposite side of its default position. The default value of the OpposedPosition property is **false**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Placing axis at the opposite side of its normal position
px=>px.OpposedPosition(true)
//....
)
// ...
)
```

Chart with X and Y axes at normal position

Copyright © 2001 - 2020 Syncfusion Inc.

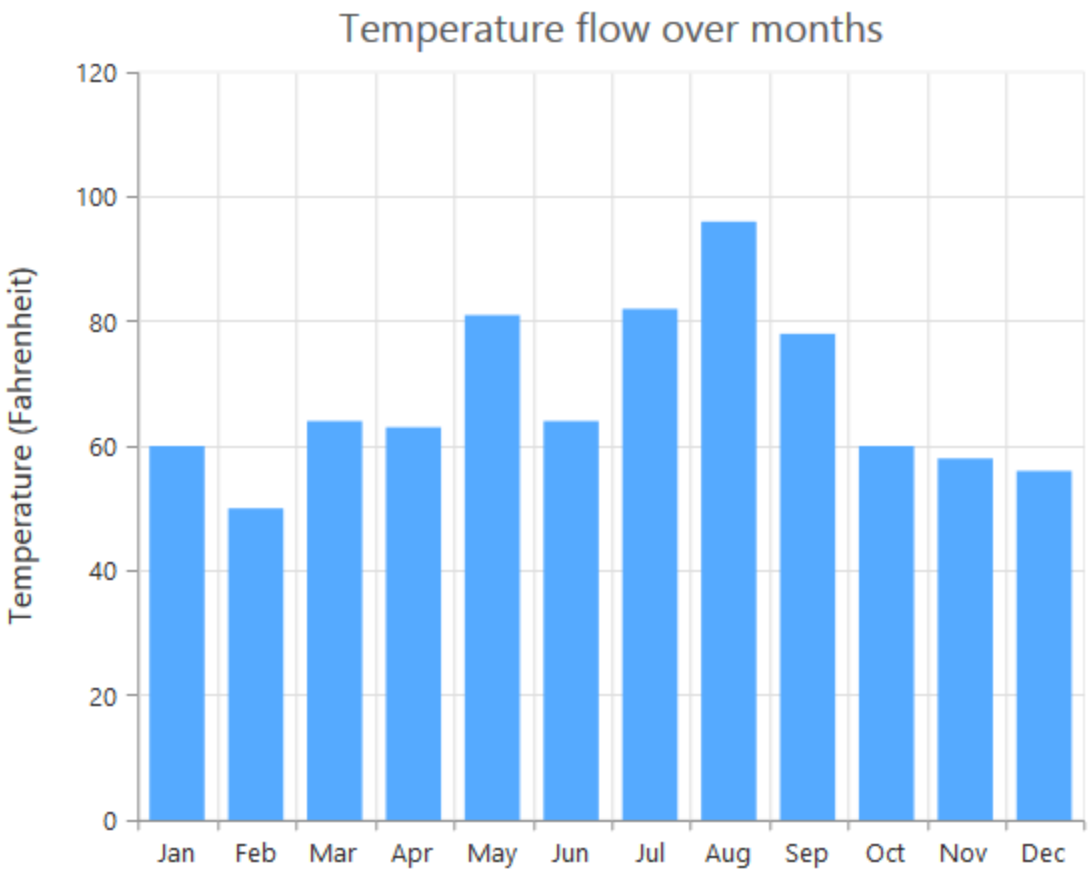


Chart with Y-axis at opposed position

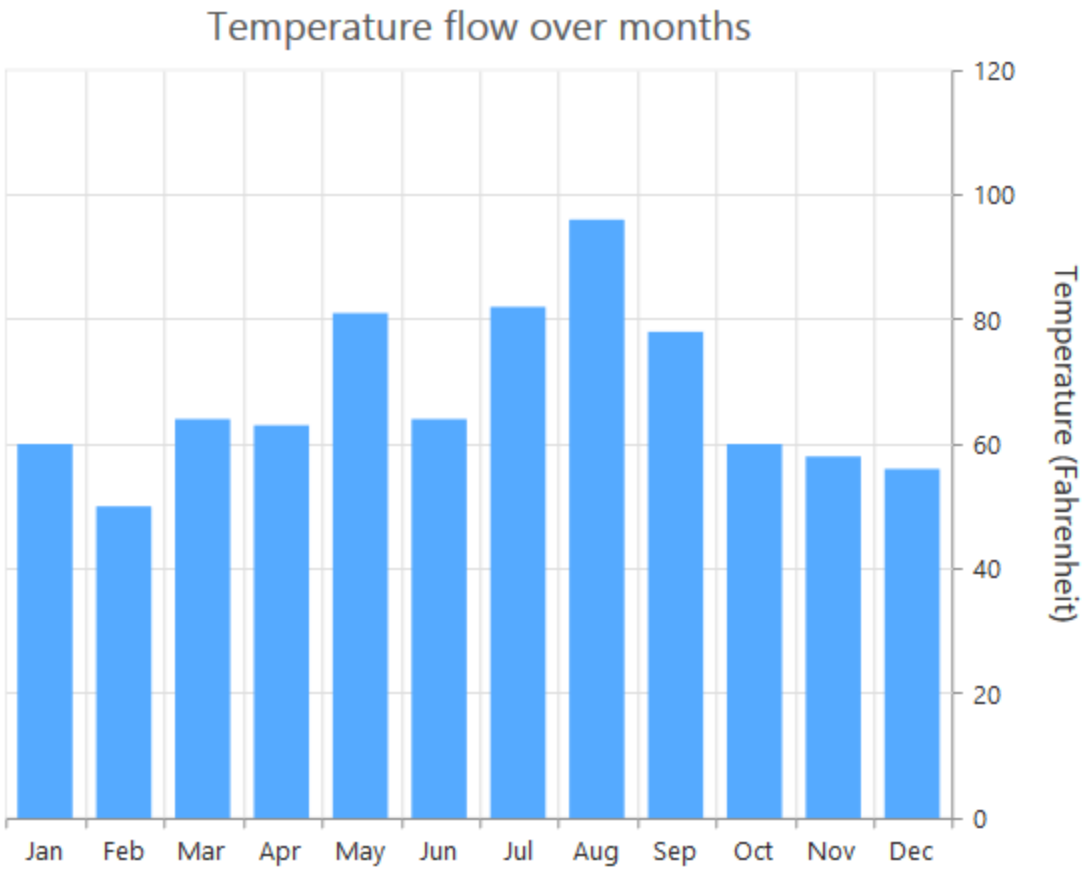
Copyright © 2001 - 2020 Syncfusion Inc.



Maximum number of labels per 100 pixels

A maximum of 3 labels are displayed for each 100 pixels in the axis, by default. The maximum number of labels that is present within the 100 pixels length can be customized by using the **MaximumLabels** property of the axis. This property is applicable only for an automatic range calculation and it does not work when you set the value for Interval property in the axis range.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryXAxis(
//Maximum number of labels per 100 pixels
px=>px.MaximumLabels(1)
//....
)
// ...
)
```

Chart before setting maximum labels per 100 pixels

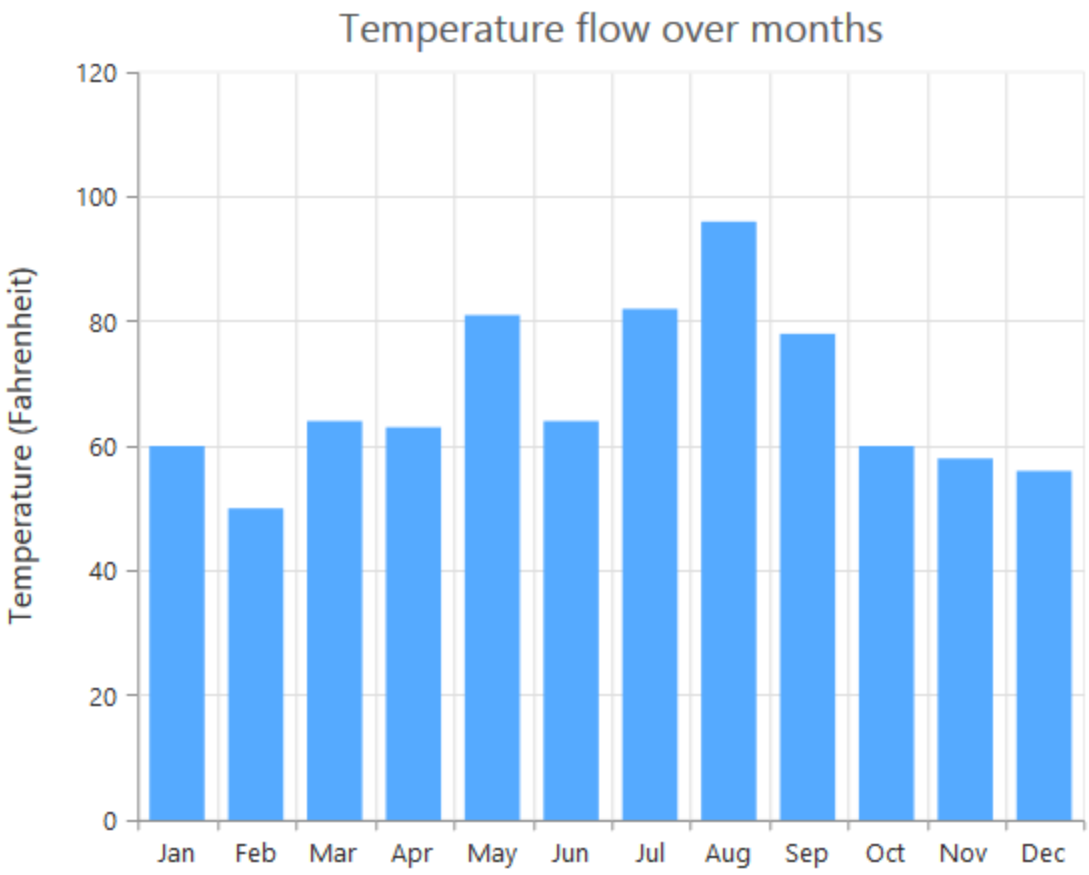


Chart after setting maximum labels one per 100 pixels

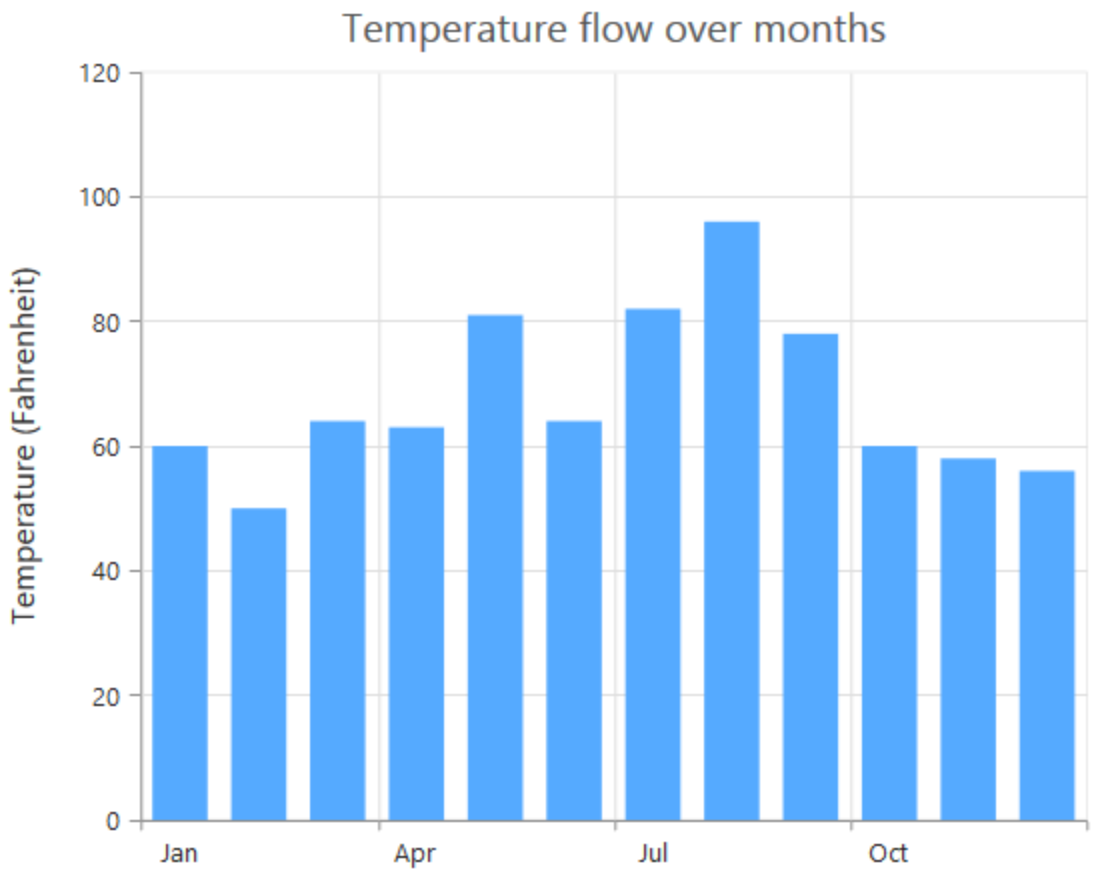
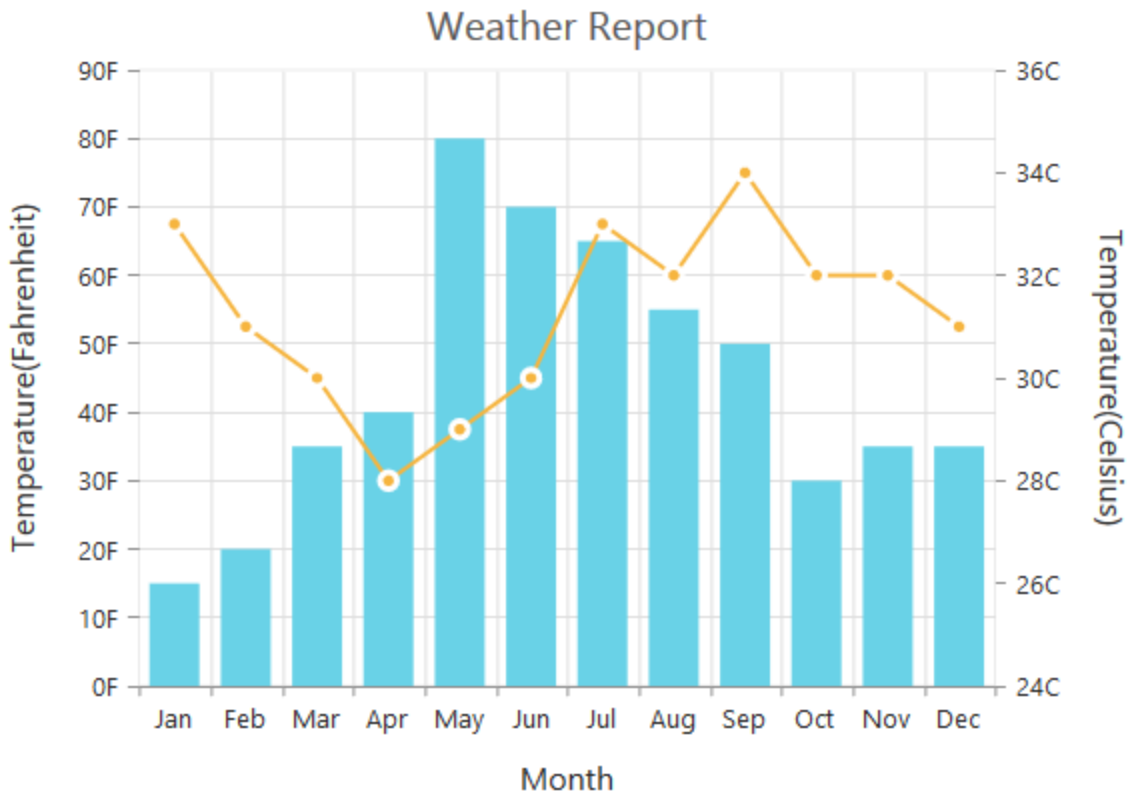
Copyright © 2001 - 2020 Syncfusion Inc.



Multiple Axis

Multiple axes can be used in the Chart and chart area can be split into multiple panes to draw multiple series with multiple axes.

Copyright © 2001 - 2020 Syncfusion Inc.

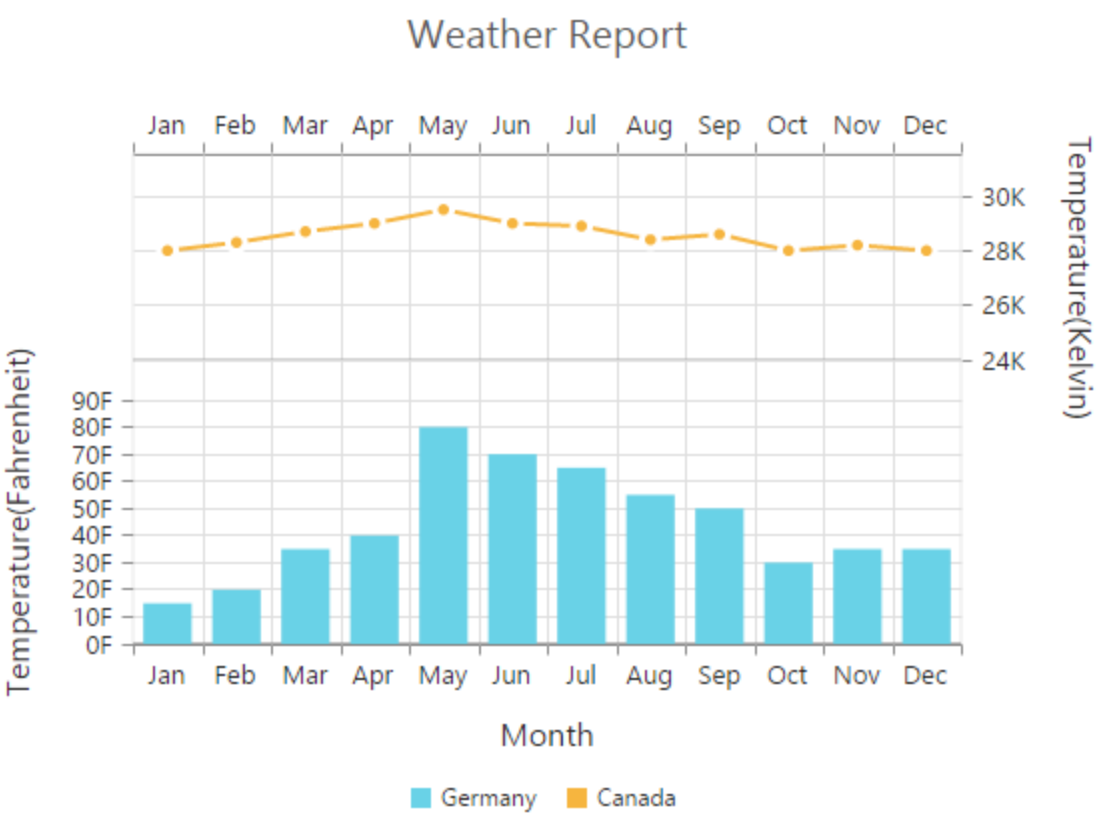


An additional horizontal or vertical axis can be added to the chart by adding an axis instance to the **Axes** collection and then you can associate it to a series by specifying the name of the axis to the **XAxisName** or **YAxisName** property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//  Creating a secondary horizontal axis
.Axes(ax => { ax.Name("SecondaryX").Add(); ax.Name("SecondaryY").Add(); })
.Series(sr =>
{
//  Binding secondary X-axis with a series
sr.XAxisName("SecondaryX")
//  Binding secondary Y-axis with a series
.YAxisName("SecondaryX").Add();
})
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the multiple axis online demo sample.

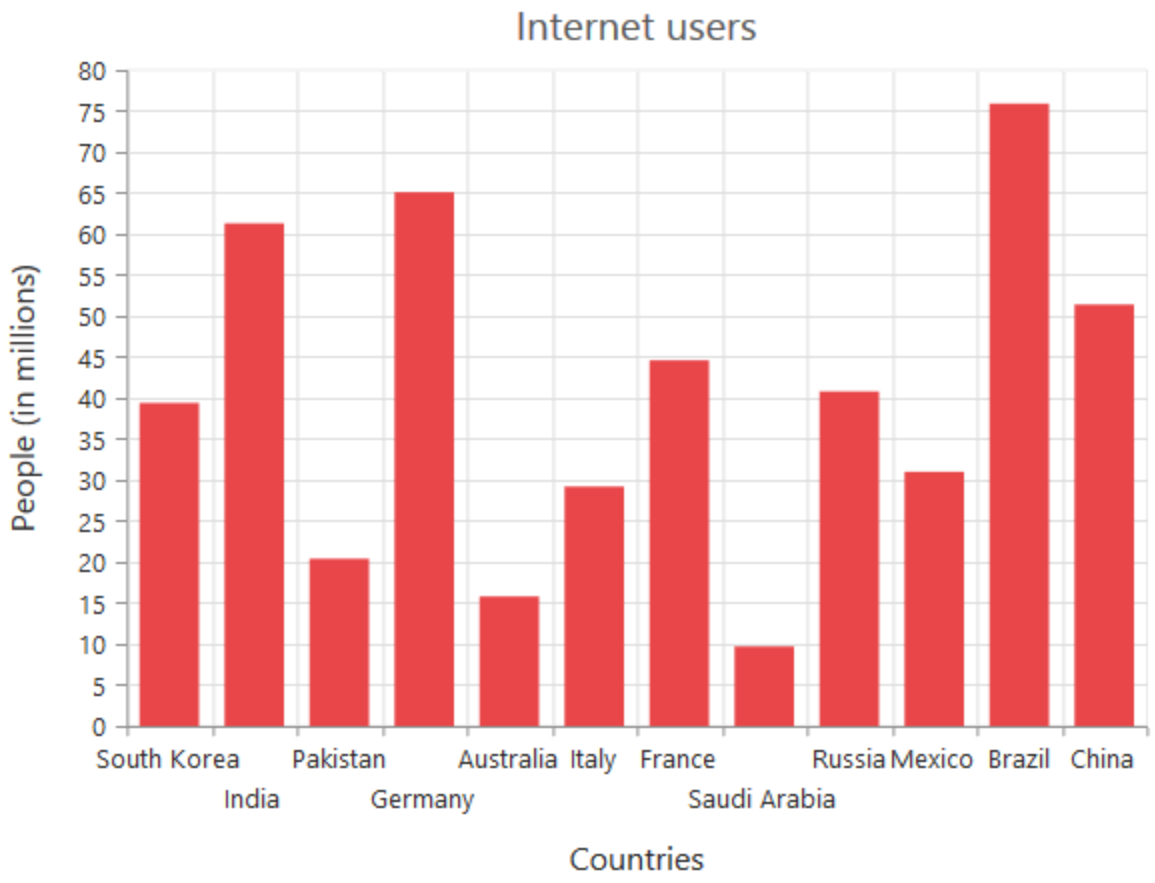
Smart Axis Labels

When the Axis labels overlap with each other based on the chart dimensions and label size, you can use the **LabelIntersectAction** property of the axis to avoid overlapping. The default value of the LabelIntersectAction is **None**. The other available values of the Label Intersect Actions are **Rotate45**, **Rotate90**, **Trim**, **MultipleRows**, **Wrap** and **Hide**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
// Avoid overlapping of x-axis labels
.PrimaryXAxis(px=>px.LabelIntersectAction(LabelIntersectAction.MultipleRows)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view our online demo sample for smart axis labels.

The following screenshot displays the result, when the LabelIntersectAction property is set as **Rotate45**.

The following screenshot displays the result, when the LabelIntersectAction property is set as **WrapByWord**.

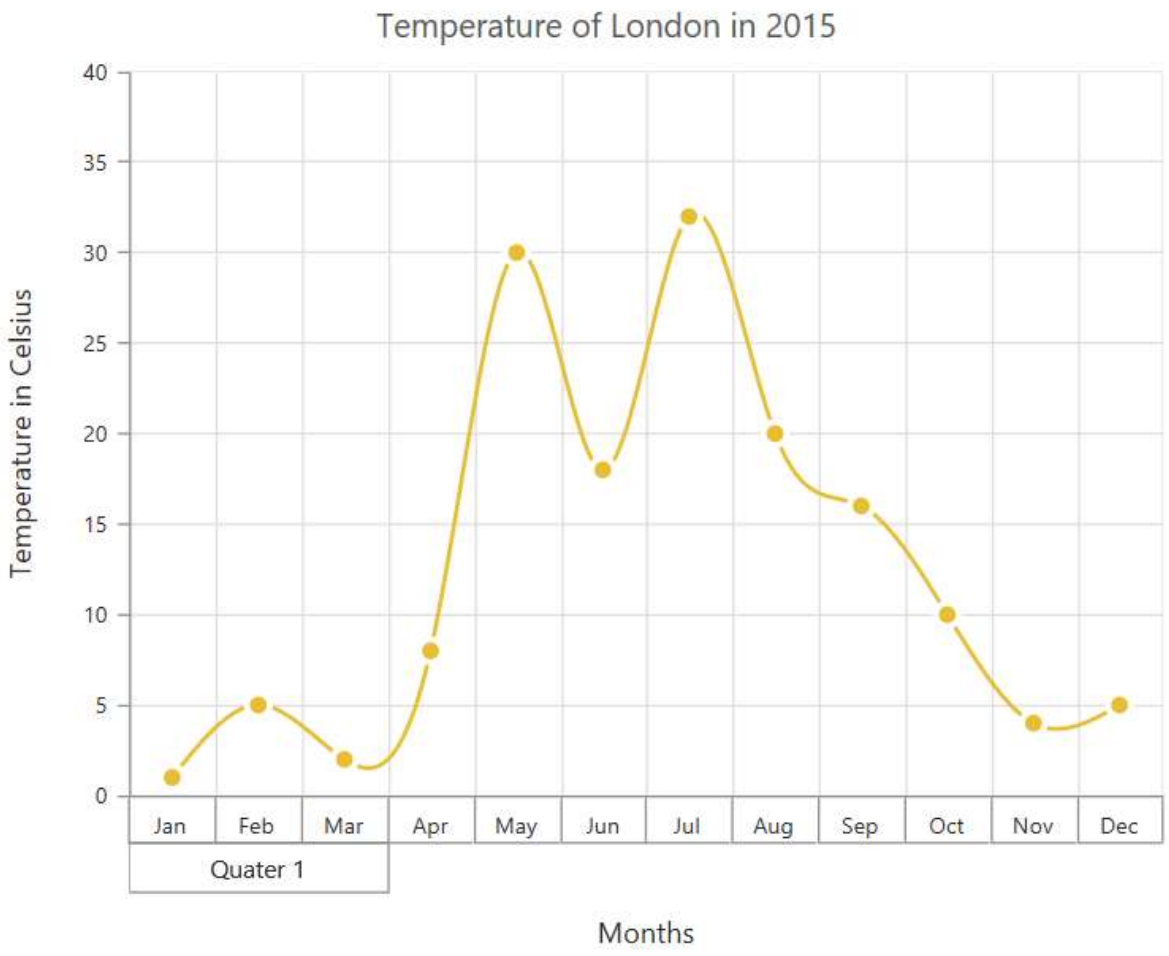
Multi-level Labels

Axis can be customized with multiple levels of labels using the **MultiLevelLabels** property. These labels are placed based on the start and end range values and we can add any number of labels to an axis.

ASPX-CS

```
@(Html.EJ().Chart("container")
.PrimaryXAxis(axis => axis.MultiLevelLabels(multiLevelLabels=> {
multiLevelLabels.Visible(true).Text("Quarter 1").Start(-0.5).End(2.5).Add();
})
))
```

Copyright © 2001 - 2020 Syncfusion Inc.

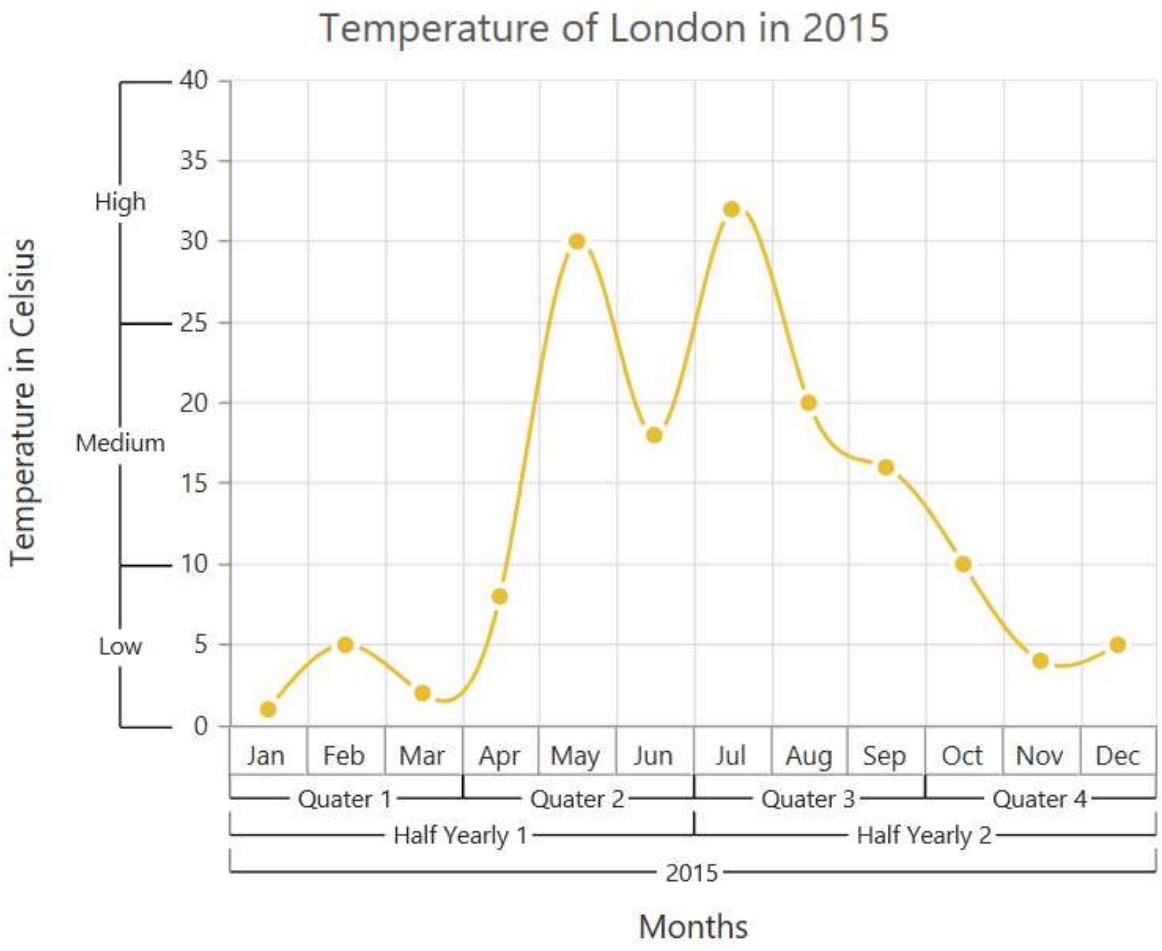


Customizing the multi-Level labels

The color, width and type of the border can be customized. The default border type is **Rectangle**. And the other supported border types are namely brace, curly brace, without top/bottom border and none.

ASPX-CS

```
@(Html.EJ().Chart("container")
.PrimaryXAxis(axis => axis.MultiLevelLabels(
multiLevelLabels=> {multiLevelLabels.
Border(br=>br.Type(MultiLevelLabelBorder.Brace).Width(2).Color("Black"))).Add();
})
))
```

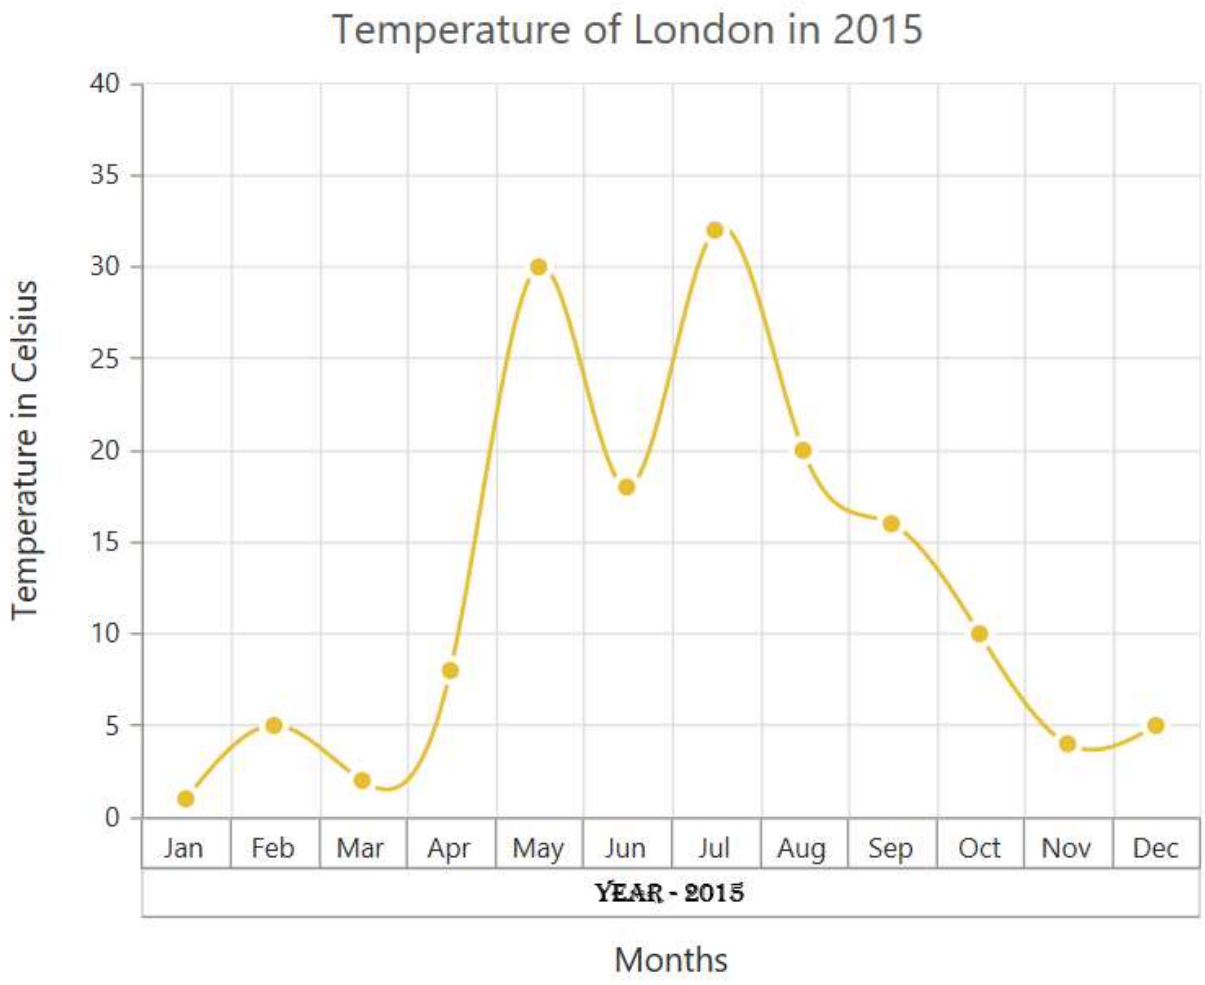


The text of the labels can be customized using the **Text** and **Font** properties

ASPX-CS

```
@(Html.EJ().Chart("container")
.PrimaryXAxis(axis =>axis.MultiLevelLabels(multiLevelLabels=>
{multiLevelLabels.Text("Year - 2015")
.Font(ft=> ft.FontFamily("Algerian").Size("12px").Color("Black")).Add();
})
))
```

Copyright © 2001 - 2020 Syncfusion Inc.

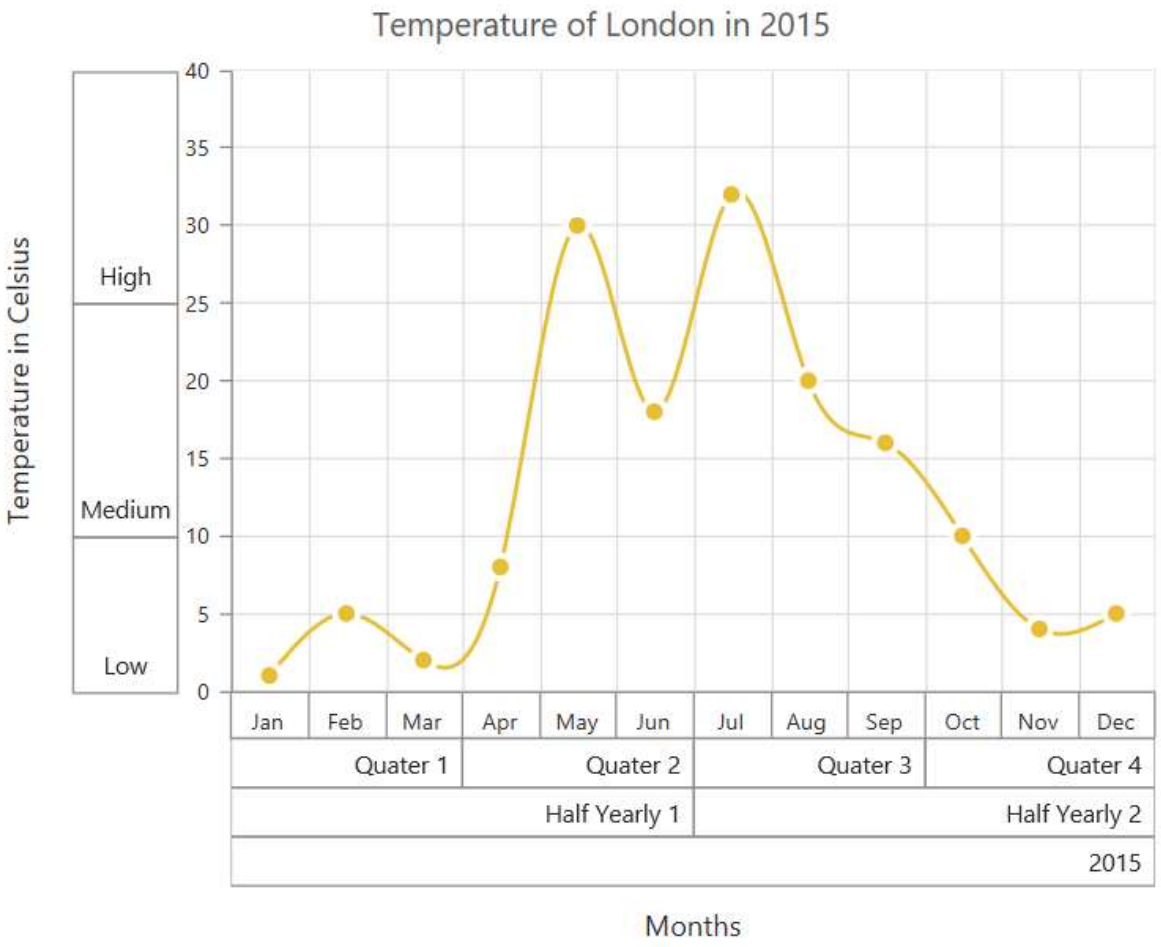


You can change the alignment of the text to far, near and center position using the **TextAlignment** property. By default, the text will be center aligned.

ASPX-CS

```
@(Html.EJ().Chart("container")
.PrimaryXAxis(axis =>axis.MultiLevelLabels(multiLevelLabels=> {
multiLevelLabels.TextAlignment(Alignment.Far).Add();
})
))
```

Copyright © 2001 - 2020 Syncfusion Inc.



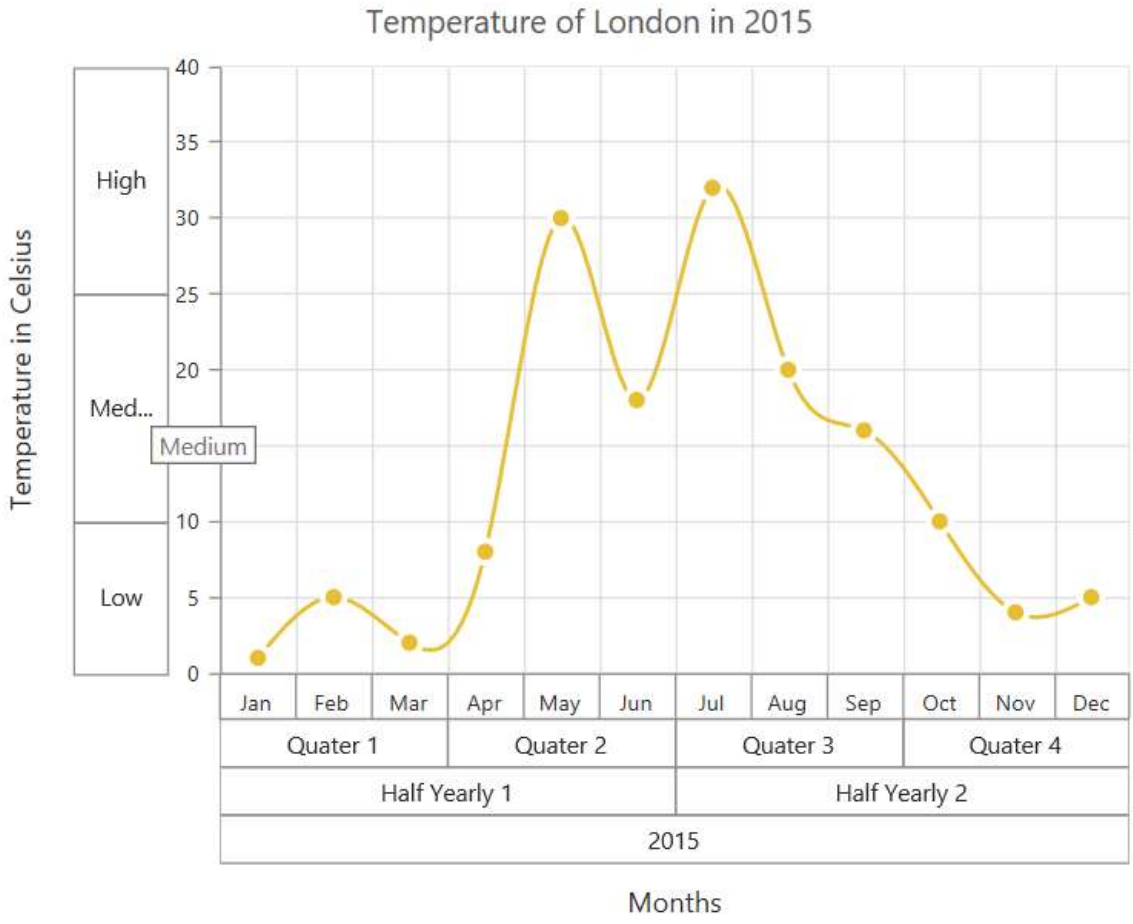
You can trim, wrap or wrapAndTrim the text if it exceeds the maximum text width value using the property **TextOverflow**

ASPX-CS

```
@(Html.EJ().Chart("container")
.PrimaryXAxis(axis =>axis.MultiLevelLabels(multiLevelLabels=> {
multiLevelLabels.TextOverflow(TextOverflow.Trim).MaximumTextWidth(40).Add();
})
))
```

The below screenshot shows the trimmed multi-level labels

Copyright © 2001 - 2020 Syncfusion Inc.



And these labels can be placed in various rows using the **Level** property.

Click here to view the multi-level labels online demo sample.

Multiple panes

Chart area can be divided into multiple panes using the **RowDefinitions** and **ColumnDefinitions** properties.

Row Definitions

To split the chart area vertically into a number of rows, use RowDefinitions of the chart.

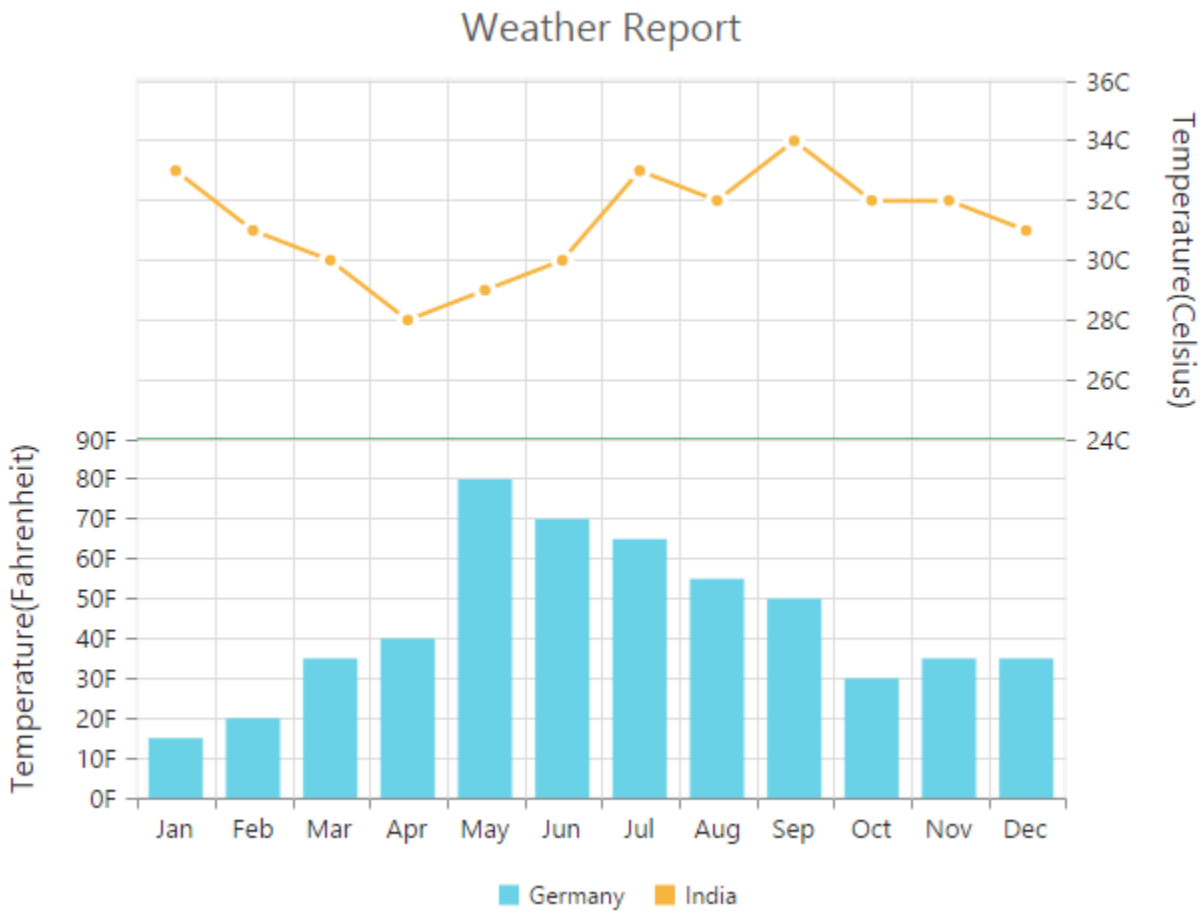
- You can allocate space for each row by using the **Unit** option that determines whether the chart area should be split by *percentage* or *pixels* for the given **RowHeight** value of the RowDefinitions.
- To associate a vertical axis to a row, specify the RowDefinitions **Index** value to the RowIndex property of the chart axis.
- To customize each row's horizontal line, use LineColor and LineWidth property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//  Splitting chart area into multiple rows
.RowDefinitions(rd =>
{
rd
//  Split first row of the chart area
.Unit("percentage").LineColor("Gray").LineWidth(0).RowHeight(50).Add();
//  Split second row of the chart area
rd.Unit("percentage").LineColor("green").LineWidth(0).RowHeight(50).Add();
})
.Axes(ax =>
{
//Create secondary axis and bind it to second row of chart area
ax.Name("yAxis1")
.RowIndex(1).Add();
})
.Series(sr =>
{
sr
//Binding vertical axis name
.YAxisName("yAxis1").Add();
})
//...
)
```



Click here to view the online demo sample for multiple panes.

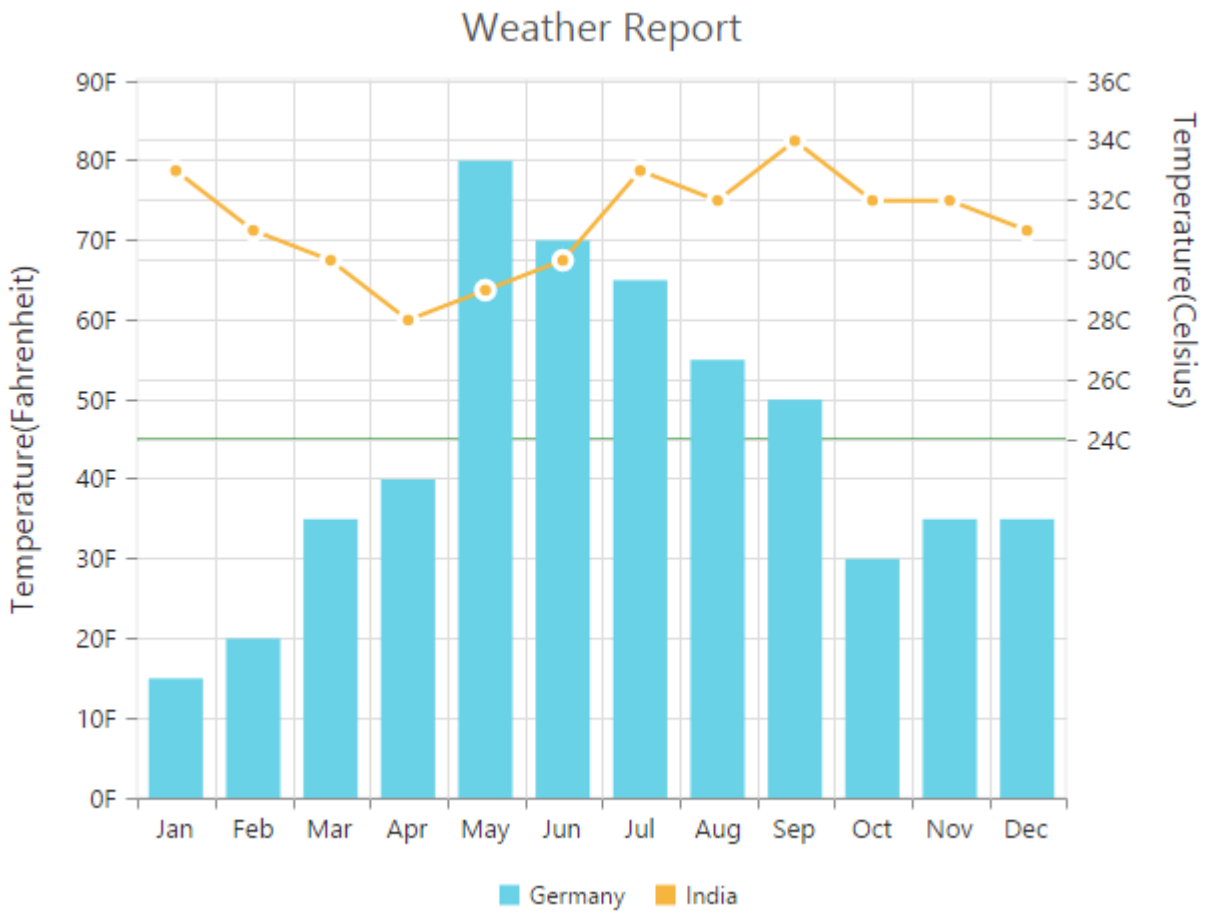
Row Span

For spanning the vertical axis along multiple panes vertically, you can use **RowSpan** property of axis.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//  Splitting chart area into multiple rows
.RowDefinitions(rd =>
{
//...
})
.Axes(ax =>
{
//..
})
.PrimaryYAxis(pry=>pry
//  Span the PrimaryYAxis
.RowSpan(2)
)
.Series(sr =>
{
//...
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Column Definitions

To split the chart area horizontally into a number of columns, use ColumnDefinitions of the chart.

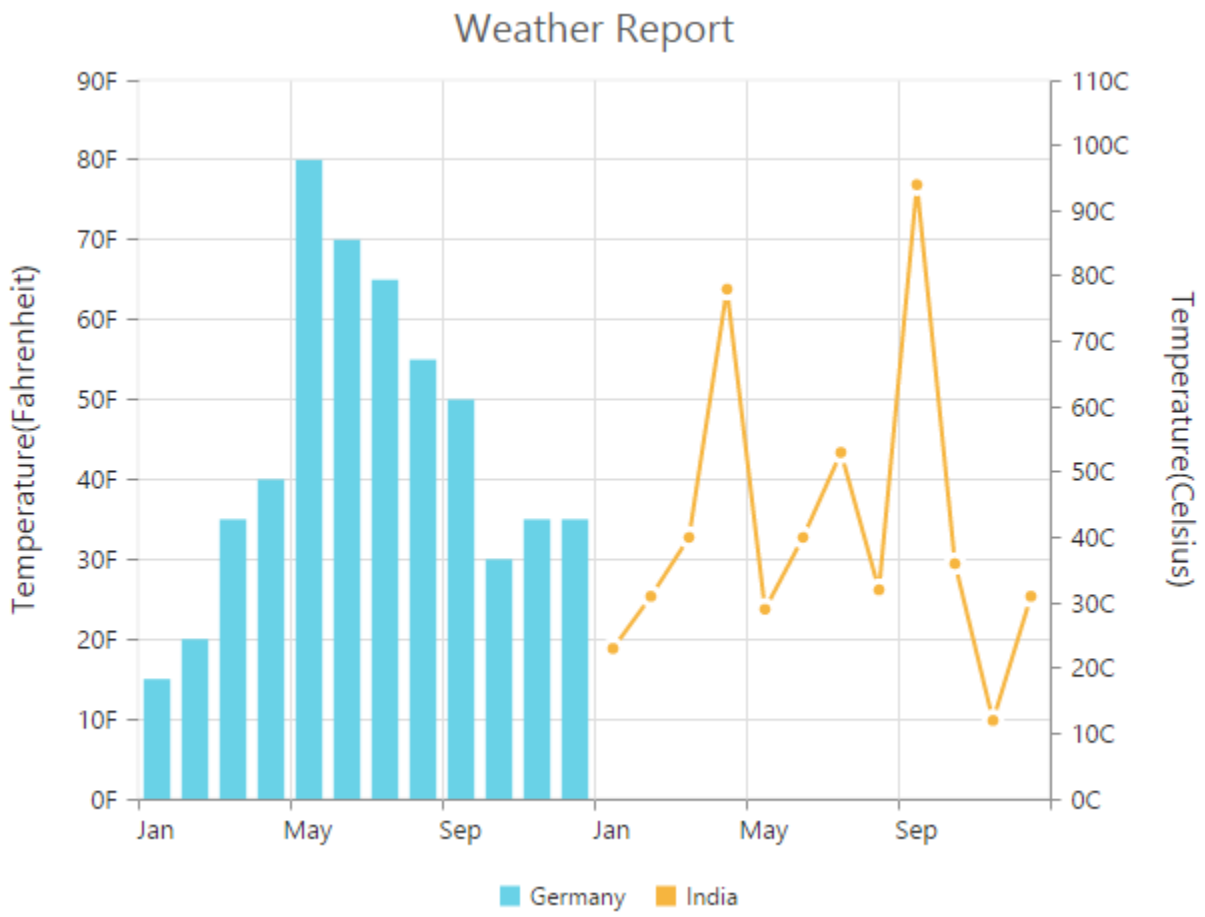
- You can allocate space for each column by using the **Unit** option that determines whether the chart area should be split by *percentage* or *pixels* for the given **ColumnWidth** value of the ColumnDefinitions.
- To associate a horizontal axis to a column, specify the ColumnDefinitions **Index** value to the **ColumnIndex** property of the chart axis.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//  Splitting chart area into multiple columns
.ColumnDefinitions(cdn =>
{
//  Split first column of the chart area
.Unit("percentage").ColumnWidth(50).Add();
//  Split second column of the chart area
cdn.Unit("percentage").ColumnWidth(50).Add();
})
.Axes(ax =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Create secondary axis and bind it to second row of chart area
ax.Name("xAxis1")
.ColumnIndex(1).Add();
})
.Series(sr =>
{
sr
//Binding horizontal axis name
.XAxisName("xAxis1").Add();
})
//...
)
```



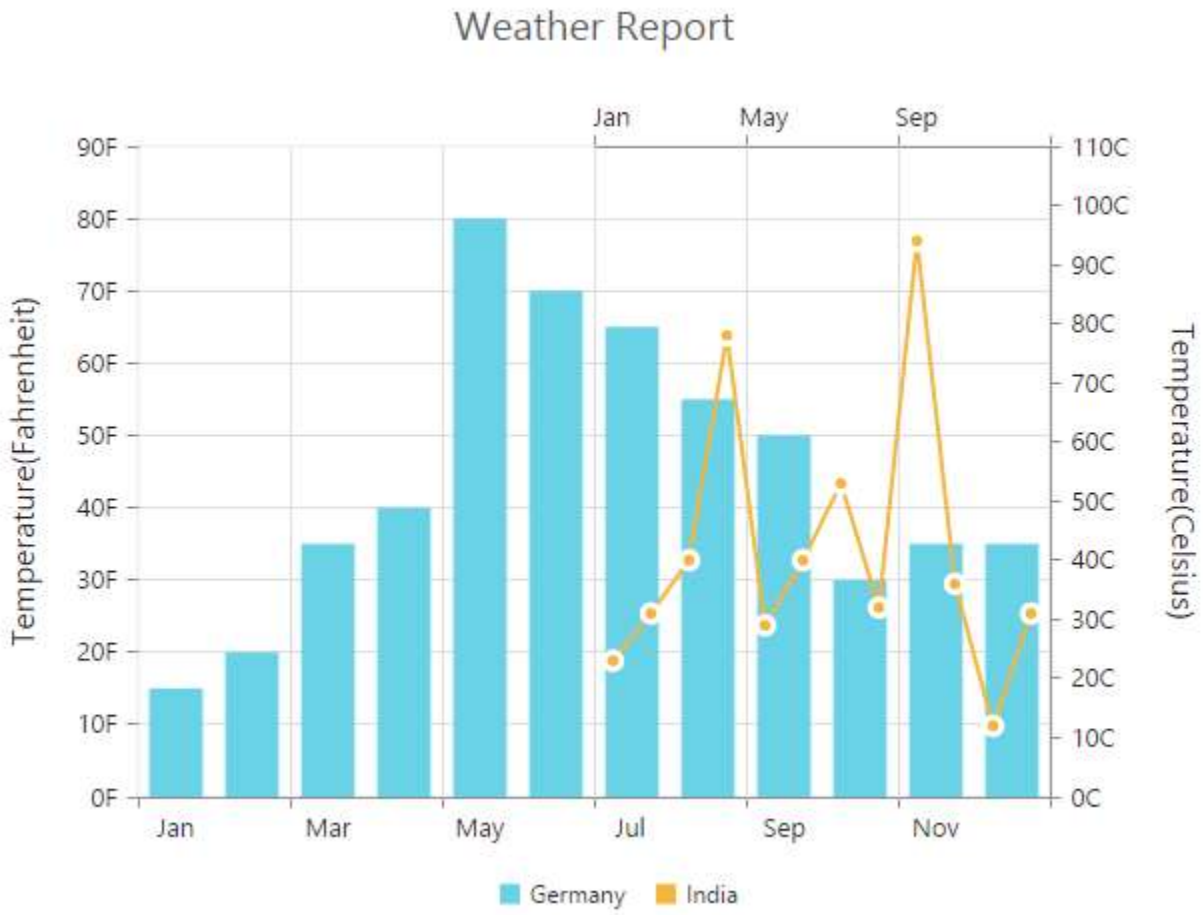
Column Span

For spanning the horizontal axis along multiple panes horizontally, you can use **ColumnSpan** property of axis.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//  Splitting chart area into multiple columns
.ColumnDefinitions(cdn =>
```

```
{
//...
})
.PrimaryXAxis(axis=>axis
//  Span the PrimaryXAxis
.Name("xAxis1").ColumnSpan(2)
)
.Axes(ax =>
{
//...
})
.Series(sr =>
{
//...
})
//...
)
```



ChartTypes

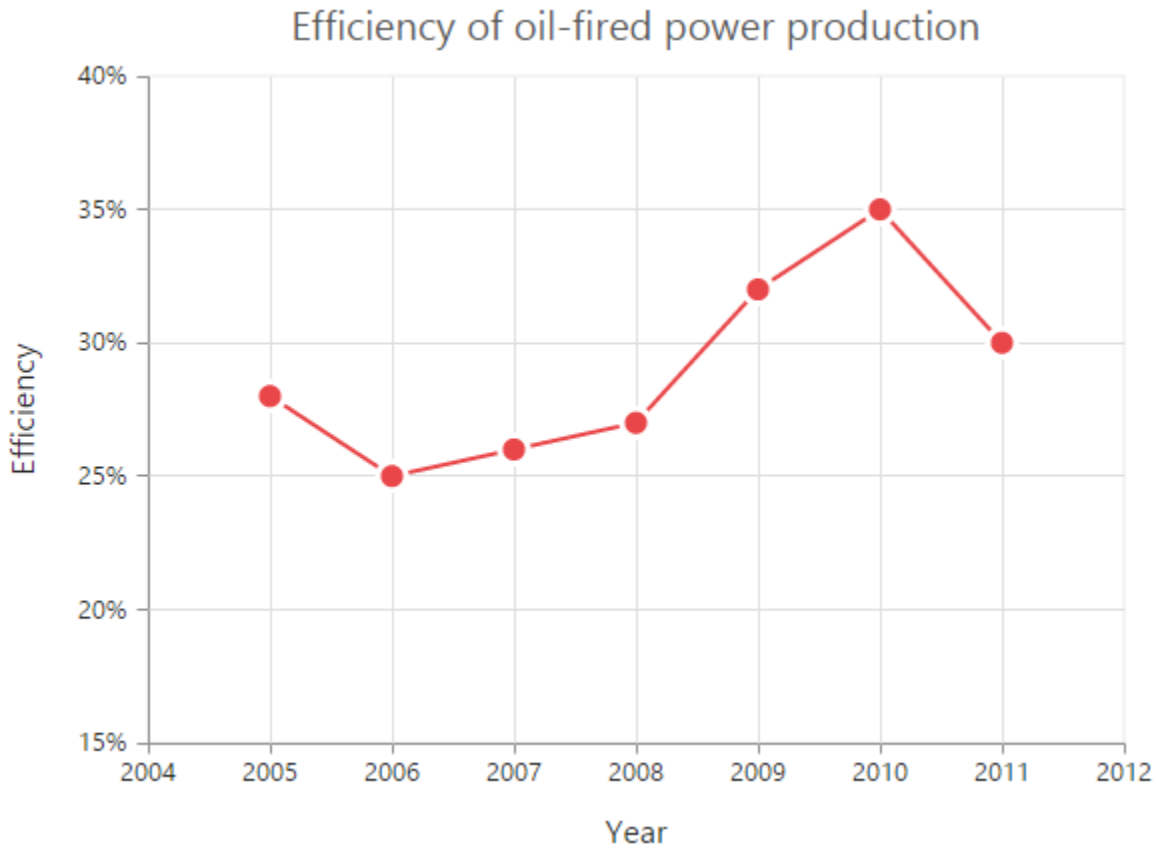
Line Chart

To render a Line Chart, set the series **Type** as **Line** in the chart series. To change the line segment color, you can use the **Fill** property of the series.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change type and color of the series.
sr.Type(SeriesType.Line).Fill("#E94649").Add();
})
//...
)
```



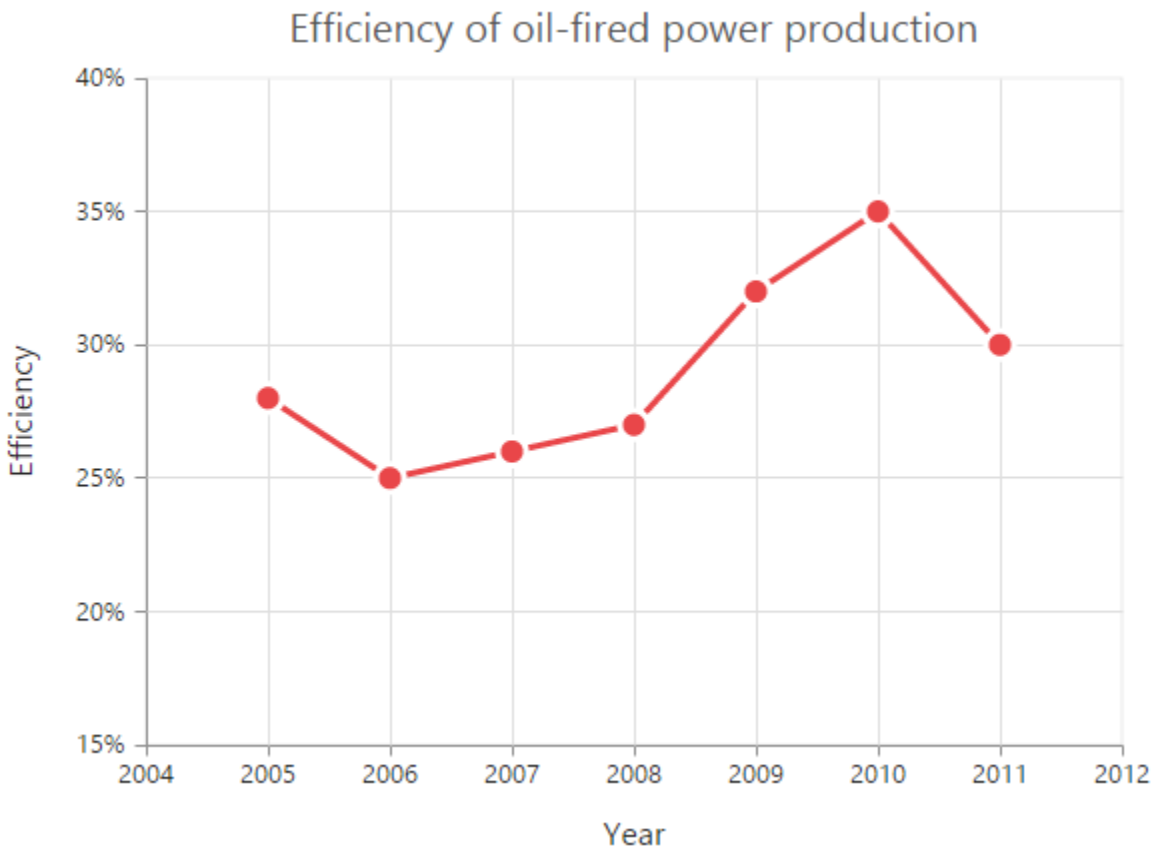
Click here to view the Line Chart online demo sample.

Change the line width

To change the width of the line segment, you can use the **Width** property in the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change the width of line series
sr.Width(3).Add();
})
//...
)
```

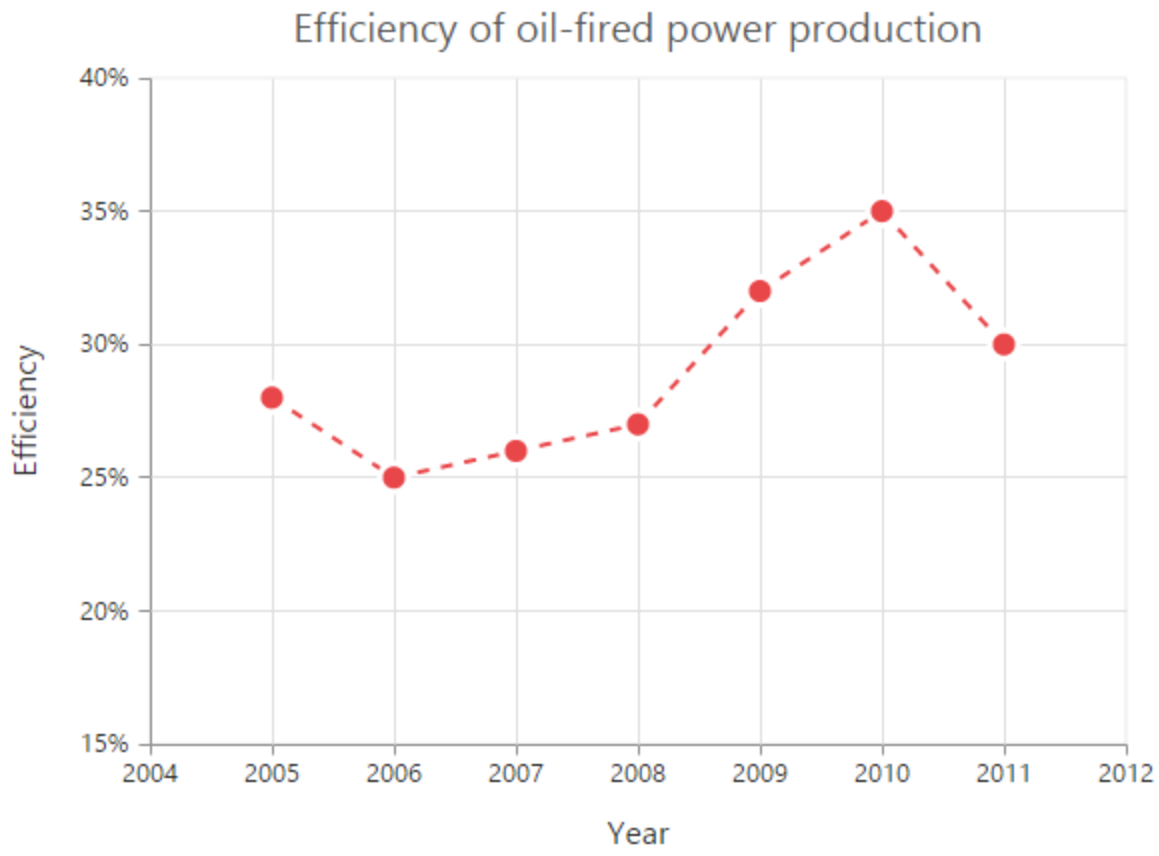


Dashed lines

To render the line series with dotted lines, you can use the **DashArray** option of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change dash array to display dotted or dashed lines
sr.DashArray("5,5").Add();
})
//...
)
```



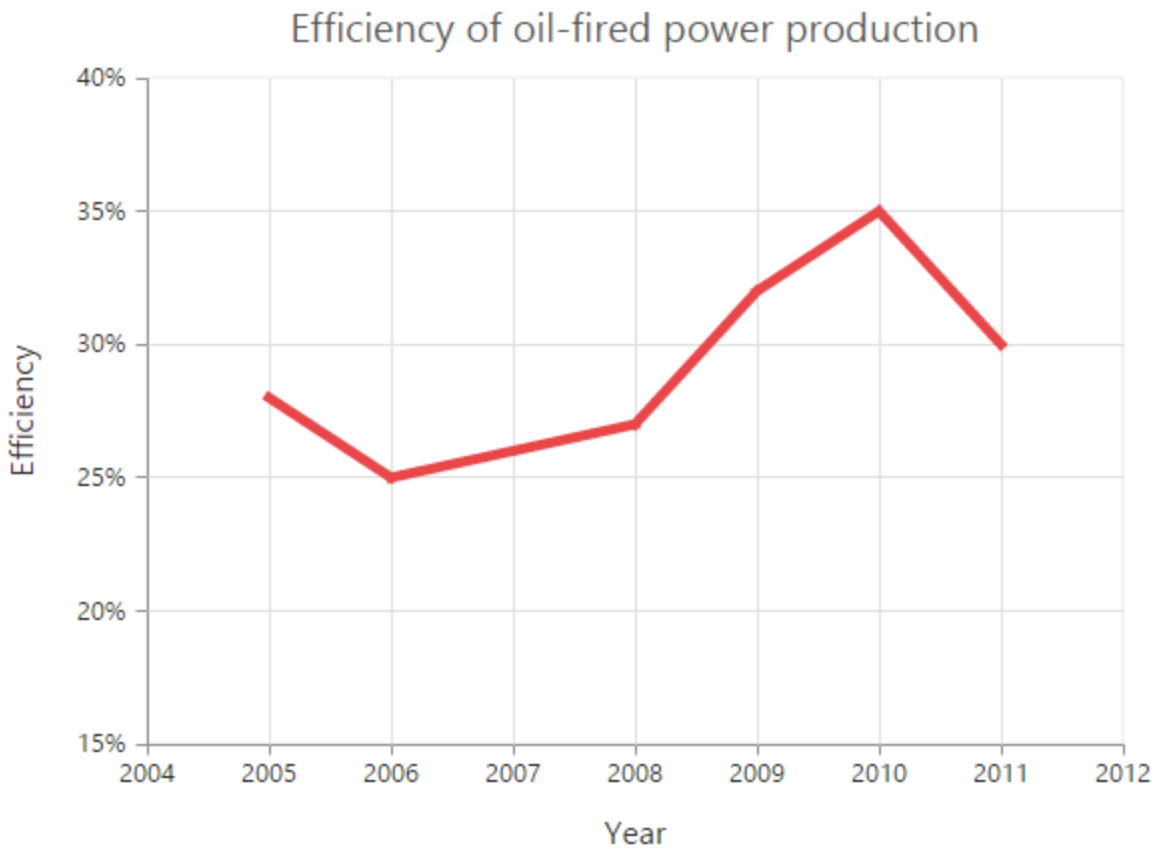
Changing the line cap

For customizing the start and end caps of the line segment, you can use the **LineCap** property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change line cap
sr.LineCap(ChartLineCap.Square).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



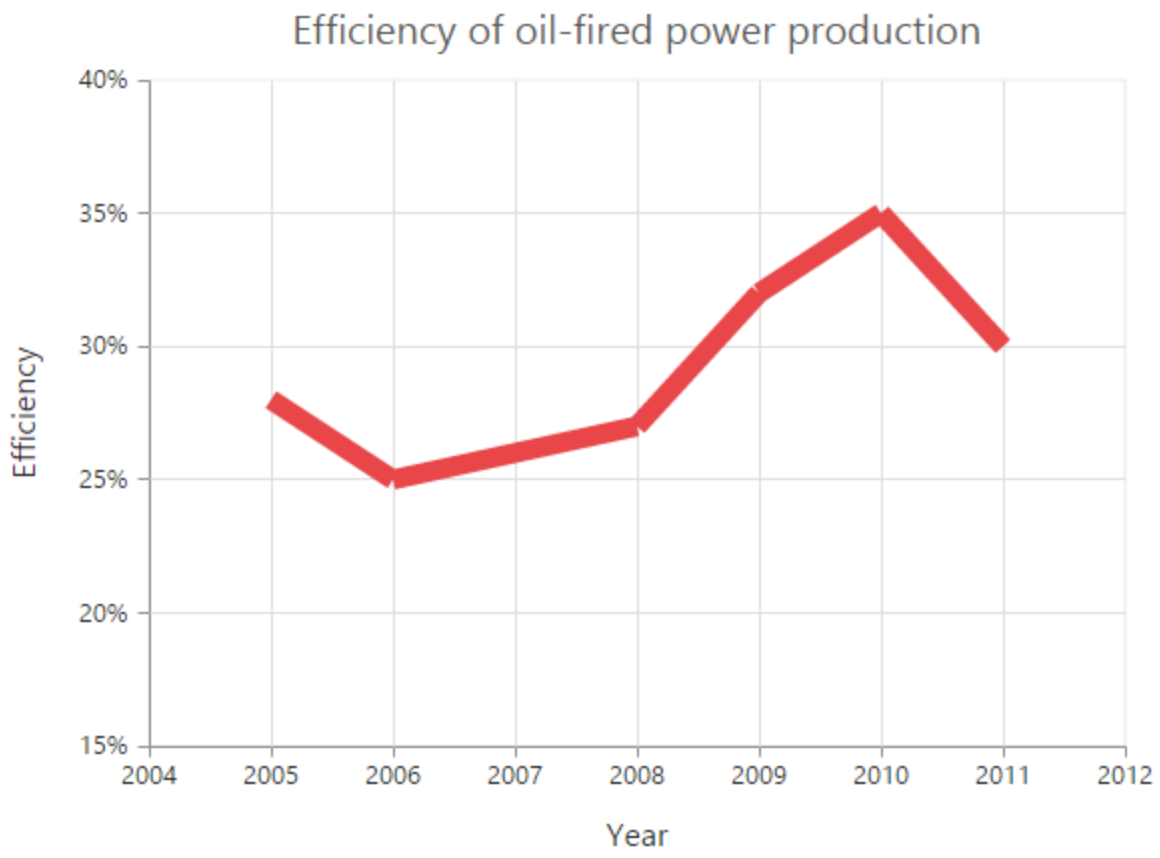
Changing the line join

You can use the **LineJoin** property to specify how two intersecting line segments should be joined.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change line join
sr.LineJoin(ChartLineJoin.Round).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

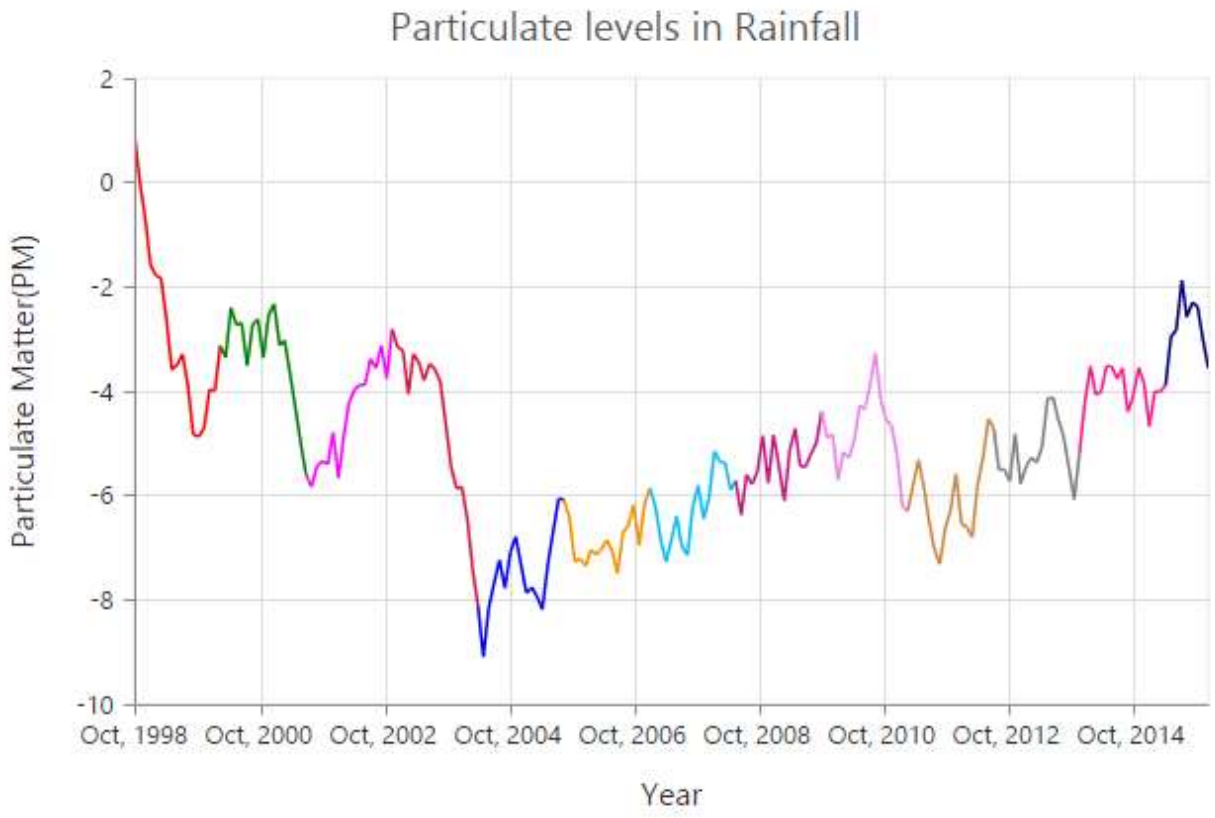


MultiColor Line

You can change the color of the line segments by using the *Fill* property of the each *Points* in the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
//Adding Candle series
sr.Points(pt=>{
pt.Fill("red").Add();
}) .Add();
})
//...
)
```



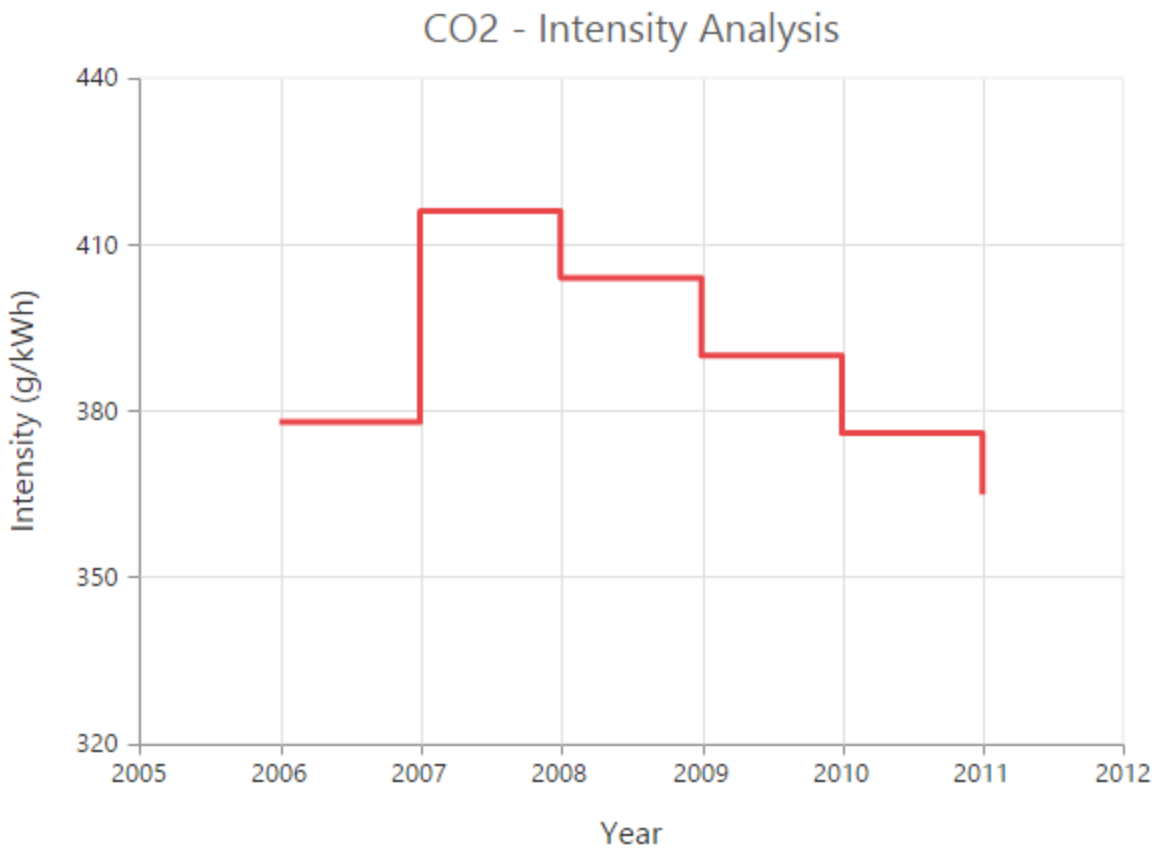
Click here to view the MultiColor Line Chart online demo sample.

Step Line Chart

To render a Step Line Chart, set the series Type as **StepLine"** in the chart series. To change the StepLine segment color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change type and color of the series.
sr.Type(SeriesType.StepLine).Fill("#E94649").Add();
})
//...
)
```



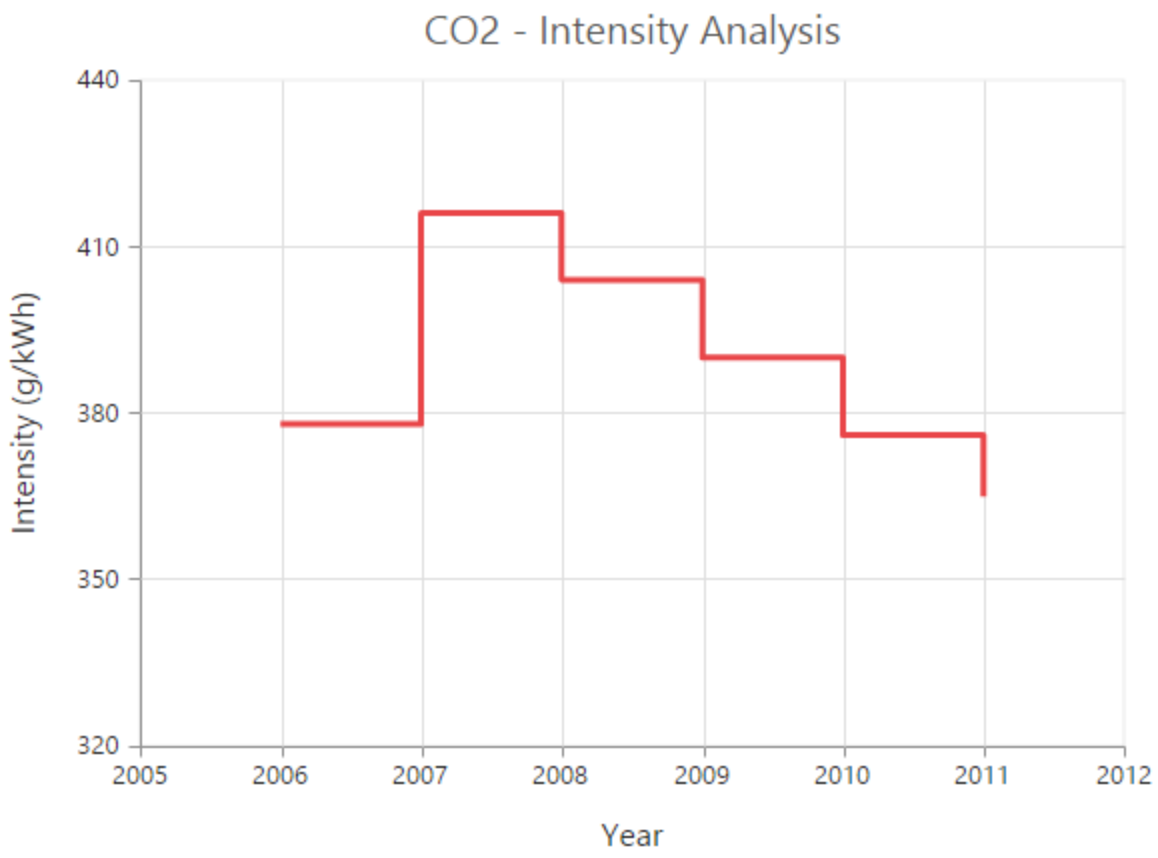
Click here to view the Step Line Chart online demo sample.

Changing the line width

To change the line width, you can use the **Width** property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change the width of step line series
sr.Width(3).Add();
})
//...
)
```

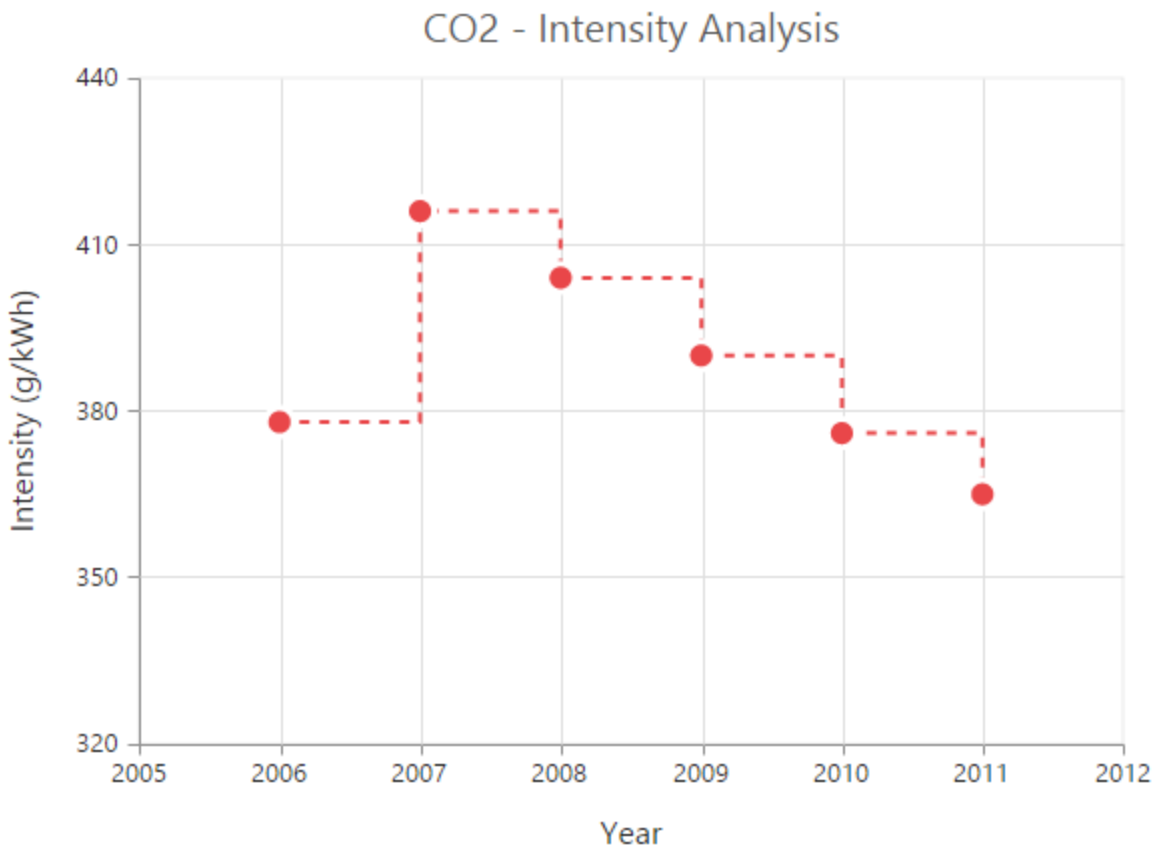


Dashed lines

To render the step line series with dotted lines, you can use the DashArray option of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change dash array to display dotted or dashed lines
sr.DashArray("5,5").Add();
})
//...
)
```



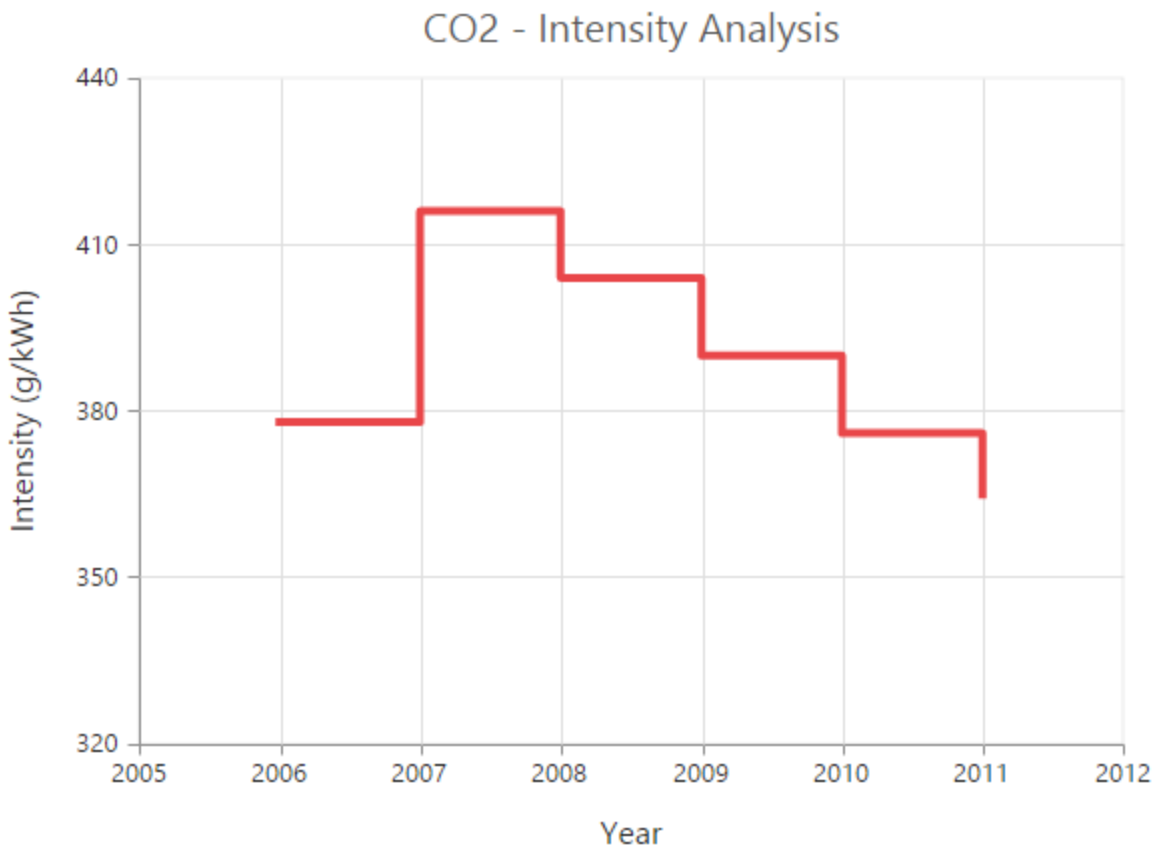
Changing the line cap

For customizing the start and end caps of the line segment, you can use the LineCap property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change line cap
sr.LineCap(ChartLineCap.Square).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



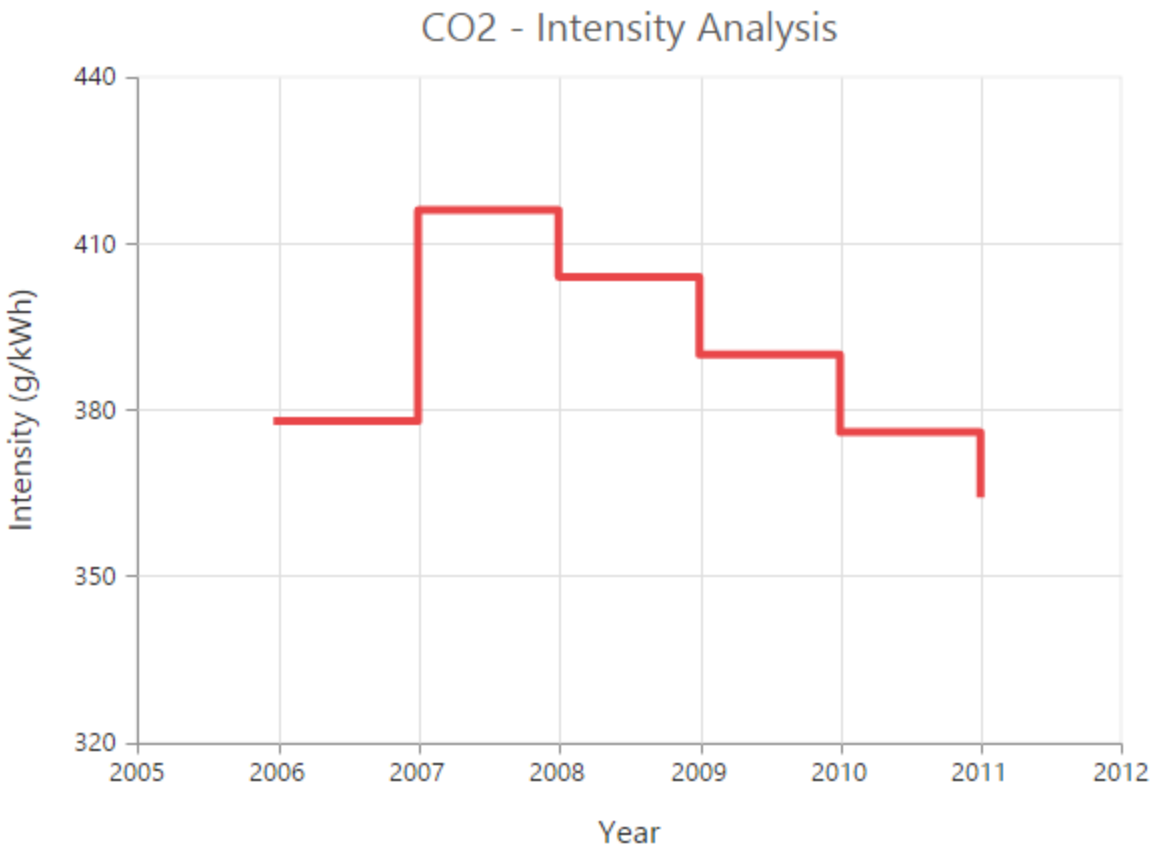
Changing the line join

You can use the LineJoin property to specify how two intersecting line segments should be joined.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change line join
sr.LineJoin(ChartLineJoin.Round).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



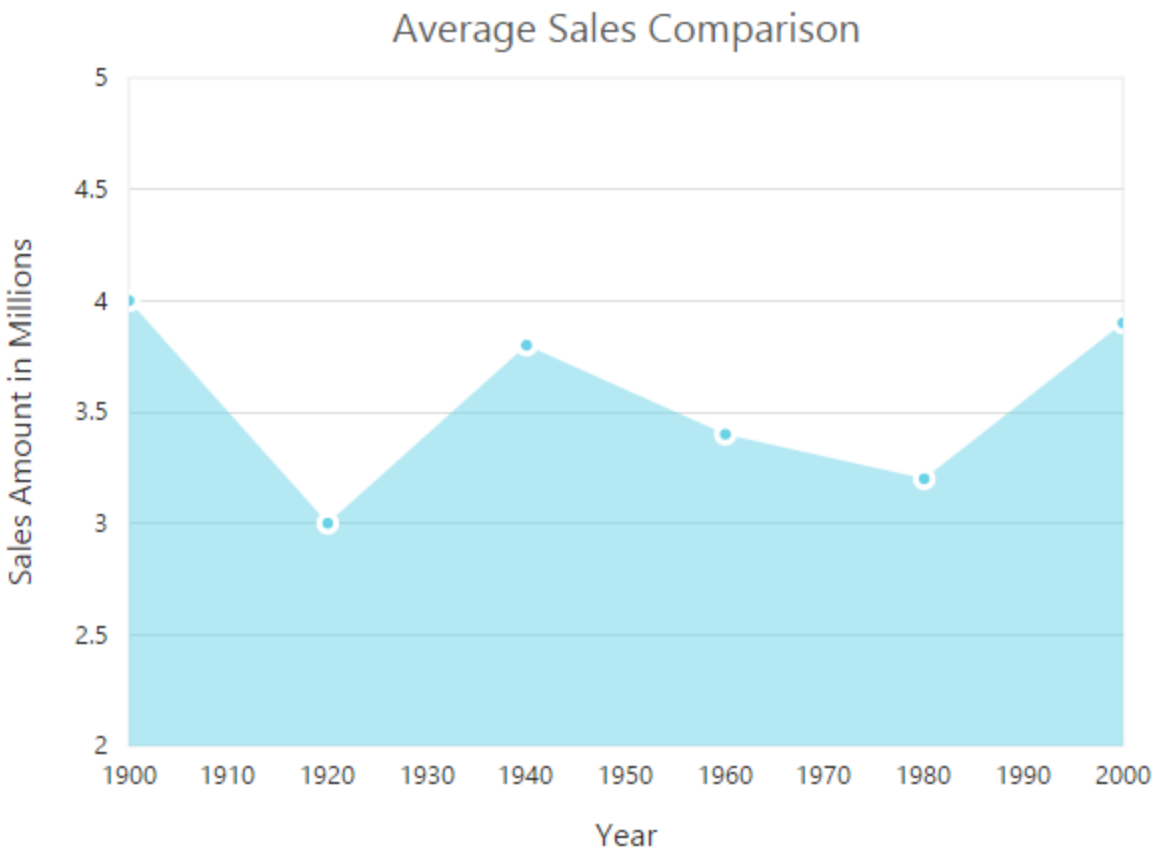
Area Chart

To render an Area chart, you can specify the series Type as **Area** in the chart series. To change the Area color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change type and color of the series.
sr.Type(SeriesType.Area).Fill("#69D2E7").Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Area Chart online demo.

Range Area Chart

To render a Range Area Chart, set the Type as **RangeArea** in the chart series. To change the RangeArea color, you can use the Fill property of the series.

Since the RangeArea series requires two y values for a point, you have to add the **High** and **Low** value. High and Low value specifies the maximum and minimum range of the points.

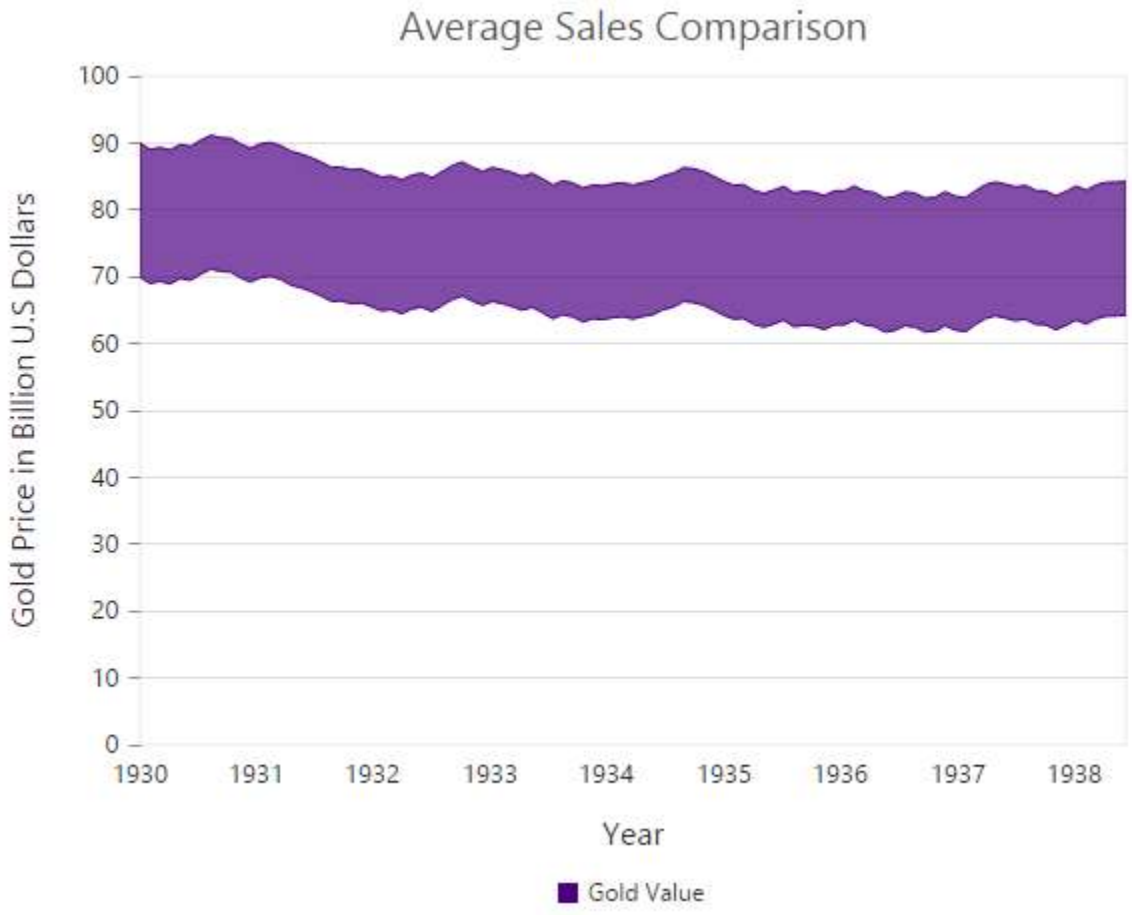
- When you are using the Points option, specify the high and low values by using the High and Low option of the point.
- When you are using the DataSource option to assign the data, map the fields from the dataSource that contain High and Low values by using the Series.High and Series.Low options.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change the series type and fill color
sr.Type(SeriesType.RangeArea).Fill("Indigo")
//Use High and Low values instead of Y
.Points(pt=>{pt.X("1935").High(80).Low(70).Add();
//..
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Add();
})
//...
)
```



Click here to view Range Area Chart online demo.

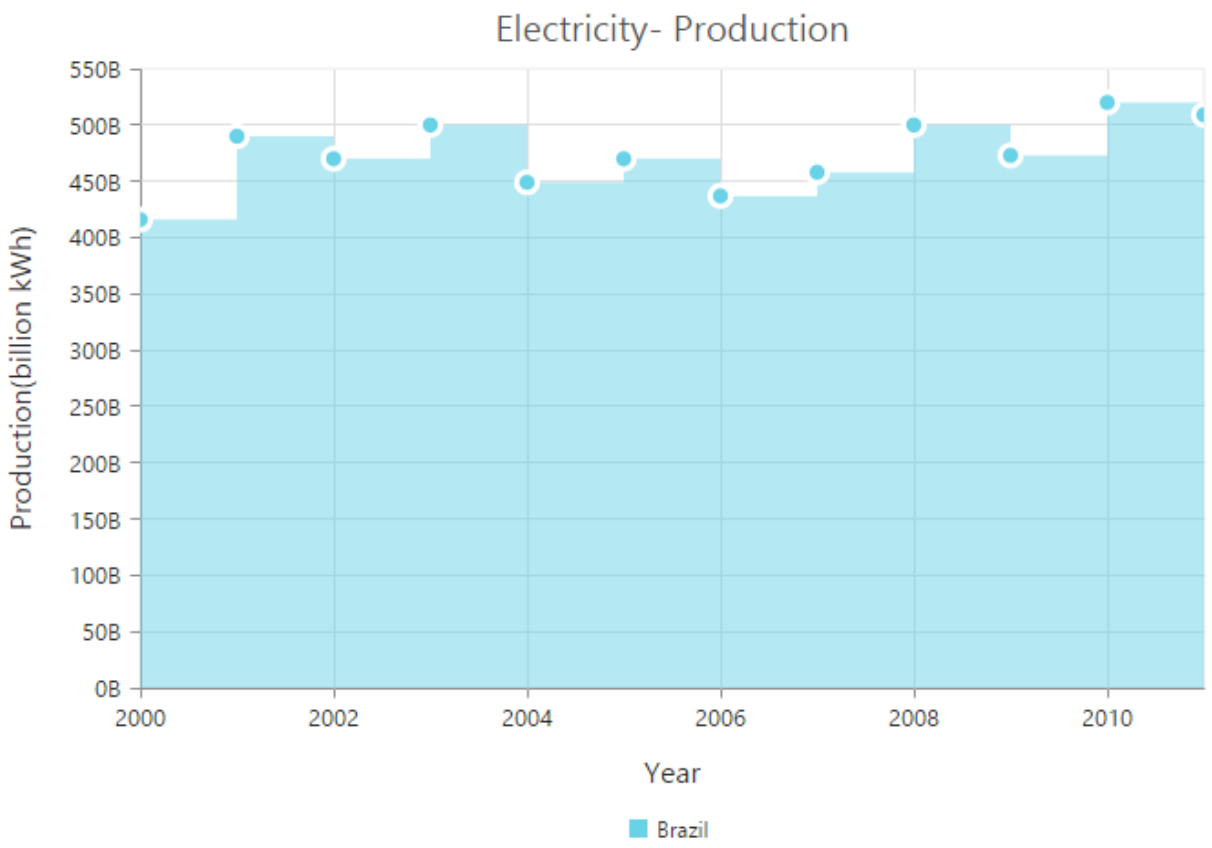
Step Area Chart

To render a Step Area Chart, set the Type as **StepArea** in the chart series. To change the StepArea color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change the series type and fill color
sr.Type(SeriesType.StepArea).Fill("#69D2E7")
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



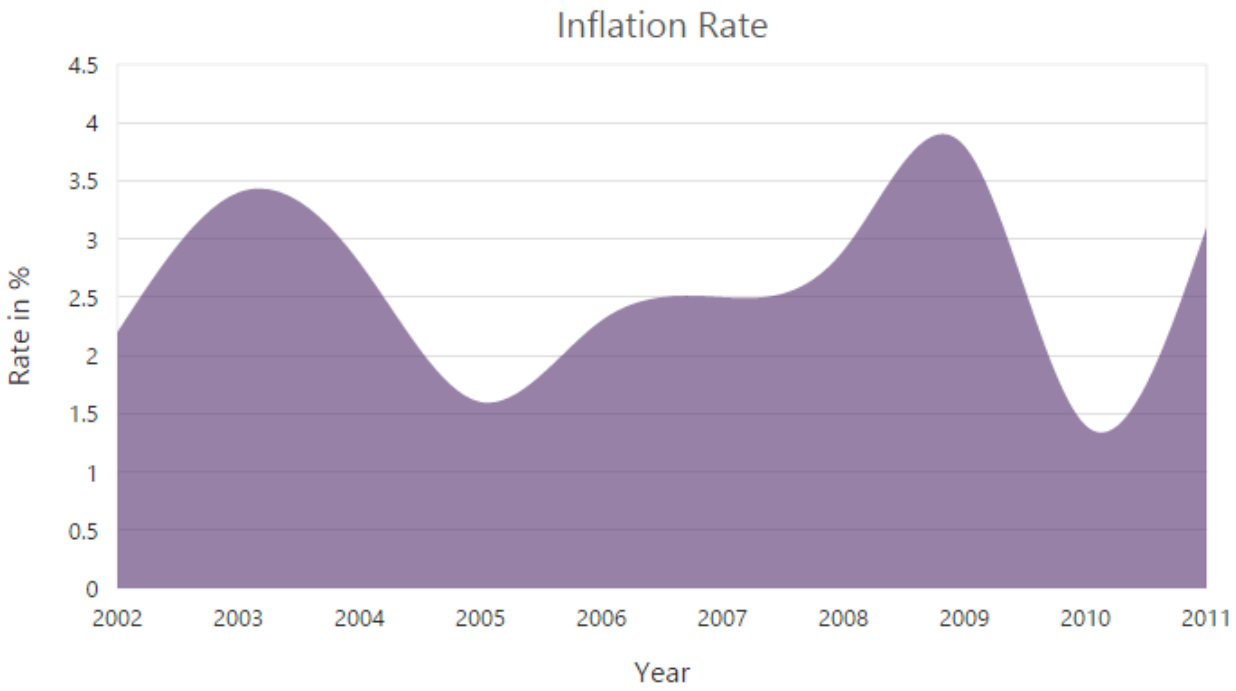
Click here to view Step Area Chart online demo.

Spline Area Chart

To render a Spline Area Chart, set the Type as **SplineArea** in the chart series. To change the SplineArea color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change the series type and fill color
sr.Type(SeriesType.SplineArea).Fill("#C4C24A")
//...
.Add();
})
//...
)
```



Click here to view Spline Area Chart online demo.

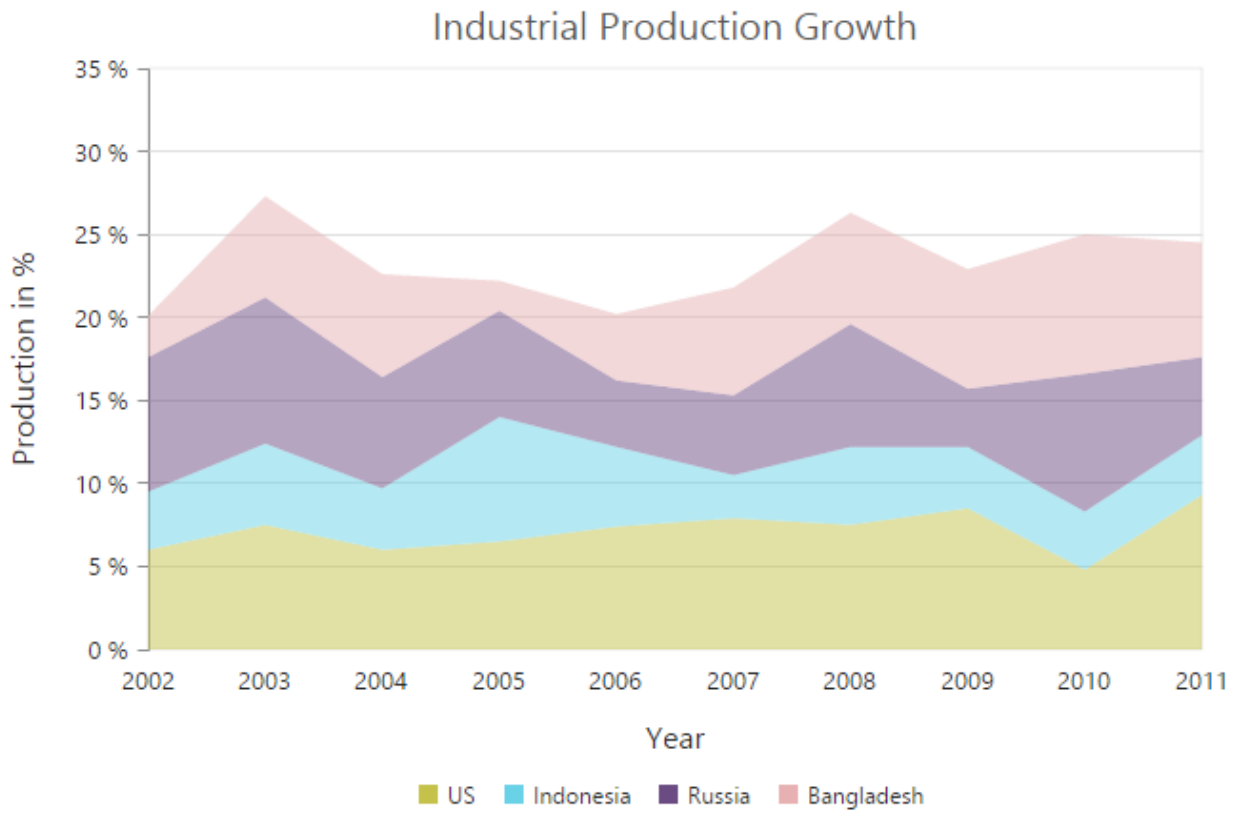
Stacked Area Chart

To render a Stacked Area Chart, set the Type as **StackingArea** in the chart series. To change the StackingArea color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change the series type and fill color
sr.Type(SeriesType.StackingArea).Fill("#69D2E7")
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



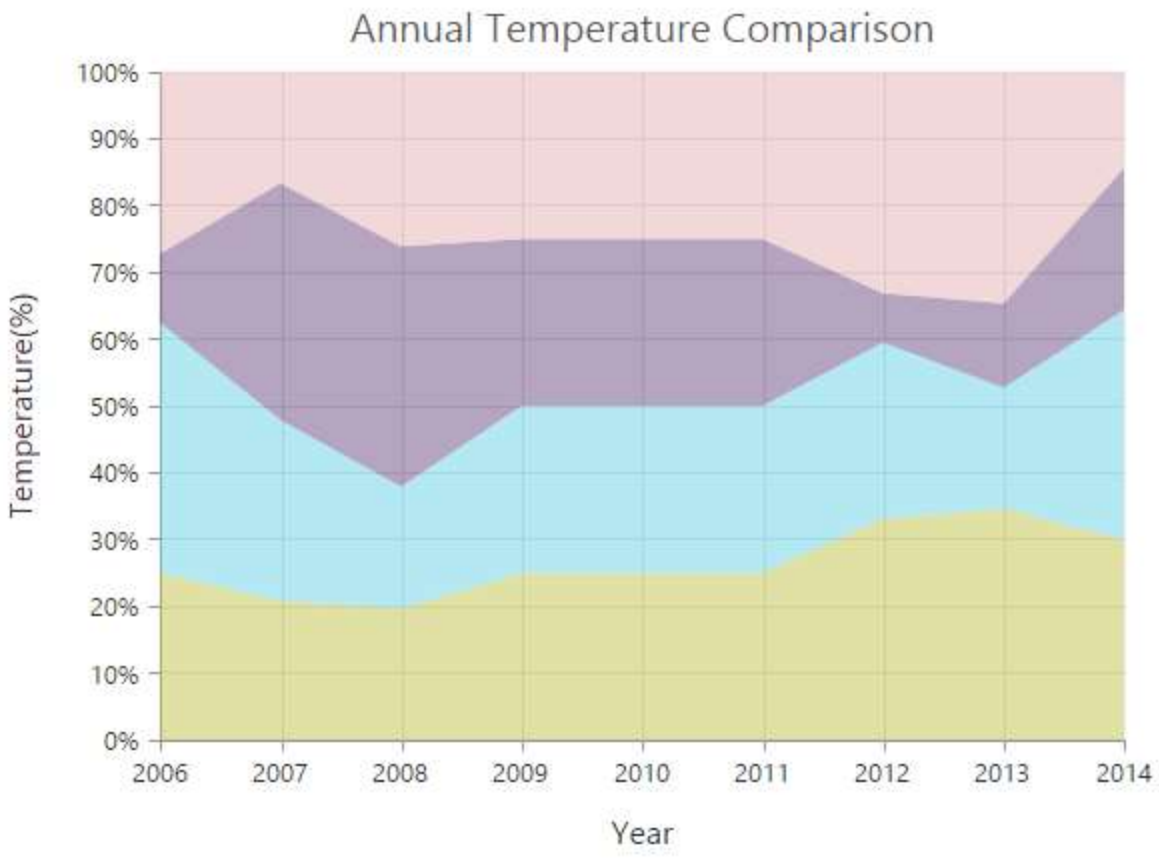
Click here to view Stacked Area Chart online demo.

100% Stacked Area Chart

To render a 100% Stacked Area Chart, set the Type as **StackingArea100** in the chart series. To change the StackingArea100 color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change the series type and fill color
sr.Type(SeriesType.StackingArea100).Fill("#C4C24A")
//...
.Add();
})
//...
)
```



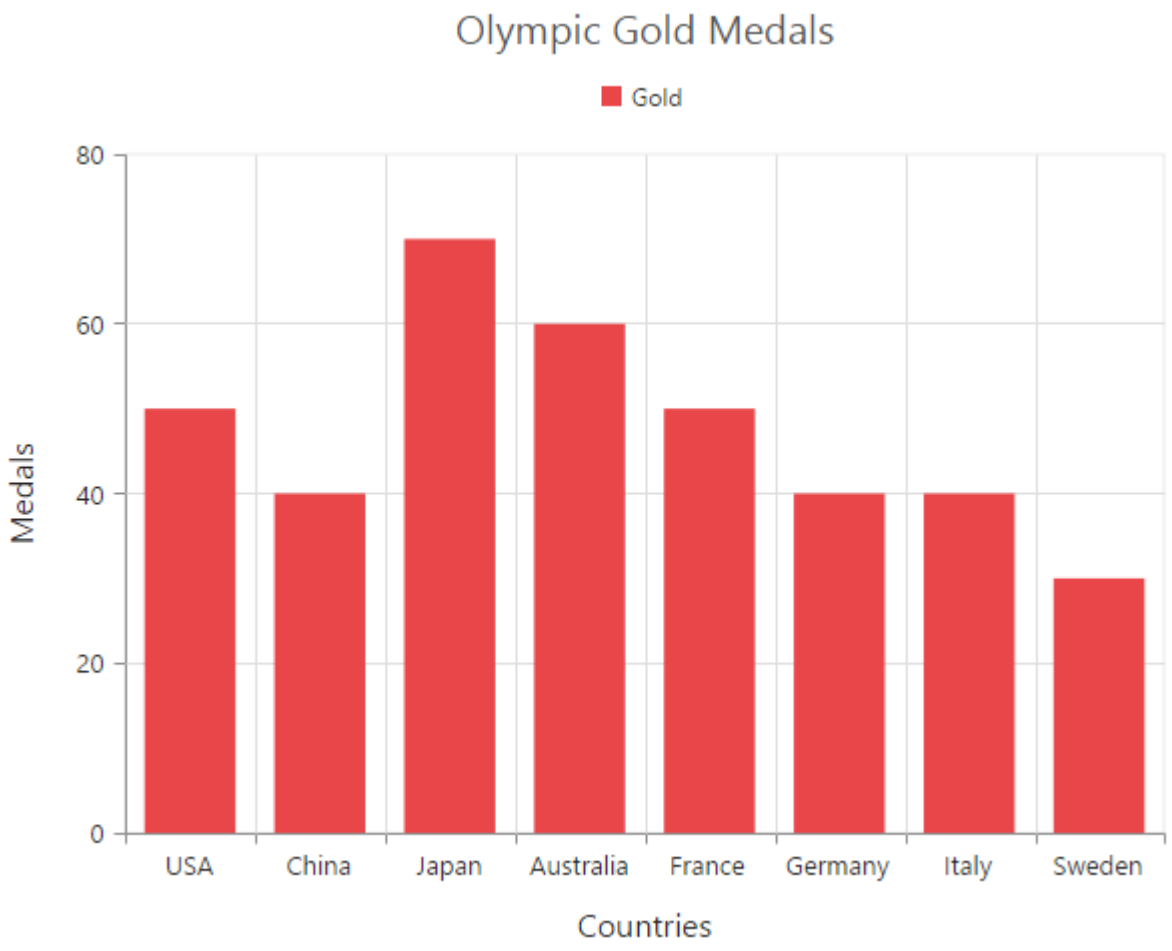
Click here to view 100% Stacked Area Chart online demo.

Column Chart

To render a Column Chart, set the Type as **Column** in the chart series. To change the color of the column series, you can use the Fill property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change the series type and fill color
sr.Type(SeriesType.Column).Fill("#E94649")
//...
.Add();
})
//...
)
```



Click here to view Column Chart demo.

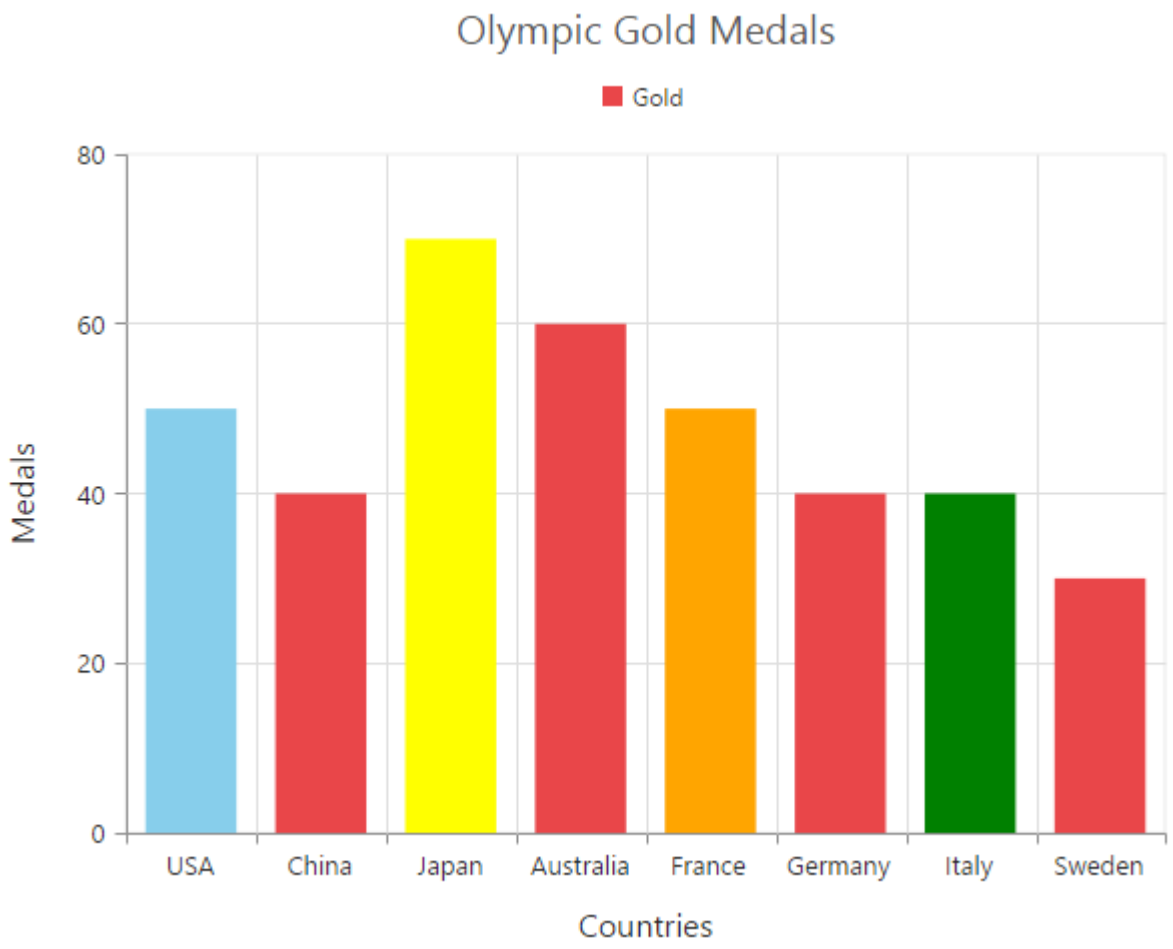
Change a point color

You can change the color of a column by using the Fill property of the point.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
sr.Points(pt=>{pt.Fill("skyblue").Add();})
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Column width customization

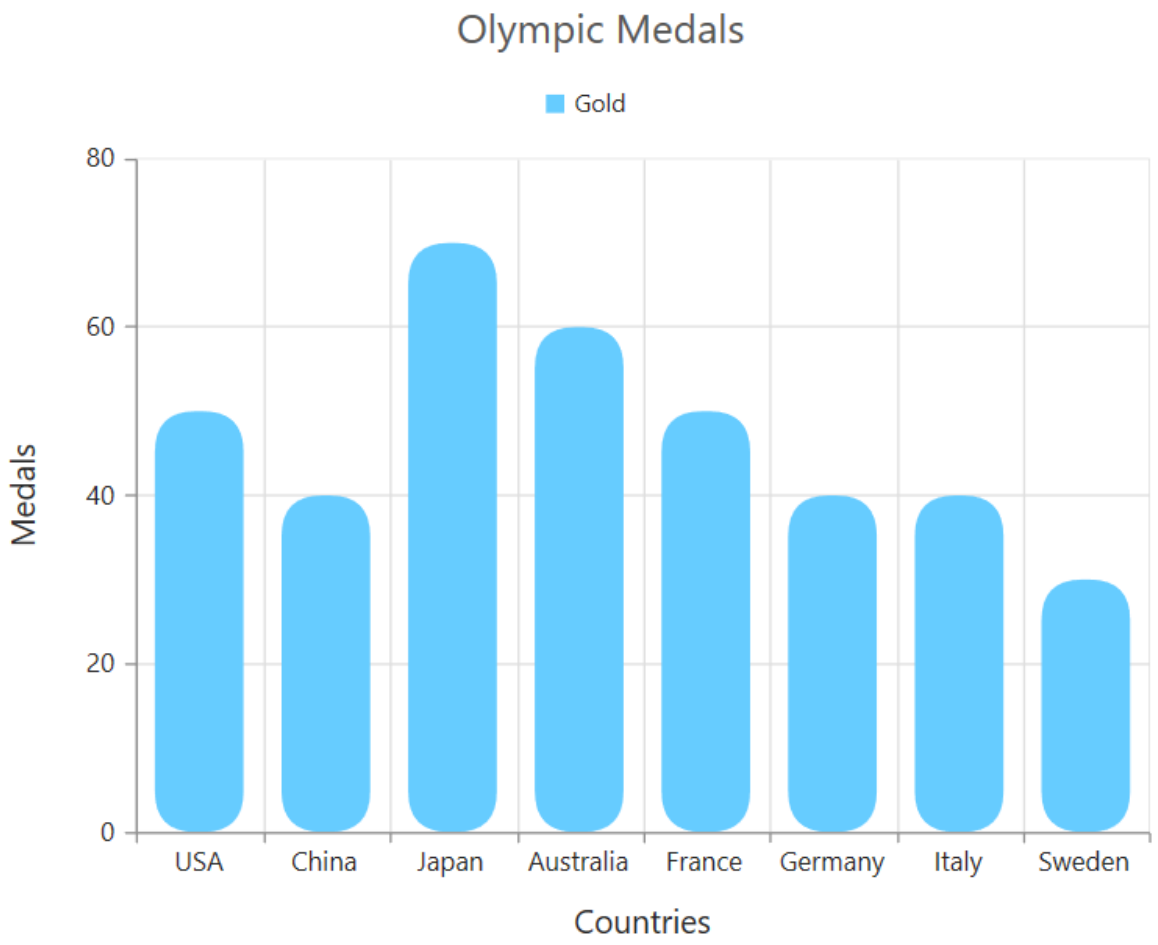
Width of any column type series can be customized by using the **ColumnWidth** property. Default value of *ColumnWidth* is 0.7. Value ranges from 0 to 1. Here 1 corresponds to 100% of available width and 0 corresponds to 0% of available width.

Note: Width of a column also depends upon the *ColumnSpacing* property, because *ColumnSpacing* will reduce the space available for drawing a column. This is also applicable for StackingColumn, StackingColumn100, Bar, StackingBar, StackingBar100, RangeColumn, HiLo, HiLoOpenClose, Candle and Waterfall charts.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
//Customizing column width for a specific series
sr.ColumnWidth(0.8).Add();
//...
})
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Column with rounded corners

Corners of the column chart can be customized by setting value to the **CornerRadius** property.

ASPX-CS

```
@(Html.EJ().Chart("container")
.CommonSeriesOptions(options => options.CornerRadius(20)
))
```

Spacing between column series

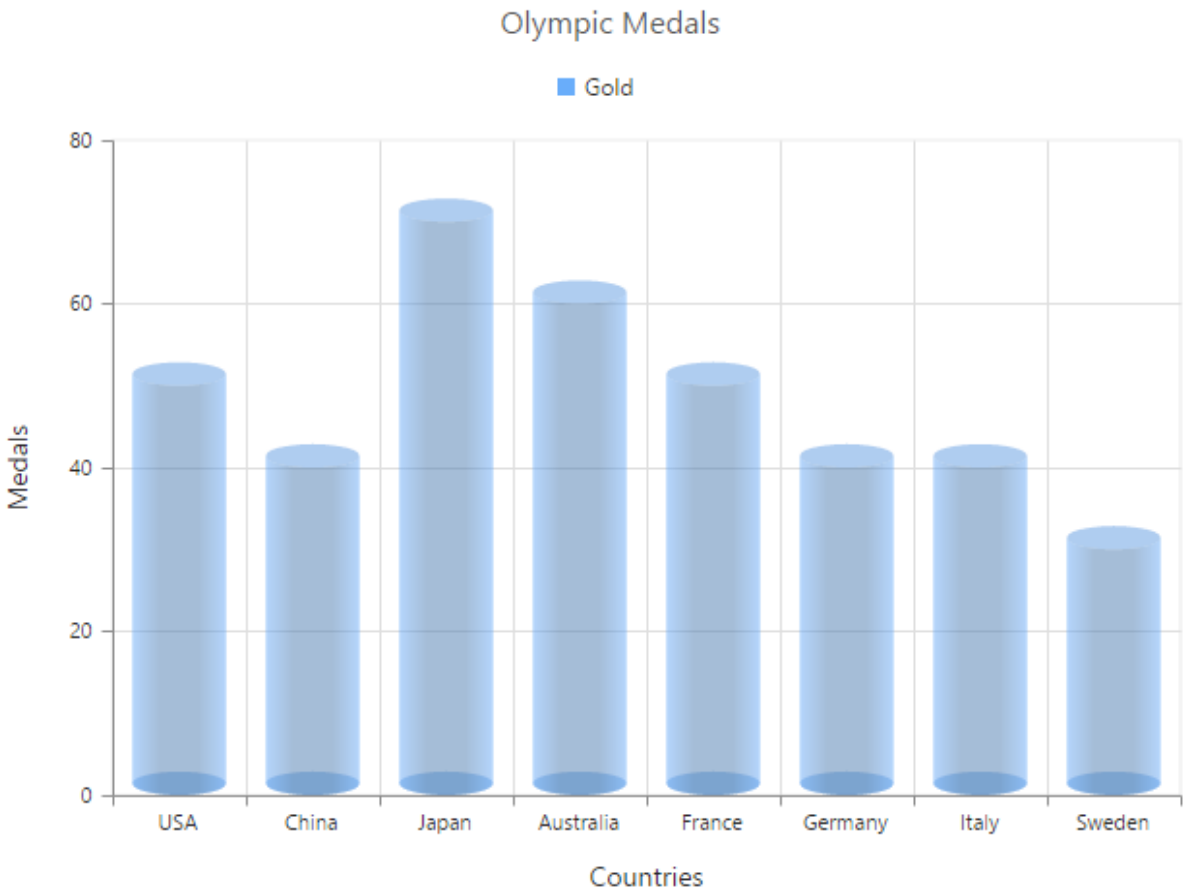
Spacing between column type series can be customized using the **ColumnSpacing** property. Default value of *ColumnSpacing* is 0. Value ranges from 0 to 1. Here 1 corresponds to 100% available space and 0 corresponds to 0% available space.

Note: Space between columns will also affect the width of the column. For example, setting 20% spacing and 100% width will render columns with 80% of total width. This is also applicable for StackingColumn, StackingColumn100, Bar, StackingBar, StackingBar100, RangeColumn, HiLo, HiLoOpenClose, Candle and Waterfall charts.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
//Customizing column spacing for a specific series
sr.ColumnSpacing(0.2).Add();
//...
})
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Cylindrical Chart

To render a cylindrical chart, set the **ColumnFacet** property as "Cylinder" in the chart series along with the series type.

The following chart types can be rendered as cylinder in both 2D and in 3D view.

- Column Chart, Bar Chart, Stacked Column Chart, Stacked Bar Chart, 100% Stacked Column Chart, 100% Stacked Bar Chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
// To change the shape of the series.
sr.Type(SeriesType.Line).ColumnFacet(ColumnFacet.Cylinder).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

RangeColumn Chart

To render a Range Column Chart, set the Type as **RangeColumn** in the chart series. To change the RangeColumn color, use the Fill property of the series.

Since, the RangeColumn series requires two y values for a point, add the High and Low value. High and Low value specifies the maximum and minimum range of the points.

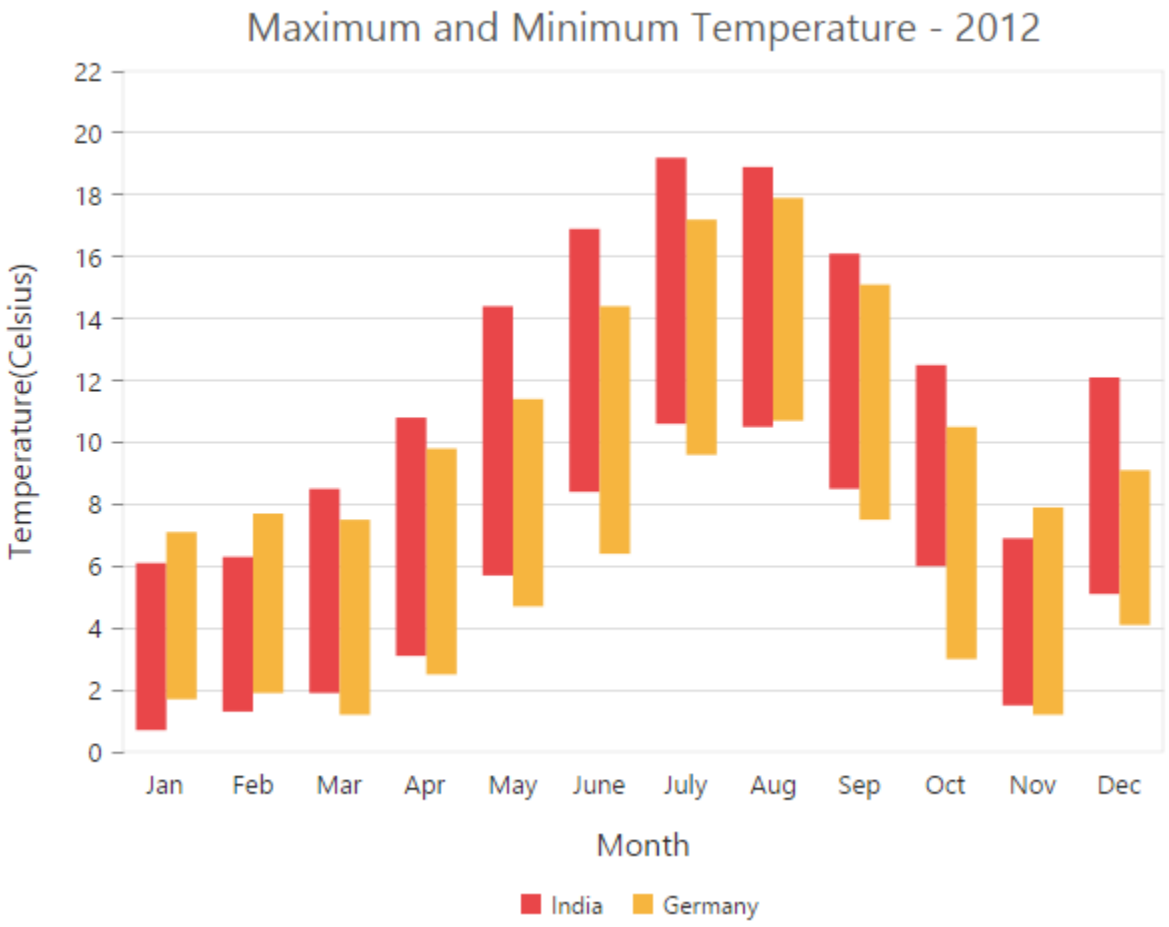
- When you are using the Points option, specify the high and low values by using the High and Low option of the point.
- When you are using the DataSource option to assign the data, you have to map the fields from the dataSource that contains high and low values by using the Series.High and Series.Low) options.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.RangeColumn).Fill("#E94649")
//Use high and low values instead of y
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Points(pt=>{pt.High("6.1").Low(0.7).Add();})
//...
.Add();
})
//...
)
```



Click here to view Range Column Chart online demo.

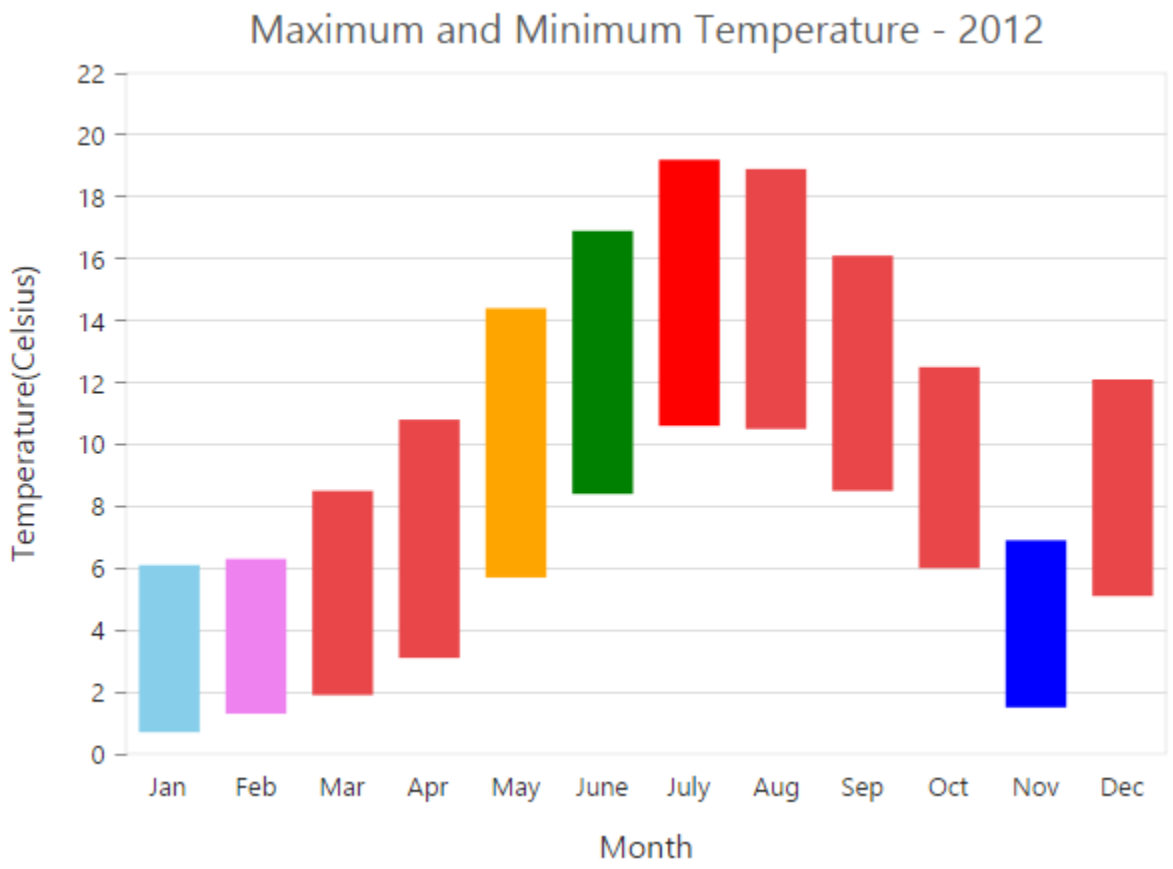
Change a point color

To change the color of a range column, you can use the Fill property of point.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//change a point color of Range column
sr.Points(pt=>{pt.Fill("skyblue").Add();})
//...
.Add();
})
//...
```

```
)
```

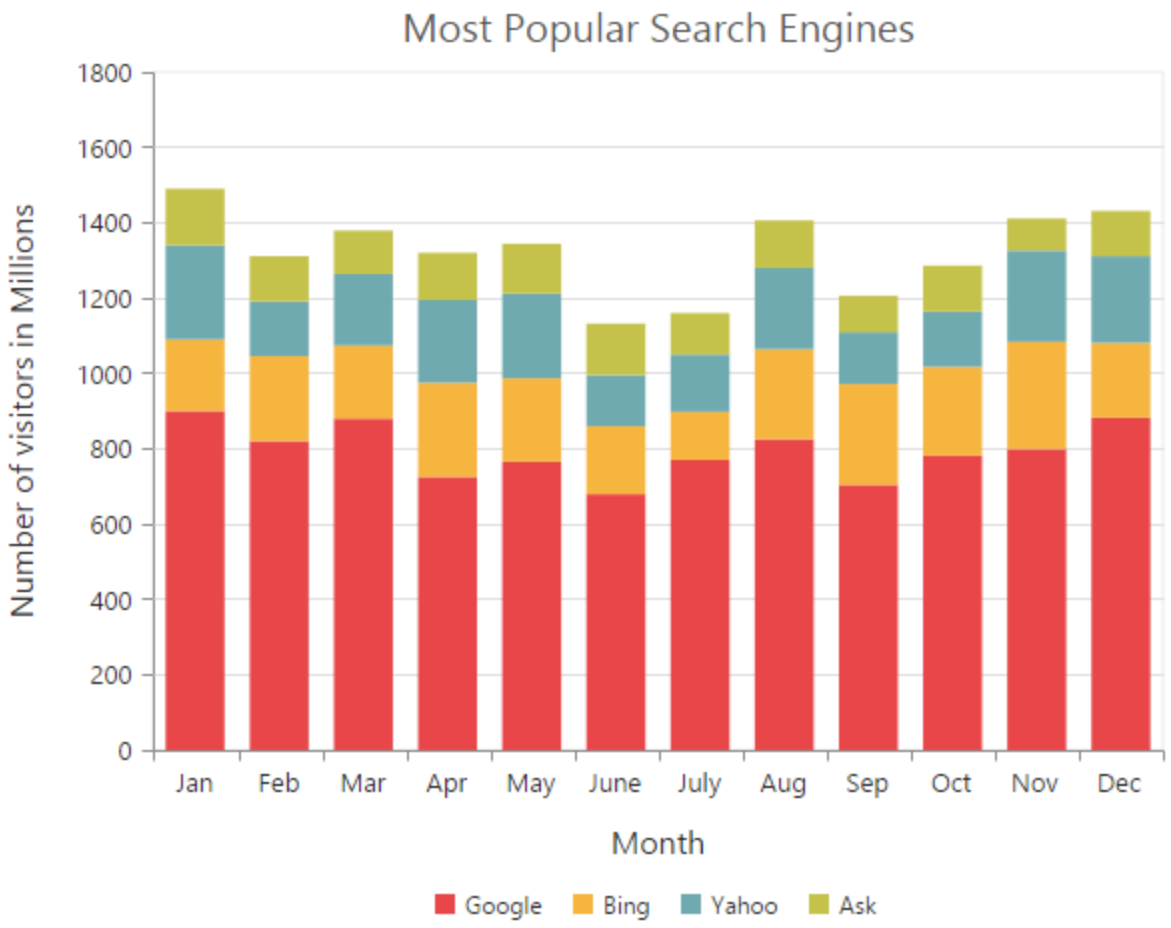


Stacked Column Chart

To render a Stacked Column Chart, set the Type as **StackingColumn** in the chart series. To change the StackingColumn color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.StackingColumn).Fill("#E94649")
//...
.Add();
})
//...
)
```



Click here to view Stacked Column Chart online demo.

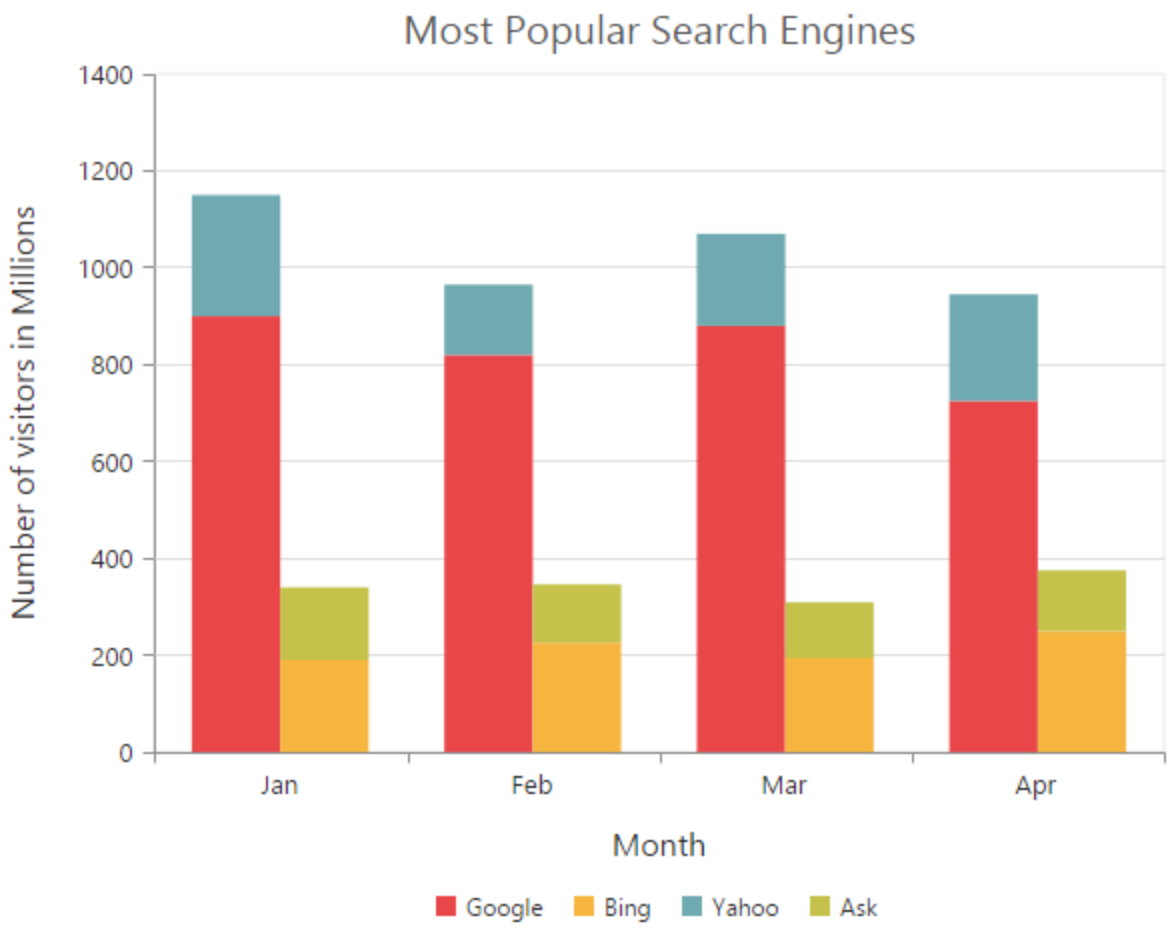
Cluster / Group stacked columns

You can use the **StackingGroup** property to group the stacked columns. Columns with same group name are stacked on top of each other.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
// For grouping stacked columns
sr.StackingGroup("GroupOne")
//...
.Add();
// For grouping stacked columns
sr.StackingGroup("GroupOne")
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



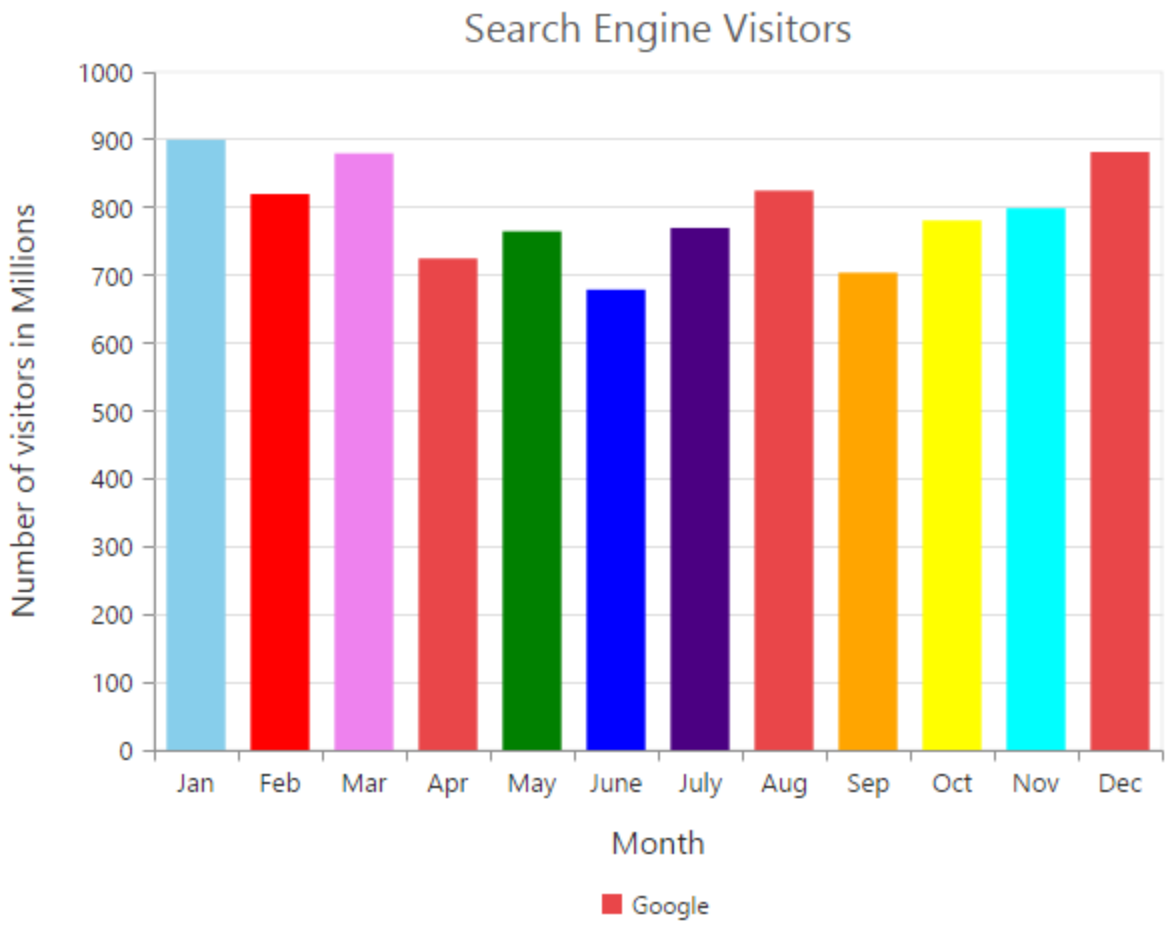
Change a point color

To change the color of a stacking column, you can use the Fill property of the point.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//change a point color of Stacking column
sr.Points(pt=>{pt.Fill("skyblue").Add();})
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



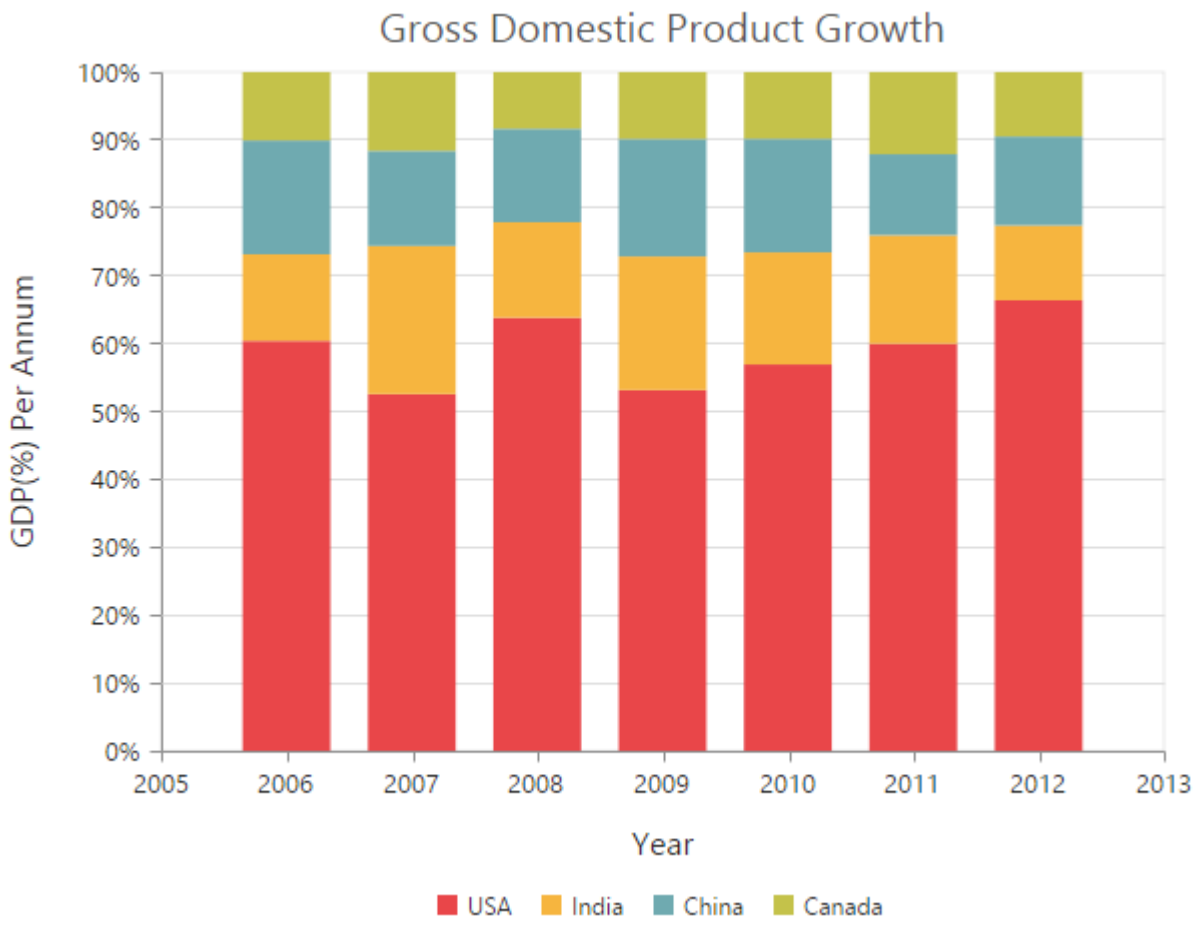
100% Stacked Column Chart

To render a 100% Stacked Column Chart, set the Type as **StackingColumn100** in the chart series. To change the StackingColumn100 color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change type and color of the series
sr.Type(SeriesType.StackingColumn100).Fill("#E94649")
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view 100% Stacked Column Chart online demo.

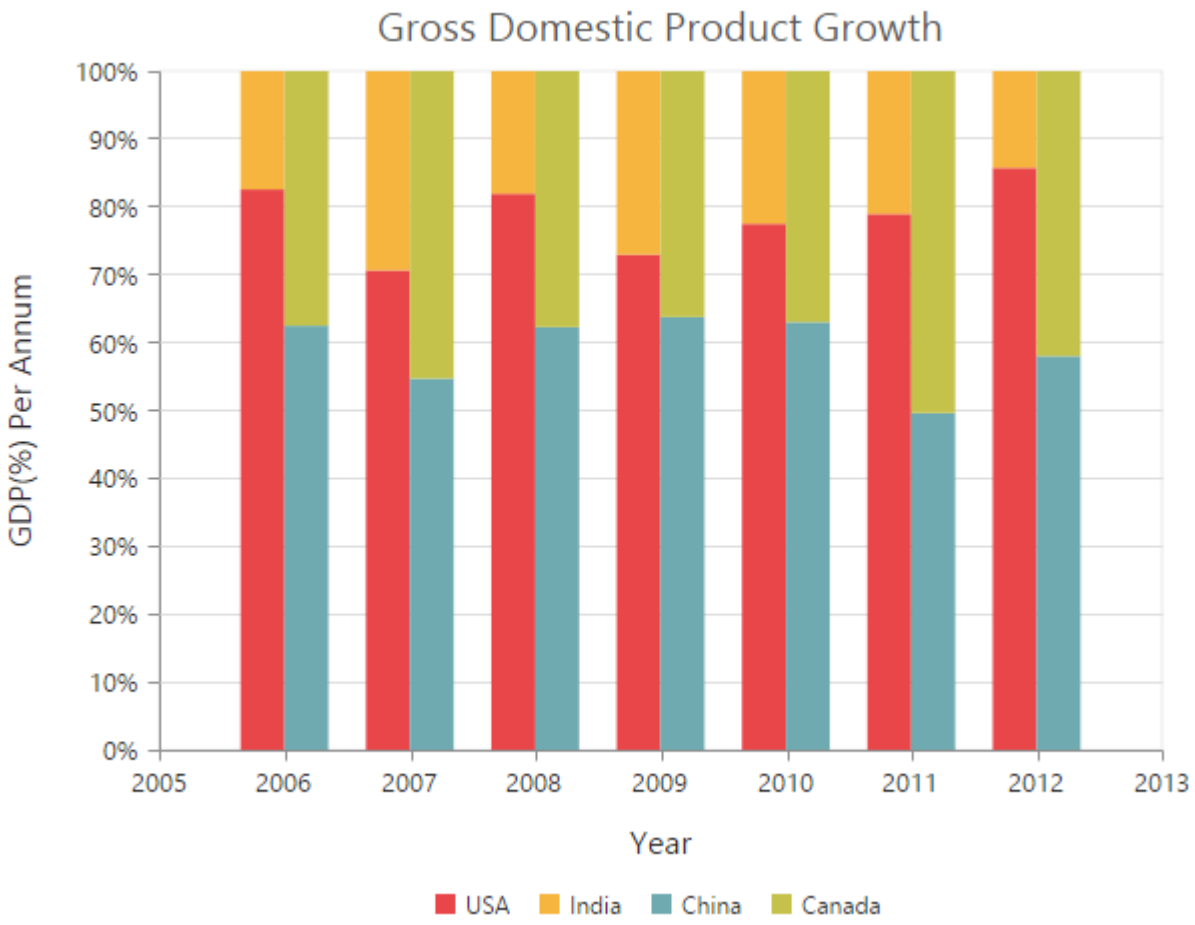
Cluster / Group 100% stacked columns

By using the **StackingGroup** property, you can group the 100% stacking columns. Columns with same group name are stacked on top of each other.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
// For grouping 100% stacked columns
sr.StackingGroup("GroupOne")
//...
.Add();
// For grouping 100% stacked columns
sr.StackingGroup("GroupOne")
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

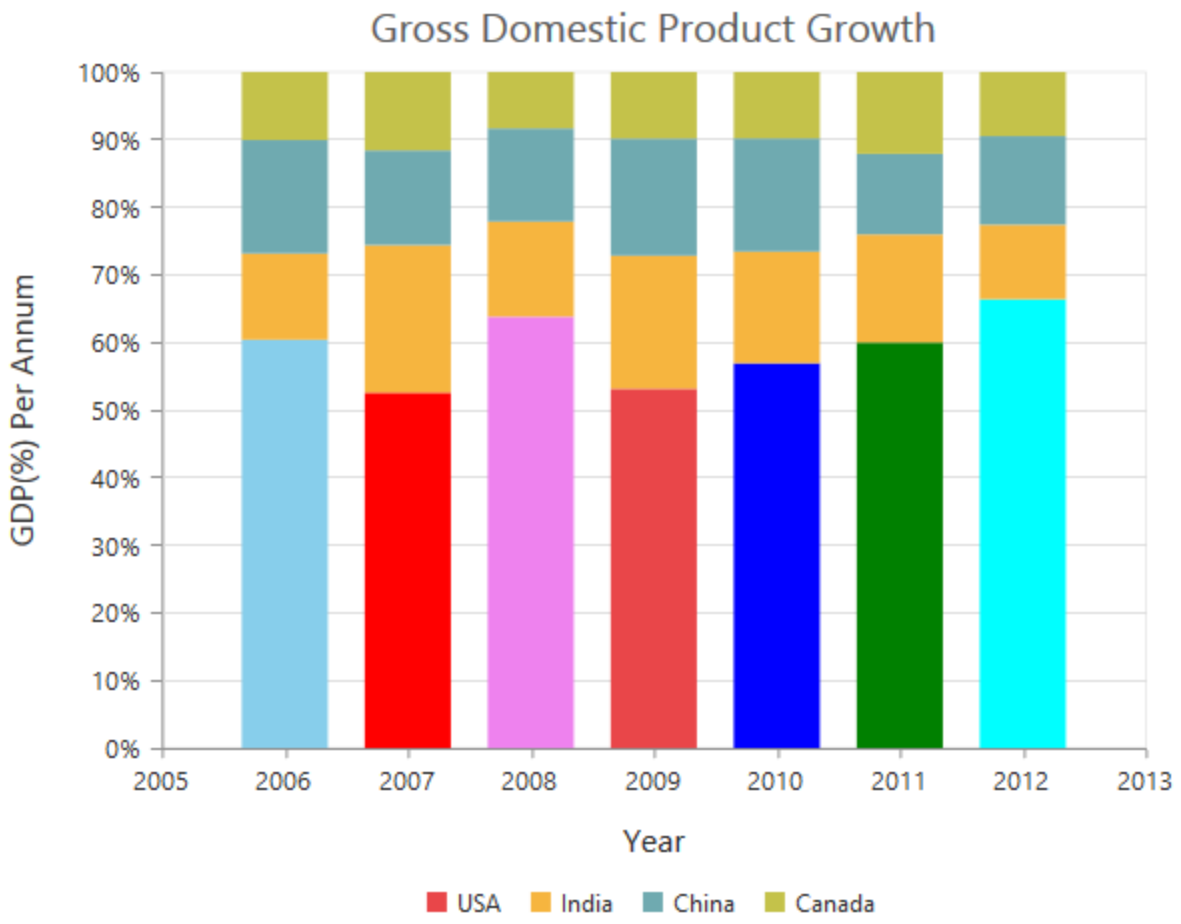


Change a point color

To change the color of a 100% stacking column, you can use the Fill property of the point.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//change a point color of 100% Stacking column
sr.Points(pt=>{pt.Fill("skyblue").Add();})
//...
.Add();
})
//...
)
```

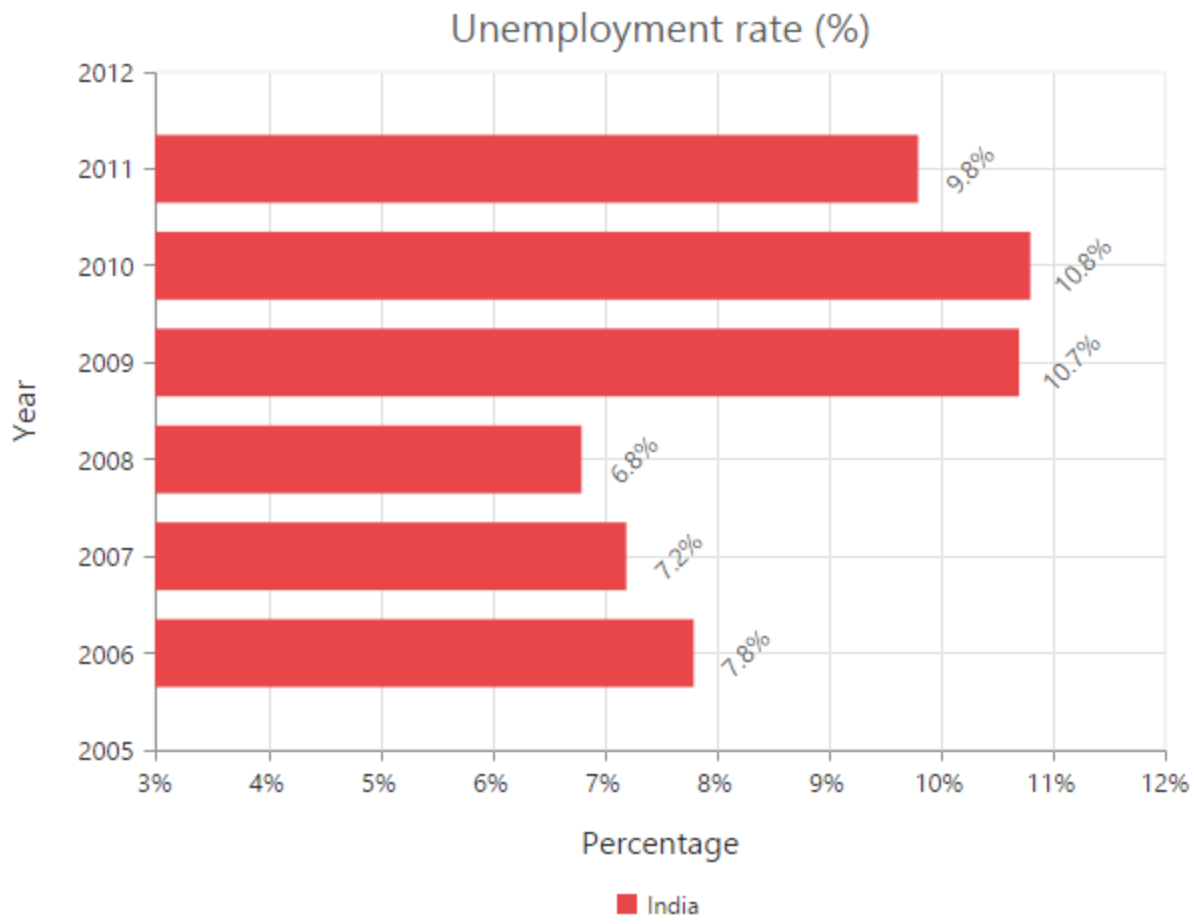


Bar Chart

To render a bar Chart, set the Type as **Bar** in the chart series. To change the bar color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change type and color of the series
sr.Type(SeriesType.Bar).Fill("#E94649")
//...
.Add();
})
//...
)
```



Click here to view Bar Chart demo.

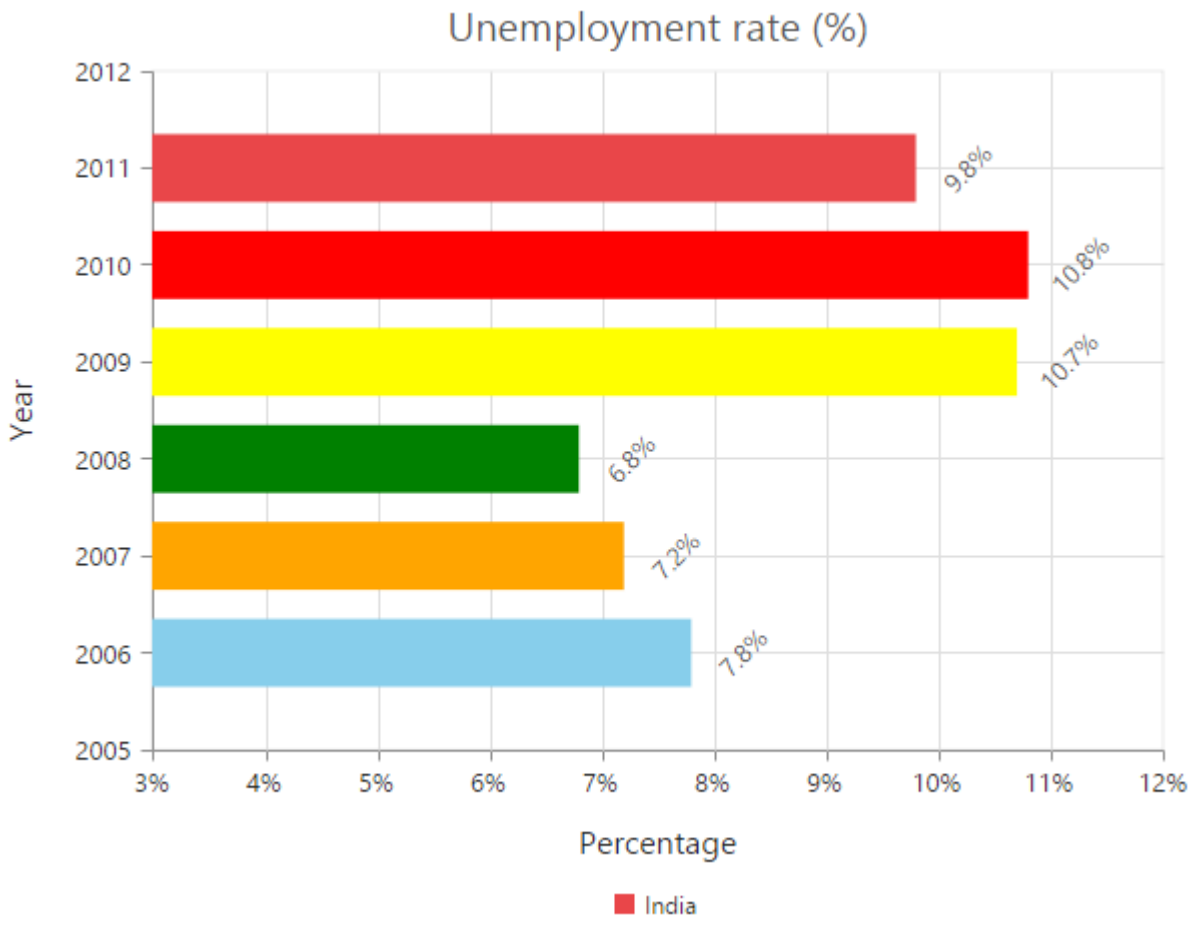
Change the color of a bar

By using the Fill property of the point, you can change the specific point of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//change a point color of bar
sr.Points(pt=>{pt.Fill("skyblue").Add();})
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

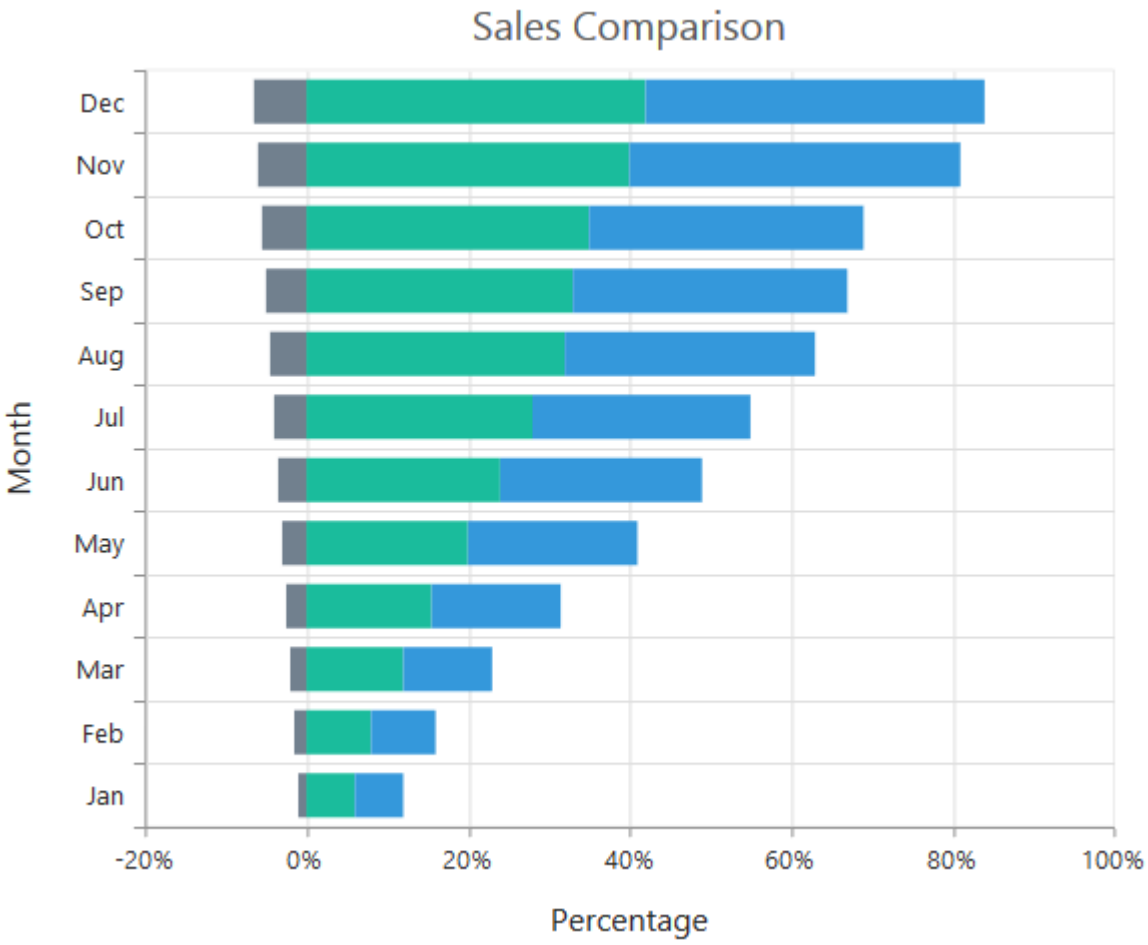


Stacked Bar Chart

To render a Stacked Bar Chart, set the Type as **StackingBar** in the chart series. To change the StackingBar color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change type and color of the series
sr.Type(SeriesType.StackingBar).Fill("#E94649")
//...
.Add();
})
//...
)
```



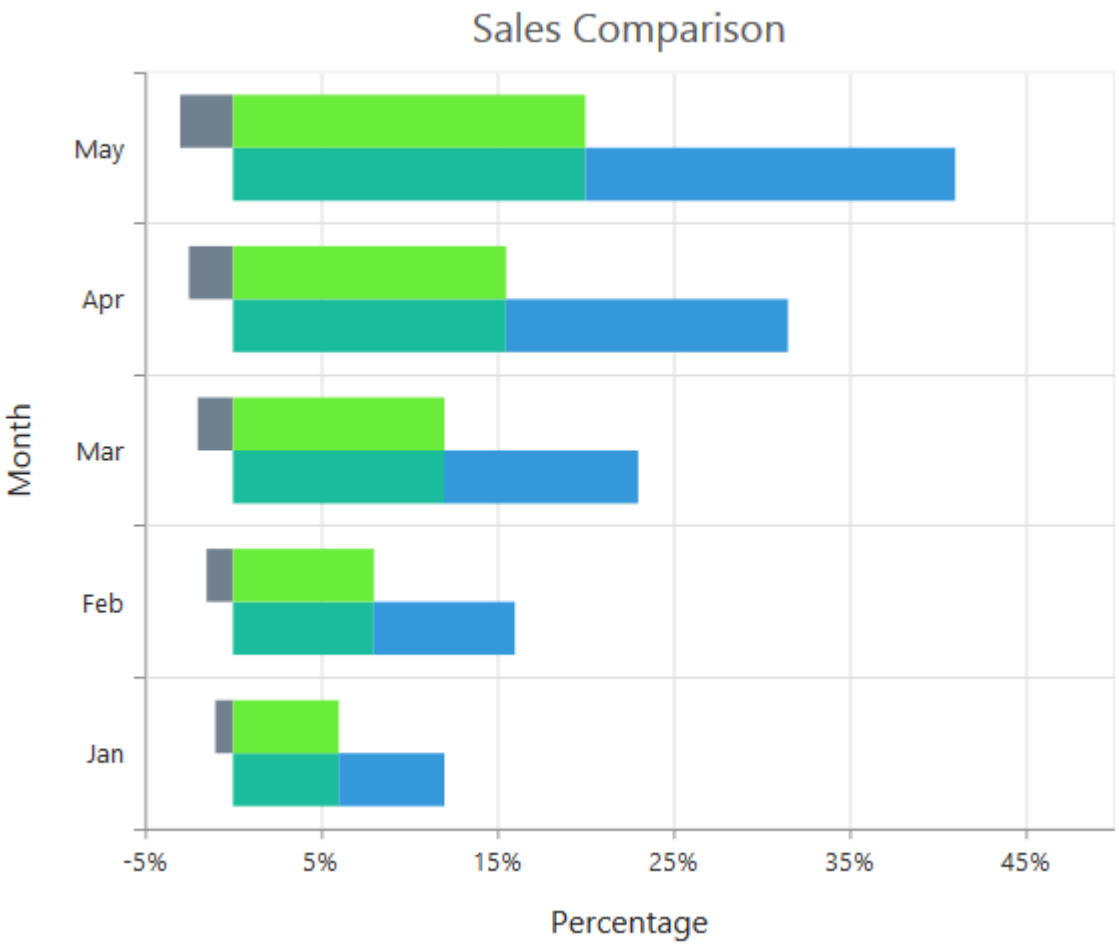
Click here to view Stacked Bar Chart online demo.

Cluster / Group stacked bars

You can use the **StackingGroup** property to group the stacking bars with the same group name.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
// For grouping stacking bar
sr.StackingGroup("GroupOne")
//...
.Add();
// For grouping stacking bar
sr.StackingGroup("GroupOne")
//...
.Add();
})
//...
)
```

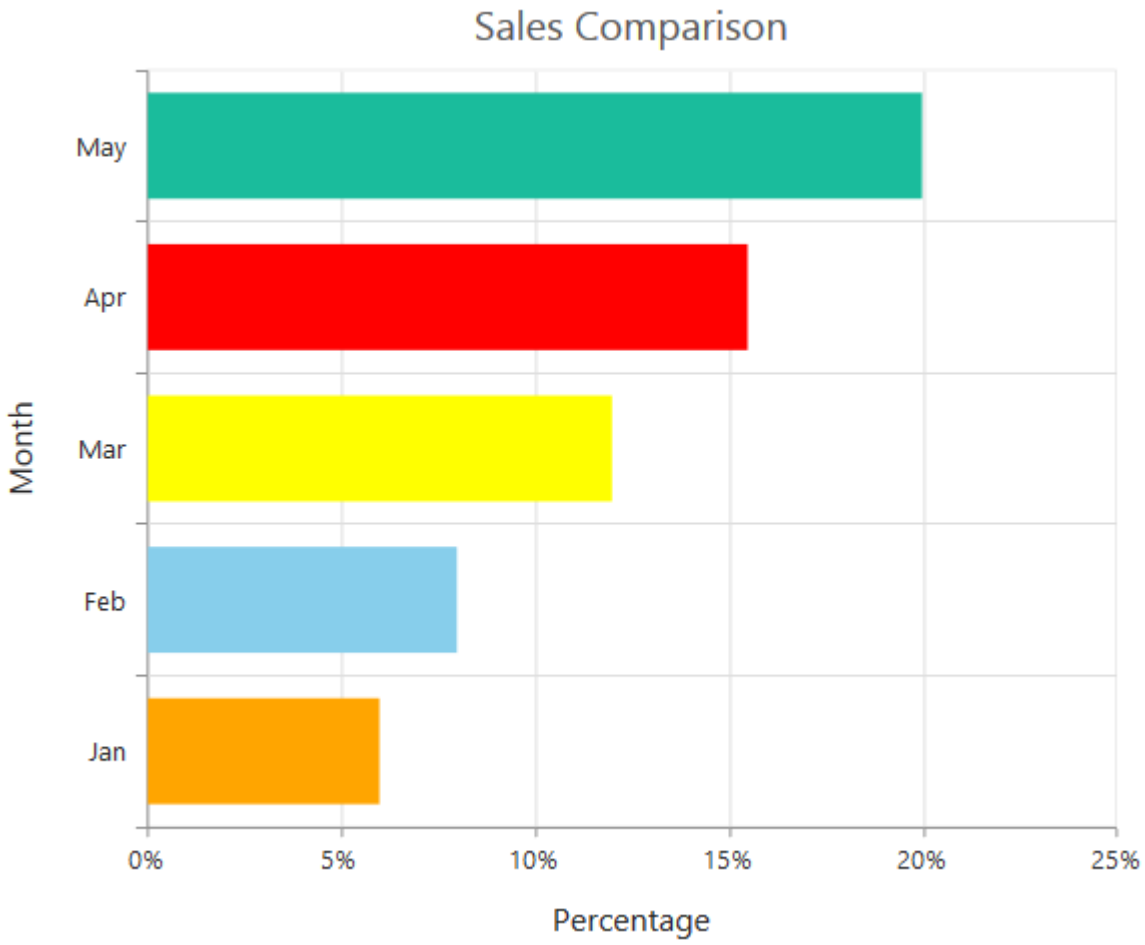


Change a point color

You can change the color of a stacking bar by using the Fill property of the point.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//change a point color of stacking bar
sr.Points(pt=>{pt.Fill("skyblue").Add();})
//...
.Add();
})
//...
)
```



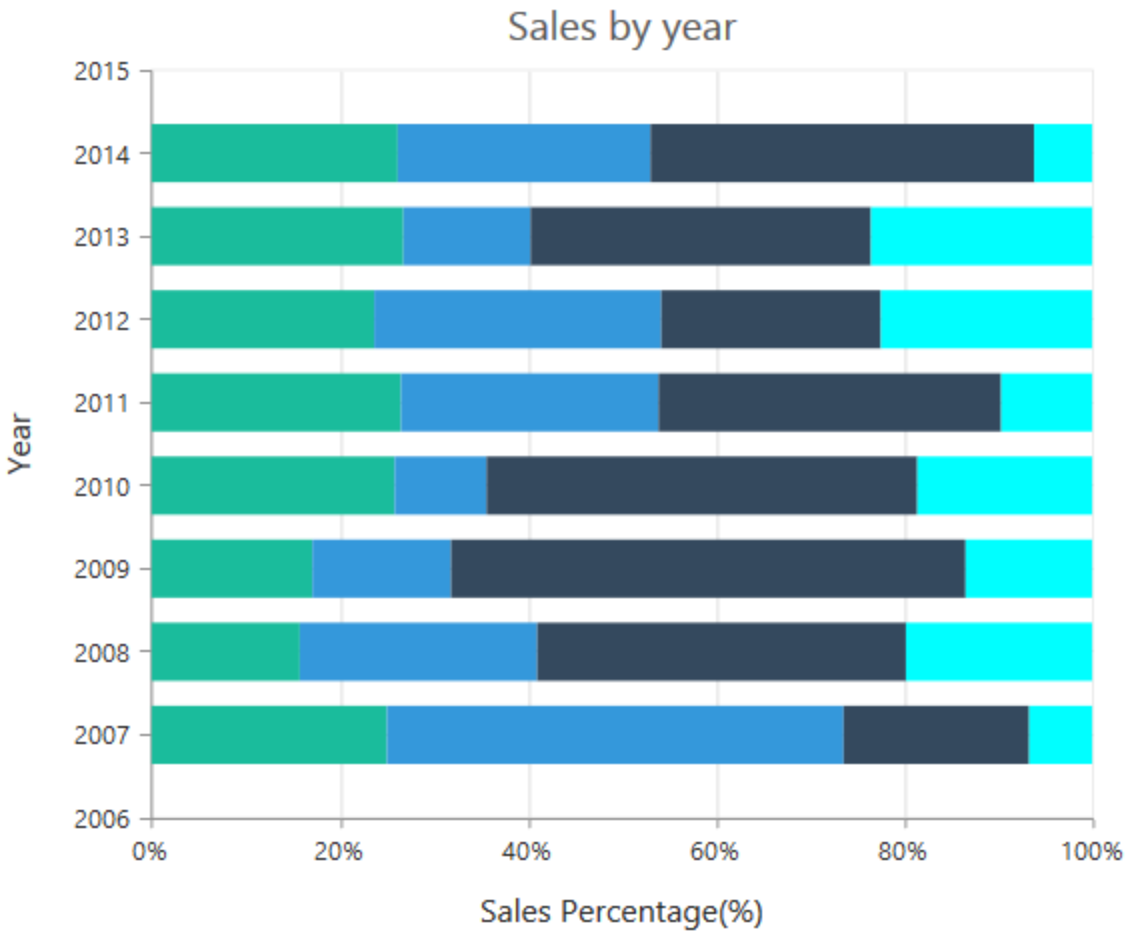
100% Stacked Bar Chart

To render a 100% Stacked Bar Chart, set the Type as **StackingBar100** in the chart series. To change the StackingBar100 color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change type and color of the series
sr.Type(SeriesType.StackingBar100).Fill("#E94649")
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



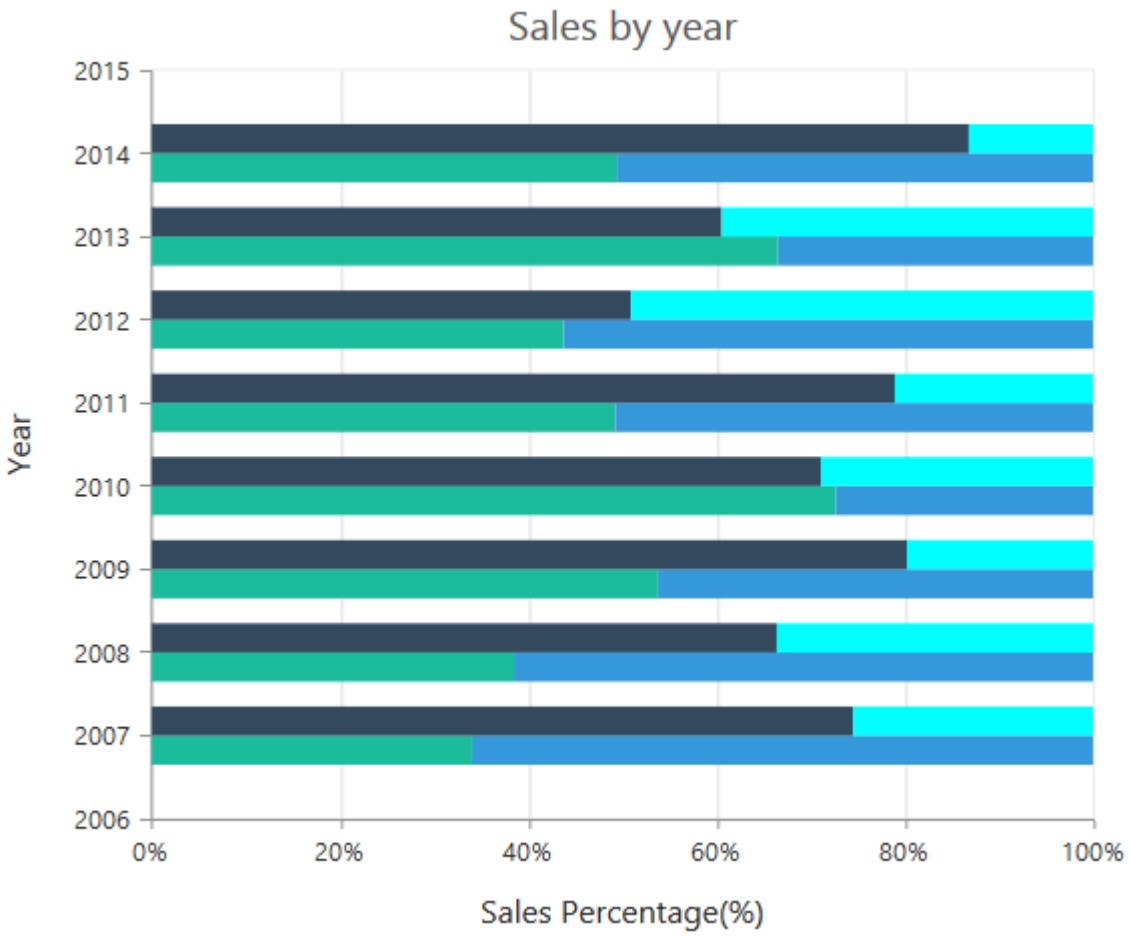
Click here to view 100% Stacked Bar Chart online demo.

By using the StackingGroup property, you can group the 100% stacking bars with the same group name.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
// For grouping 100% stacking bar
sr.StackingGroup("GroupOne")
//...
.Add();
// For grouping 100% stacking bar
sr.StackingGroup("GroupOne")
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

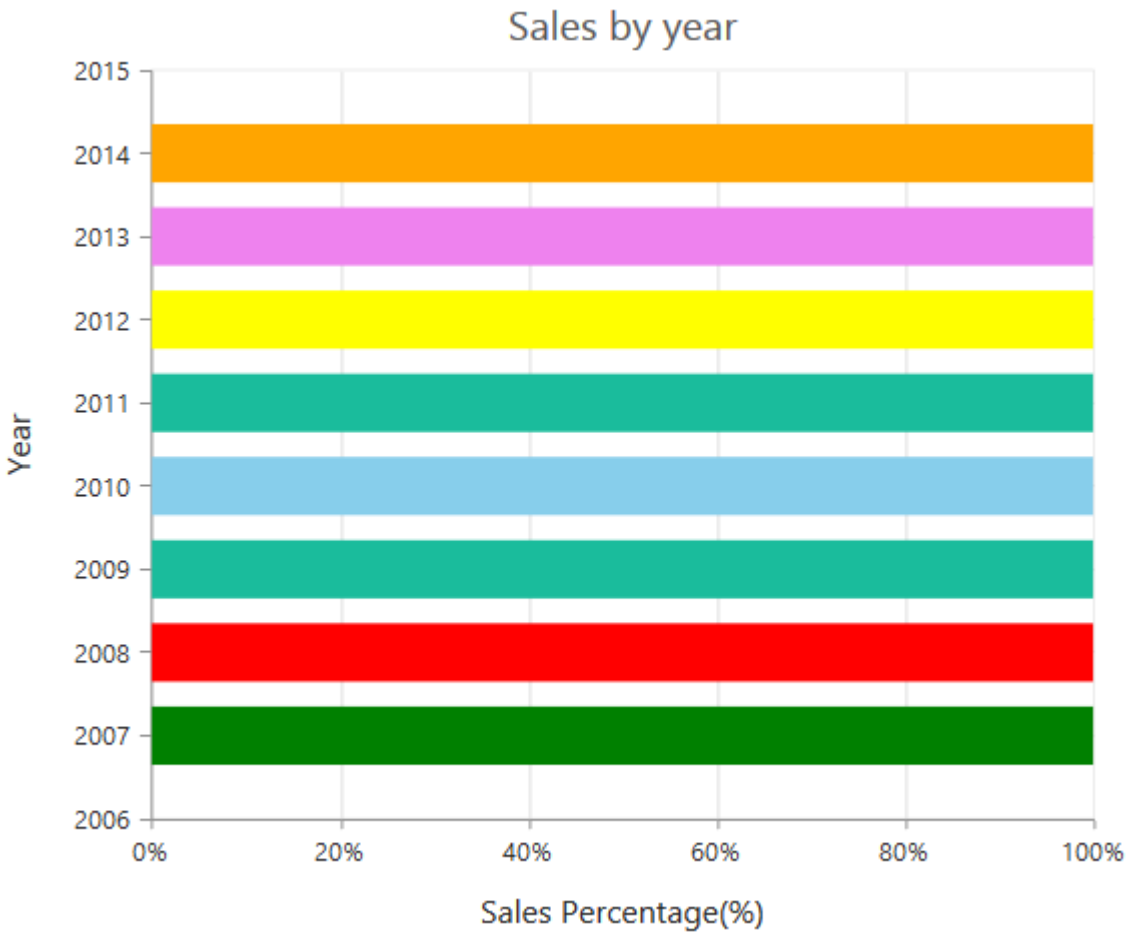


Change a point color

To change the color of a 100% stacking bar, you can use the Fill property of the point.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//change a point color of 100% stacking bar
sr.Points(pt=>{pt.Fill("skyblue").Add();})
//...
.Add();
})
//...
)
```

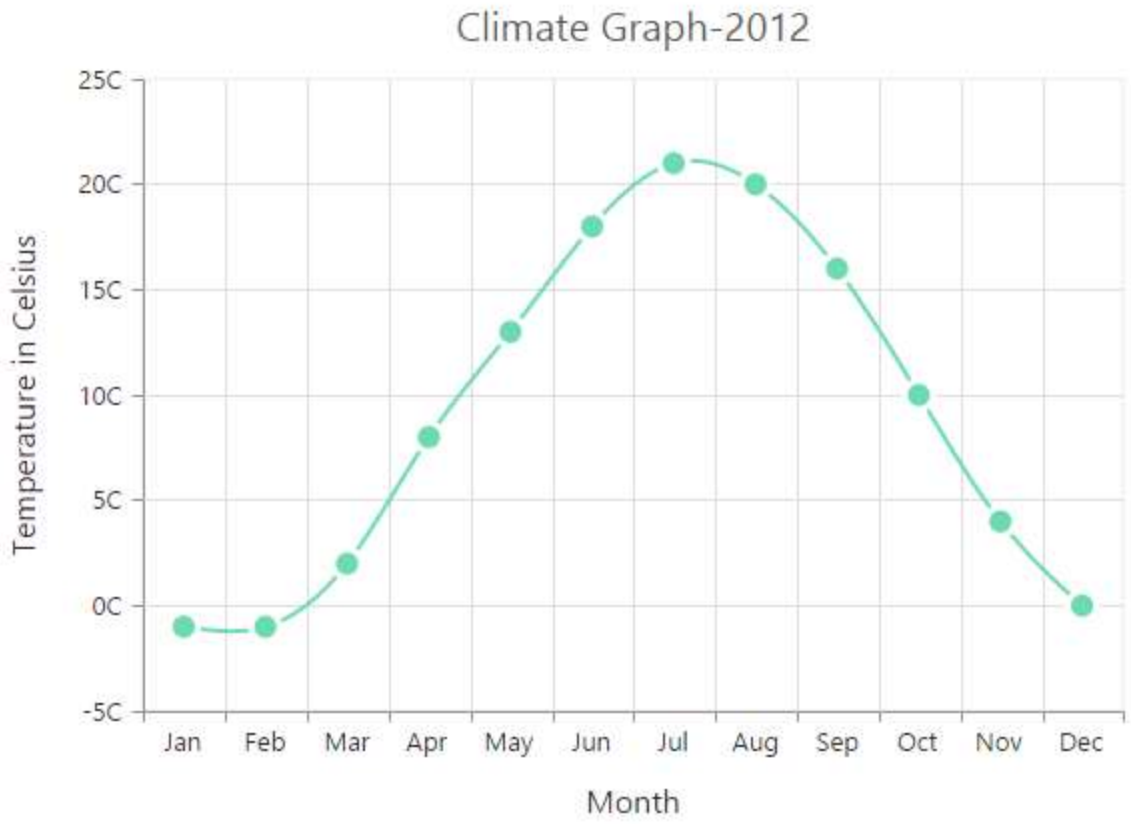


Spline Chart

To render a Spline Chart, set the Type as **Spline** in the chart series. To change the Spline segment color, you can use the Fill property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change type and color of the series
sr.Type(SeriesType.Spline).Fill("#6ADCB0")
//...
.Add();
})
//...
)
```



Click here to view the Spline Chart online demo sample.

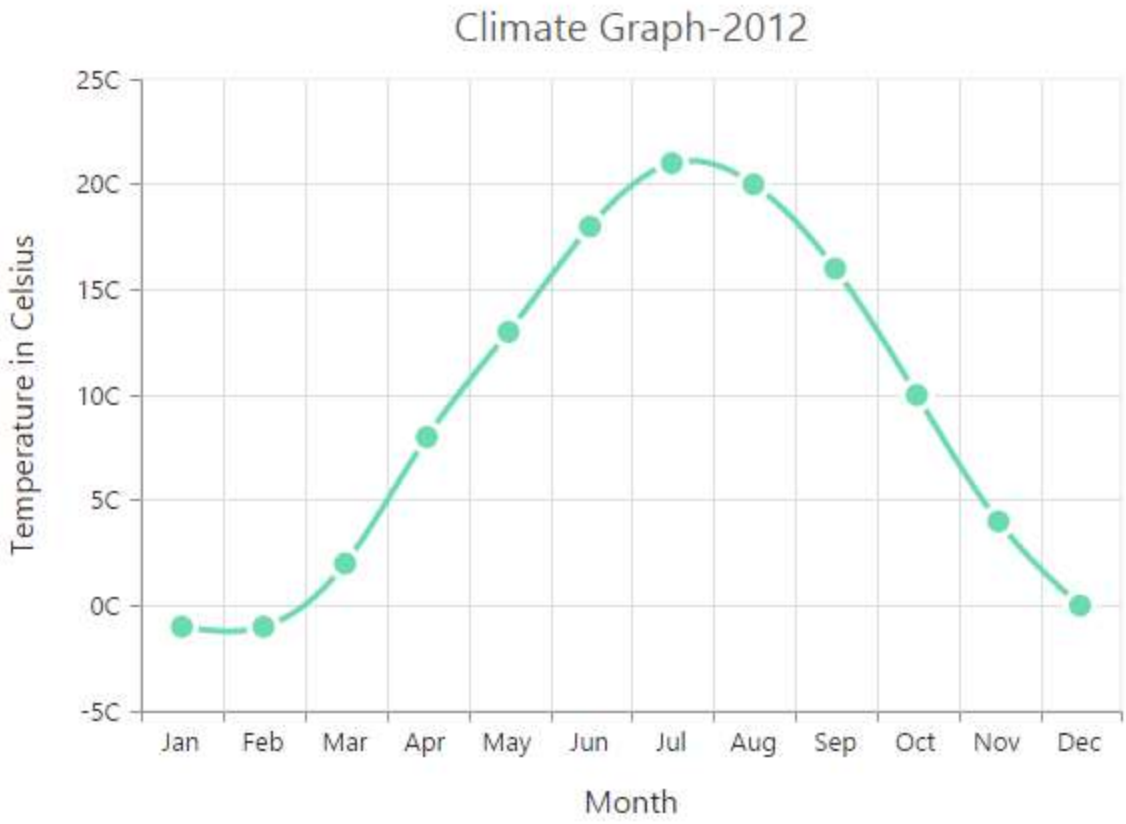
Change the spline width

To change the spline segment width, you can use the Width property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change the width of spline series
sr.Width(3)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

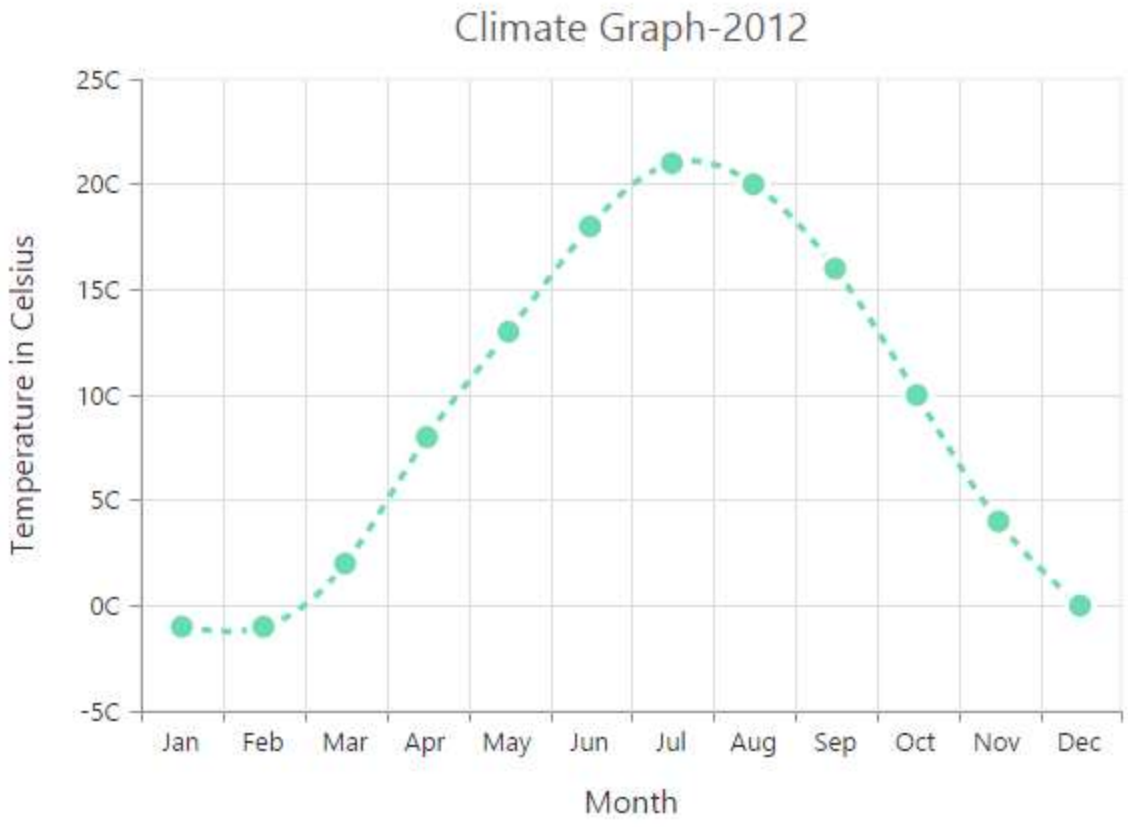


Dashed lines

To render the spline series with dotted lines, you can use the DashArray option of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change dash array to display dotted or dashed splines
sr.DashArray("5,5")
//...
.Add();
})
//...
)
```



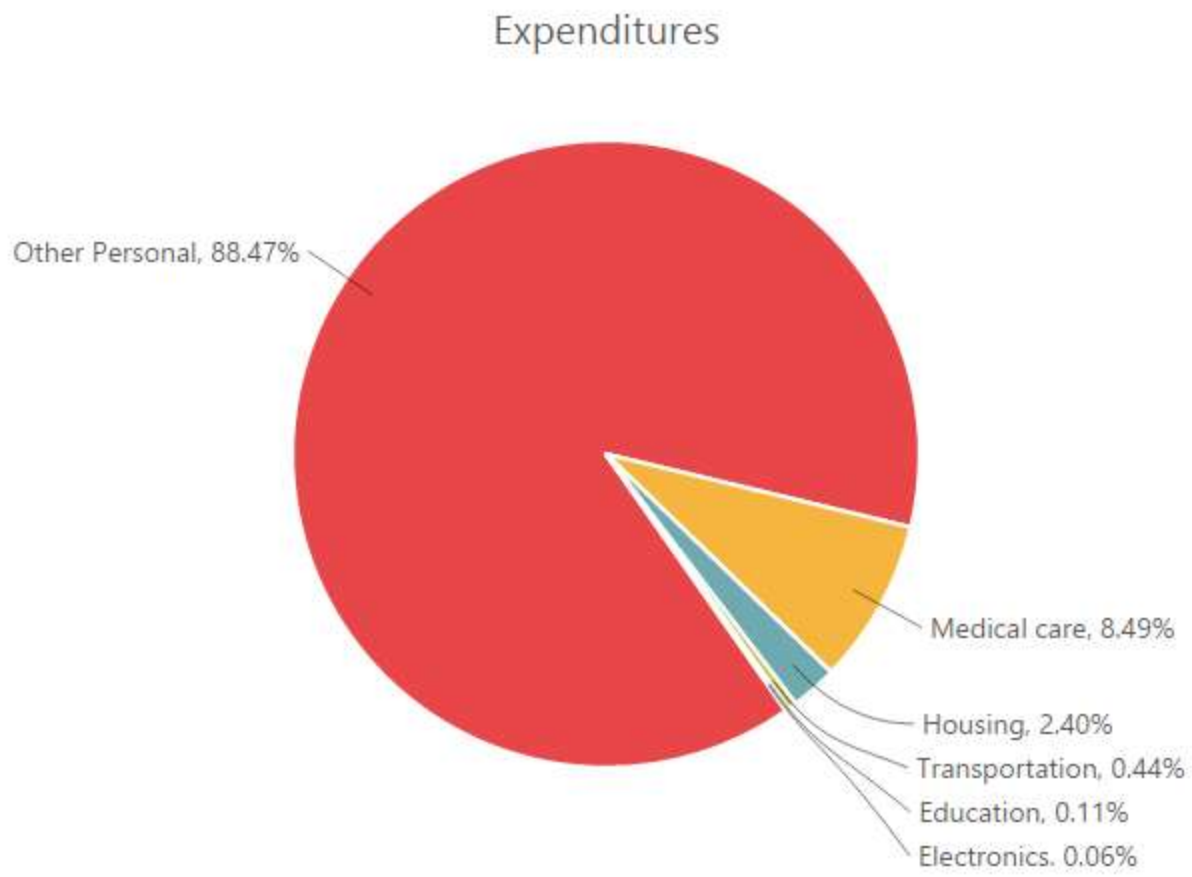
Pie Chart

You can create a pie chart by setting the series Type as **Pie** in the chart series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.Pie)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Pie chart online demo sample.

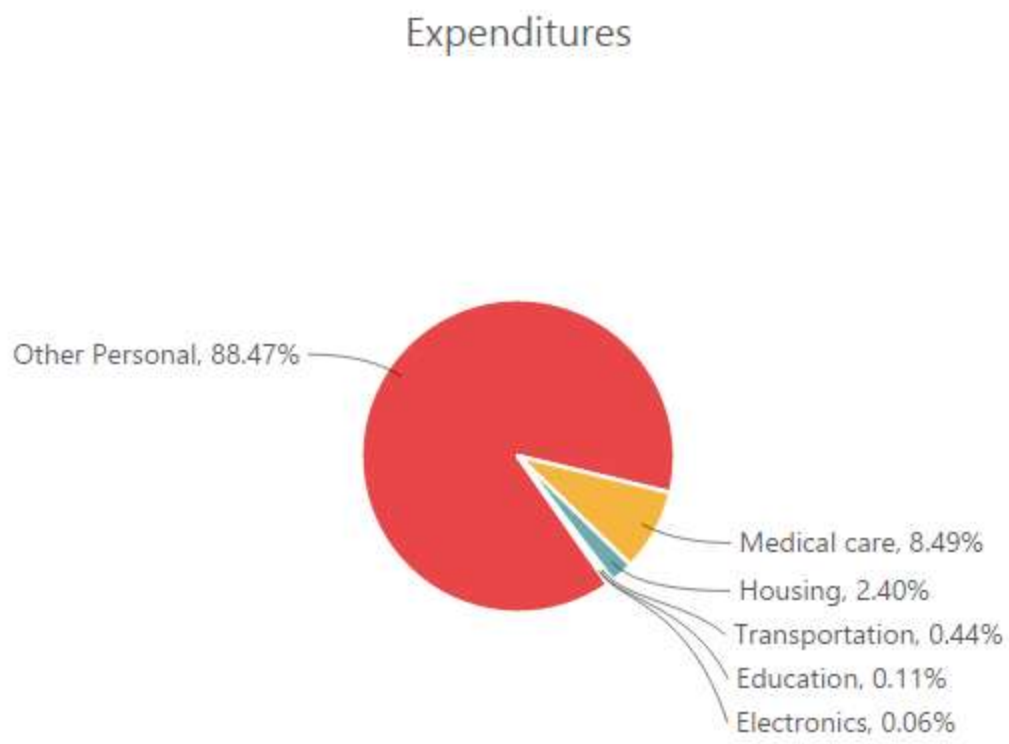
Change the pie size

You can use the **PieCoefficient** property to change the diameter of the Pie chart with respect to the plot area. It ranges from 0 to 1 and the default value is **0.8**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change pie chart coefficient value
sr.PieCoefficient(0.4f)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



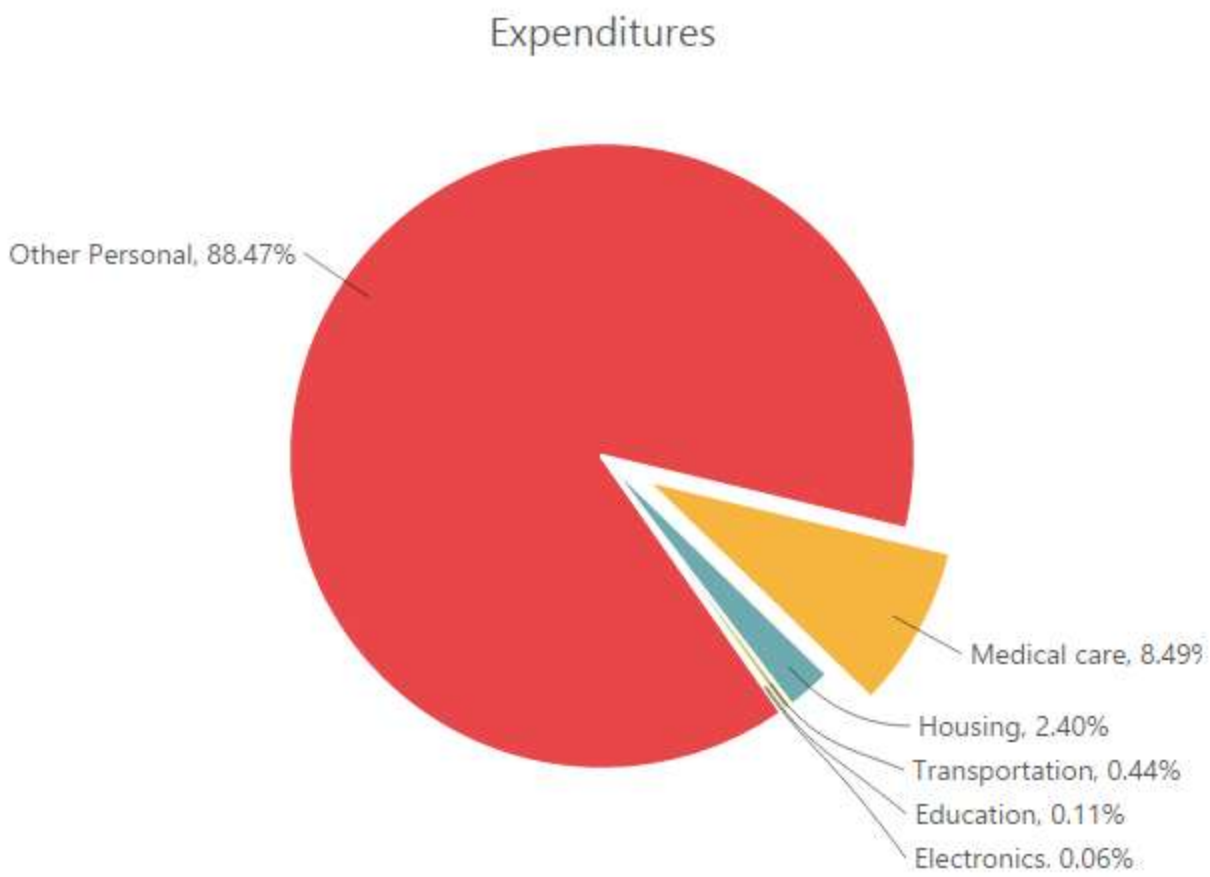
Explode a pie segment

You can explode a pie segment on the chart load by using the **ExplodeIndex** of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set point index value to explode the pie segment.
sr.ExplodeIndex(1)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



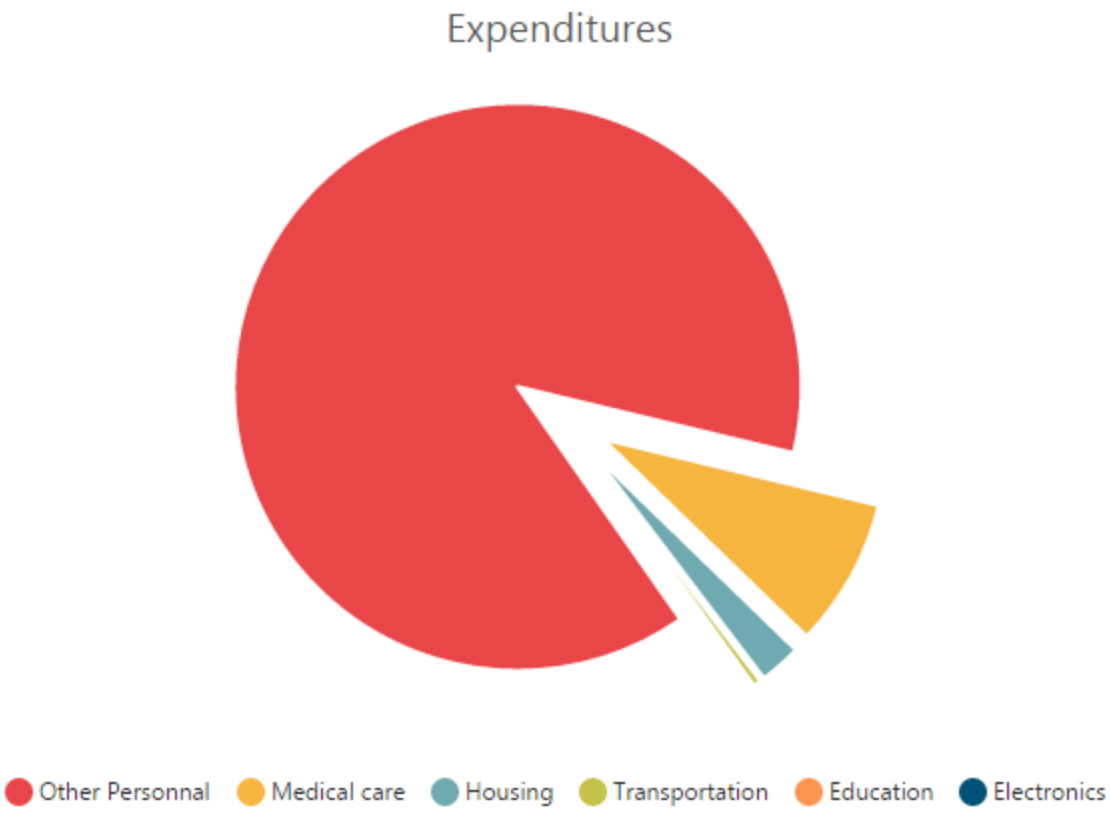
Explode all the segments

To explode all the segments of the Pie chart, you can enable the **ExplodeAll** property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Enable explodeAll property for pie chart.
sr.ExplodeAll(true)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



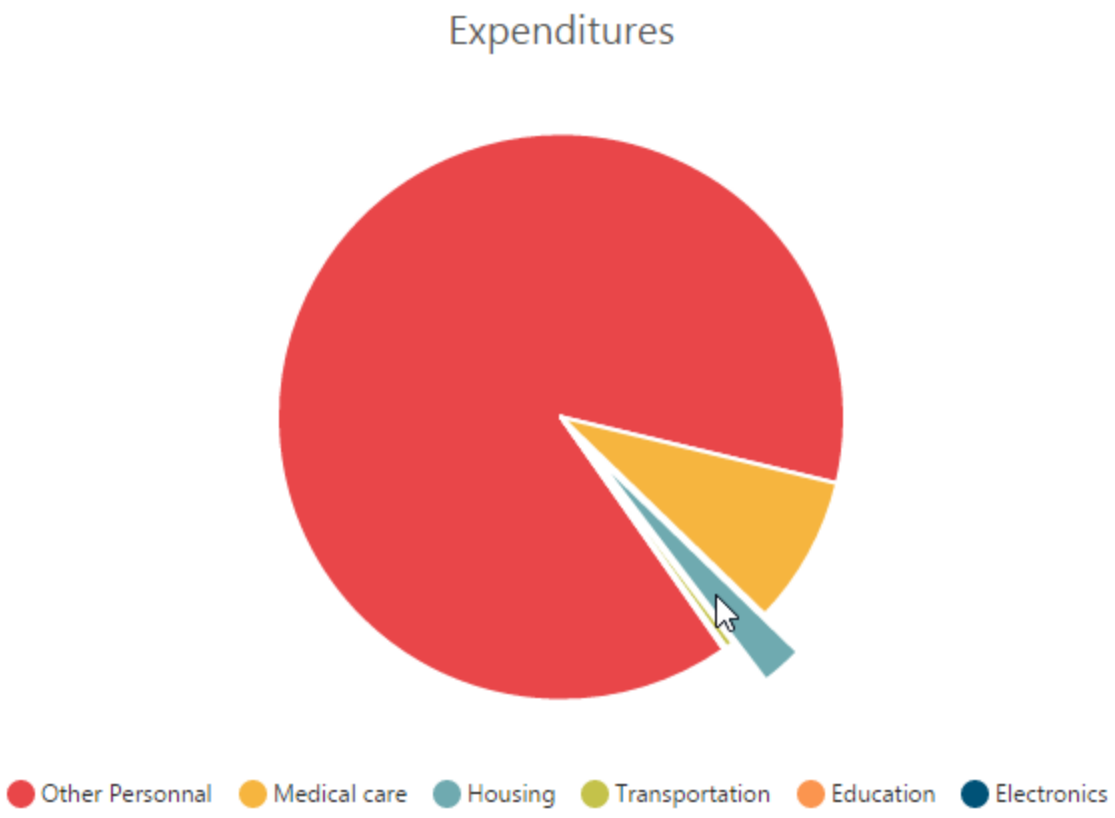
Explode a pie segment on mouse over

To explode a pie segment on a mouse over, you can enable the **Explode** property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Enable pie explode option on mouse over the chart
sr.Explode(true)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



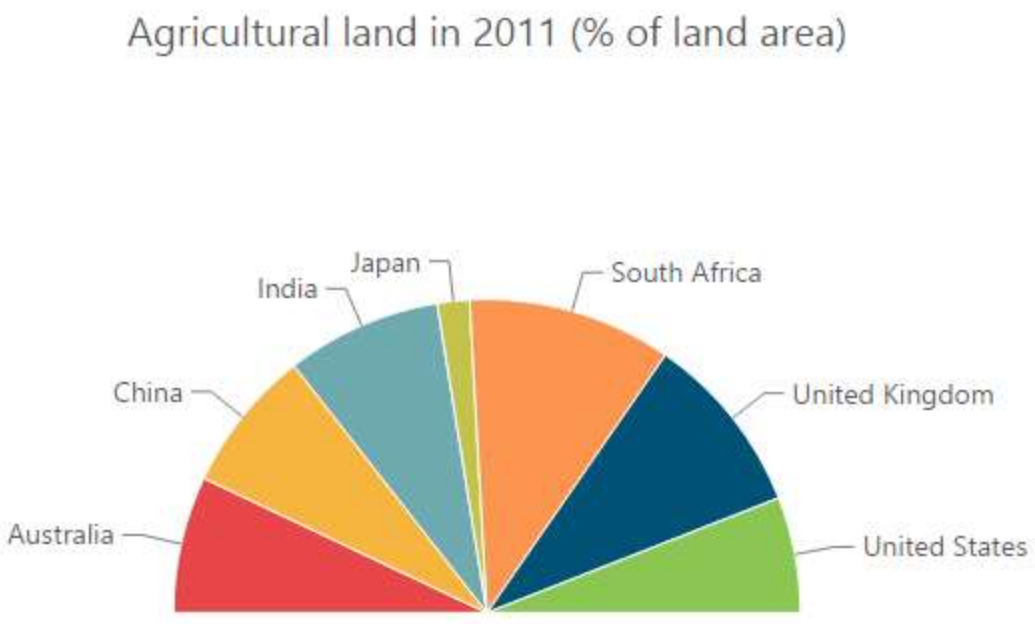
Sector of Pie

EjChart allows you to render all the data points/segments in the semi-pie, quarter-pie or in any sector by using the **StartAngle** and **EndAngle** options.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
sr.Type(SeriesType.Pie)
//Set startAngle and endAngle to draw the semi pie chart
.StartAngle(-90).EndAngle(90)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



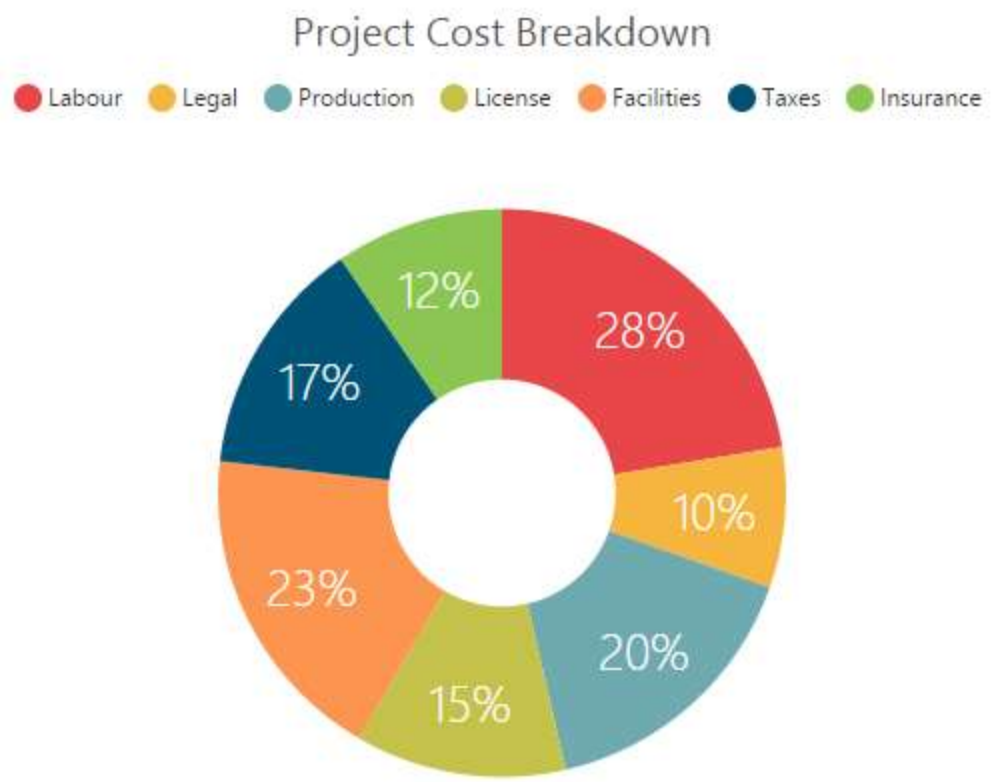
Click here to view the Semi Pie Chart online demo sample.

Doughnut Chart

To create a Doughnut chart, you can specify the series Type as **Doughnut** in the chart series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.Doughnut)
//...
.Add();
})
//...
)
```



Click here to view the Doughnut Chart online demo sample.

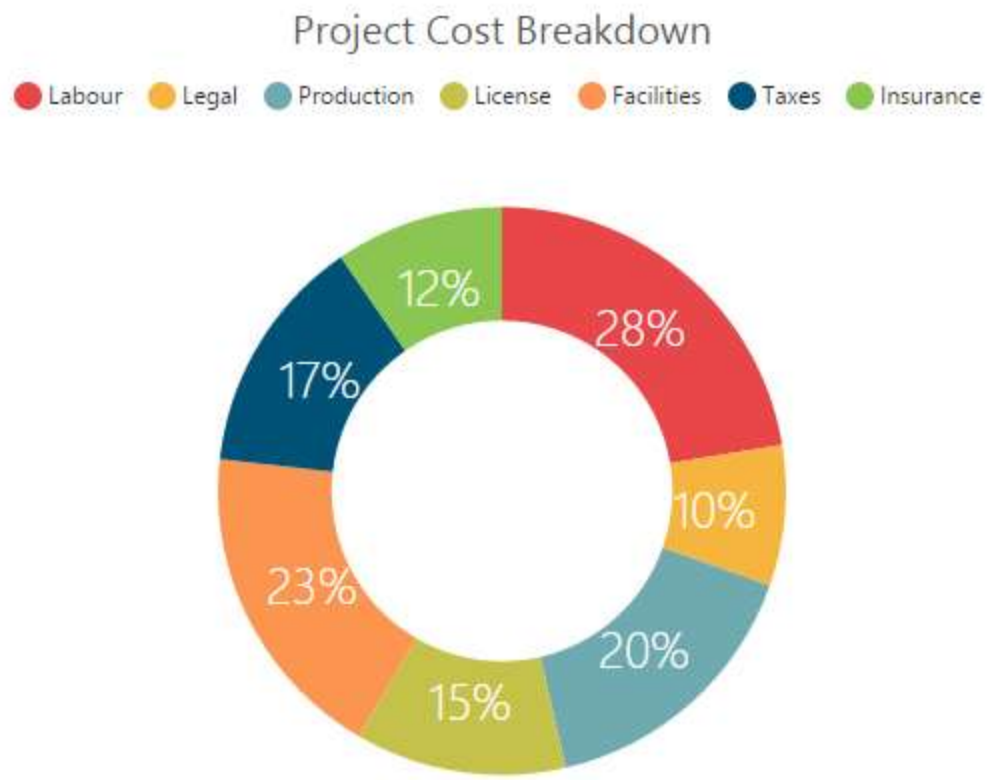
Change Doughnut inner radius

You can change the doughnut chart inner radius by using the **DoughnutCoefficient** with respect to the plot area. It ranges from 0 to 1 and the default value is **0.4**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change doughnut chart coefficient value
sr.DoughnutCoefficient(0.6f)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Change the doughnut size

You can use the **DoughnutSize** property to change the diameter of the Doughnut chart with respect to the plot area. It ranges from 0 to 1 and the default value is **0.8**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change doughnut chart coefficient value
sr.DoughnutSize(0.4f)
//...
.Add();
})
//...
)
```

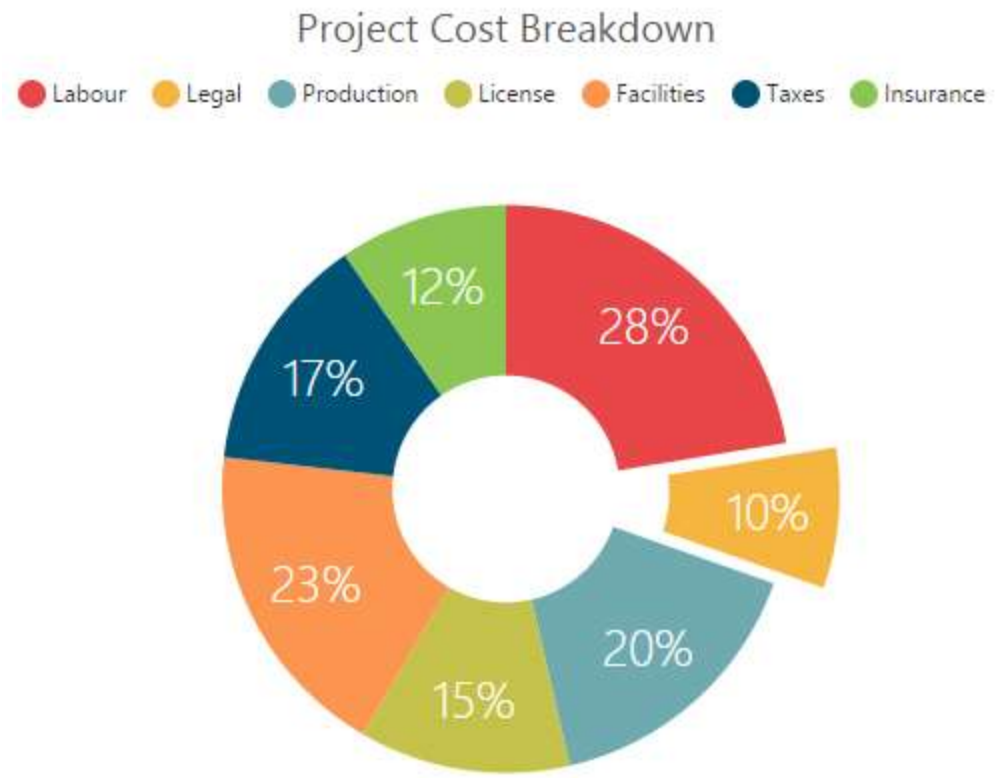
Explode a doughnut segment

To explode a specific doughnut segment, set the index to be exploded by using the **ExplodeIndex** option of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set point index value to explode the doughnut segment.
sr.ExplodeIndex(1)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



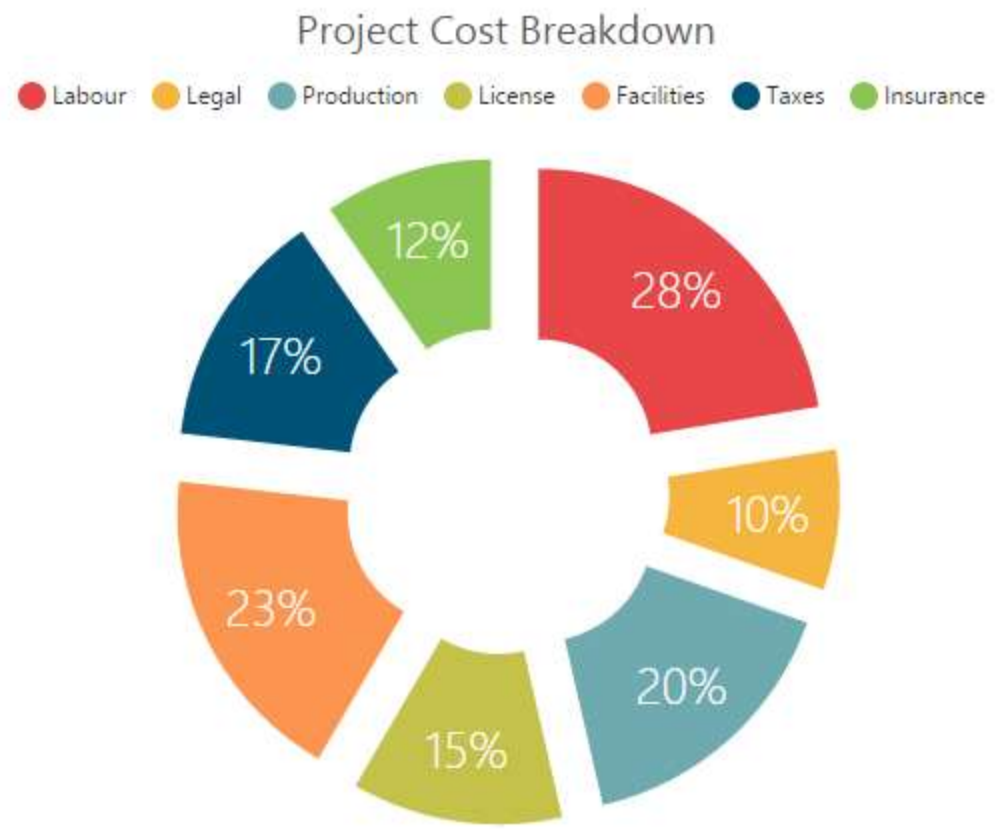
Explode all the segments

To explode all the segments, you can enable the **ExplodeAll** property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Enable explodeAll property of doughnut chart
sr.ExplodeAll(true)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



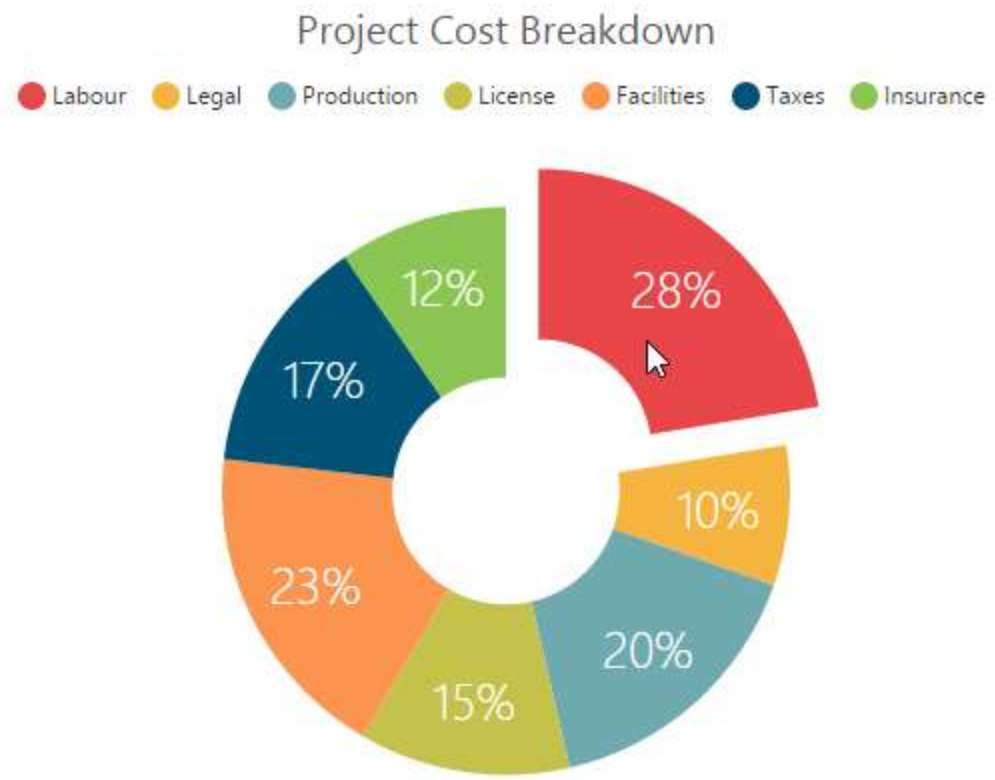
Explode a doughnut segment on mouse over

To explode a doughnut segment on a mouse over, you can enable the **Explode** property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Enable doughnut explode option on mouse over the chart
sr.Explode(true)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



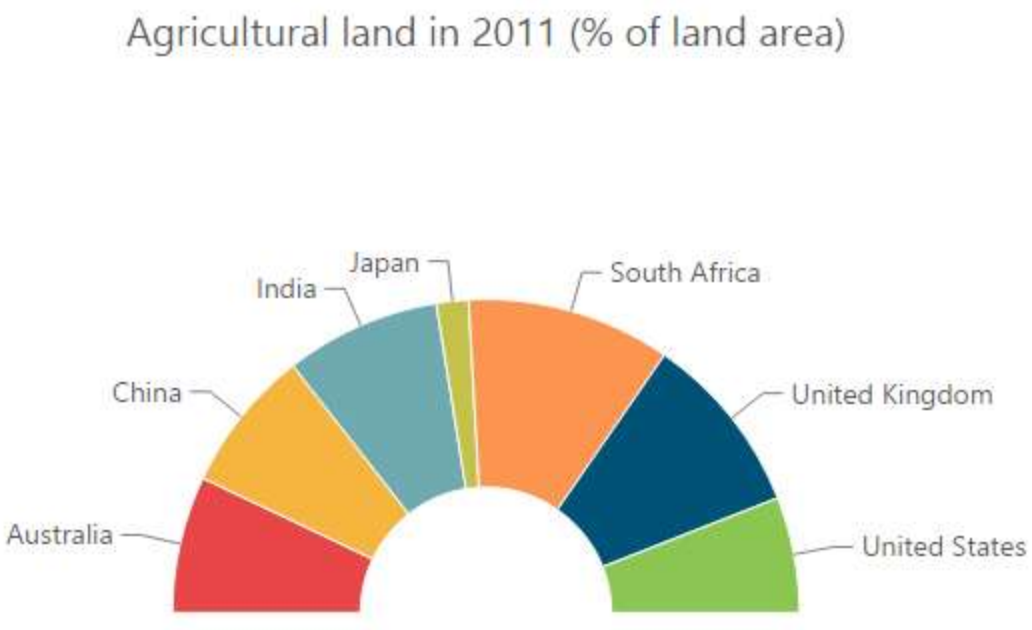
Sector of Doughnut

EjChart allows you to render all the data points/segments in the semi-doughnut, quarter- doughnut or in any sector by using the **StartAngle** and **EndAngle** options.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
sr.Type(SeriesType.Doughnut)
//Set startAngle and endAngle to draw the semi doughnut chart
.StartAngle(-90).EndAngle(90)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Semi Doughnut Chart online demo sample.

Multiple Pie Chart

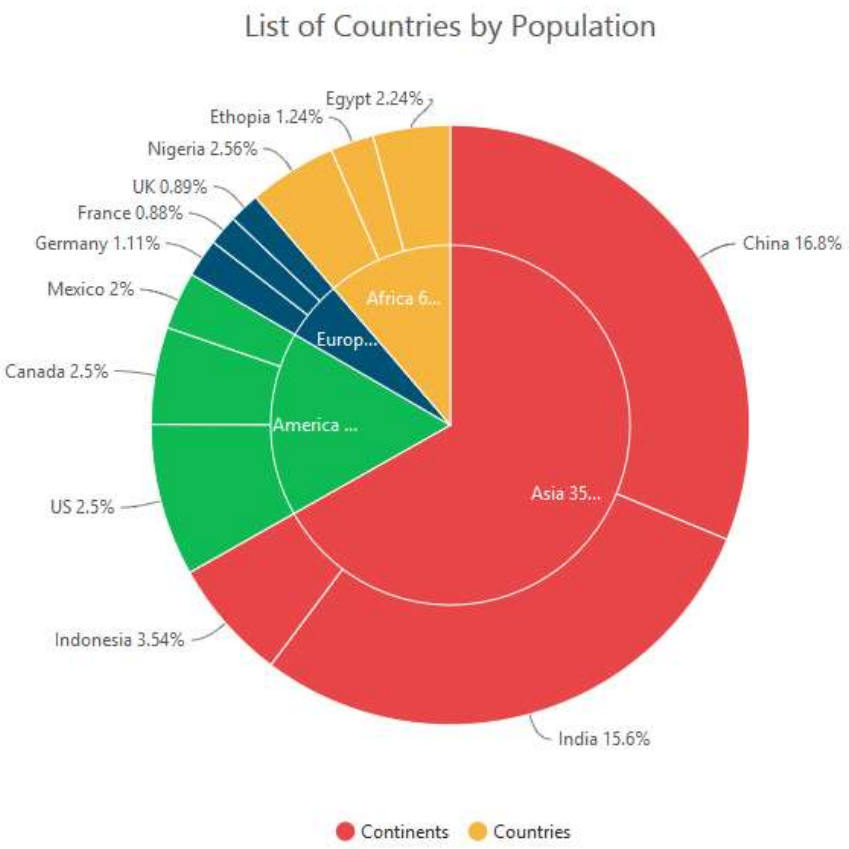
EjChart provides support to render more than one series in pie and in doughnut chart. Radius of each series is calculated based on the radius of the previous series. And in addition legend is displayed according to the list of chart series.

ASPX-CS

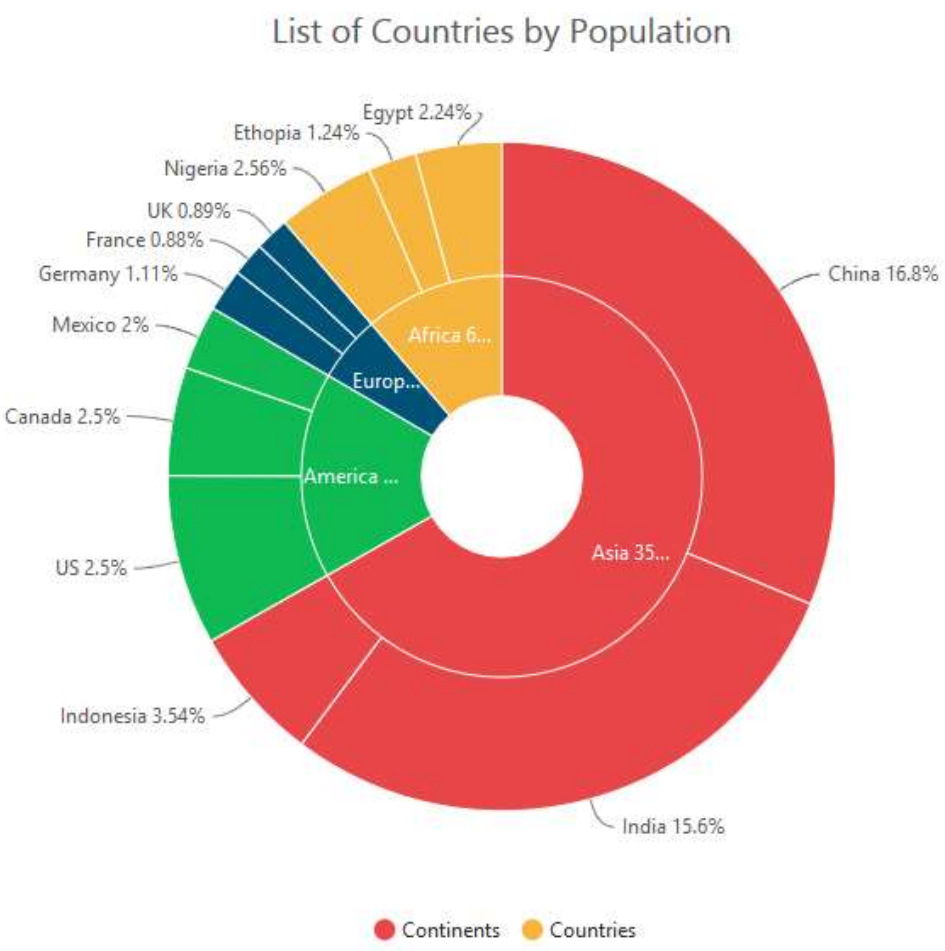
```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Adding multiple pie series
sr.Type(SeriesType.Pie)
//...
.Add();
//Adding multiple pie series
sr.Type(SeriesType.Pie).Add();
})
//...
)
```

Multiple Pie

Copyright © 2001 - 2020 Syncfusion Inc.



Multiple Doughnut



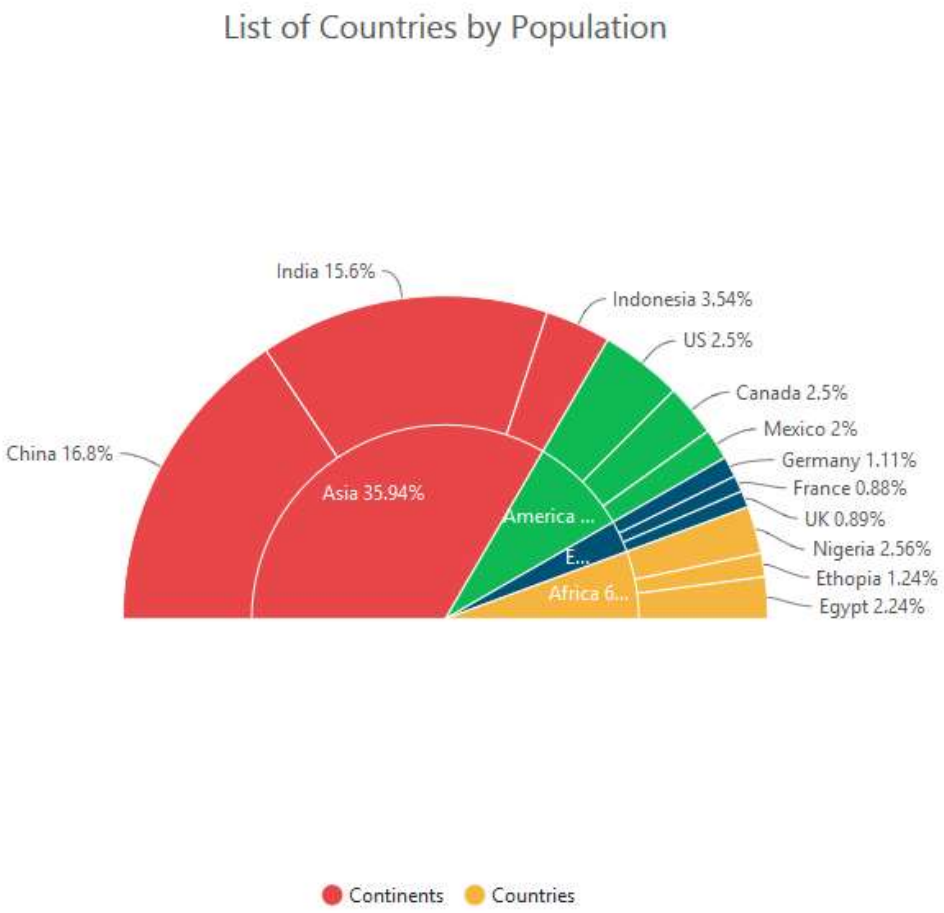
Click here to view the Multiple Pie chart online demo sample.

Start and End Angle Support

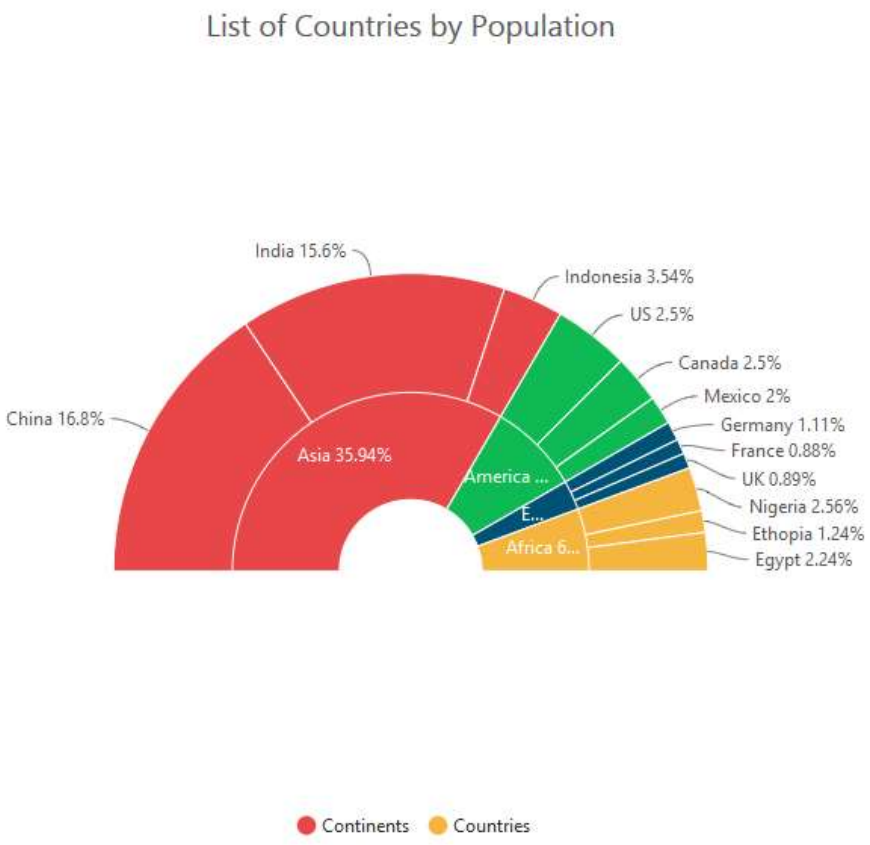
In the Multiple Pie chart, the start and end angle property is also supported.

Sector of Multiple Pie

Copyright © 2001 - 2020 Syncfusion Inc.



Sector of Multiple Doughnut



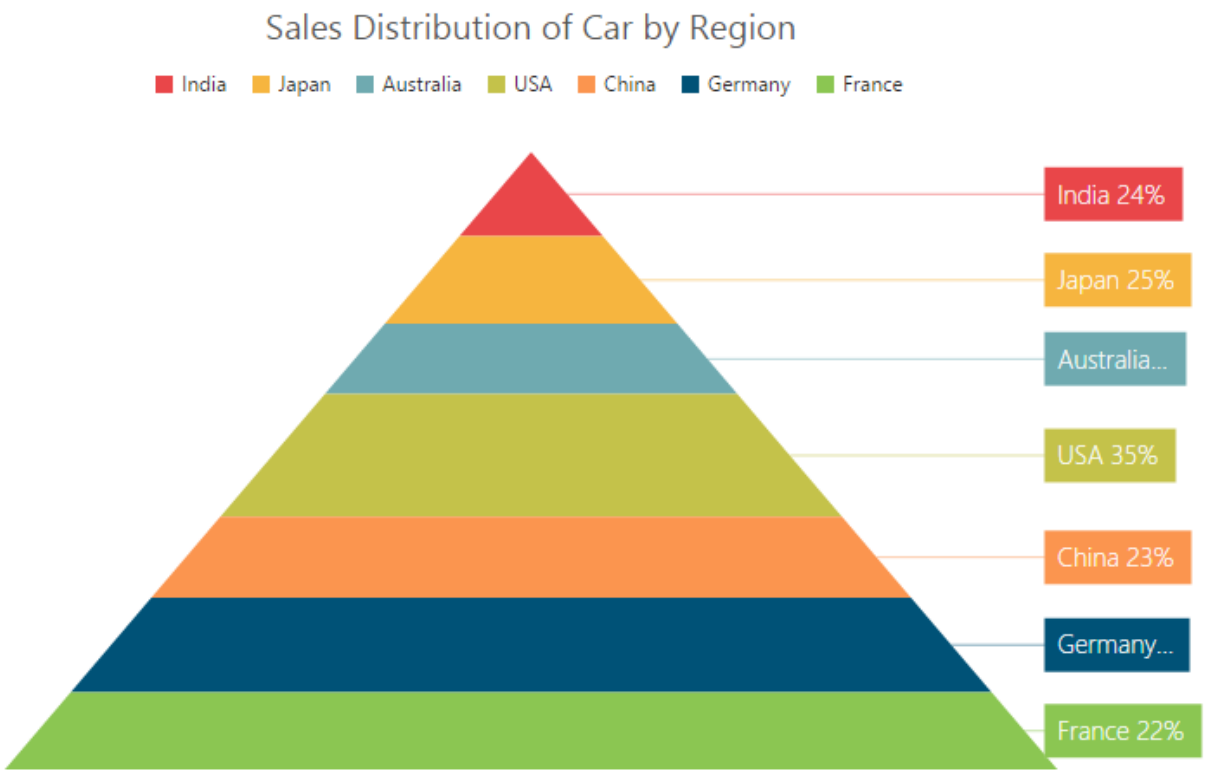
Pyramid Chart

To create a Pyramid chart, you can specify the series Type as **Pyramid** in the chart series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.Pyramid)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Pyramid Chart online demo sample.

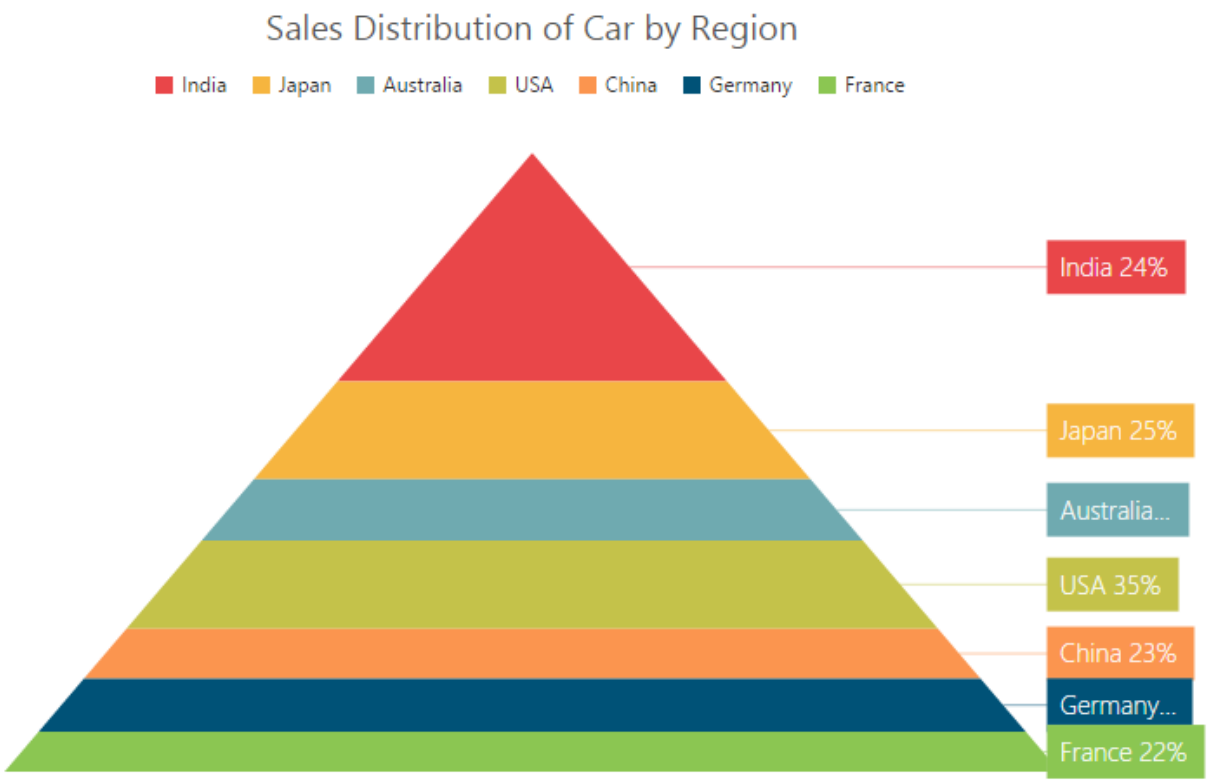
Pyramid Mode

Pyramid mode has two types, *Linear* and *Surface* respectively. The default **PyramidMode** type is "Linear".

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change pyramid mode
sr.PyramidMode(PyramidMode.Surface)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



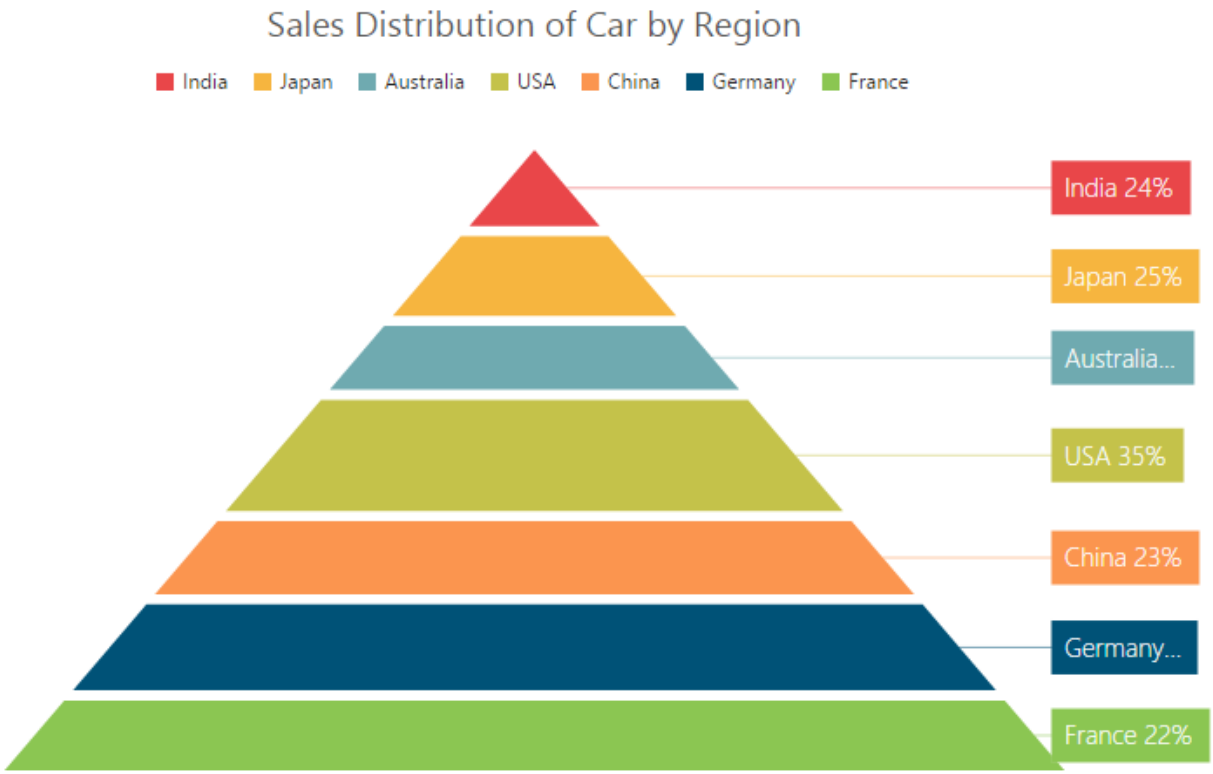
Gap between the segments

You can control the gap between the segments by using the **GapRatio** option of the series. Its ranges from 0 to 1.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set gapRatio value to pyramid chart
sr.GapRatio(0.1f)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



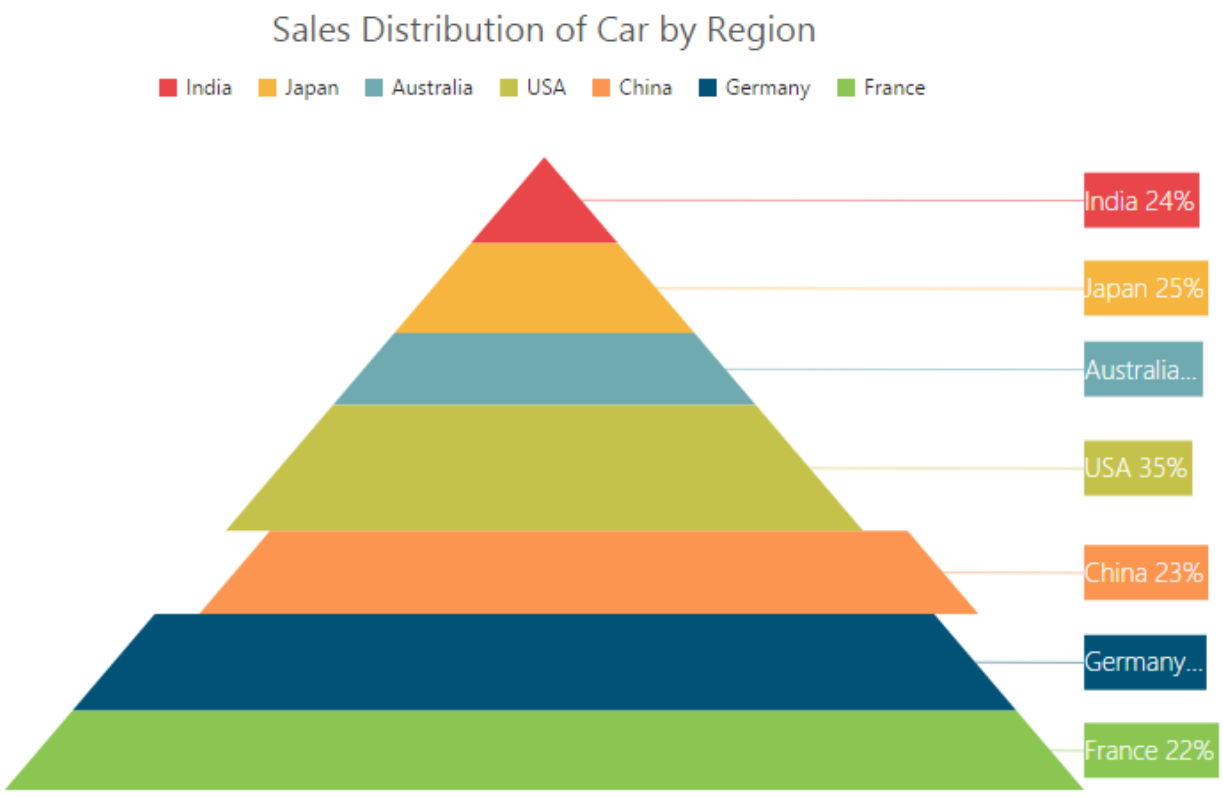
Explode a pyramid segment

You can explode a pyramid segment on the chart load by using the **ExplodeIndex** of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set point index value to explode the pyramid segment.
sr.ExplodeIndex(4)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



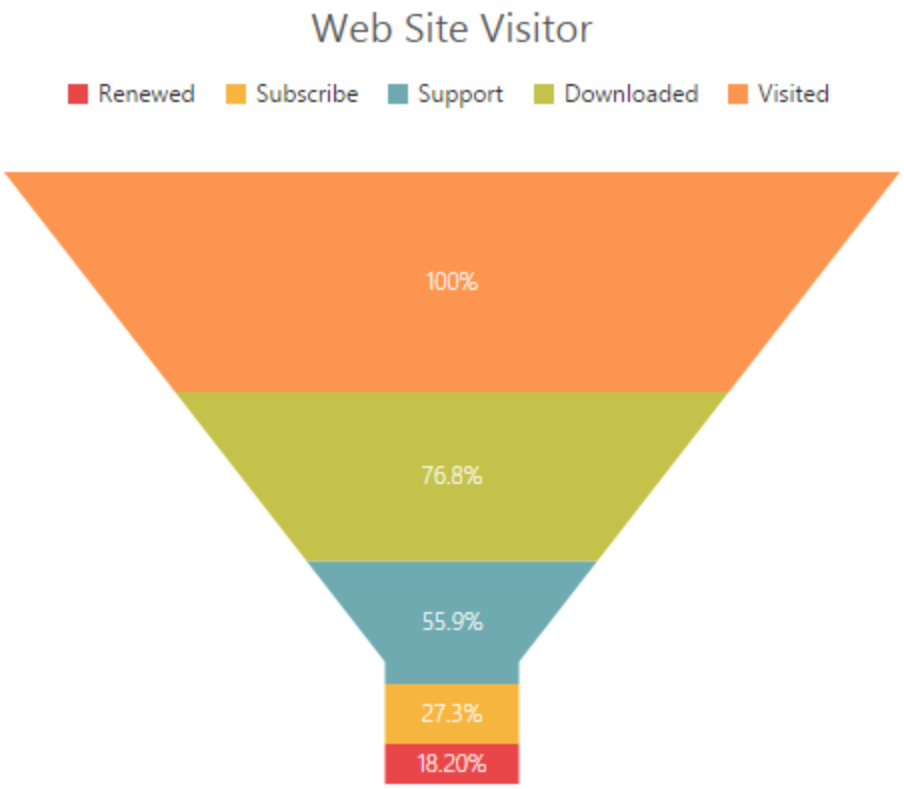
Funnel Chart

You can create a funnel chart by setting the series Type as **Funnel** in the chart series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.Funnel)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Funnel Chart online demo sample.

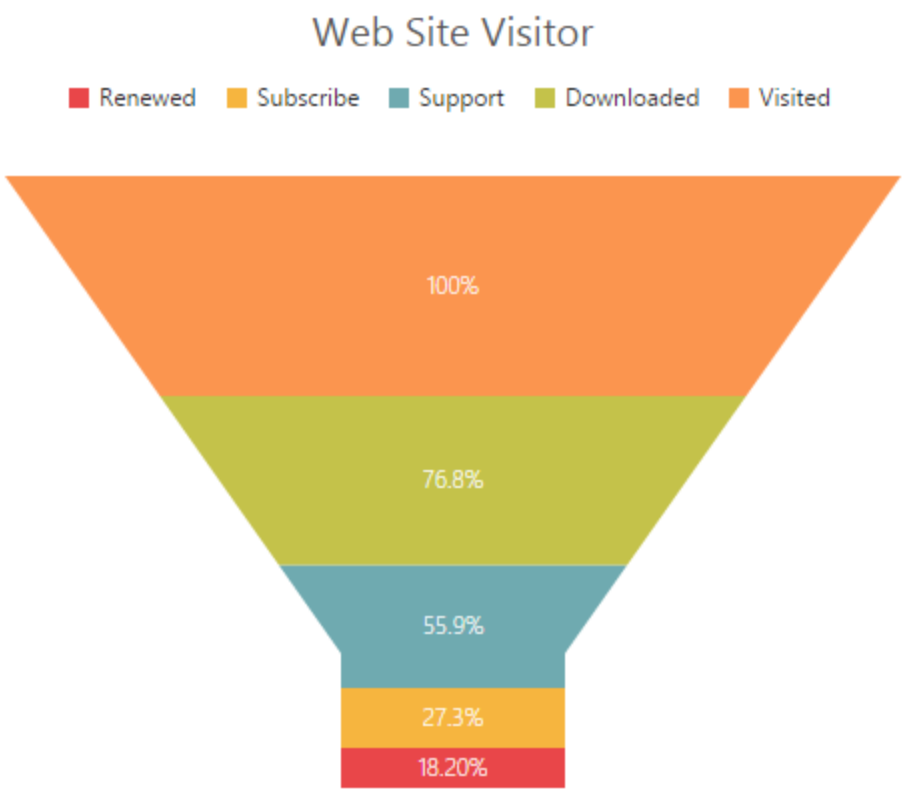
Change the funnel width and height

Funnel segments height and width is calculated from the chart size, by default. You can change this height and width directly without changing the chart size by using the **FunnelHeight** and **FunnelWidth** property of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change funnel height and width
sr.FunnelHeight("22%")
.FunnelWidth("25%")
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



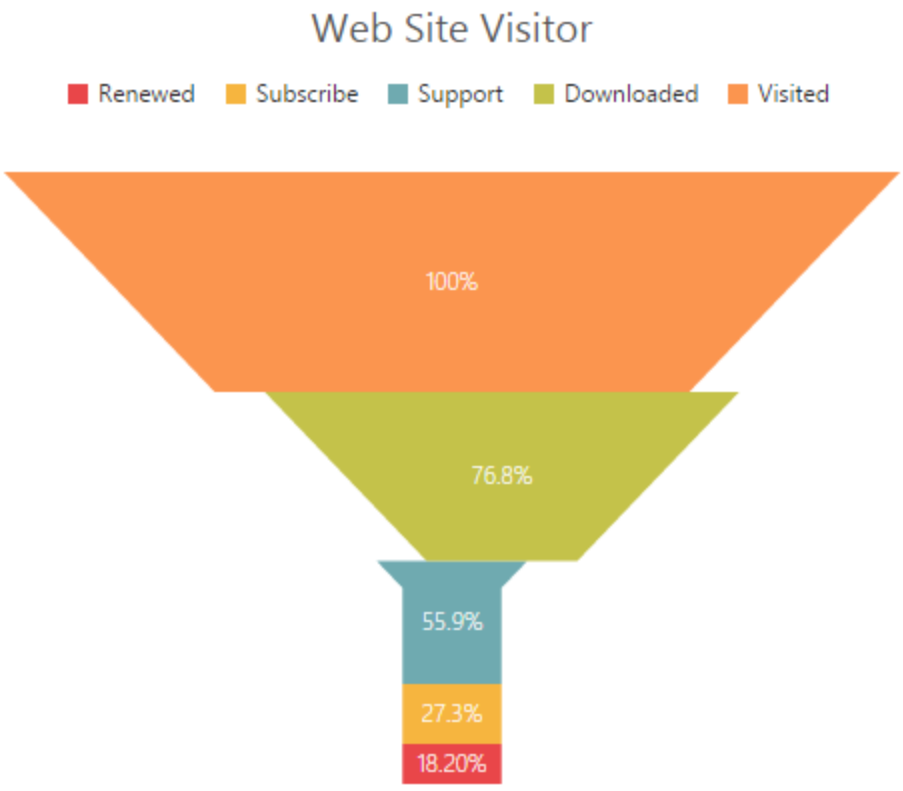
Explode a funnel segment

You can explode a funnel segment on the chart load by using the **ExplodeIndex** of the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set point index value to explode the funnel segment.
sr.ExplodeIndex(3)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Bubble Chart

To create a Bubble chart, you can set the series Type as **Bubble** in the chart series. Bubble chart requires 3 fields (*X, Y and Size*) to plot a point. Here, **Size** is used to specify the size of each bubble segment.

CSHARP

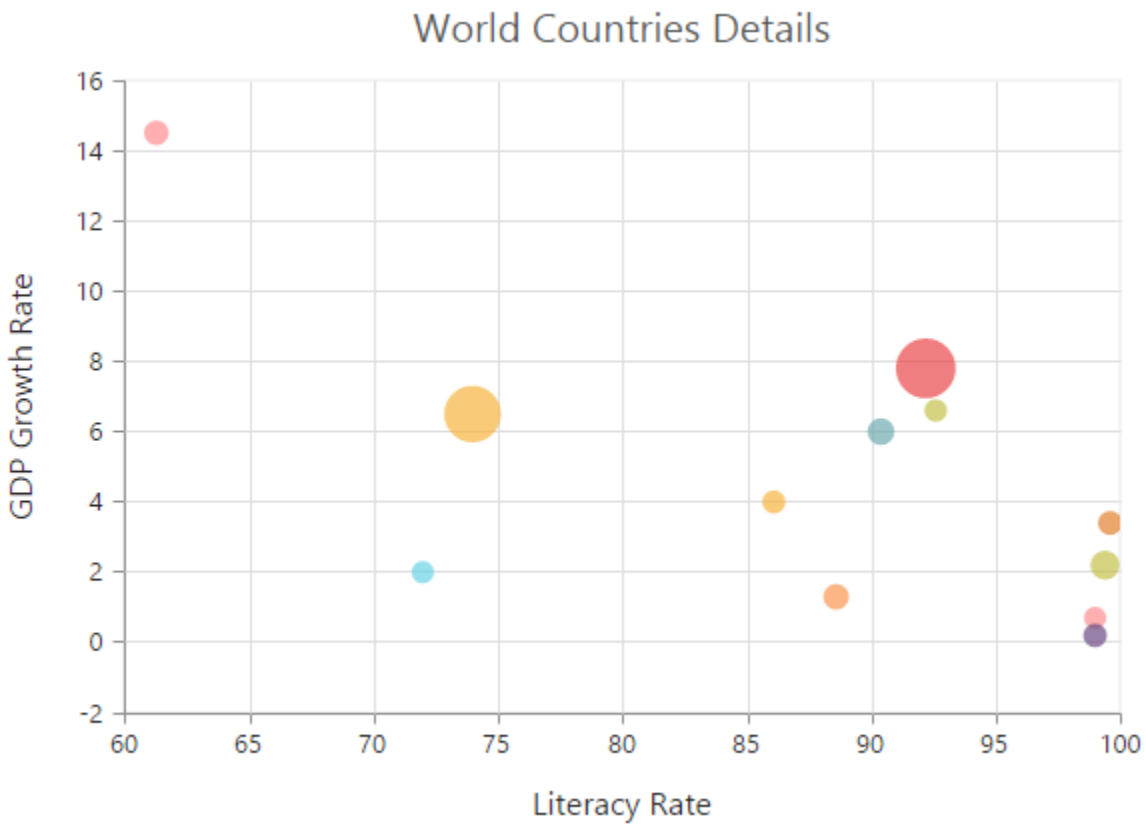
```
// Create dataSource to bubble chart
List<ChartData> data =new List<ChartData>();
data.Add(new ChartData("Jan", 35, 1.34));
data.Add(new ChartData("Feb", 28, 1.05));
data.Add(new ChartData("Mar", 34, 0.45));
data.Add(new ChartData("Apr", 32, 1.10));
ViewBag.ChartData = data;
```

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.Bubble)
//Add datasource and set xName, yName and size to bubble chart
.XName("Month")
.XName("Sales")
.Size("Profit")
.DataSource(ViewBag.ChartData)
//...
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Add();
})
//...
)
```



Click here to view the Bubble Chart online demo sample.

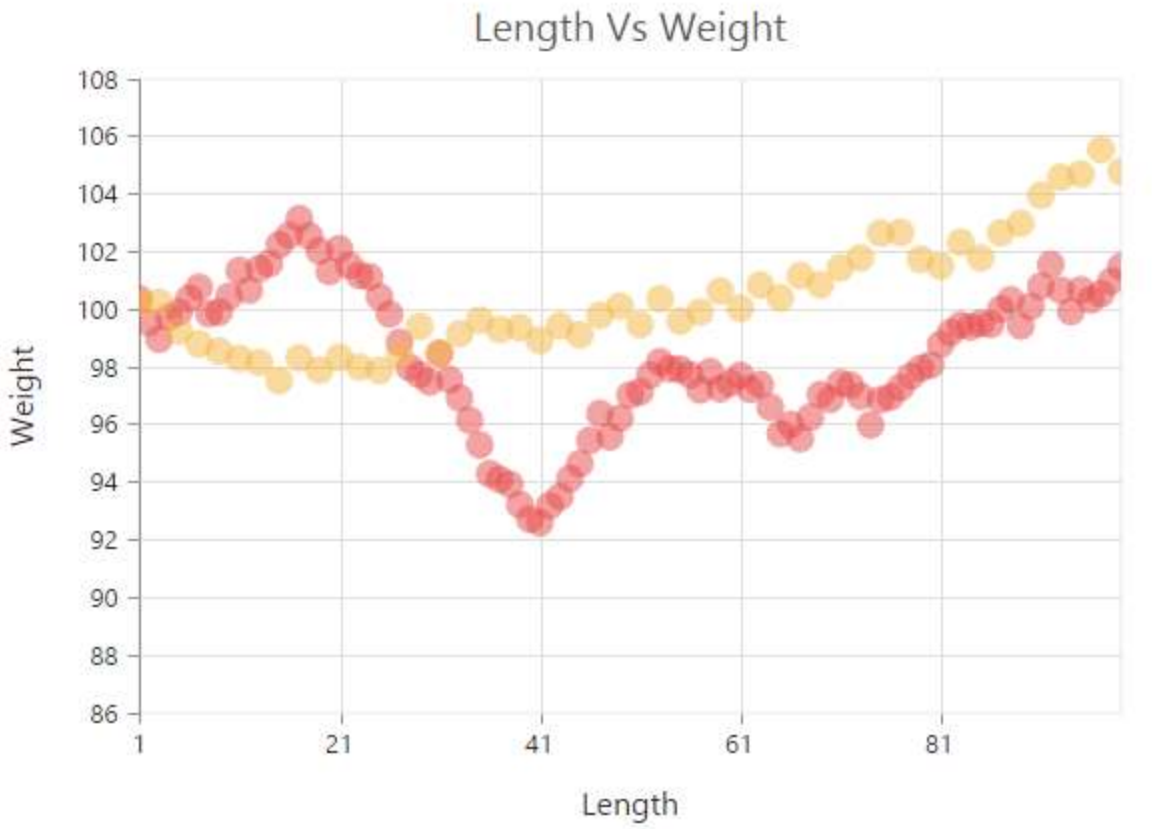
Scatter

To create a Scatter chart, you can set the series Type as **Scatter** in the chart series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.Scatter)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



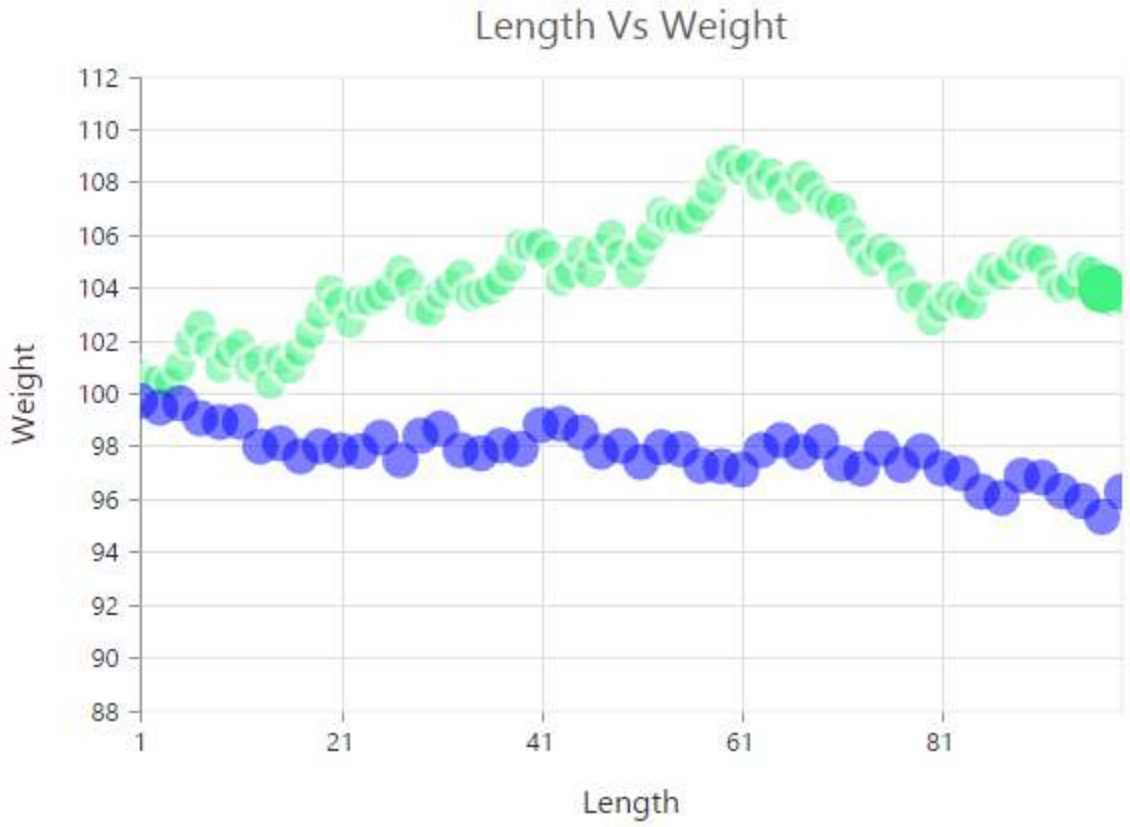
Click here to view the Scatter Chart online demo sample.

Customize the scatter chart

You can change the scatter size by using the **Size** property of the series marker. And you can change the scatter color by using the series Fill property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
sr.Marker(marker=>marker.Size(size=>size.Height(15).Width(15)))
//Set fill color to scatter series
.Fill("#41F282")
//...
.Add();
})
//...
)
```



HiLoOpenClose Chart

To create a HiLoOpenClose chart, you can set the series Type as **HiloOpenClose** in the chart series. HiLoOpenClose chart requires 5 fields *(X, High, Low, Open and Close)* to plot a segment.

CSHARP

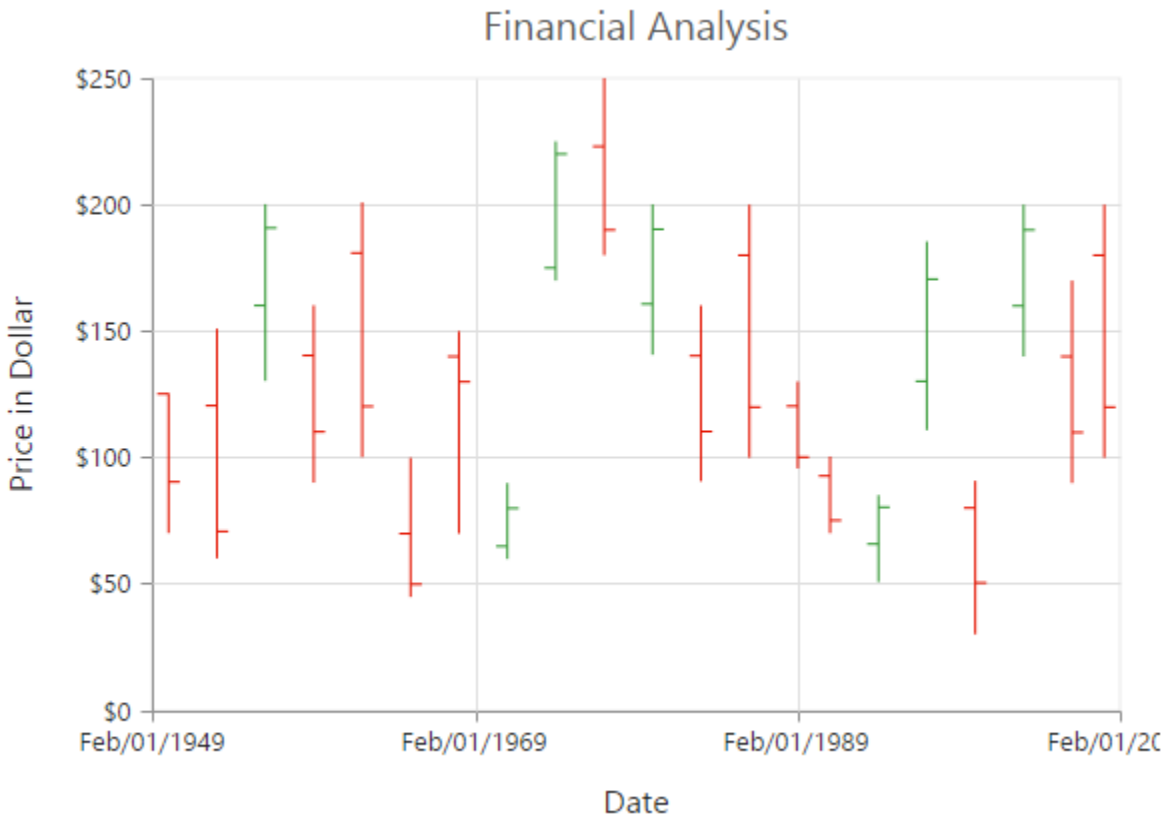
```
// Create dataSource to chart
List<ChartData> data =new List<ChartData>();
data.Add(new ChartData("Jan", 38, 10,38, 29));
data.Add(new ChartData("Feb", 28, 15, 18, 27));
data.Add(new ChartData("Mar", 54, 35, 38, 49));
data.Add(new ChartData("Apr", 52, 21, 35, 29));
ViewBag.ChartData = data;
```

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.HiloOpenClose)
//Add datasource and set xName, high and low to HiLo open close chart
.XName("Month")
.High("High")
.Low("Low")
.Open("Open")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Close("Close")
.DataSource(ViewBag.ChartData)
//...
.Add();
})
//...
)
```



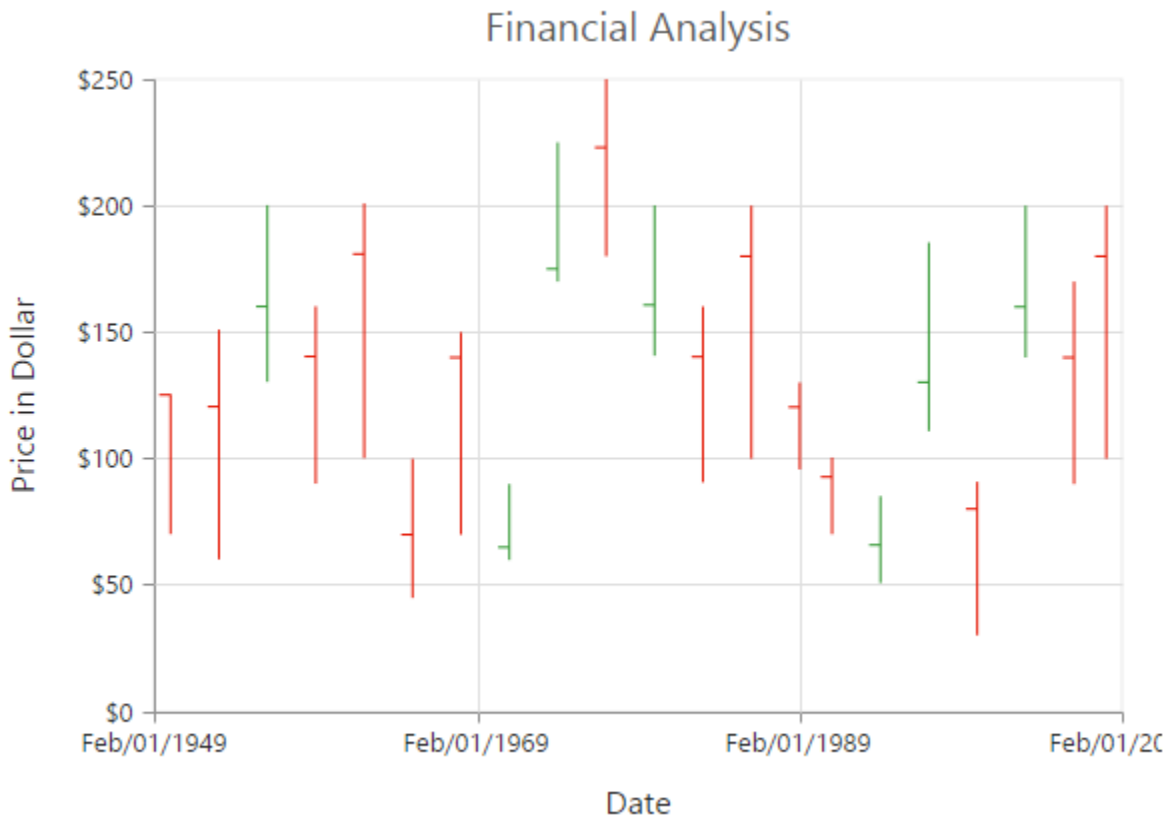
Click here to view the HiLoOpenClose Chart online demo sample.

DrawMode

You can change the HiLoOpenClose chart **DrawMode** to *Open, Close* or *Both*. The default value of DrawMode is **Both**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change the OHLC drawMode type
sr.DrawMode(SeriesDrawMode.Open)
//...
.Add();
})
//...
)
```



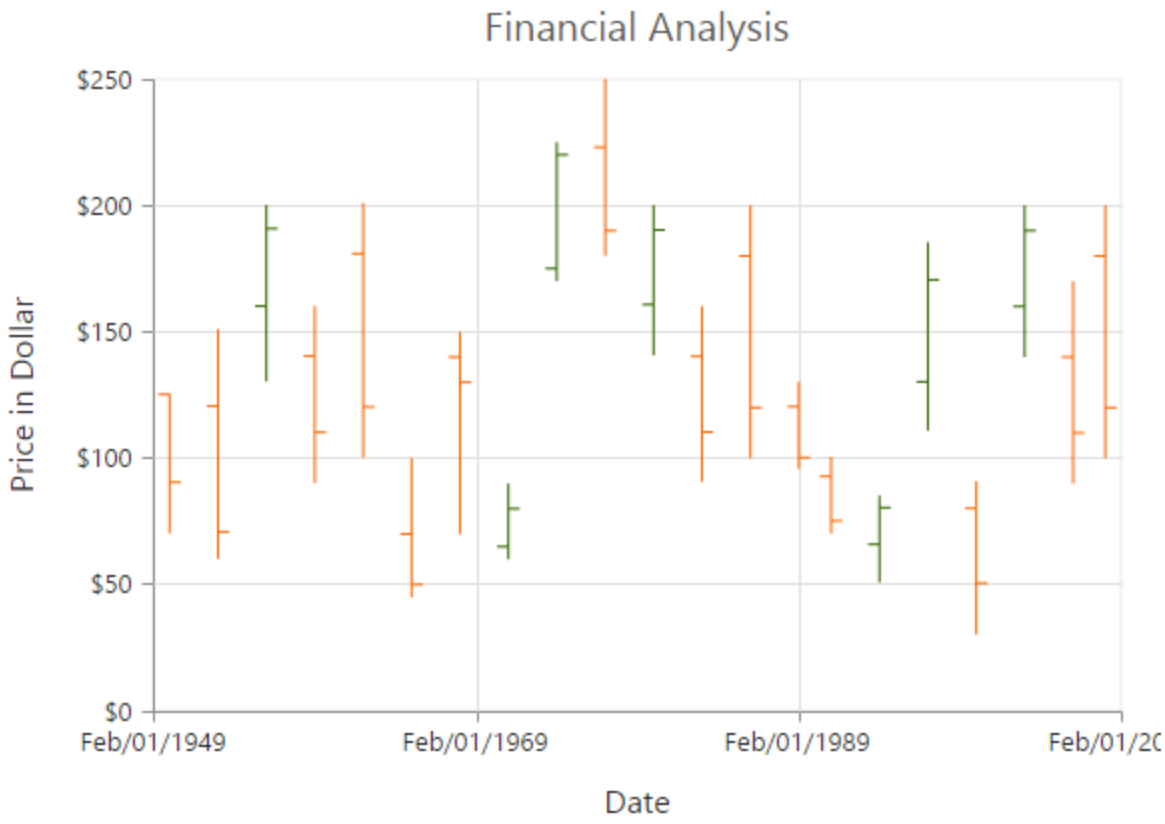
Bull and Bear Color

HiLoOpenClose chart **BullFillColor** is used to specify a fill color for the segments that indicates an increase in stock price in the measured time interval and **BearFillColor** is used to specify a fill color for the segments that indicates a decrease in the stock price in the measured time interval.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change bullFill and bearFill color of HiLo open close chart
sr.BearFillColor("#FF6600")
.BullFillColor("#336600")
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Candle

You can create a Candle chart by specifying the series Type as **Candle** in the chart series. Candle chart requires 5 fields *(X, High, Low, Open and Close)* to plot a segment.

CSHARP

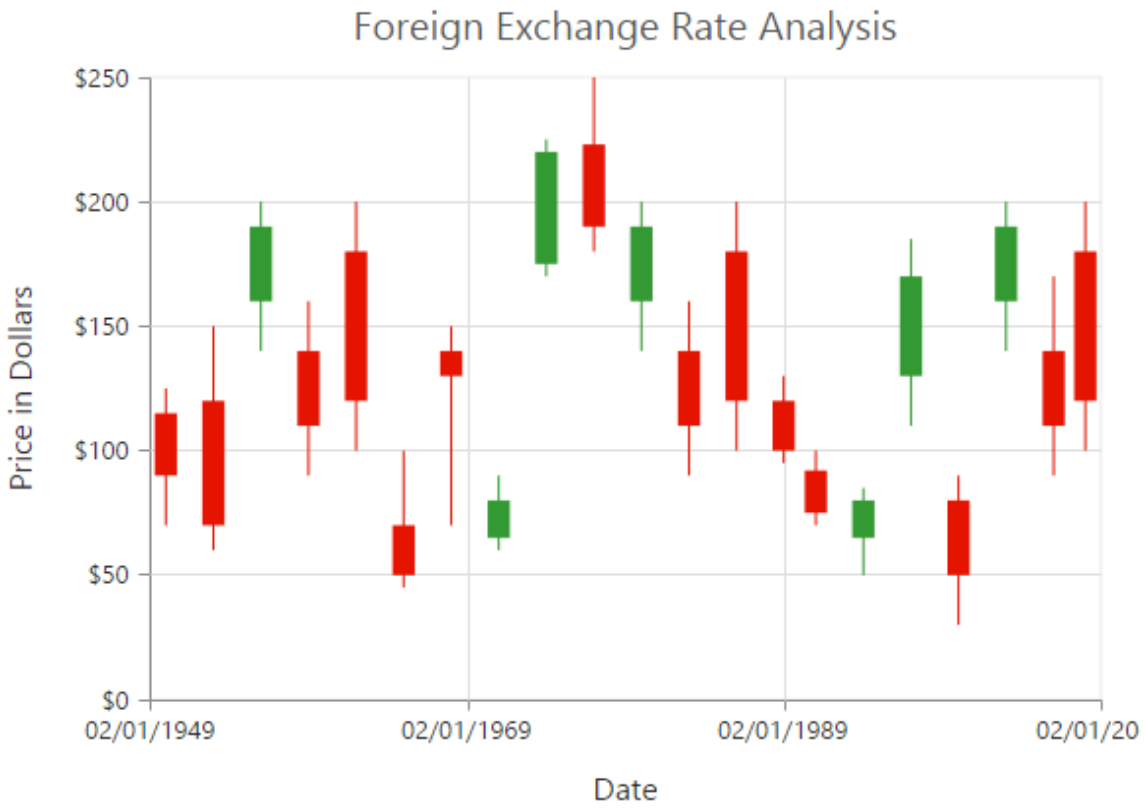
```
// Create dataSource to chart
List<ChartData> data =new List<ChartData>();
data.Add(new ChartData("Jan", 38, 10,38, 29));
data.Add(new ChartData("Feb", 28, 15, 18, 27));
data.Add(new ChartData("Mar", 54, 35, 38, 49));
data.Add(new ChartData("Apr", 52, 21, 35, 29));
ViewBag.ChartData = data;
```

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.Candle)
//Add datasource and set xName, high and low to candle chart
.XName("Month")
.High("High")
.Low("Low")
.Open("Open")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Close("Close")
.DataSource(ViewBag.ChartData)
//...
.Add();
})
//...
)
```



Click here to view the Candle Chart online demo sample.

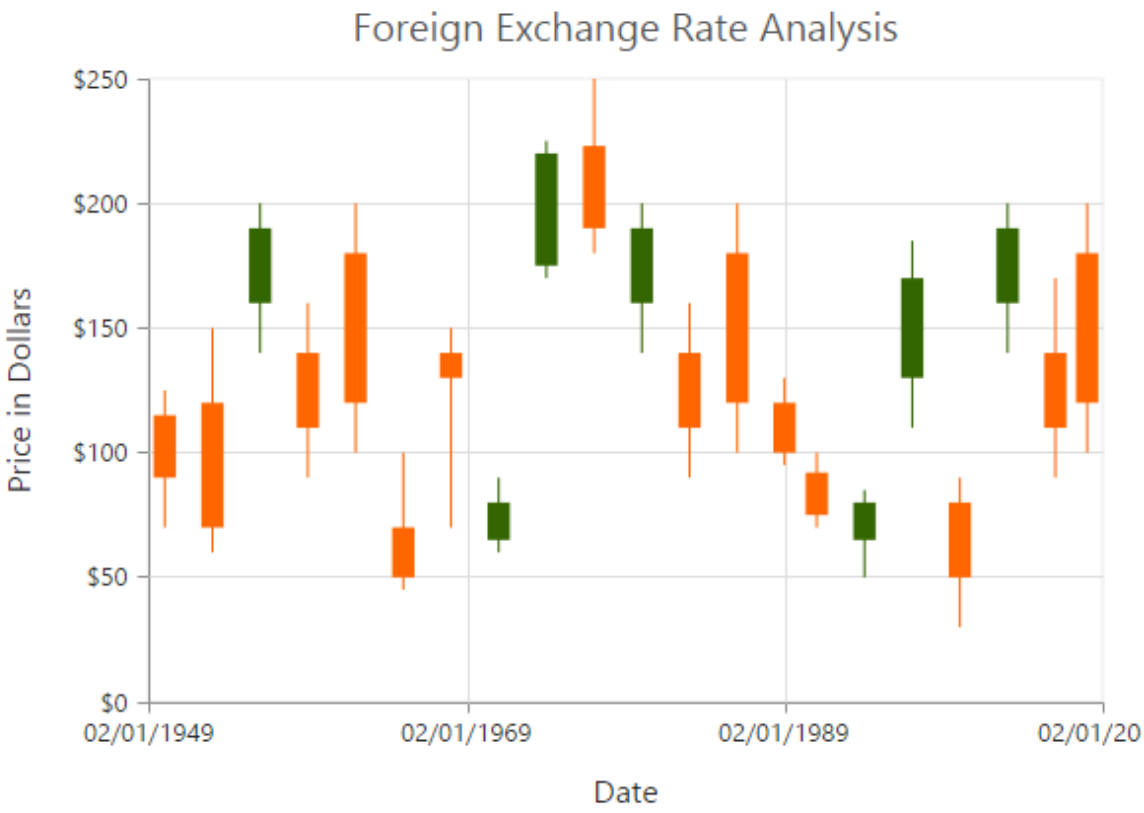
Bull and Bear Color

Candle chart **BullFillColor** is used to specify a fill color for the segments that indicates an increase in the stock price in the measured time interval and **BearFillColor** is used to specify a fill color for the segments that indicates a decrease in the stock price in the measured time interval.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change bullFill and bearFill color of candle chart
sr.BearFillColor("#FF6600")
.BullFillColor("#336600")
//...
.Add();
```

```
})
//...
)
```



HiLo

HiLo chart is created by setting the series Type as **Hilo** in the chart series. HiLo chart requires 3 fields *(X, High and Low)* to plot a segment.

CSHARP

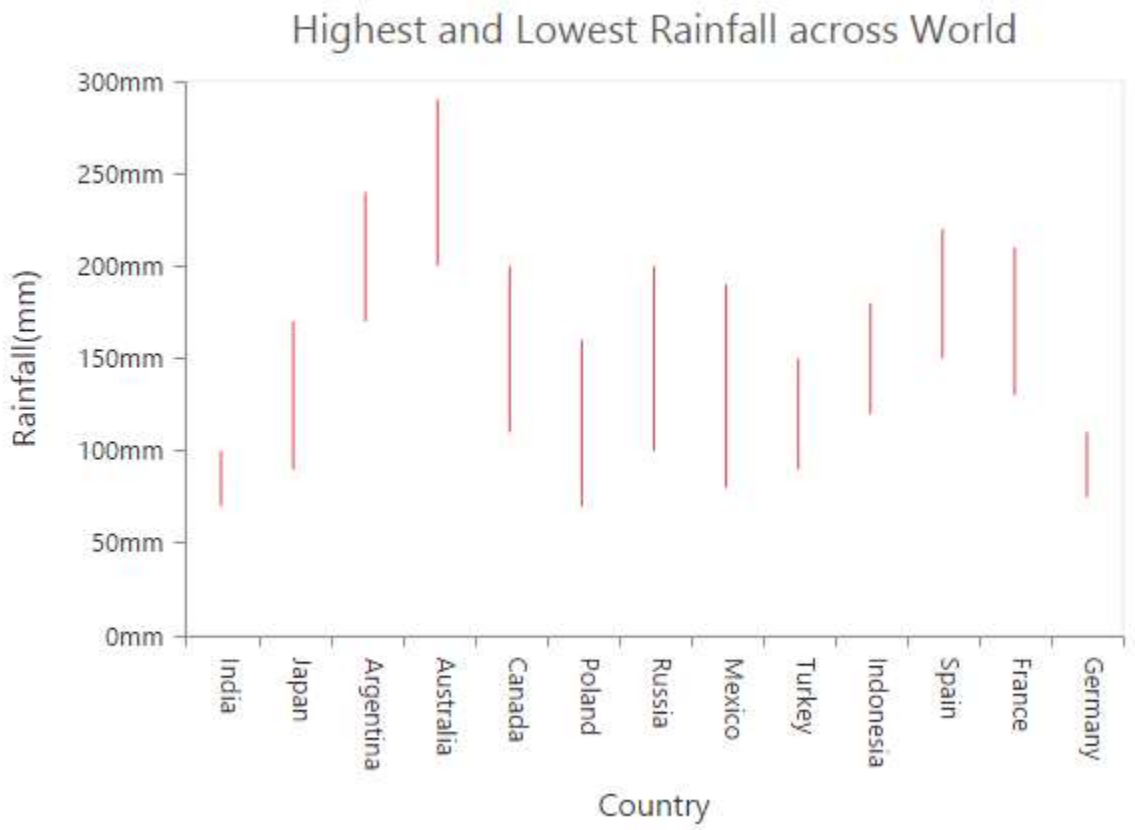
```
// Create dataSource to chart
List<ChartData> data =new List<ChartData>();
data.Add(new ChartData("Jan", 38, 10));
data.Add(new ChartData("Feb", 28, 15));
data.Add(new ChartData("Mar", 54, 35));
data.Add(new ChartData("Apr", 52, 21));
ViewBag.ChartData = data;
```

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.Hilo)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Add datasource and set xName, high and low to HiLo chart
.XName("Month")
.High("High")
.Low("Low")
//...
.Add();
})
//...
)
```



Click here to view the HiLo Chart online demo sample.

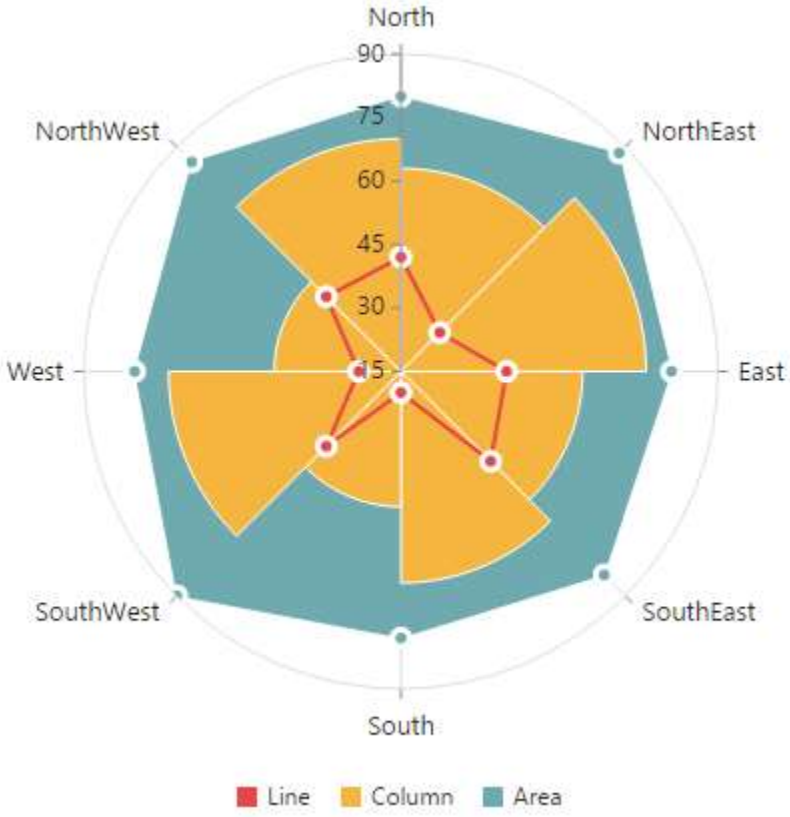
Polar

Polar chart is created by setting the series Type as **Polar** in the chart series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.Polar)
//...
.Add();
})
```

```
//...
)
```



Click here to view the Polar Chart online demo sample.

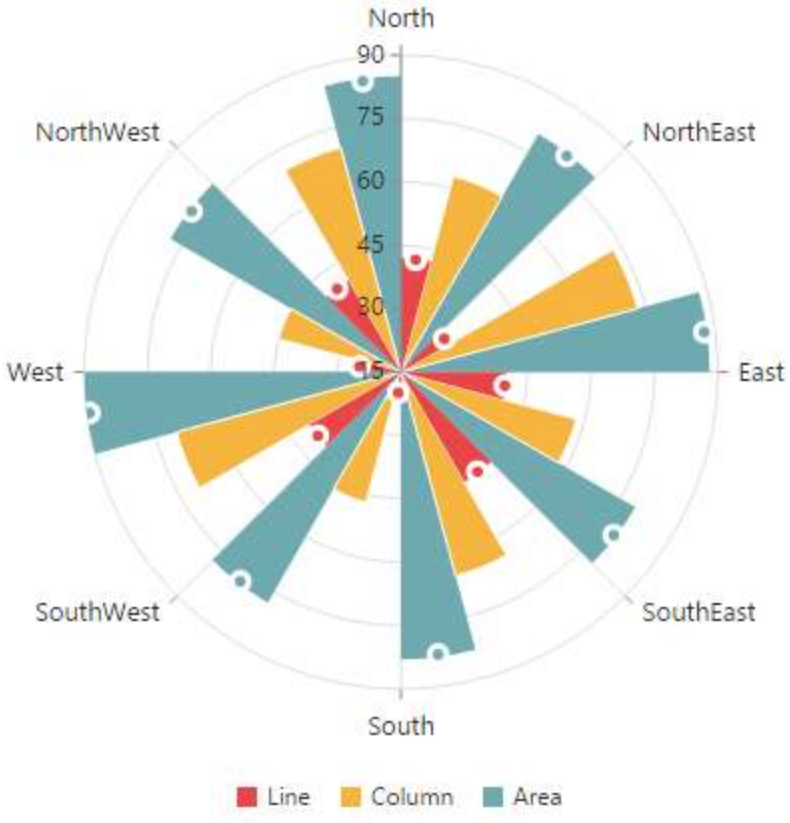
DrawType

Polar **DrawType** property is used to change the series plotting type to *Line*, *Column* or *Area*. The default value of DrawType is **Line**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change polar series drawType
sr.DrawType(DrawType.Column)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

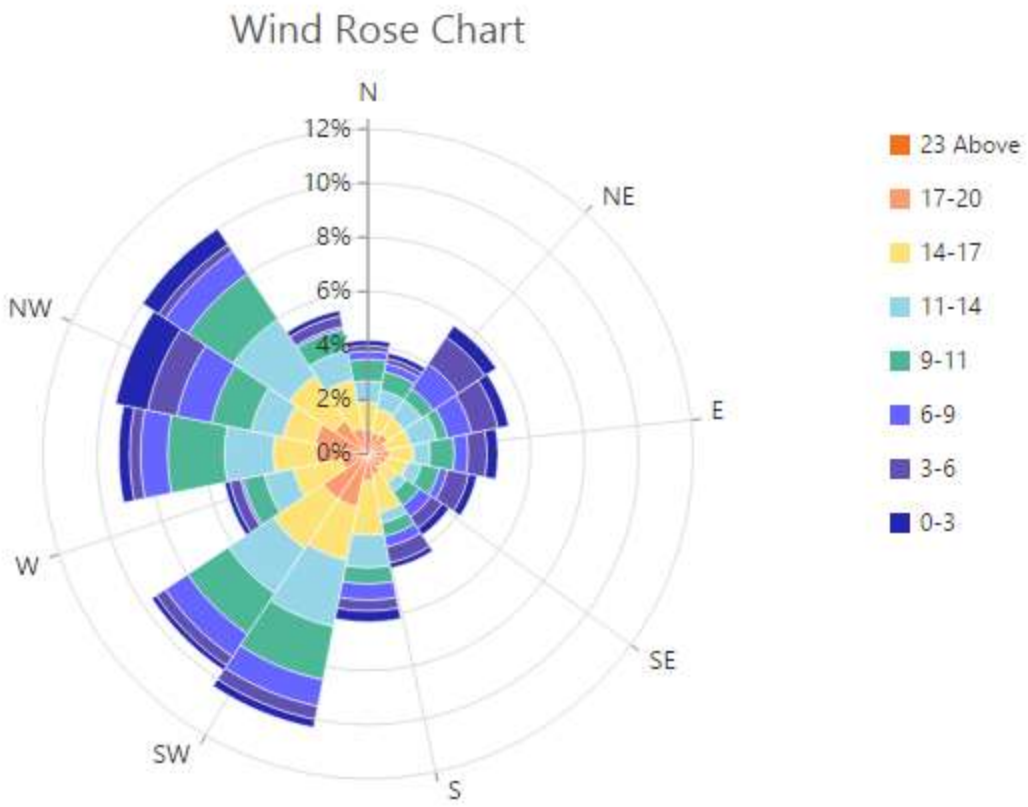


Stack columns in Polar chart

By using the **IsStacking** property, you can specify whether the column has to be stacked when the DrawType is column. Its default value is **false**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Enable isStacking property for stacked column polar chart
sr.IsStacking(true)
//...
.Add();
})
//...
)
```



Click here to view the Polar Wind Rose Chart online demo sample.

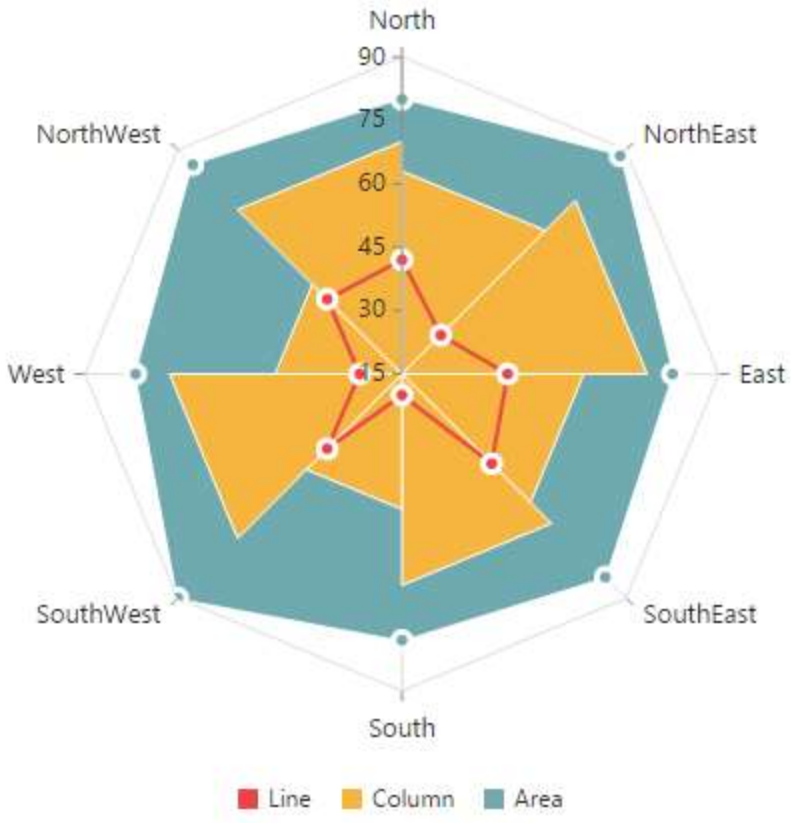
Radar Chart

To create a Radar chart, you can specify the series Type as **Radar** in the chart series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Set chart type to series
sr.Type(SeriesType.Radar)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Radar Chart online demo sample.

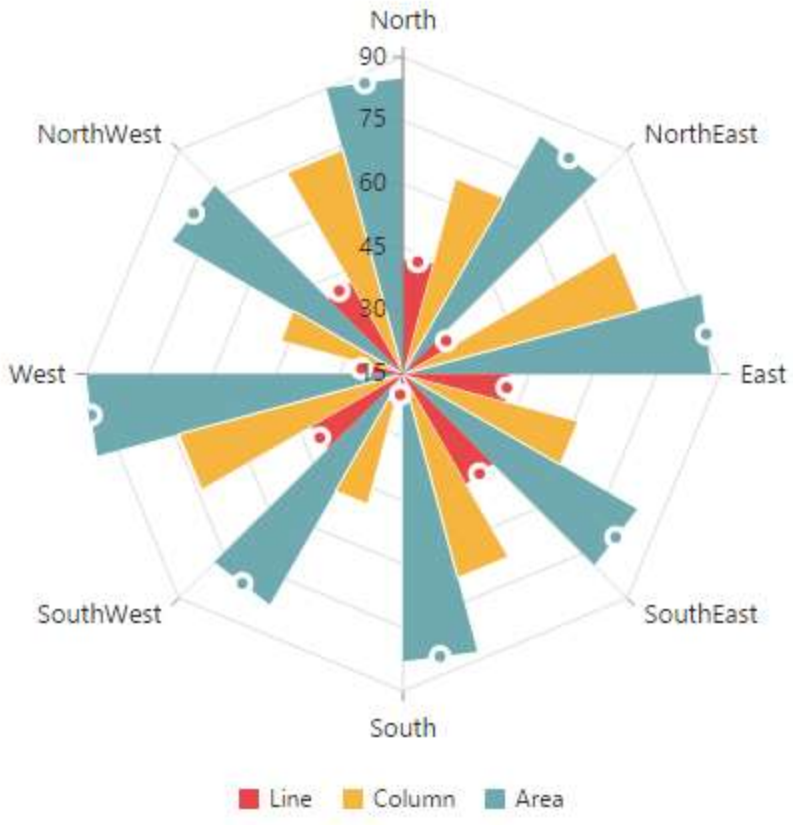
DrawType

Radar **DrawType** property is used to change the series plotting type to *Line*, *Column* or *Area*. The default value of DrawType is **Line**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Change radar series drawType
sr.DrawType(DrawType.Column)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



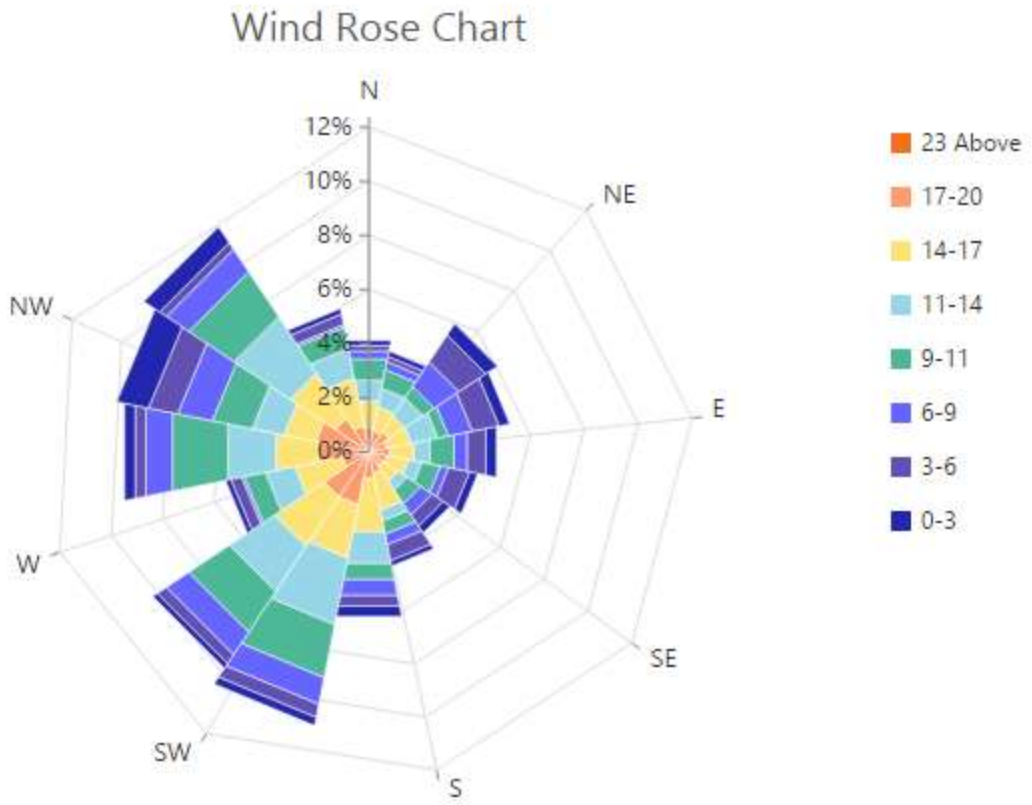
Stack columns in Radar chart

By using the **IsStacking** property, you can specify whether the column has to be stacked when the DrawType is set as Column. Its default value is set to *false*.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
//Enable isStacking property for stacked column radar chart
sr.IsStacking(true)
//...
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Waterfall Chart

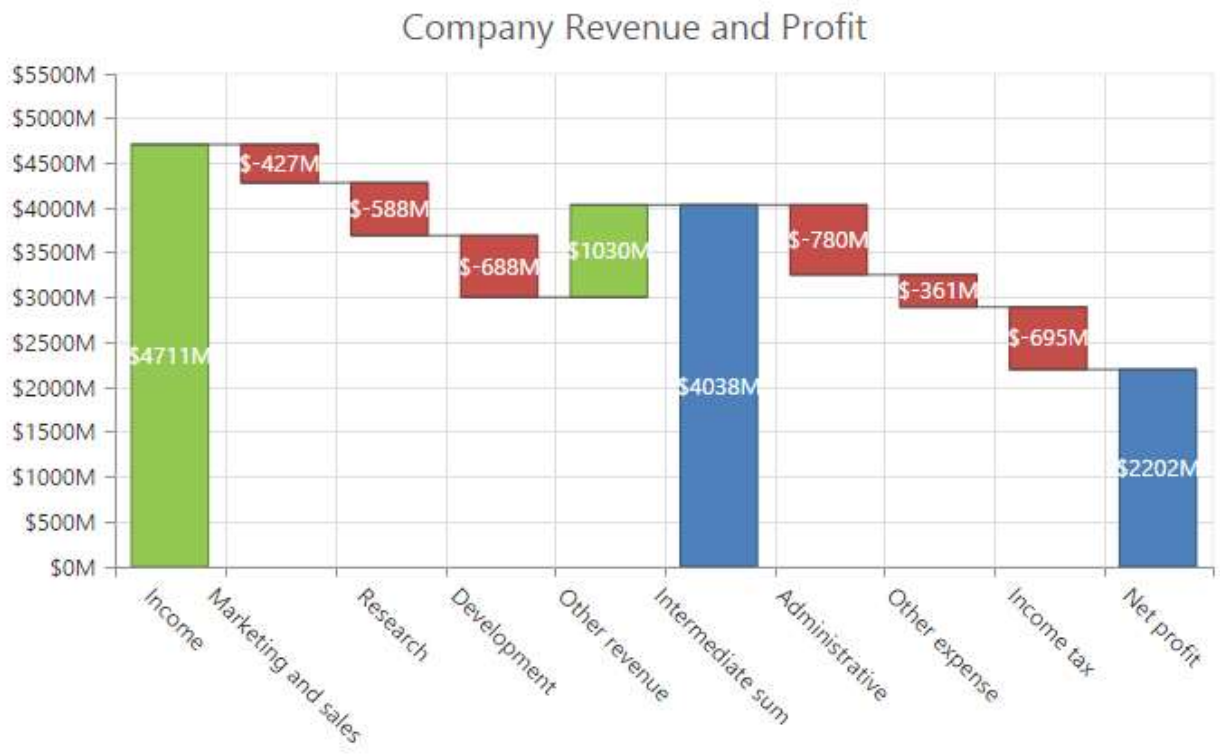
For rendering a Waterfall chart, set series *Type* as **Waterfall** in the chart series. To change the waterfall series segment color use *Fill* option of series and use *PositiveFill* property to differentiate the positive segments.

Note: The inline property of the **Series.PositiveFill** has the first priority and override the **Series.Fill**.

ASPX-CS

```
@(Html.EJ().Chart("container")
.Series(sr =>
{
//...
//Change series type
sr.Type(SeriesType.Waterfall)
.Fill("#C64E4A").PositiveFill("#93C952").Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Waterfall Chart online demo sample.

ShowIntermediateSum

To display the summary of values since the last intermediate point of the waterfall series, set **ShowIntermediateSum** property as true in the specific point.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
sr.Points(pt =>
{
//Enable showIntermediateSum in to a point.
pt.X("Intermediate sum").ShowIntermediateSum(true).Add();
//...
}).Add();
})
//...
)
```

ShowTotalSum

The sum of all previous point in the waterfall series is displayed on enabling the **ShowTotalSum** property for a specific point.

ASPX-CS

```
@(Html.EJ().Chart("container")
```

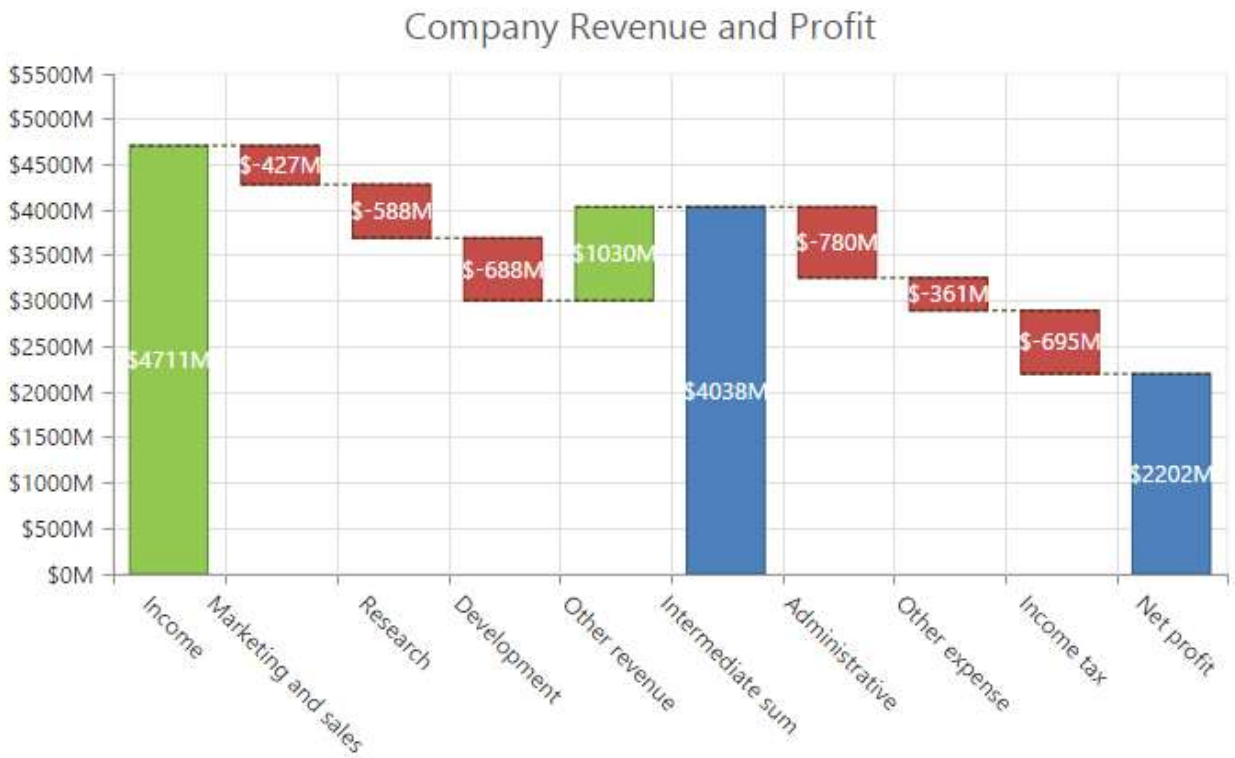
```
//...
.Series(sr =>
{
sr.Points(pt =>
{
//Enable showTotalSum in to a point.
pt.X("Total sum").ShowTotalSum(true).Add();
//...
}).Add();
})
//...
)
```

ConnectorLine

To customize the connector line color, width, opacity and dashArray of the waterfall series, you can use **ConnectorLine** option of series.

ASPX-CS

```
@(Html.EJ().Chart("container")
.Series(sr =>
{
sr .ConnectorLine(cl=>cl.Color("#333000")
.Width(1).Opacity(1).DashArray("2,3"))
.Add();
})
//...
)
```



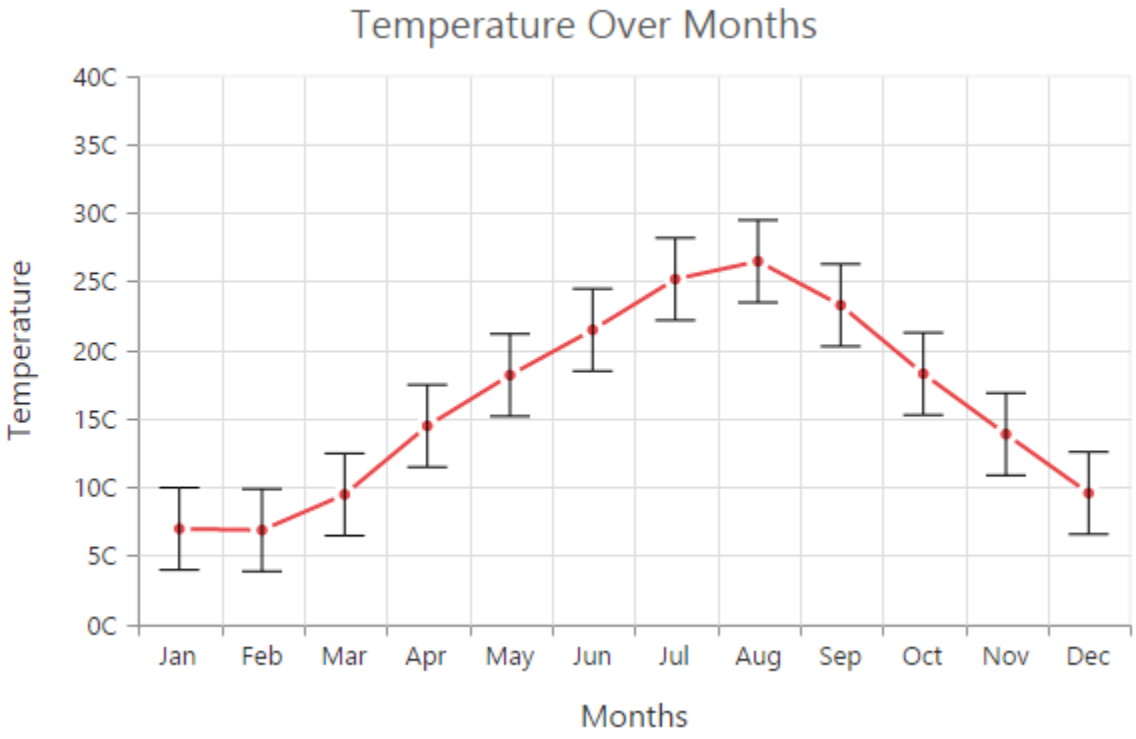
Copyright © 2001 - 2020 Syncfusion Inc.

ErrorBar Chart

EjChart can generate Error bar for Cartesian type series *(Line, Column, Bar, Scatter, Area, Candle, HiLo, etc.)*. To render the Error bar for the series, set *Visibility* as *"visible"* to **ErrorBar** in the series.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
//To toggle the error bar visibility
sr.ErrorBar(era =>
era.Visible("visible")).Add();
})
//...
)
```



Click here to view the ErrorBar Chart online demo sample.

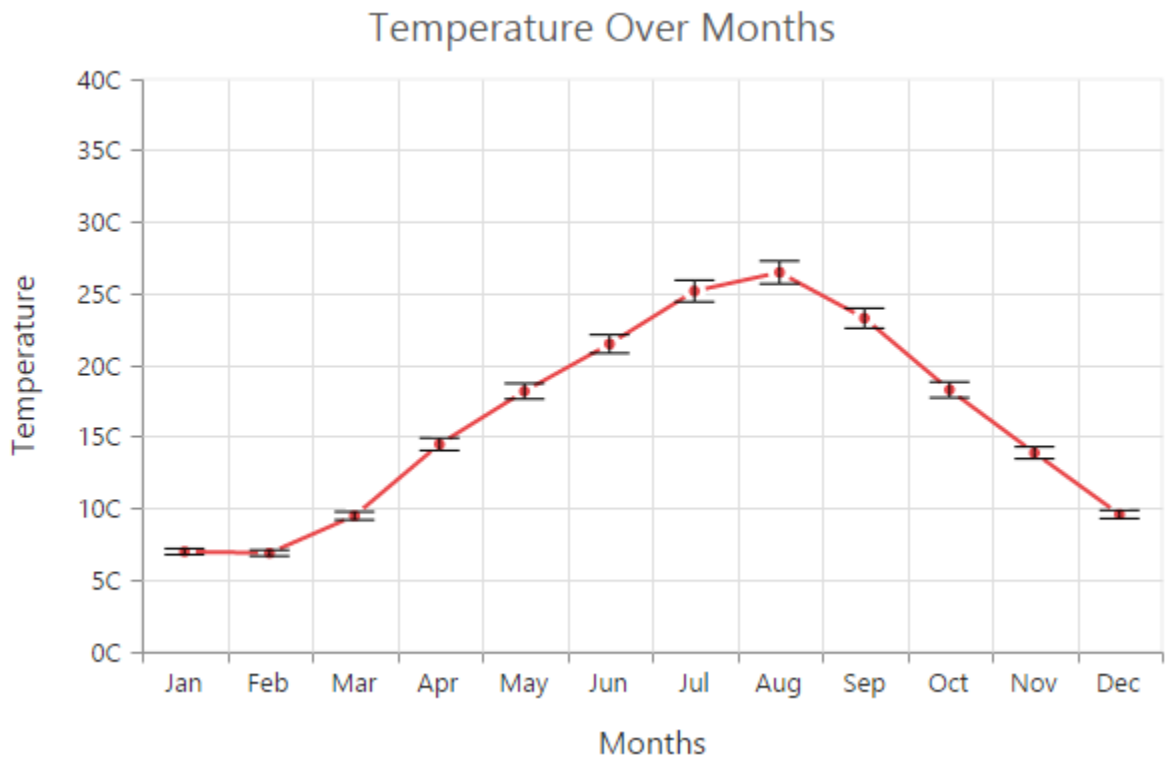
Changing Error Bar Type

You can change the error bar rendering type using **Type** *(like FixedValue, Percentage, StandardDeviation, StandardError and Custom)* option of errorBar. To change the error bar line length you can use **VerticalErrorValue** property.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
//To change the error bar type
```

```
sr.ErrorBar(era =>
era.Type(ErrorBarType.FixedValue)
.VerticalErrorValue(3)).Add();
})
//...
)
```



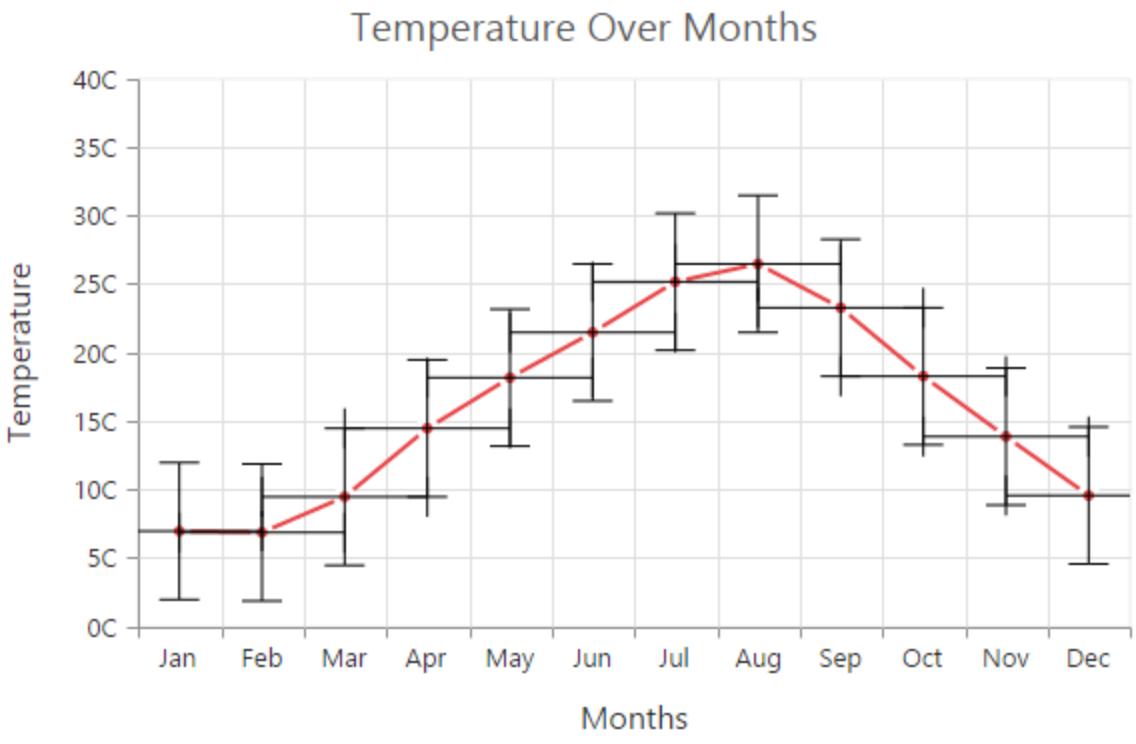
Customizing error bar type

To customize the error bar type, set error bar Type as **Custom** and then change the horizontal/vertical positive and negative value of error bar.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
//To change the error bar type.
sr.ErrorBar(era =>
era.Type(ErrorBarType.Custom)
.VerticalPositiveErrorValue(5)
.HorizontalPositiveErrorValue(1)
.VerticalNegativeErrorValue(5)
.HorizontalNegativeErrorValue(1)).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



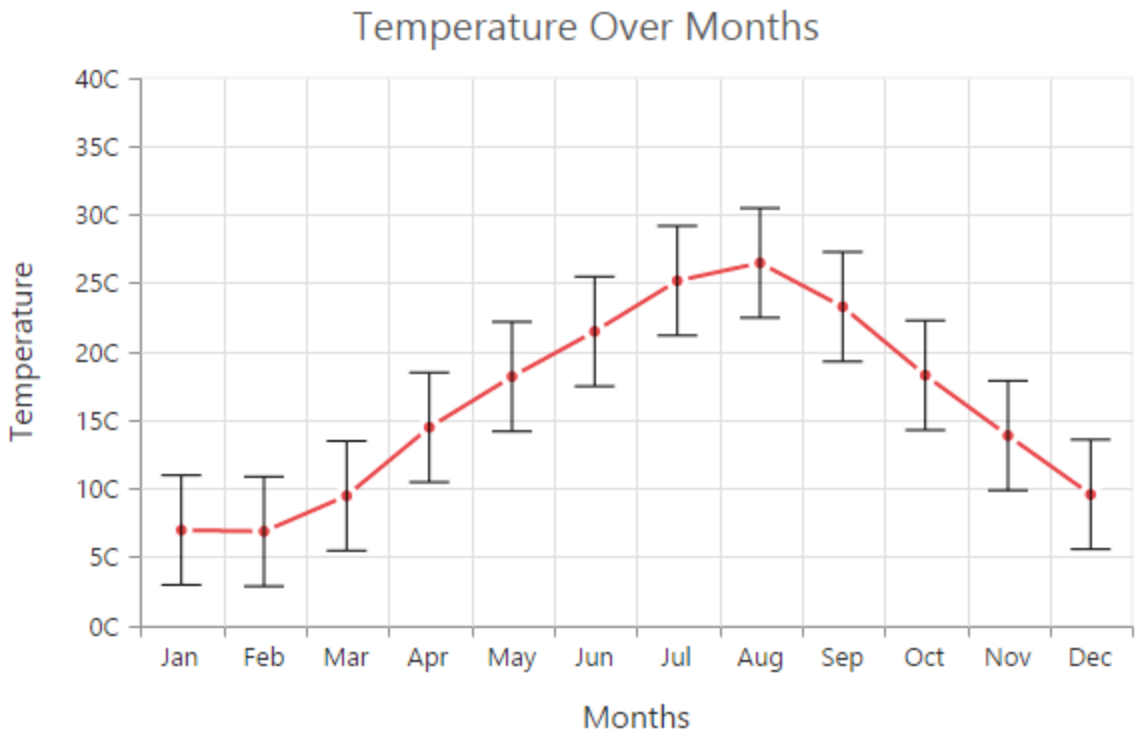
Changing Error Bar Mode

Error bar mode is used to define whether the error bar line has to be drawn *Horizontally, Vertically* or in *Both* side. To change the error bar mode use ErrorBar.Mode option.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
//To change the error bar mode.
sr.ErrorBar(era =>
era.Type(ErrorBarType.FixedValue)
.Mode(ErrorBarMode.Vertical)).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



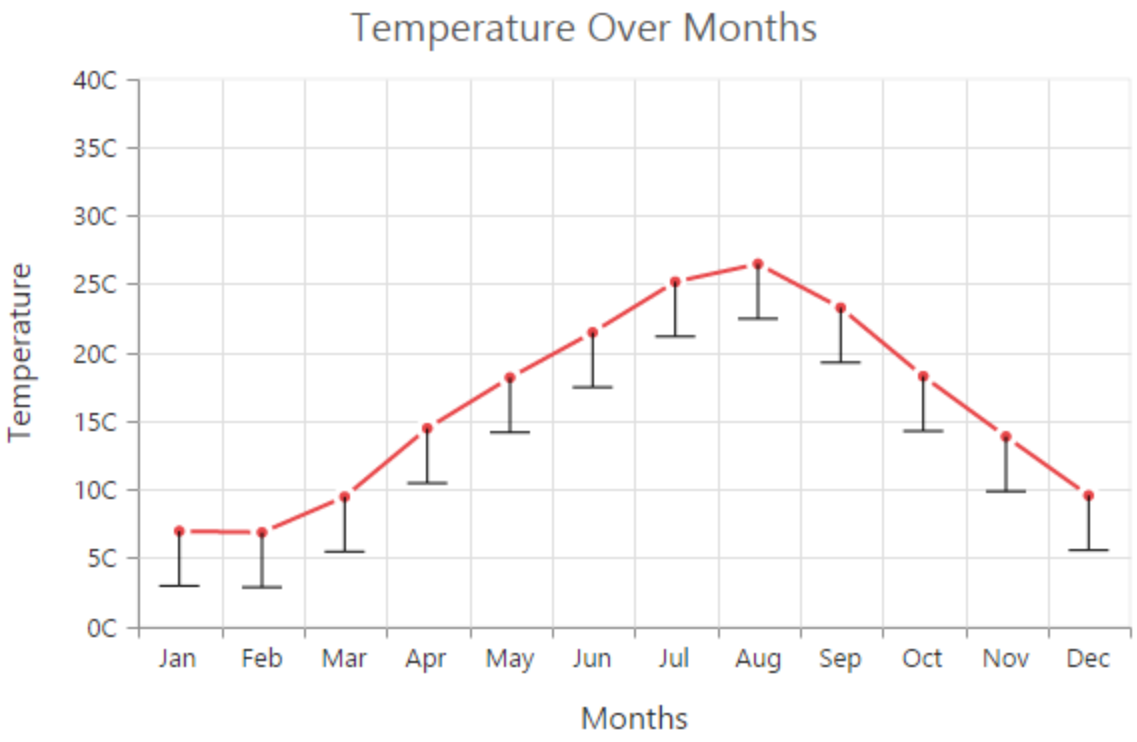
Changing Error Bar Direction

You can change the error bar direction to plus, minus or both side using ErrorBar.Directions option.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
//To change the error bar direction
sr.ErrorBar(era =>
era.Type(ErrorBarType.FixedValue)
.Mode(ErrorBarMode.Vertical)
.Direction(ErrorBarDirection.Minus)).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

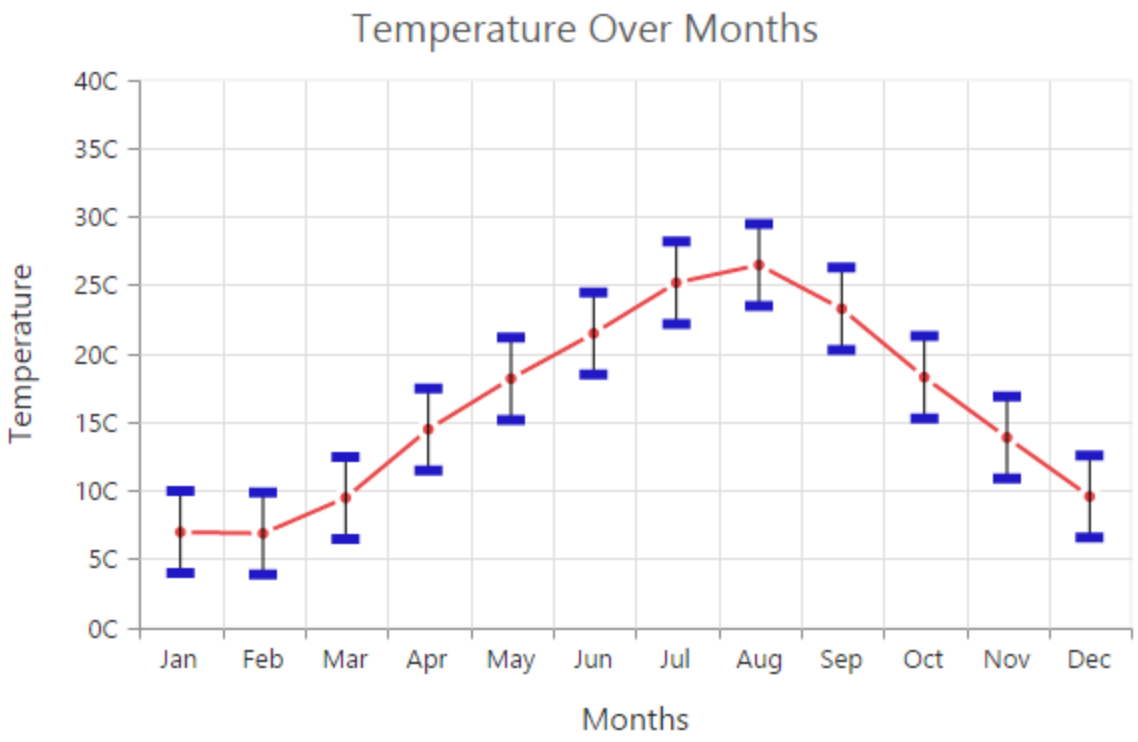


Customizing Error bar cap

To customize the errorBar cap visibility, length, width and fill color, you can use **Cap** option in the **Series.ErrorBar**.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
//To customize the error bar cap
sr.ErrorBar(era =>
era.Cap(cap=>
cap.Visible(true)
.Length((20),
.Width(1),
.Fill("#000000"))).Add();
})
//...
)
```



Box and Whisker Chart

To render a Box and Whisker Chart, set the series *type* as **BoxAndWhisker** .Box and Whisker chart requires

2 fields (x and y) to plot a segment. The field y requires n number of data or it should contain minimum of five values to plot a segment.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
sr.Points(pt =>
{
pt.X("Development").Y(22,22,23,25,25,25,26,27,27,28,28,29,30,32,34,32,34,36,
35,38).Add();
pt.X("Testing").Y(22,33,23,25,26,28,29,30,34,33,32,31,50).Add();
pt.X("HR").Y(22,24,25,30,32,34,36,38,39,41,35,36,40,56).Add();
pt.X("Finance").Y(26,27,28,30,32,34,35,37,35,37,45).Add();
pt.X("R&D").Y(26,27,29,32,34,35,36,37,38,39,41,43,58).Add();
})
.Type(SeriesType.BoxAndWhisker)
})
//...
)
```

BoxPlotMode

You can change the rendering mode of the Box and Whisker series using the *BoxPlotMode* property .The default value of *BoxPlotMode* is **exclusive**.

The other boxPlotModes available are inclusive and normal.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
.BoxPlotMode(BoxPlotMode.Inclusive)
})
//...
)
```

ShowMedian

Box and Whisker *showMedian* property is used to show the box and whisker average value. The default value of *showMedian* is **false**.

ASPX-CS

```
@(Html.EJ().Chart("container")
```

```
//...
.Series(sr =>
{
.ShowMedian(true)
})
//...
)
```

Customize the Outlier

Outlier symbol, width and height can be customized using outlierSettings through *outlierSettings* property. By default Outlier symbol is displayed as circle with a height and width of 6 pixels.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
.OutlierSettings(outlier=>outlier.Shape(ChartShape.Triangle)
.Size(size=>size.Height(10).Width(10))).Add();
})
//...
)
```

Click here to view the Box and Whisker Chart online demo sample.

Pie Of Pie Chart

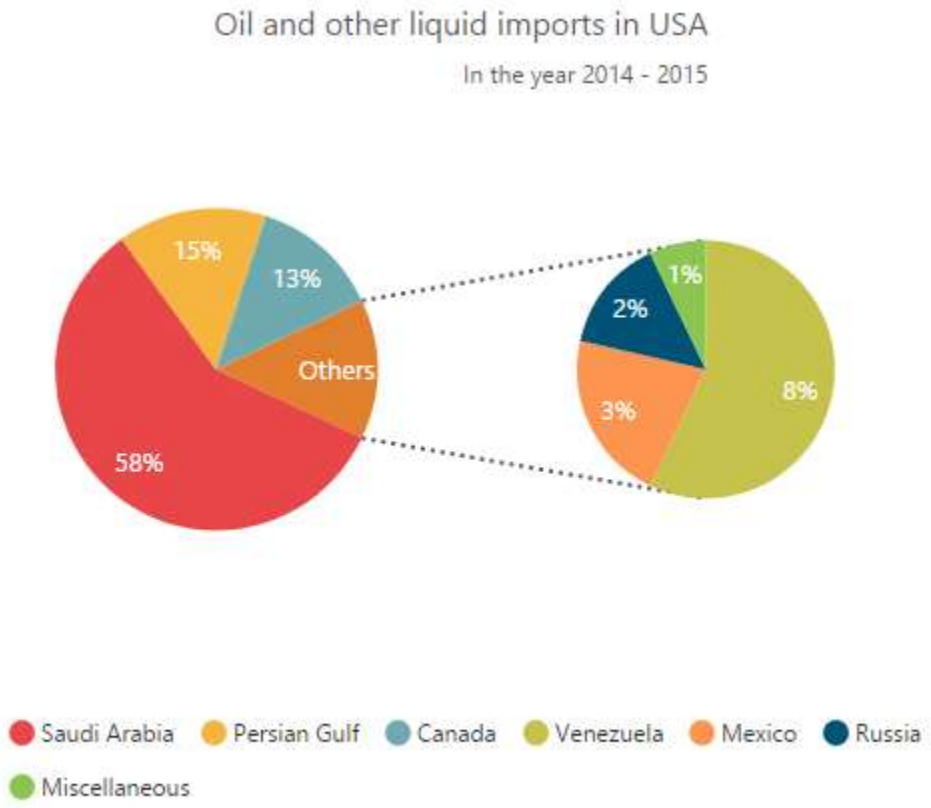
To render the pie of pie chart, set the series Type as **PieOfPie**. Pie of pie chart is used for displaying the data of a pie slice as another pie chart. The values in the second pie is displayed based on the **splitMode** property.

ASPX-CS

```
@(Html.EJ().Chart("container")
.Series(sr =>
{
sr.Points(pt =>
{
pt.X("Saudi Arabia").Y(58).Text("58%").Add();
pt.X("Persian Gulf").Y(15).Text("15%").Add();
pt.X("Canada").Y(13).Text("13%").Add();
pt.X("Venezuela").Y(8).Text("8%").Add();
pt.X("Mexico").Y(3).Text("3%").Add();
pt.X("Russia").Y(2).Text("2%").Add();
pt.X("Miscellaneous").Y(1).Text("1%").Add();
})
.SplitValue("10")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Type(SeriesType.PieOfPie).Add();
})
)
```



Click here to view the Pie Of Pie Chart online demo sample.

Split Mode and Split Value

The points to be displayed in the second pie is decided based on the splitMode property.**SplitMode** property takes the following values.

- Position – Have to split the data points based on its position
- Value – Have to split the data points based on its Y value
- Percentage – Have to split the points based on the percentage value
- Indexes – The data points with the specified indexes are split separately

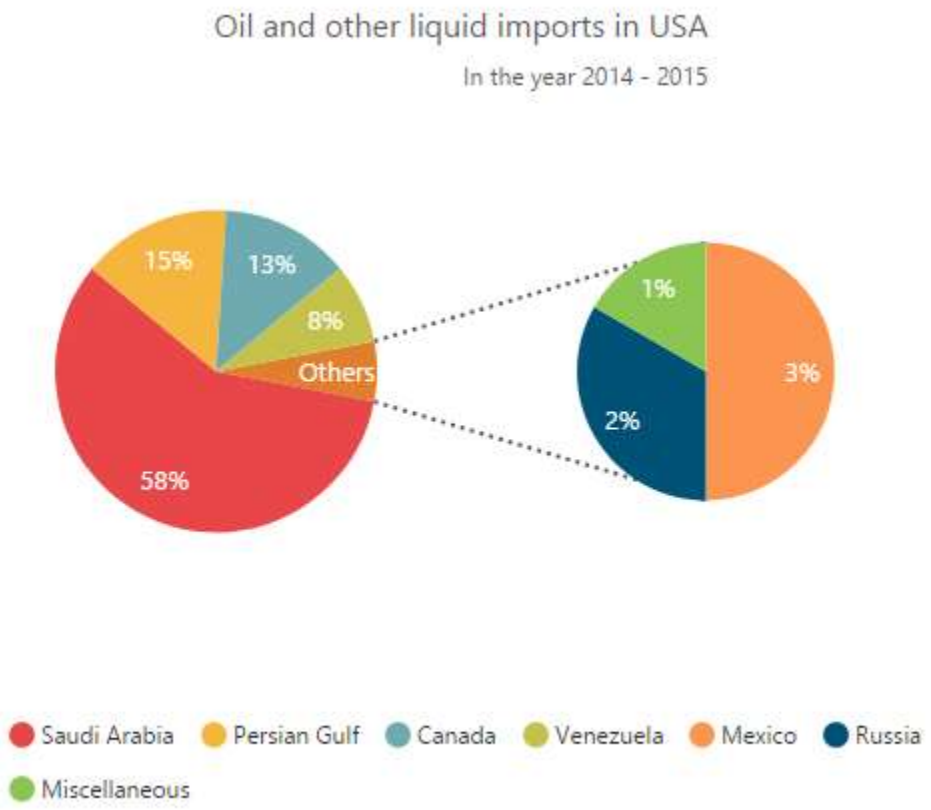
By default, the splitMode is set to **Value**.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
.SplitMode(SplitMode.Position)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.SplitValue("3").Add();
})
//...
)
```



Changing Pie Of Pie Size

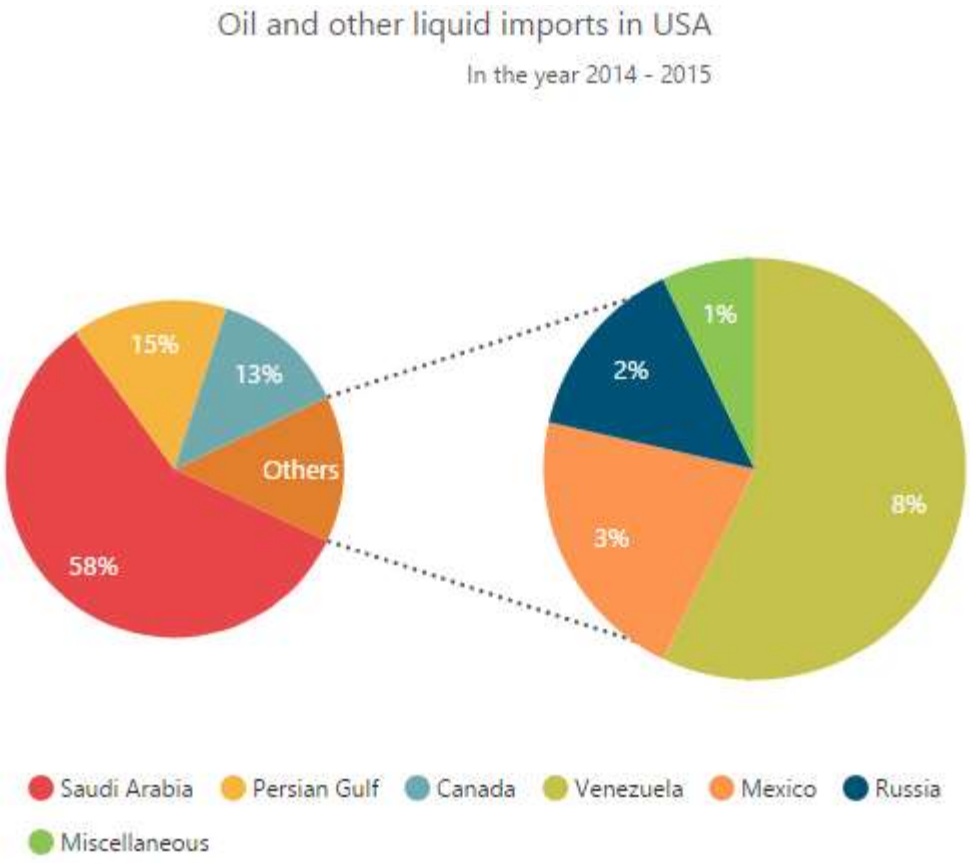
The size of the second Pie can be customized by using the PieOfPieCoefficient property. The default value of pieOfPieCoefficient is **0.6**.Its value ranges from 0 to 1.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
.PieOfPieCoefficient("1").Add();
})
//...
)
```

The following screenshot represents the pie of pie series with pieOfPieCoefficient as 1

Copyright © 2001 - 2020 Syncfusion Inc.



Customizing the Gap

The distance between the two pies in the pie of pie chart can be controlled by using the GapWidth property. The default value is **50**.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.Series(sr =>
{
.GapWidth("150").Add();
})
//...
)
```

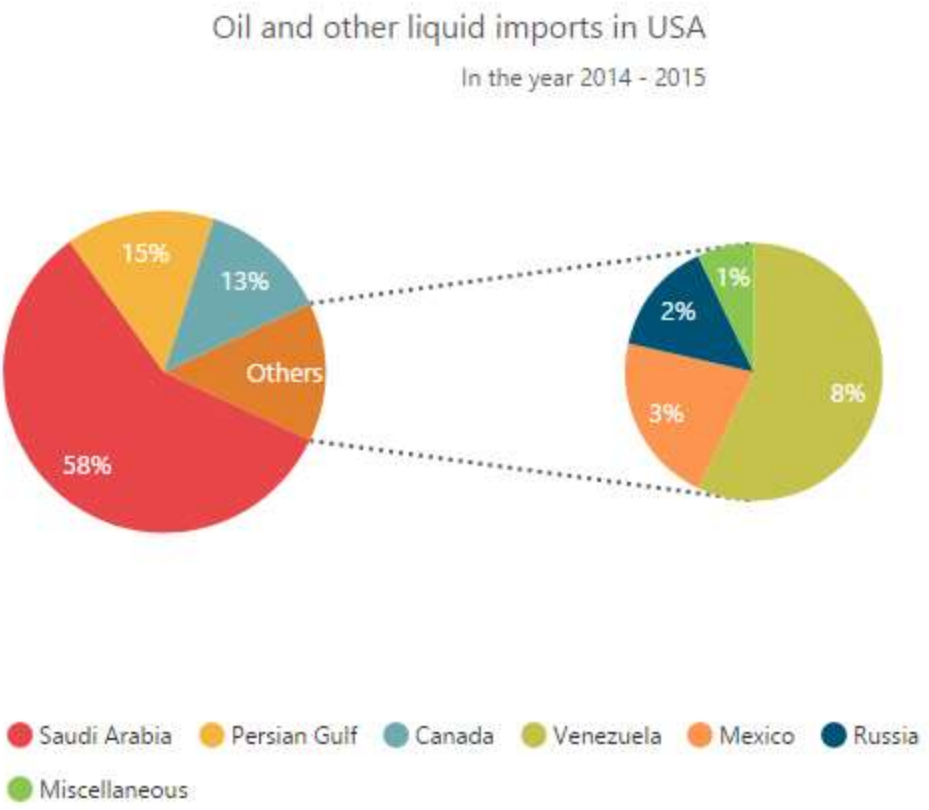


Chart Series

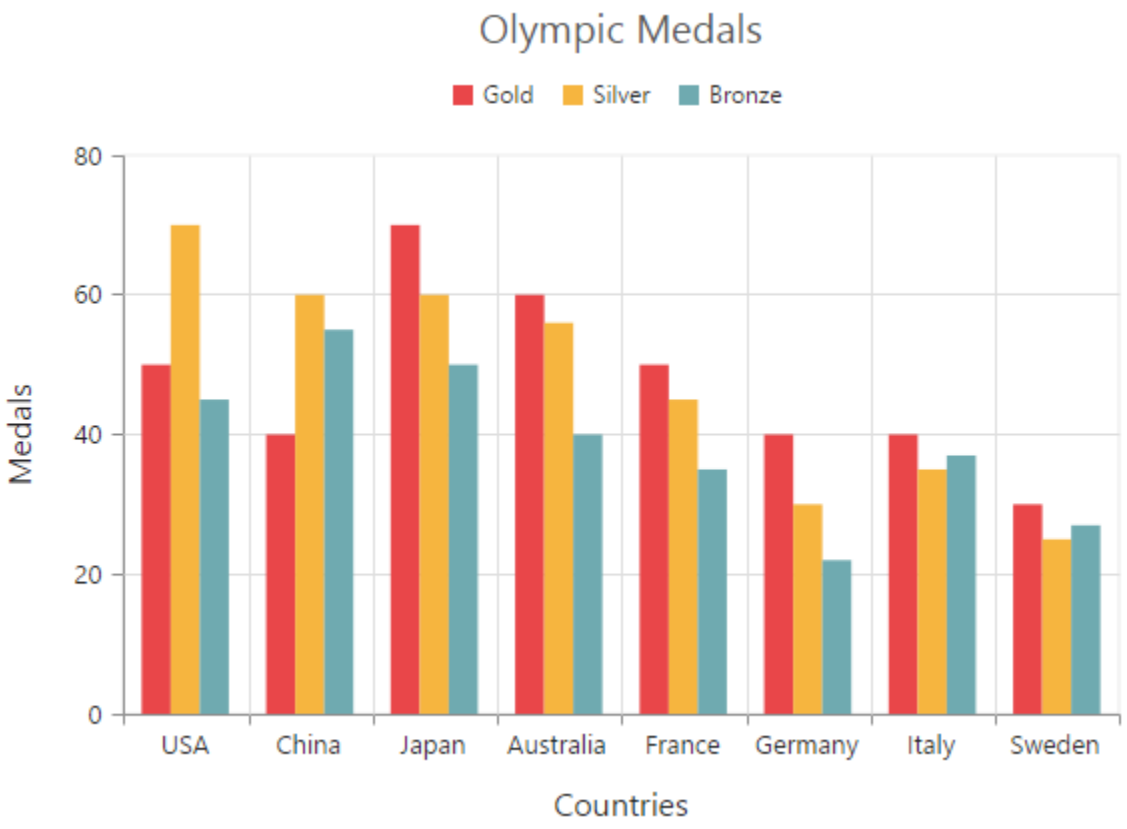
Multiple Series

In EjChart, you can add multiple series object in the **Series** options. The series are rendered in the order it is added to the Series option, by default. You can change this order by using the **ZOrder** option.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Adding Multiple Series
.Series(sr =>
{
// Add first series
sr.Type(SeriesType.Column).Points(pt=>{
pt.X("USA").Y(50).Add();
//...
}).Add();
// Add second series
sr.Type(SeriesType.Column).Points(pt => {
pt.X("USA").Y(70).Add();
//...
}).Add();
// Add third series
sr.Type(SeriesType.Column).Points(pt => {
pt.X("USA").Y(45).Add();
//...
```

```
}).Add();
})
)
```



Click here to view the multiple series online demo sample.

Customizing all series together

By using the **CommonSeriesOptions**, you can customize the series options for all the series commonly, instead of setting the options directly on each series object.

Note: The inline properties of the series has the first priority and override the commonSeriesOptions.

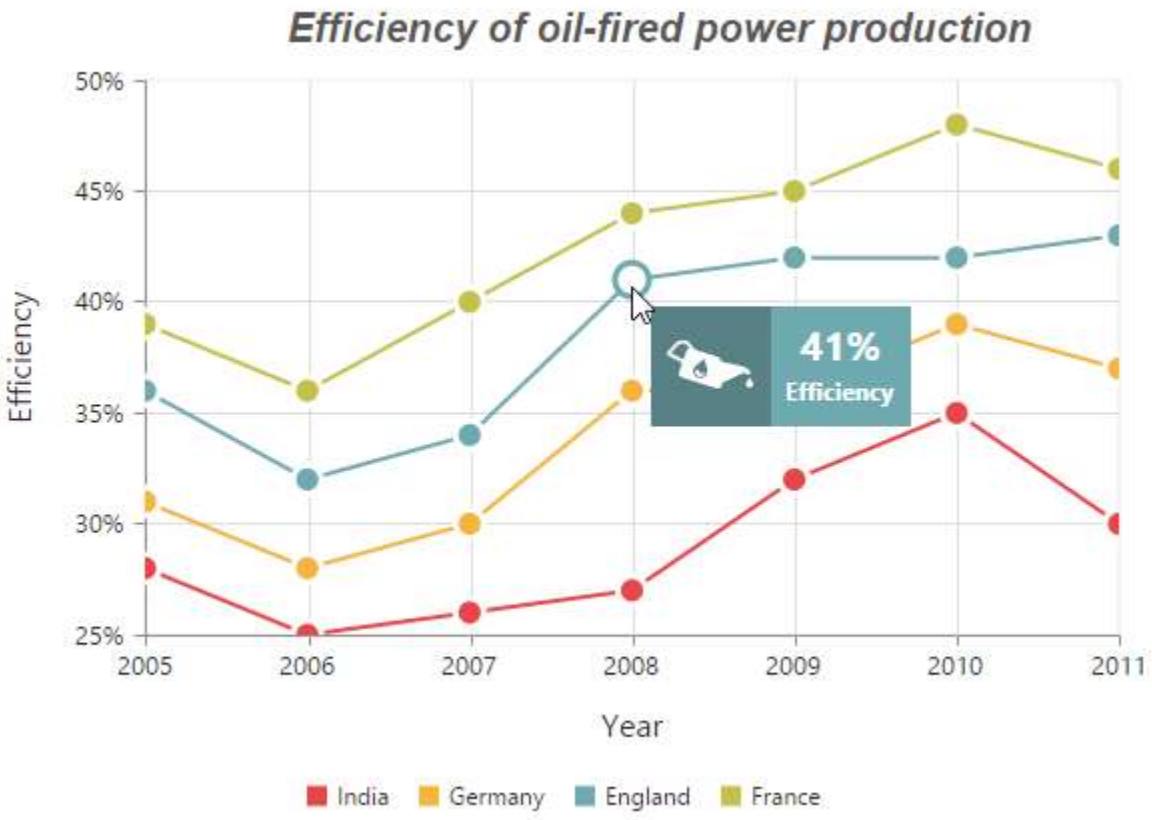
The following code example explains on how to enable marker, tooltip and animation for the chart series by using the commonSeriesOptions.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Common Properties for all the series
.CommonSeriesOptions(options=>options.Type(SeriesType.Line).EnableAnimation(
true)
.Border(border=>border.Width(2))
.Marker(marker=>marker.Visible(true).Shape(ChartShape.Circle).Size(size=>siz
e.Height(10).Width(10)))
.Tooltip(tooltip=>tooltip.Visible(true).Template("Tooltip")))
//Adding Multiple Series
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Series(sr =>
{
// Add first series
sr.Points(pt=>{
pt.X("USA").Y(50).Add();
//...
}).Add();
// Add second series
sr.Points(pt => {
pt.X("USA").Y(70).Add();
//...
}).Add();
// Add third series
sr.Points(pt => {
pt.X("USA").Y(45).Add();
//...
}).Add();
})
)
```



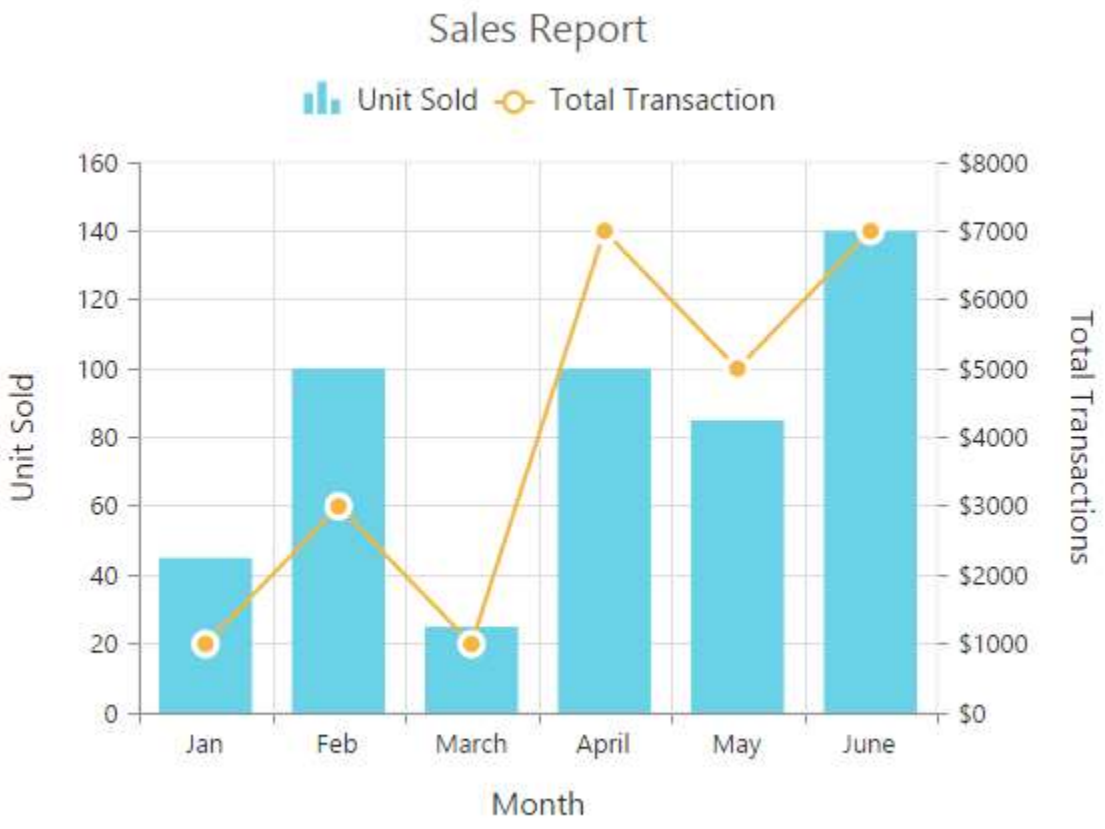
Combination Series

EjChart allows you to render the combination of different series in the chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
```

```
// ...
//Adding Multiple Series
.Series(sr =>
{
// Add first series
sr.Type(SeriesType.Column).Points(pt=>{
pt.X("USA").Y(50).Add();
//...
}).Add();
// Add second series
sr.Type(SeriesType.Line).Points(pt => {
pt.X("USA").Y(70).Add();
//...
}).Add();
})
)
```



Click here to view the combination series online demo sample.

Limitation of combination chart

- Bar, StackingBar, and StackingBar100 cannot be combined with the other Cartesian type series.
- Cartesian type series cannot be combined with the accumulation series Pie, Doughnut, Funnel, and Pyramid.
- Polar and Radar series cannot be combined with the accumulation and Cartesian type series.

Copyright © 2001 - 2020 Syncfusion Inc.

When the combination of Cartesian and accumulation series types are added to the series option, the series that are similar to the first series are rendered and other series are ignored. The following code example illustrates this,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(sr =>
{
// Add line series
sr.Type(SeriesType.Line).Points(pt=>{
pt.X("Jan").Y(50).Add();
//...
}).Add();
// Add pie series
sr.Type(SeriesType.Pie).Points(pt => {
pt.X("Jan").Y(70).Add();
//...
}).Add();
})
)
```

Data Markers

Data markers are used to provide information about the data point to the user. You can add a shape and label to adorn each data point.

Copyright © 2001 - 2020 Syncfusion Inc.

Add Shapes

You can add shapes to any chart types but they are often used with line, area and spline series to indicate each data point. It is highlighted when you hover the mouse on the shape.

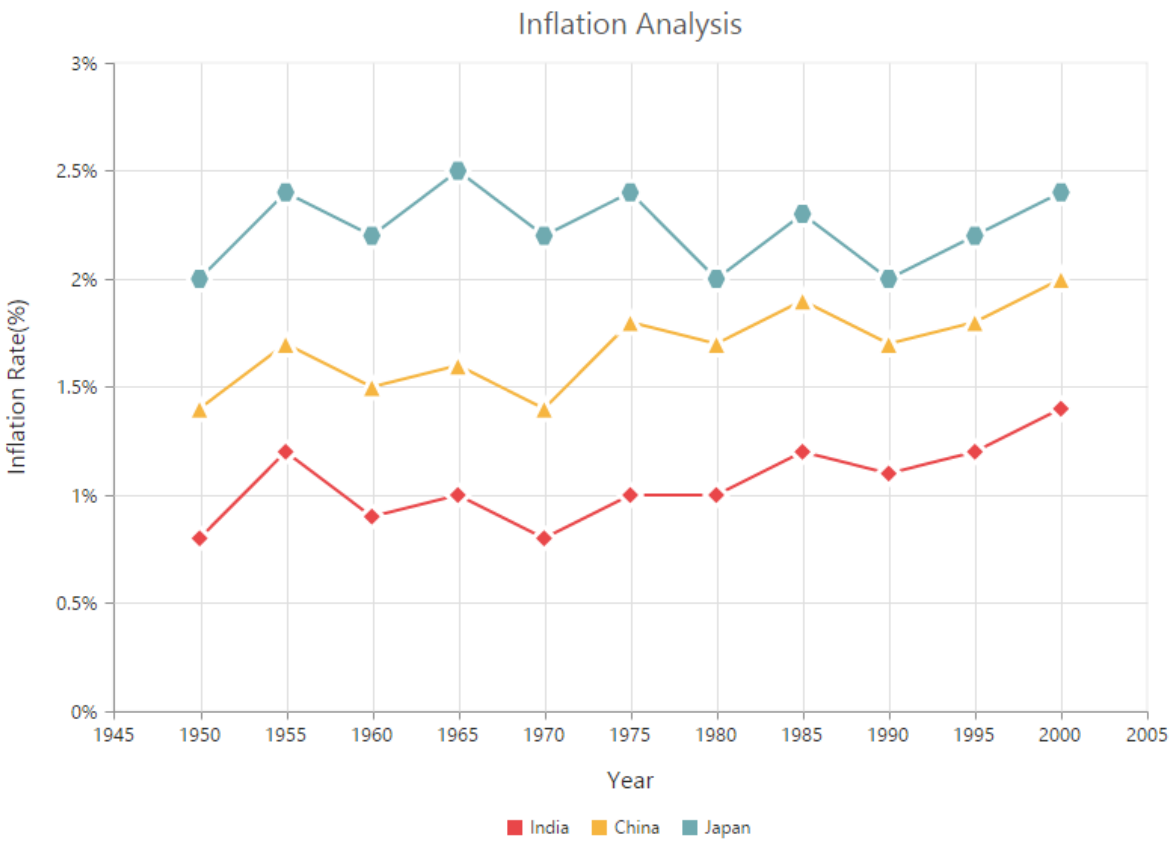
Shapes can be added to the chart by enabling the Visible option of the **Marker** property. There are different shapes you can add to the chart by using the **Shape** option such as Rectangle, Circle, Diamond etc.

The following code example explains on how to enable series marker and add shapes,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
//Adding shapes to series1
sr
//...
.Marker(mr=>mr.Visible(true).Shape(ChartShape.Diamond)).Add();
//Adding shapes to series2
sr
//...
.Marker(mr => mr.Visible(true).Shape(ChartShape.Triangle)).Add();
//Adding shapes to series3
sr
//...
.Marker(mr => mr.Visible(true).Shape(ChartShape.Hexagon)).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Add image as marker

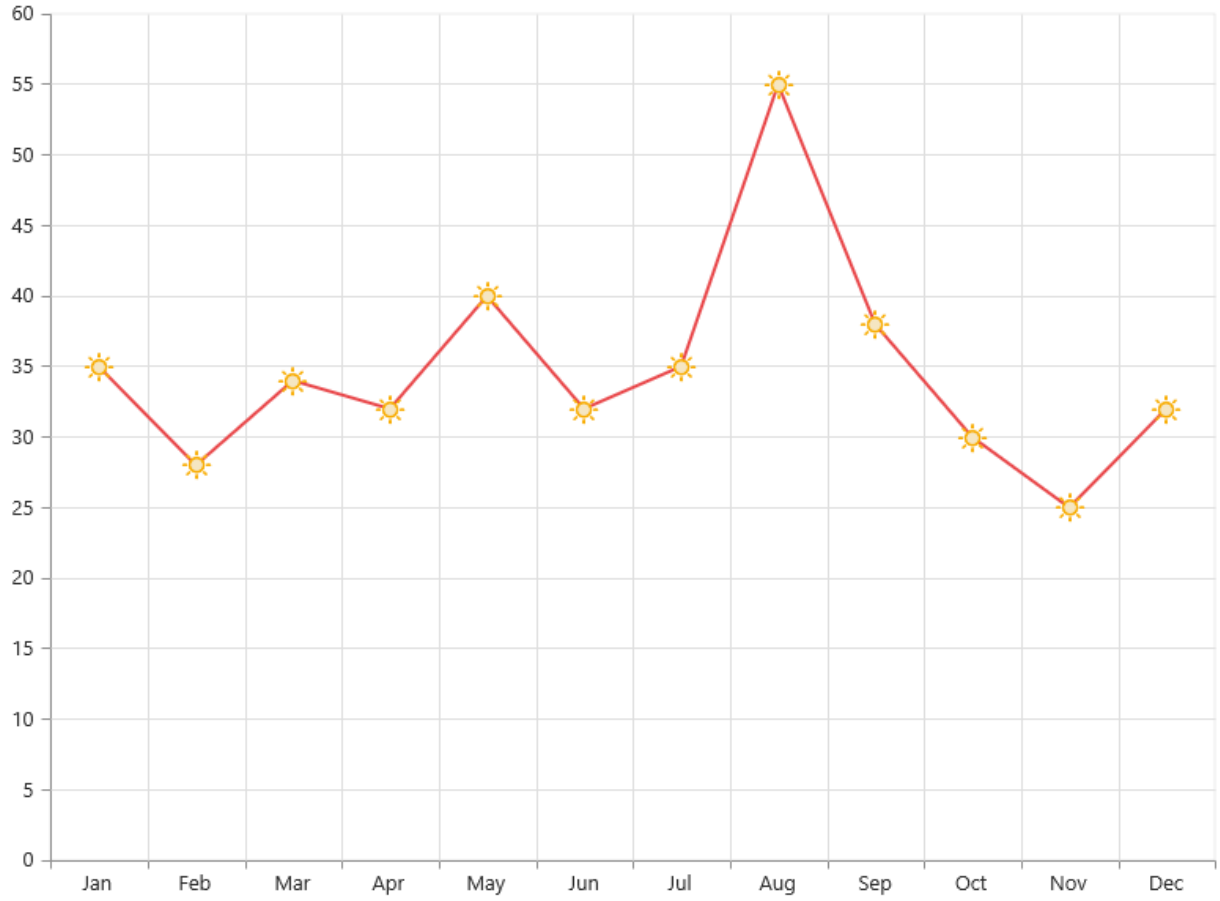
Apart from the shapes, you can also add images to mark the data point by using the **ImageUrl** option.

The following code example illustrates this,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
//Adding shapes to series1
sr
//..
.Marker(mr=>mr.Visible(true).Shape(ChartShape.Image)
.Size(size => size.Height(20).Width(20)).ImageUrl("sun_annotation.png")
).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Add labels

Data label can be added to a chart series by enabling the *Visible* property in the **DataLabel** option. The labels appear at the top of the data point, by default.

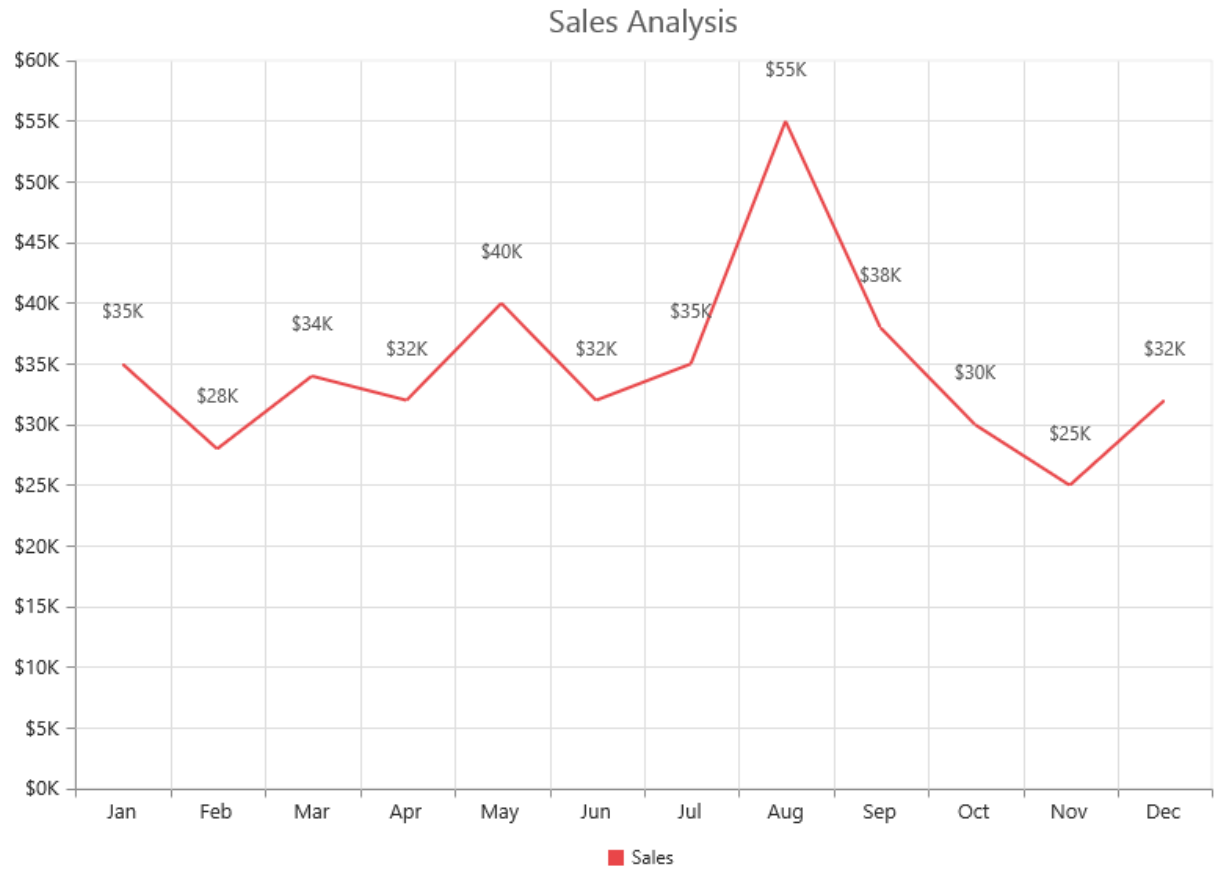
The following code example shows how to enable data label and set its horizontal and vertical text alignment.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
//Adding shapes to series1
sr
//..
.Marker(mr=>mr
.DataLabel(label=>label
//Set text alignment to data label text
.Visible(true)
.HorizontalTextAlignment(Syncfusion.JavaScript.DataVisualization.TextAlignme
nt.Center)
.VerticalTextAlignment(Syncfusion.JavaScript.DataVisualization.TextAlignment
.Far))
).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
//...
)
```



Label content can be formatted by using the template option. Inside the template, you can add the placeholder text *"point.x"* and *"point.y"* to display corresponding data points x & y value.

You can adorn the labels with background shapes by setting *Shape* option.

The following code example shows how to add background shapes and set template to data label.

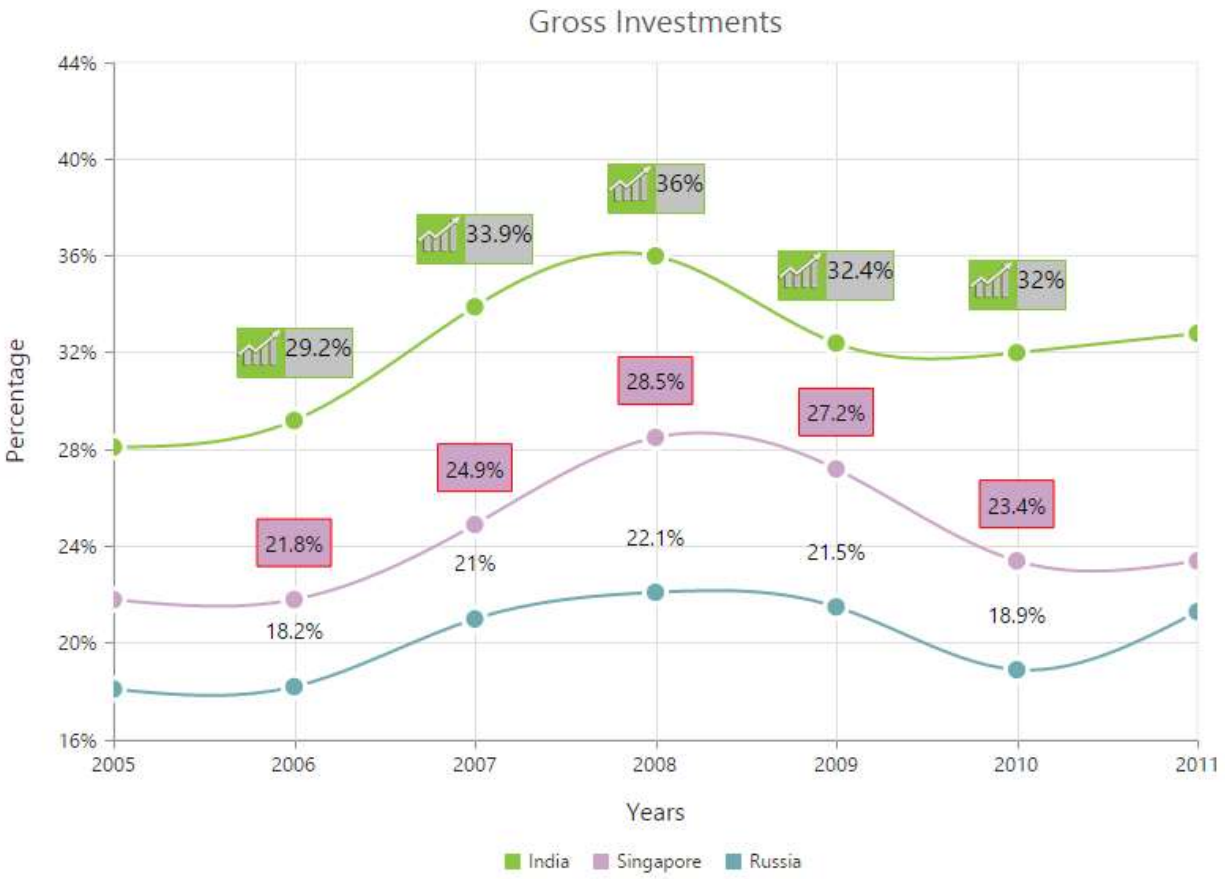
ASPX-CS

```
<div id="template">
<div id="left">
<img src="../images/chart/icon_investments.png"/>
</div>
<div id="right">
<div id="point">#point.y#%</div>
</div>
</div>
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
//Adding shapes to series1
sr
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//..
.Marker(mr=>mr
.DataLabel(label=>label
.Visible(true)
//Set template to data label
.Template("template"))
).Add();
//Adding shapes to series2
sr
//..
.Marker(mr=>mr
.DataLabel(label=>label
.Visible(true)
//Add background shape to the data label
.Shape(ChartShape.Rectangle).Border(br=>br.Width(1).Color("red"))
)
).Add();
//Adding shapes to series3
sr
//..
.Marker(mr=>mr
.DataLabel(label=>label
.Visible(true))
).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

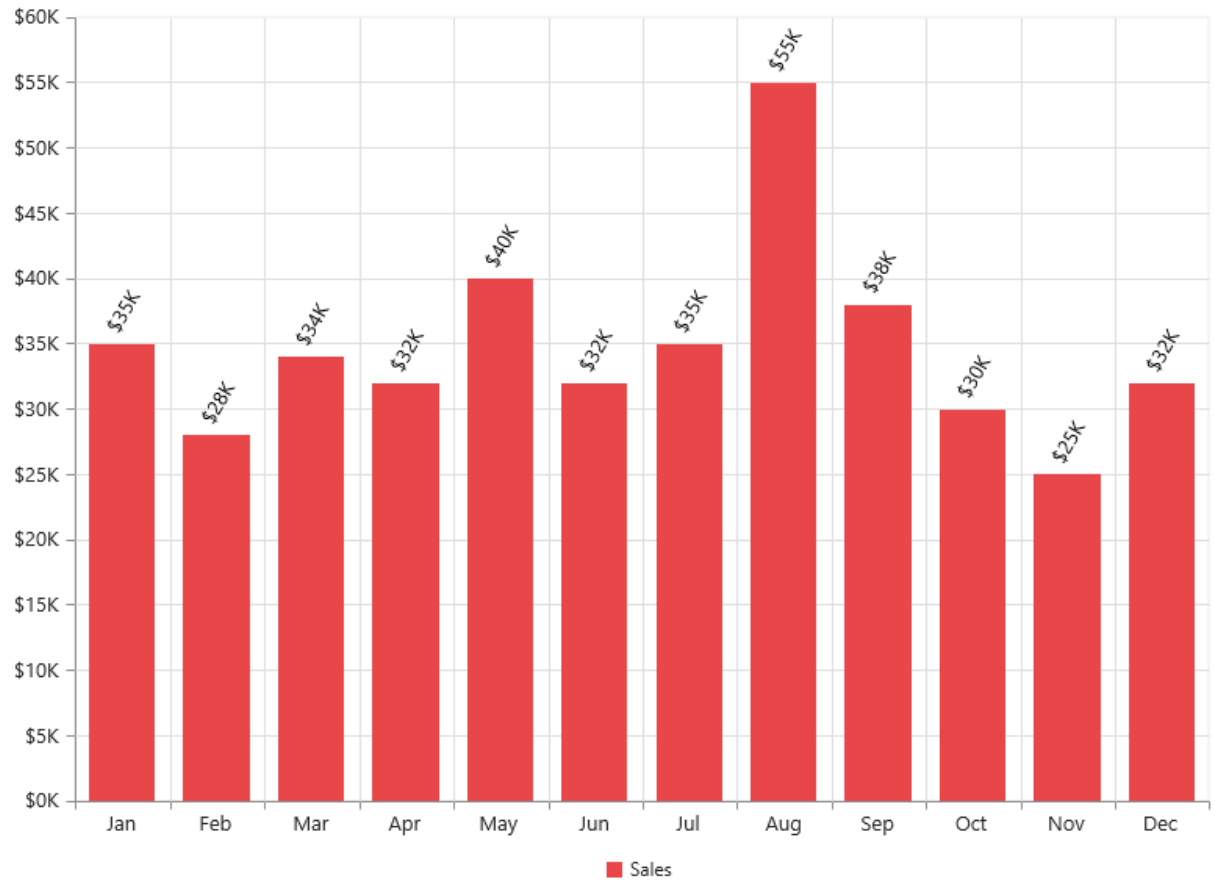


The appearance of the labels can be customized by using the *Font* and *Offset* options. The Offset option is used to move the labels vertically. Also, labels can be rotated by using the *Rotate* option.

The following code example shows how to rotate data label text and customize the font.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
//Adding shapes to series1
sr
//..
.Marker(mr=>mr
.DataLabel(label=>label
.Visible(true)
//Rotate data label and customize the font
.Angle(300)
.Offset(15)
.Font(font=>font.Color("black").Size("13px"))
)
).Add();
})
//...
)
```



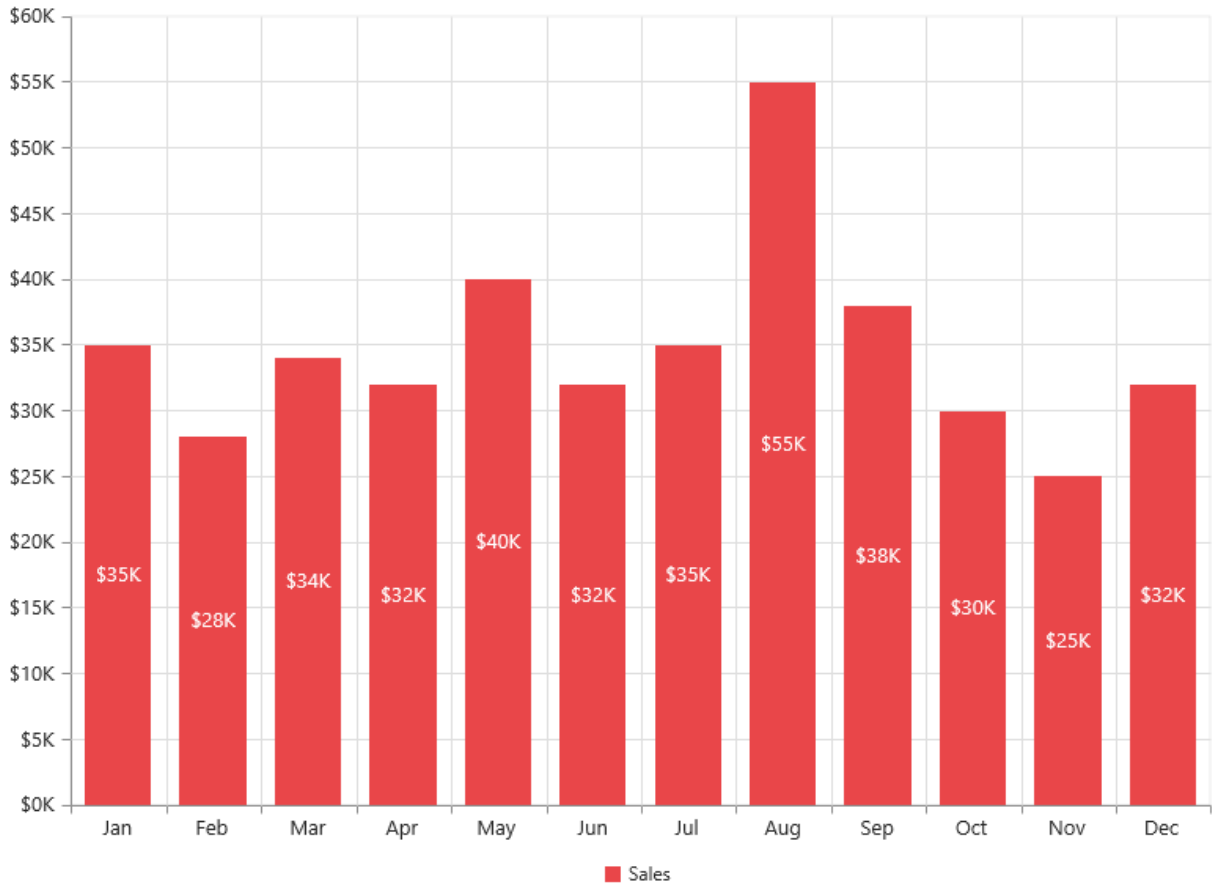
You can position the label to the top, center or bottom position of the segment by using the **TextPosition** option for the chart types such as Column, Bar, Stacked bar, Stacked column, 100% Stacked bar, 100% Stacked column, Candle and OHLC.

The following code example shows how to set textPosition to display data label in the middle of the column rectangle.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
//Adding shapes to series1
sr
//..
.Marker(mr=>mr
.DataLabel(label=>label
.Visible(true)
// Place the data label text position in the center of the rectangle
.TextPosition(TextPosition.Middle)
)
).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



The label can be positioned inside or outside the perimeter of the series by using the **LabelPosition** option for the chart types such as Pie and Doughnut, .

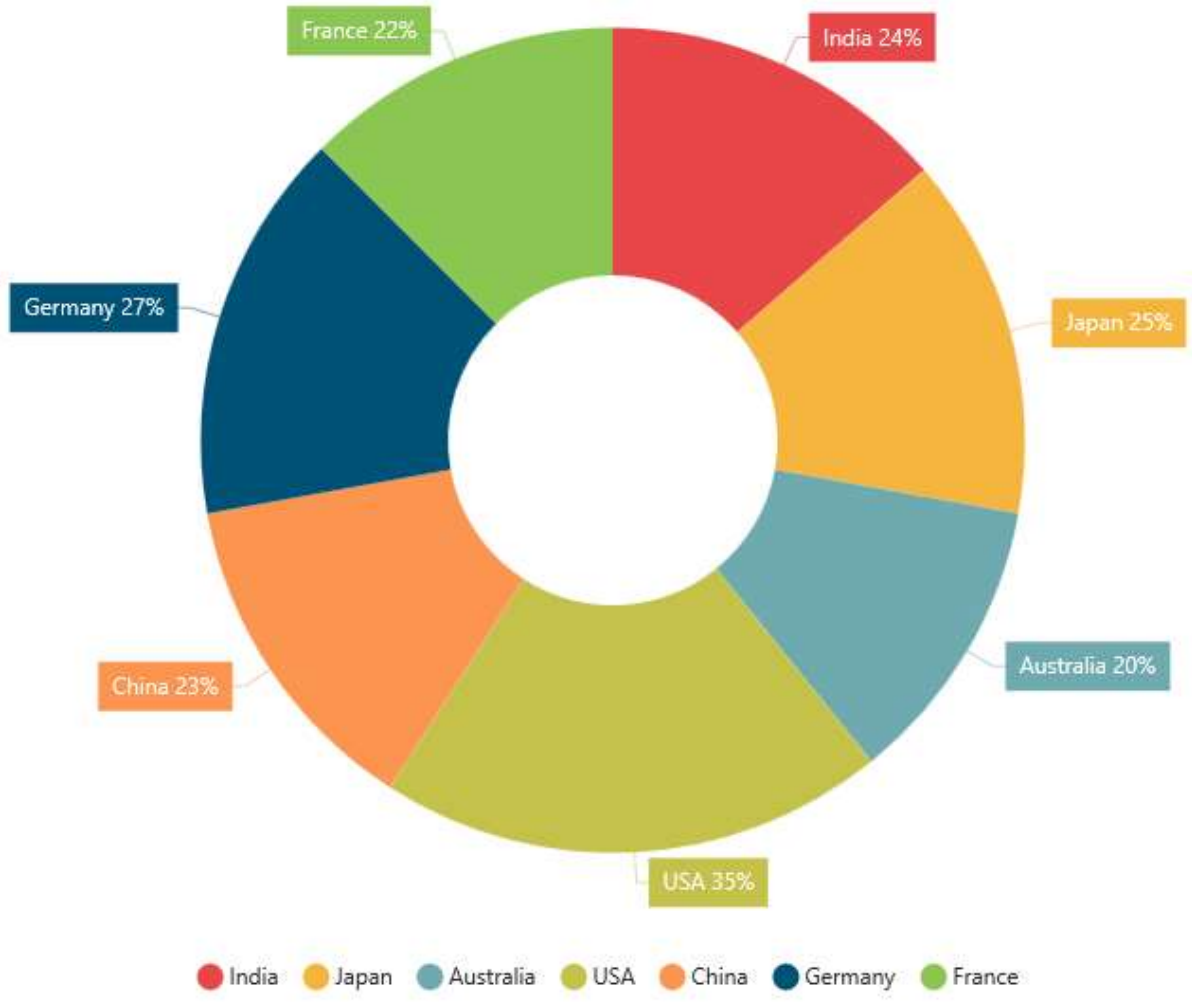
The following code example shows how to set the LabelPosition,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
//Adding shapes to series1
sr
.Points(pt=>{
pt.X("India").Y(24).Text("India 24%").Add();
pt.X("Japan").Y(25).Text("Japan 25%").Add();
pt.X("Australia").Y(20).Text("Australia 20%").Add();
pt.X("USA").Y(35).Text("USA 35%").Add();
pt.X("China").Y(23).Text("China 23%").Add();
pt.X("Germany").Y(27).Text("Germany 27%").Add();
pt.X("France").Y(22).Text("France 22%").Add();
})
.Marker(mr=>mr
.DataLabel(label=>label
.Visible(true)
```

Copyright © 2001 - 2020 Syncfusion Inc.

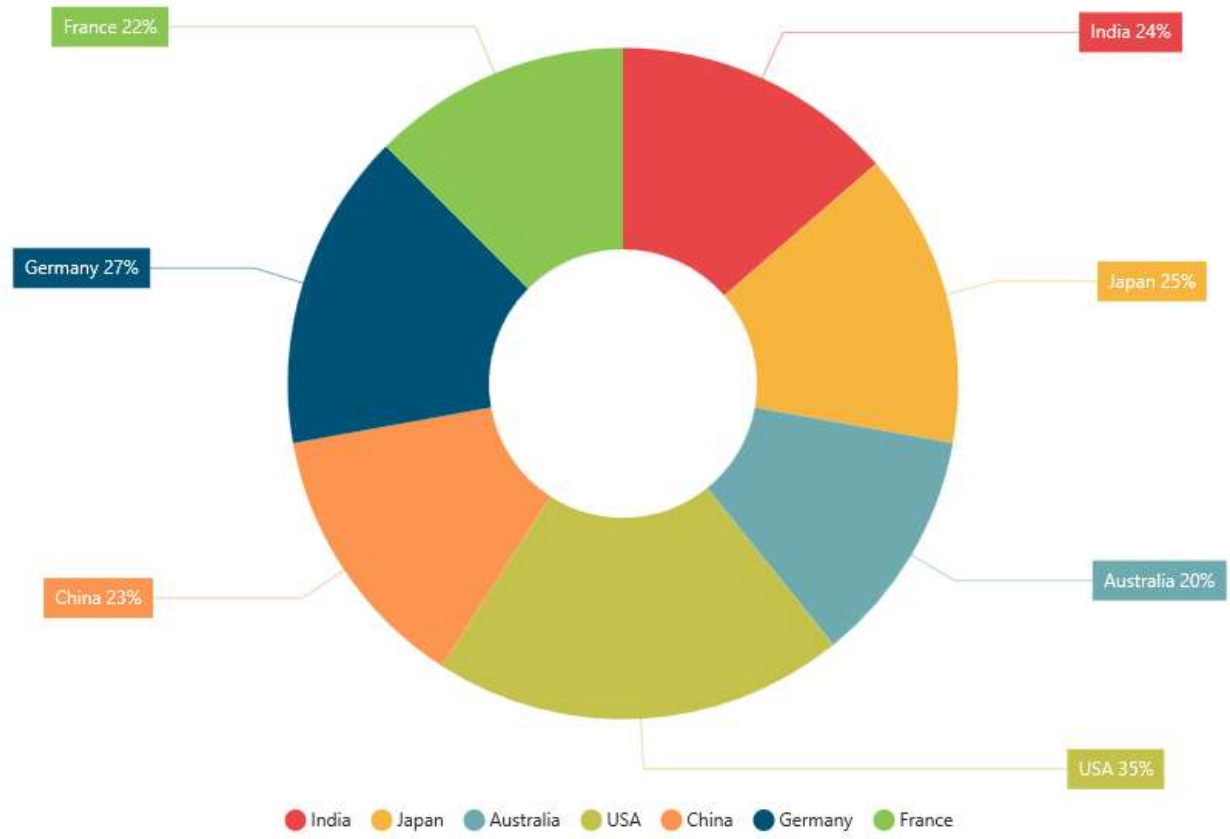
```
.Shape(ChartShape.Rectangle)
.Font(font=>font.Color("white"))
)
)
//Display data label outside position
.LabelPosition(ChartLabelPosition.Outside)
.Type(SeriesType.Doughnut).Add();
})
//...
)
```



The following screenshot displays the labels when the LabelPosition is set as *Inside* position.

The following screenshot displays the labels when the LabelPosition is set as *OutsideExtended* position.

Copyright © 2001 - 2020 Syncfusion Inc.

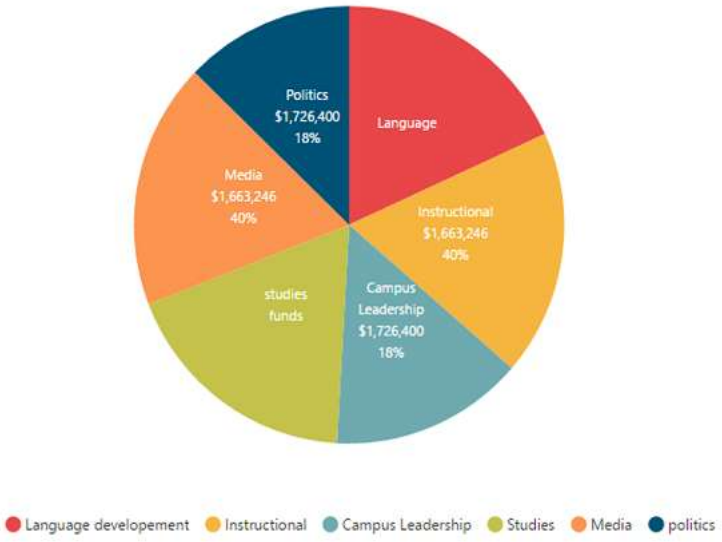


The label can be wrapped for pie, doughnut, funnel, and pyramid series by setting the enableWrap property.

JAVASCRIPT

```
@(Html.EJ().Chart("chartContainer")
//.... . .
.Series(sr => {
//Adding series
sr.Marker(mr => mr.DataLabel(label=>
label.Visible("true")
.EnableWrap("true")
.MaximumLabelWidth(32)
))
//.... . .
}).Add();
//.... . .
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Binding label from the datasource

You can bind the text value to the data label from the datasource and then you need to map the text value field with the **TextMappingName** property respectively.

ASPX-CS

```
//data source for chart with label
var chartData = [
{ month: 'Jan', sales: 35 , text: 'January'},
{ month: 'Feb', sales: 28 , text: 'February'}
//..
];
function onChartLoad(sender) {
var data = GetData();
sender.model.series[0].dataSource = chartData;
sender.model.series[0].xName = "month";
sender.model.series[0].yName = "sales";
}
@(Html.EJ().Chart("chartContainer")
//.... . .
.Series(sr => {
sr.Marker(mr => mr.DataLabel(label=>
label.Visible("true")
.TextMappingName("text")
))
.Add();
//.... . .
})
.Load("onChartLoad")
//....
})
)
```

Binding fill color to the points from the datasource

You can bind the color value to the points from the datasource and then you need to map the color value field to the **PointColorMappingName** property respectively.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
//data source for chart with fill color
var chartData = [
{ month: 'Jan', sales: 35 , color: 'red'},
{ month: 'Feb', sales: 28 , color: 'blue'}
//..
];
function onChartLoad(sender) {
var data = GetData();
sender.model.series[0].dataSource = chartData;
sender.model.series[0].xName = "month";
sender.model.series[0].yName = "sales";
}
@(Html.EJ().Chart("chartContainer")
//.... . .
.Series(sr => {
//Mapping the color values to the points
sr.PointColorMappingName("color") .Add();
//.... . .
})
.Load("onChartLoad")
//....
})
)
```

Customize specific points

By using the ejChart, you can also customize the individual/specific markers with different colors, shapes and also with different images.

There are two ways to achieve this based on how the data is fed to the series.

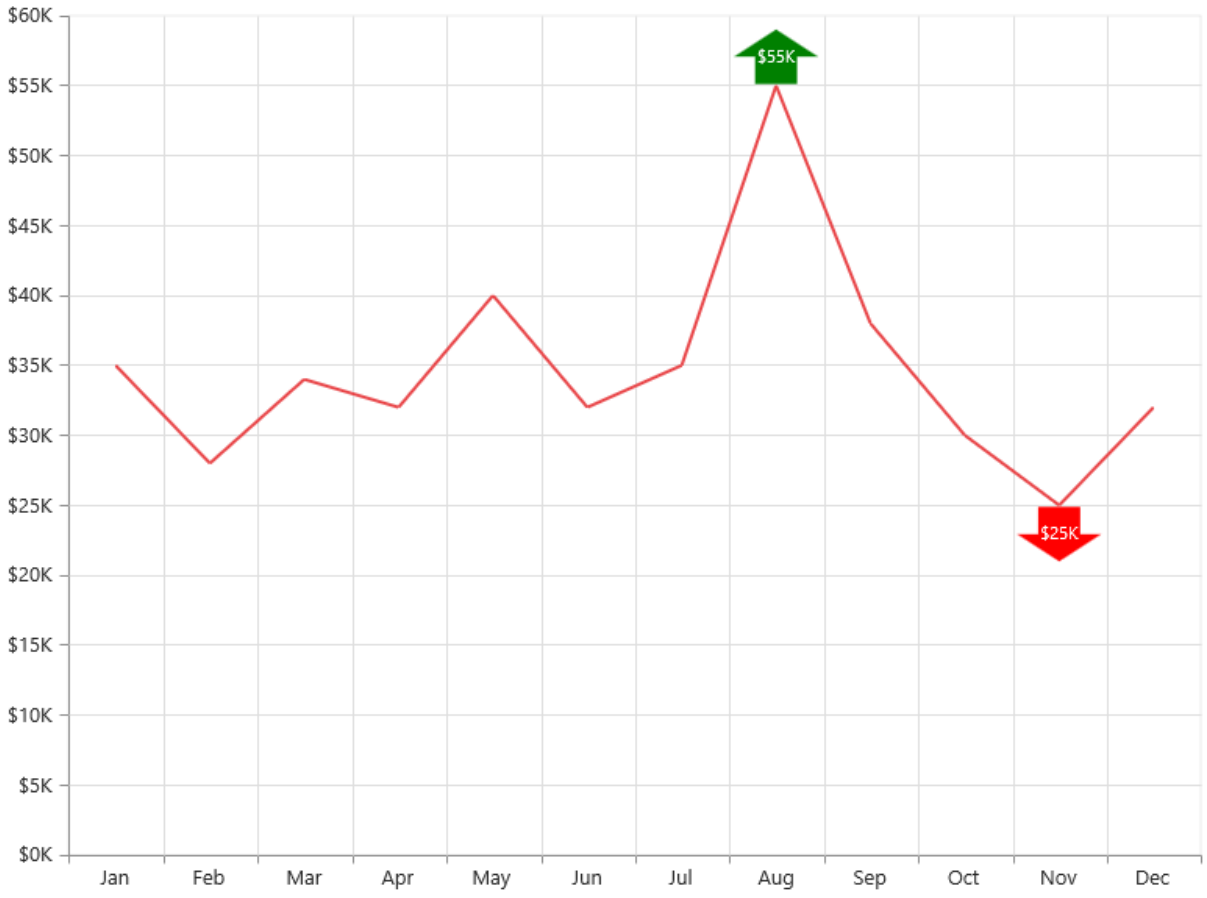
When the data is provided by using the Points option, you can add marker for each data point or specific point by using the Marker option as illustrated in the following code example.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
//Adding shapes to series1
sr
.Points(pt=>{
pt.X("Jan").Y(35).Add();
pt.X("Feb").Y(28).Add();
pt.X("Mar").Y(34).Add();
pt.X("Apr").Y(32).Add();
pt.X("May").Y(40).Add();
pt.X("Jun").Y(32).Add();
pt.X("Jul").Y(35).Add();
pt.X("Aug").Y(55).Marker(mr=>mr
//Enable and customize the data label for a point
.DataLabel(label=>label.Visible(true).Offset(-10).Shape(ChartShape.UpArrow)
.Font(font=>font.Color("white").Size("11px"))
.Margin(margin=>margin.Right(15).Left(15).Top(10).Bottom(10))
.Fill("green"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
).Add();
pt.X("Sep").Y(38).Add();
pt.X("Oct").Y(30).Add();
pt.X("Nov").Y(25).Marker(mr => mr
//Enable and customize the data label for a point
.DataLabel(label => label.Visible(true).Offset(-
22).Shape(ChartShape.DownArrow)
.VerticalTextAlignment(Syncfusion.JavaScript.DataVisualization.TextAlignment
.Near)
.Font(font => font.Color("white").Size("11px"))
.Margin(margin => margin.Right(15).Left(15).Top(10).Bottom(10))
.Fill("red"))
).Add();
pt.X("Dec").Y(32).Add();
}).Add();
})
//...
)
```



When the data is bound to the series by using the DataSource option, you can customize the points in the **SeriesRendering** event as illustrated in the following code example,

ASPX-CS

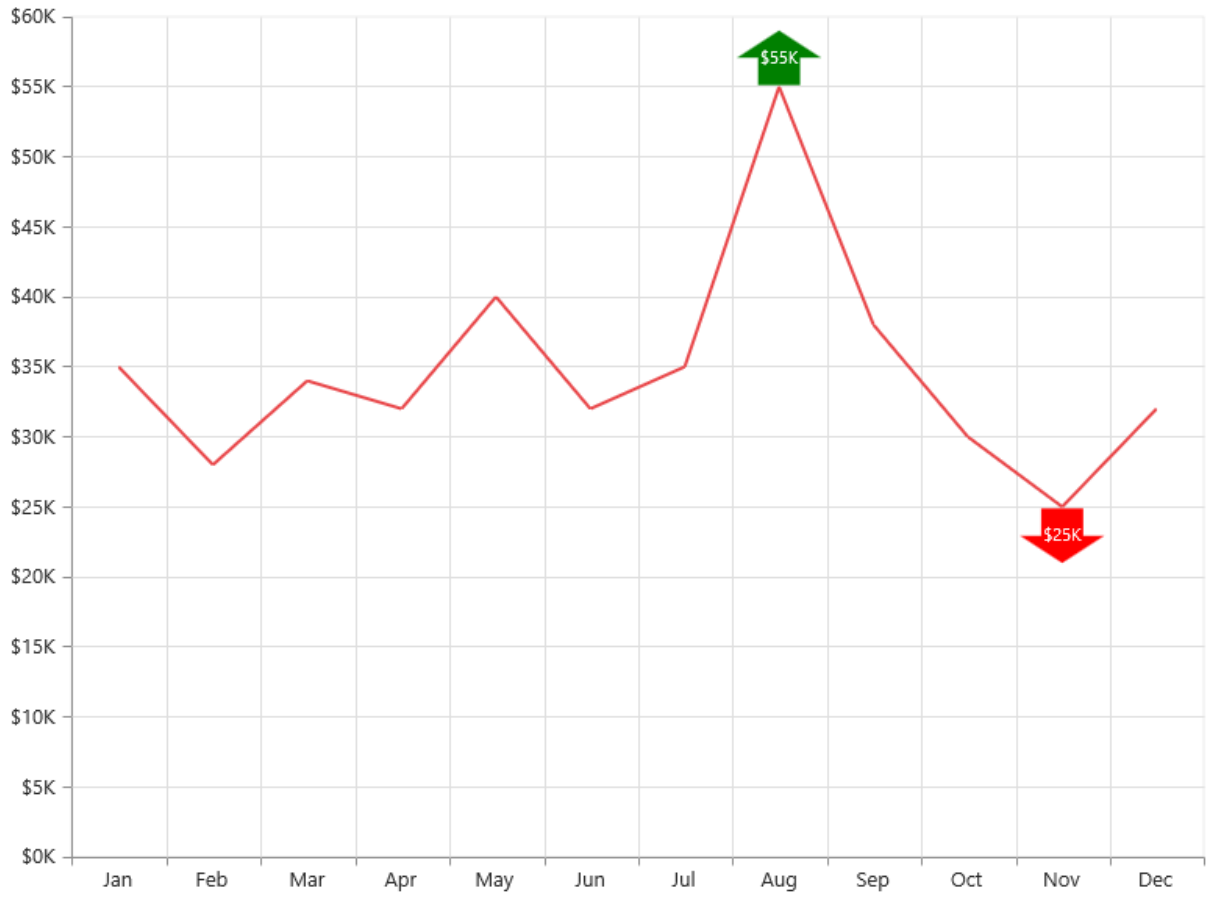
```
@(Html.EJ().Chart("chartContainer")
```

```
//...
.Series(sr =>
{
//Adding shapes to series1
sr
//Add datasource and set xName and yName
.XName("Month").YName("Sales")
.DataSource(ViewBag.ChartData)
.Add();
})
//Fires on rendering the series
.SeriesRendering("onSeriesRender")
//...
)
```

JS

```
//Define the seriesRendering client side event
function onSeriesRender(sender) {
//Enable and customize the dataLabel for a point using event
sender.data.series.points[7].marker = {
dataLabel: {
visible: true,
offset: -10,
shape: "upArrow", font: { color: "white", size: '11px' },
margin: { left: 15, right: 15, top: 10, bottom: 10 },
fill: "green"
}};
sender.data.series.points[10].marker = {
//Enable and customize the dataLabel for a point using event
dataLabel: {
visible: true,
offset: -22,
verticalTextAlignment: 'near',
shape: "downArrow", font: { color: "white", size: '11px' },
margin: { left: 15, right: 15, top: 10, bottom: 10 },
fill: "red"
}};
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Connect Line

This feature is used to connect label and data point by using a line. It can be enabled only for Pie, Doughnut, Pyramid and Funnel chart types. **ConnectorLine** types can be set as *Bezier* or *Line* by using the **Type** option.

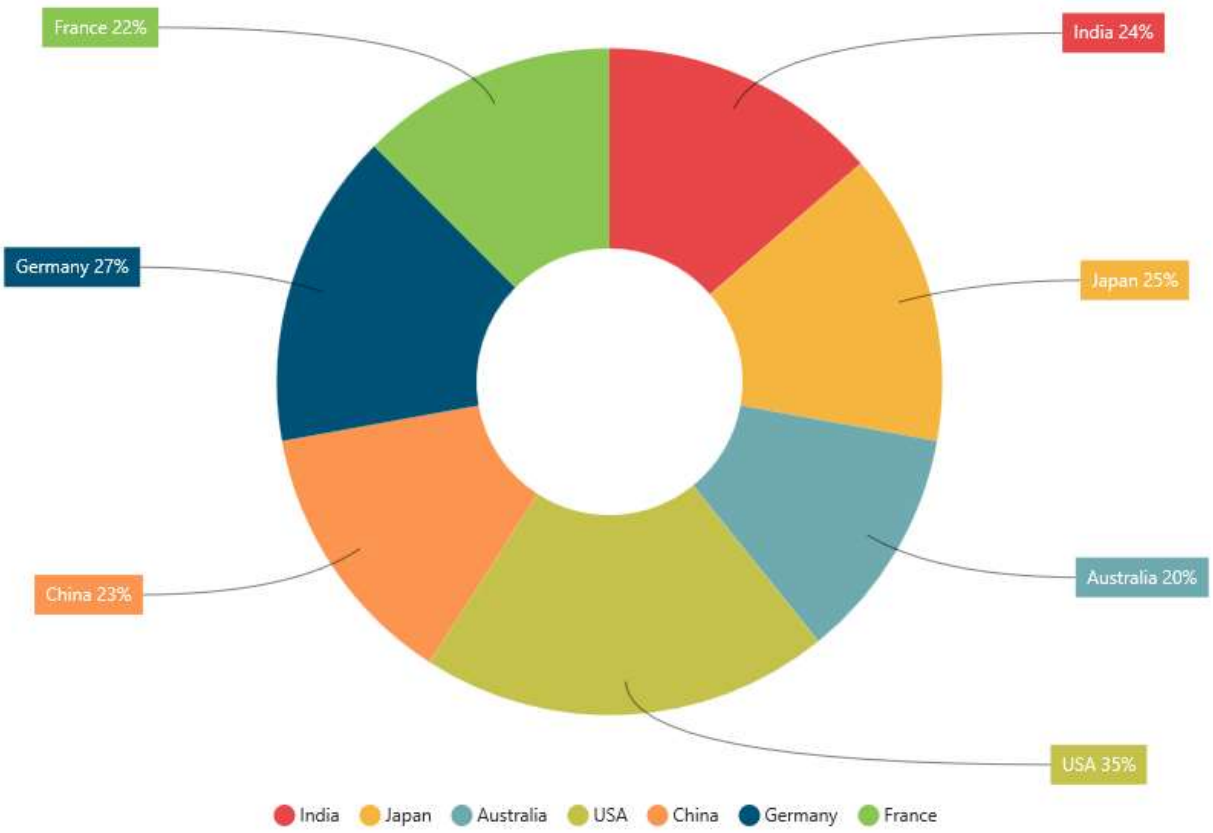
The following code example illustrates this,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
//Adding shapes to series1
sr
.Marker(mr=>mr.DataLabel(label=>label
// Set connector line type and customize the color
.ConnectorLine(cl=>cl.Color("black").Type(ConnectorType.Bezier))
))
.LabelPosition(ChartLabelPosition.OutsideExtended)
.Type(SeriesType.Doughnut)
.Add();
})
//Fires on rendering the series
.SeriesRendering("onSeriesRender")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//...
)
```



Smart labels

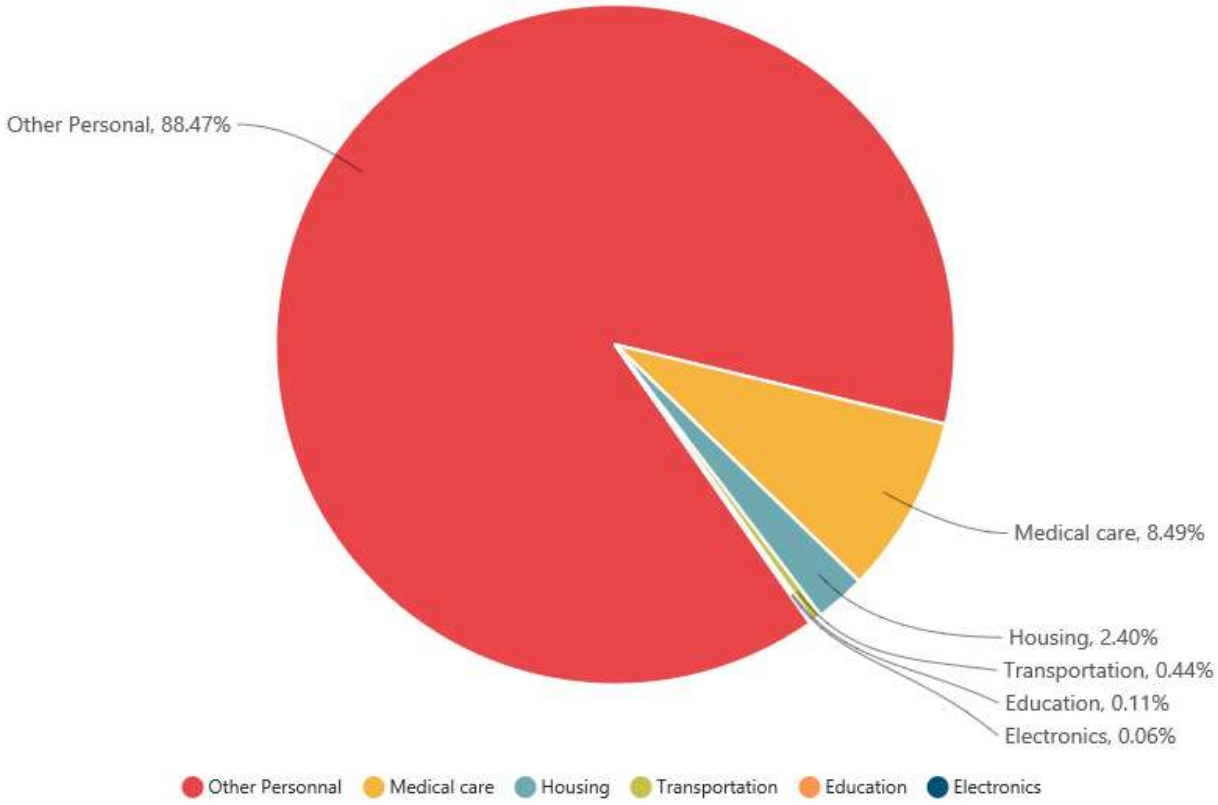
Overlapping of the labels can be avoided by enabling the **EnableSmartLabels** property. The default value is *true* for *Accumulation type series* and *false* for *other series types*.

The following code example shows how to enable smart labels,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
sr
//...
.EnableSmartLabels(true).StartAngle(145)
.Marker(mr =>
{
mr.DataLabel(label =>
{
label.Visible(true).ConnectorLine(cl => cl.Color("black")
.Height(60).Type(ConnectorType.Bezier)).Shape(ChartShape.None)
.Font(font => { font.Size("14px"); });
});
}).Name("Expenses").Type(SeriesType.Pie).Add();
```

```
})
//...
)
```



Click here to view the SmartLabel online demo sample.

Legend

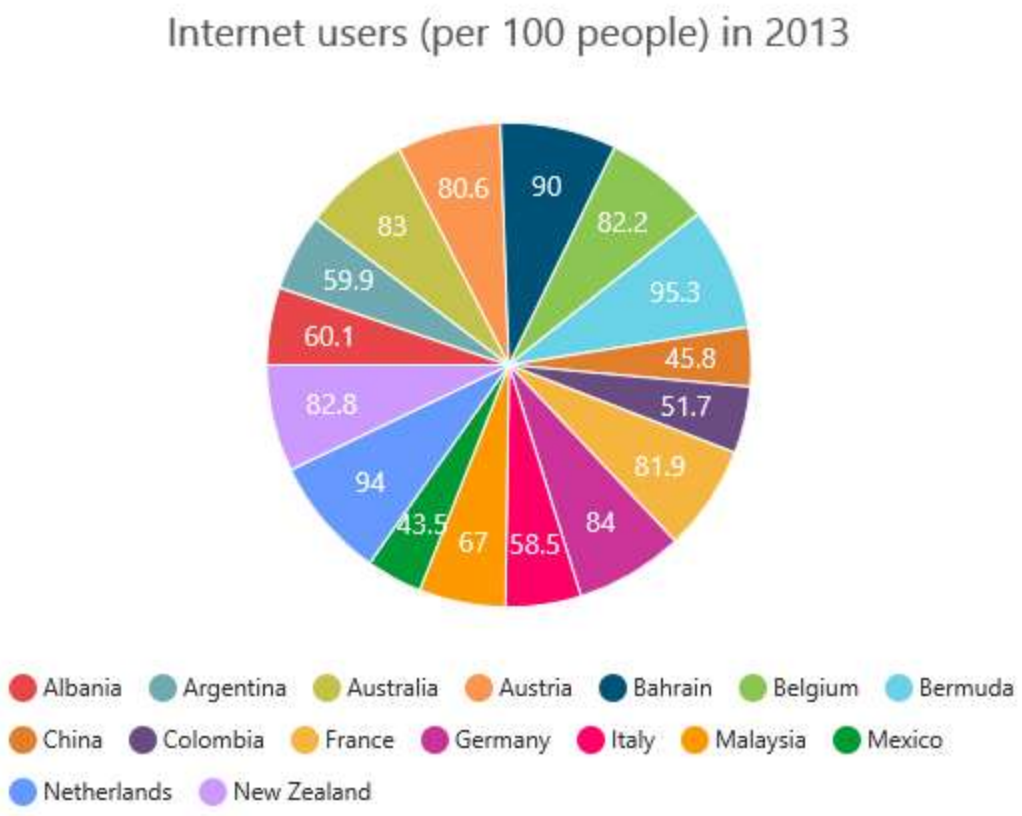
The legend contains the list of Chart Series and Trendlines that appear in a chart.

Legend Visibility

By default, the legend is enabled in the chart. You can enable or disable it by using the *Visible* option of the **Legend**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Visible chart legend
.Legend(lg=>lg.Visible(true))
//...
)
```



Click here to view the online demo sample for legend customization.

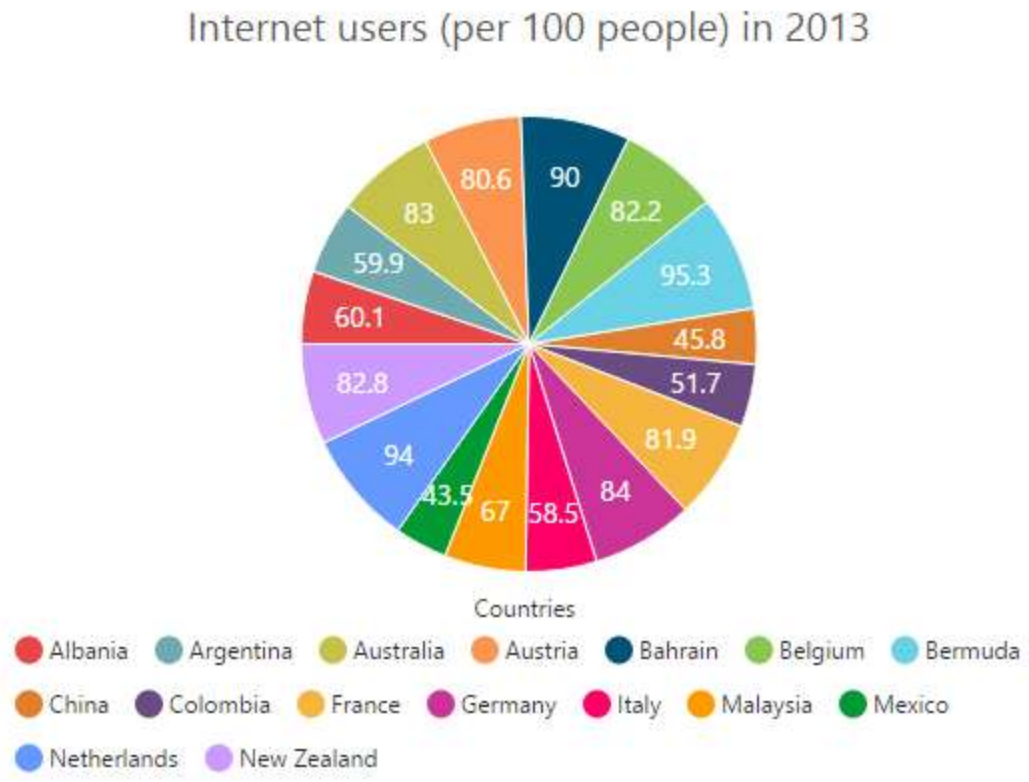
Legend title

To add the title to the legend, you have to specify the **Legend.Title.Text** option.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Visible chart legend
.Legend(legend=>legend.Title(title=>
//Add title to the chart legend
title.Text("Countries"))
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



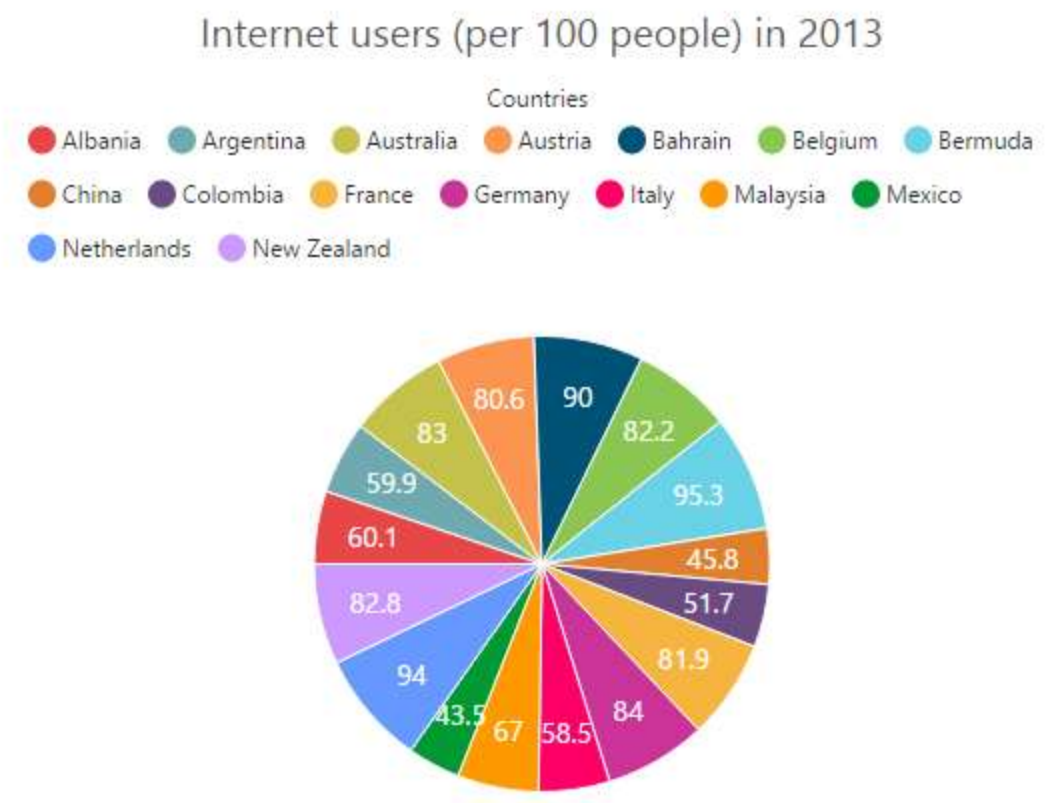
Position and Align the Legend

By using the **Position** option, you can position the legend at *Left*, *Right*, *Top* or *Bottom* of the chart. The legend is positioned at the **Bottom** of the chart, by default.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg.
//...
//Place the legend at top of the chart
Position(LegendPosition.Top)
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



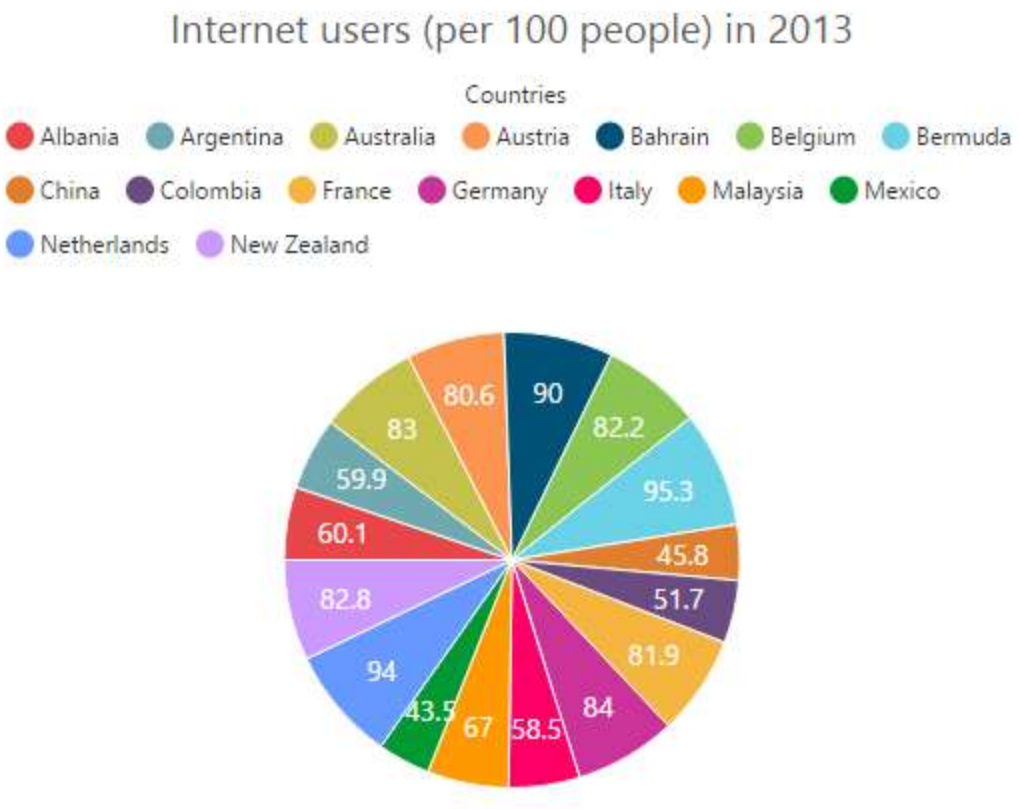
Legend Alignment

You can align the legend to the *Center*, *Far* or *Near* based on its position by using the **Alignment** option.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg.
//...
//The below two settings will place the legend at the top-right corner of
the chart.
Position(LegendPosition.Top)
.Alignment(Syncfusion.JavaScript.DataVisualization.TextAlignment.Far)
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Arrange legend items in the rows and columns

You can arrange the legend items horizontally and vertically by using the **RowCount** and **ColumnCount** options of the legend.

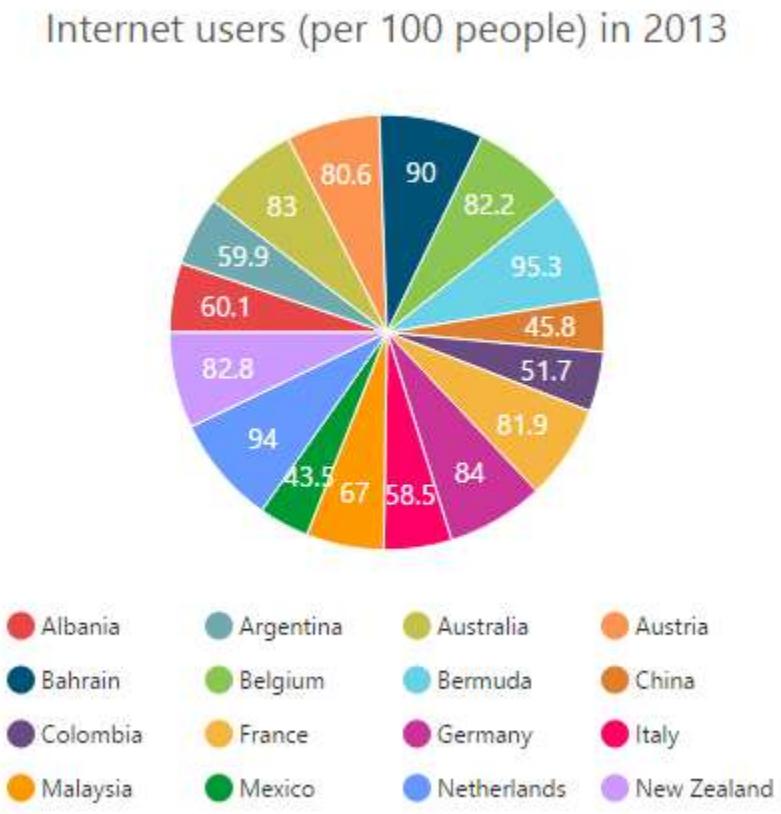
- When only the RowCount is specified, the legend items are arranged according to the RowCount and number of columns may vary based on the number of legend items.
- When only the ColumnCount is specified, the legend items are arranged according to the ColumnCount and number of rows may vary based on the number of legend items.
- When both the options are specified, then the one which has higher value is given preference. For example, when the RowCount is 4 and ColumnCount is 3, legend items are arranged in 4 rows.
- When both the options are specified and have the same value, the preference is given to the ColumnCount when it is positioned at the top/bottom position. The preference is given to the RowCount when it is positioned at the left/right position.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg
//...
//Arrange legend items in 4 rows and approximately 4 columns. Column
couldn't may vary based on number of items.
.RowCount(4)
.ColumnCount(4)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
//...
)
```



Customization

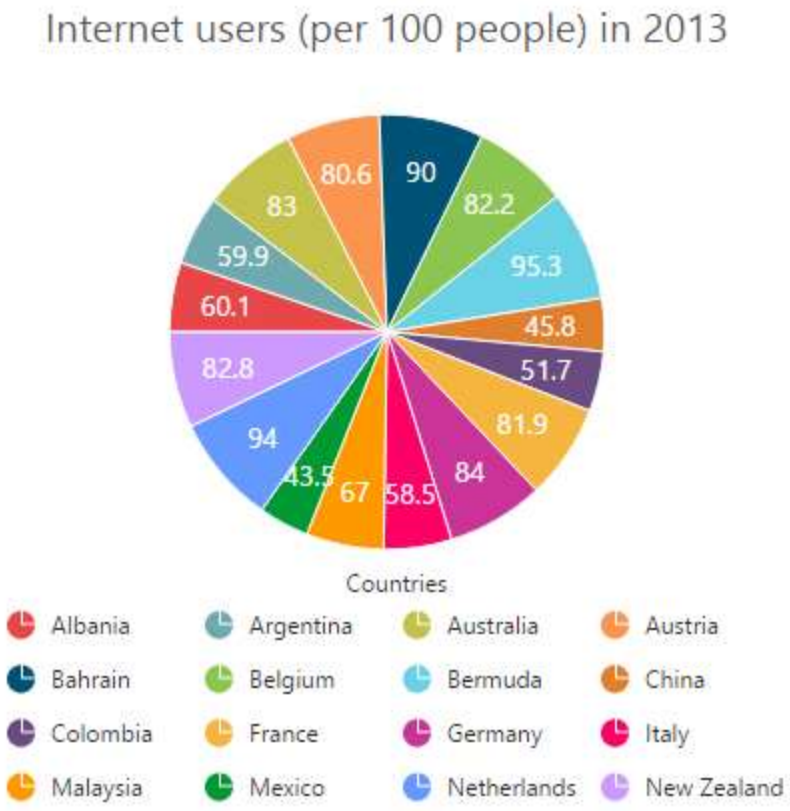
Legend shape

To change the legend icon shape, you have to specify the shape in the **Shape** property of the legend. When you want the legend icon to display the prototype of the series, you have to set the **SeriesType** as shape.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg
//...
//Change legend shape
.Shape(ChartShape.SeriesType)
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



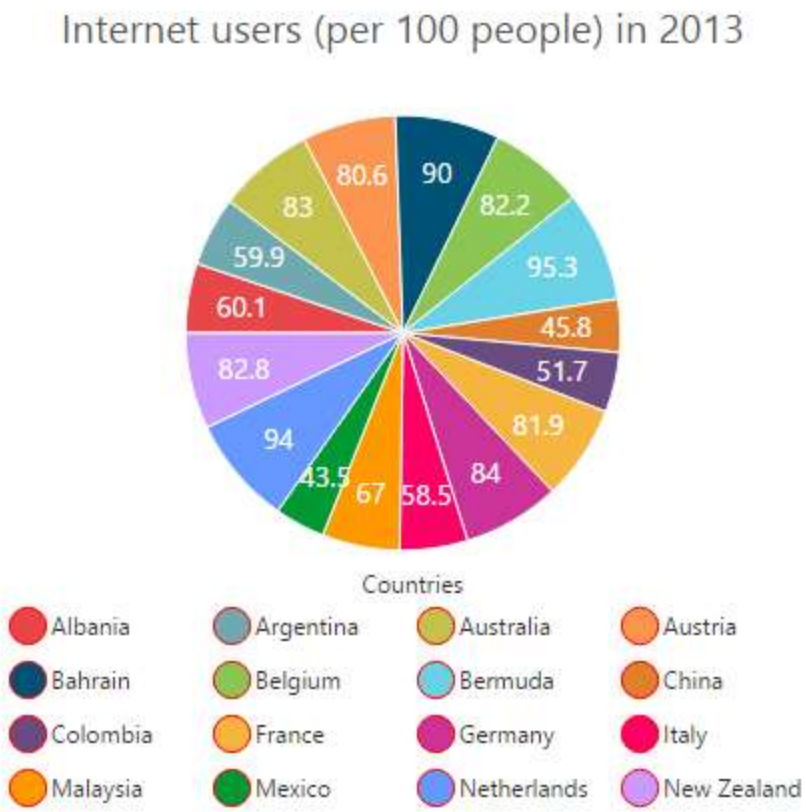
Legend items size and border

You can change the size of the legend items by using the *ItemStyle.Width* and *ItemStyle.Height* options. To change the legend item border, use **Border** option of the legend ItemStyle.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg
//...
//Change legend items border, height and width
.ItemStyle(item=>item.Width(13).Height(13).Border(br=>br.Width(1).Color("#FF
0000")))
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



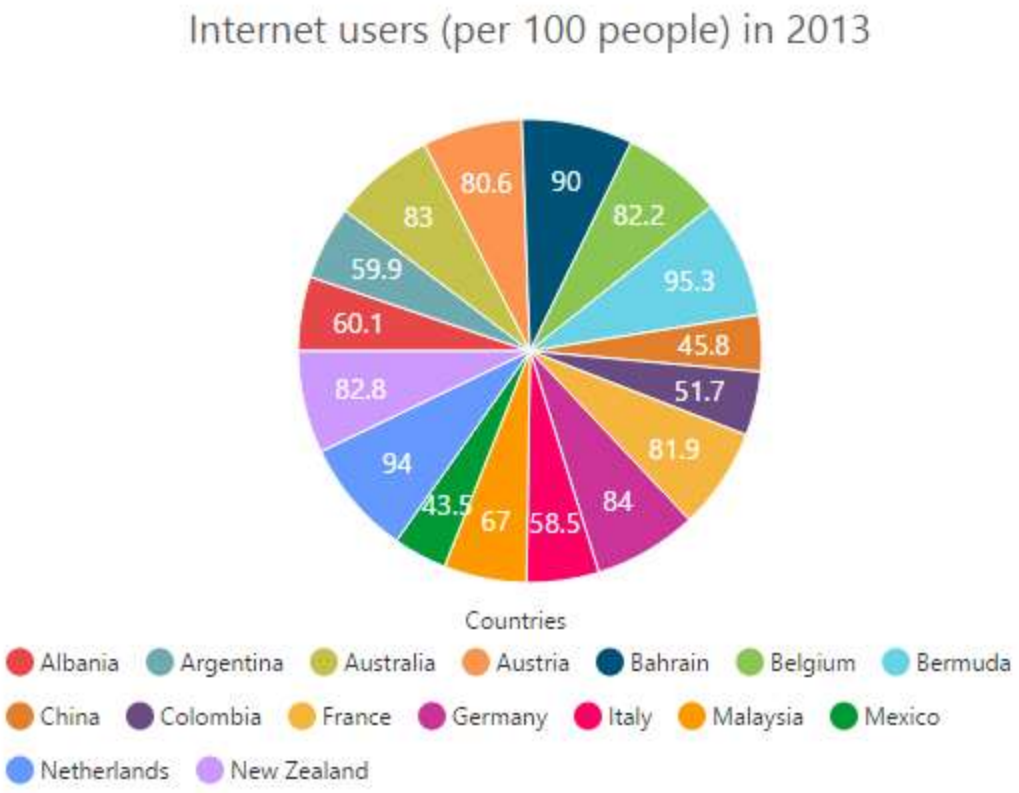
Legend size

By default, legend takes 20% of the **Height** horizontally when it was placed on the top or bottom position and 20% of the **Width** vertically while placing on the left or right position of the chart. You can change this default legend size by using the **Size** option of the legend.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg
//...
//Change legend size
.Size(size=>size.Height("100").Width("550"))
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



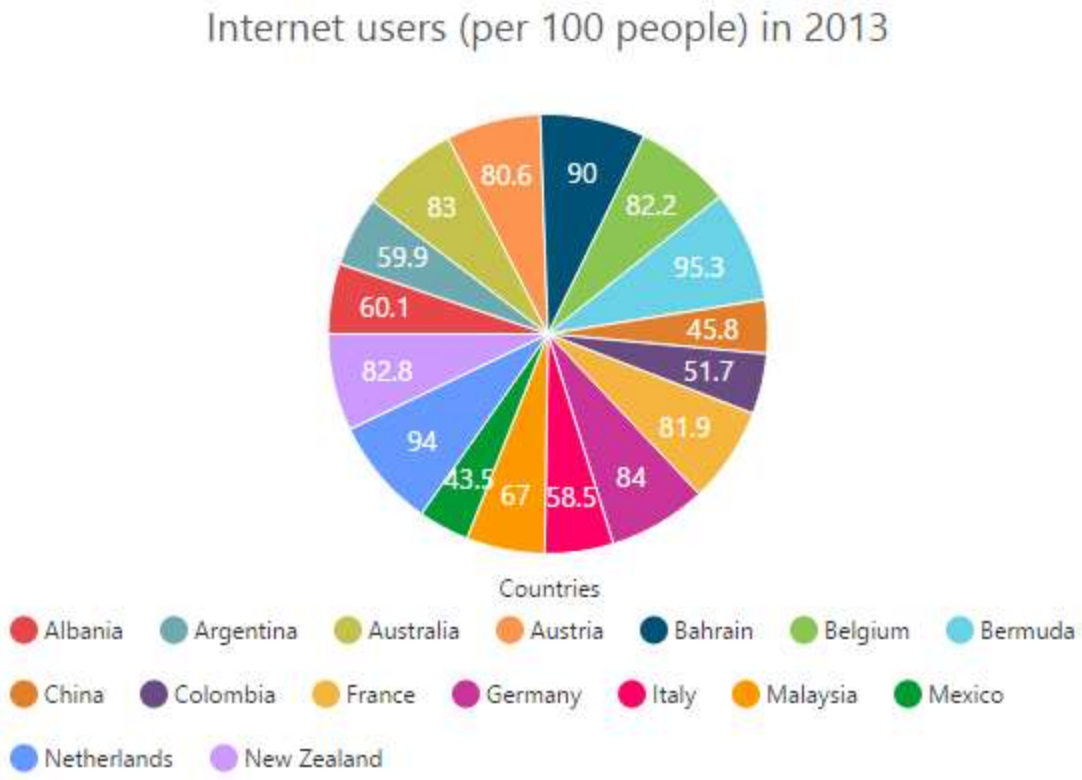
Legend Item Padding

You can control the spacing between the legend items by using the **ItemPadding** option of the legend. The default value is 10.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg
//...
//Add space between each legend item
.ItemPadding(15)
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



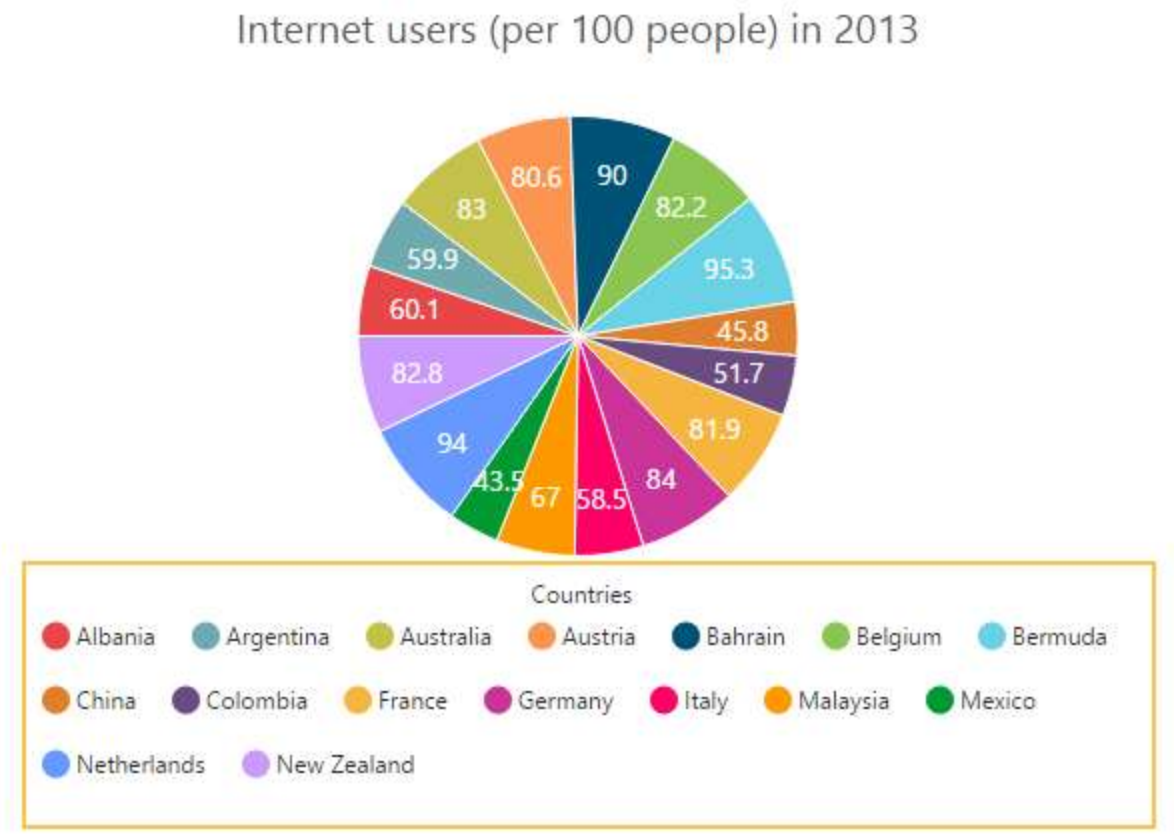
Legend border

You can customize the legend border by using the **Border** option in the legend.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg
//...
//Set border color and width to legend
.Border(br=>br.Color("#FFC342").Width(2))
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



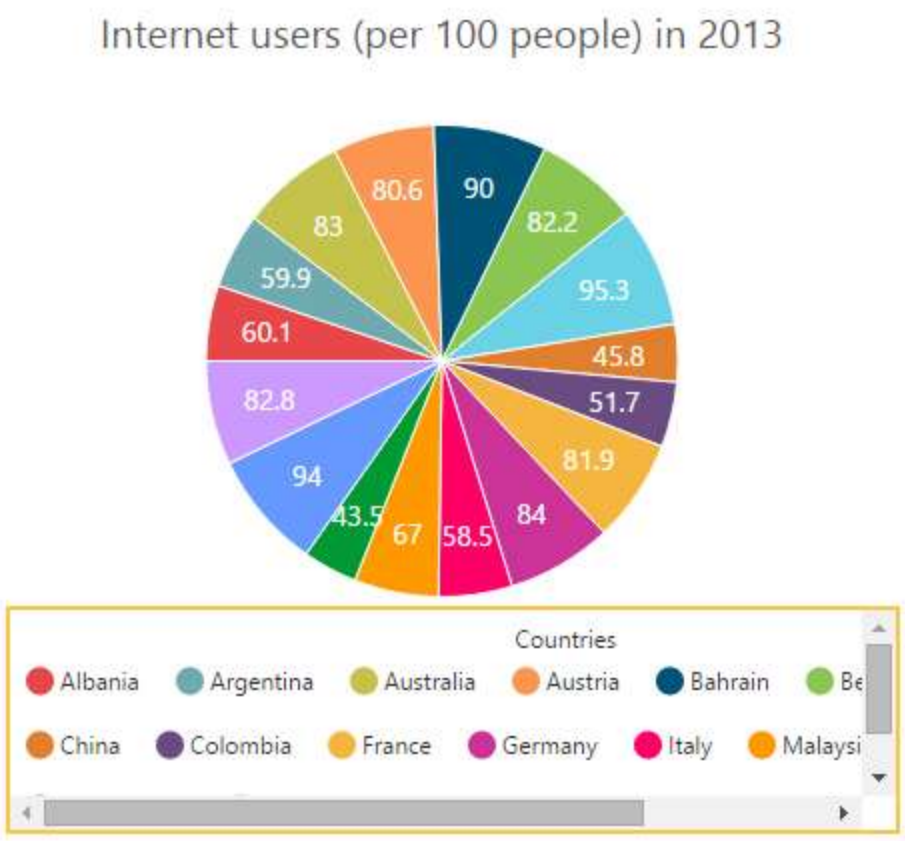
Scrollbar for legend

You can enable or disable the legend scrollbar by using the **EnableScrollbar** option of the legend. When you disable the scrollbar option, the legend does not consider the default size and chart draws in the remaining space. If you have specified the **size** to the legend with the scrollbar disabled, then the legends beyond this limit will get clipped.The default value of EnableScrollbar option is **true**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg
//...
//Enable scrollbar option in for legend
.EnableScrollbar(true)
.Size(size=>size.Width("430").Height("80"))
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



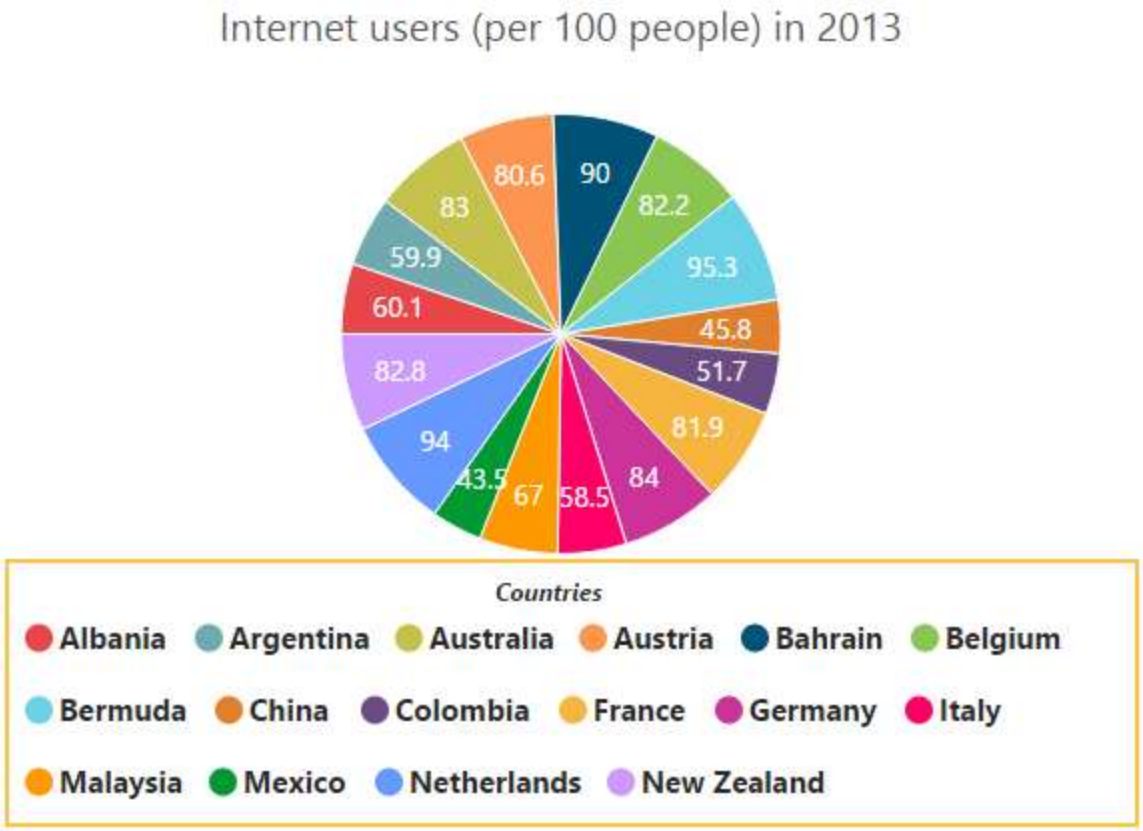
Customize the legend text

To customize the legend item text and title you can use the **Legend.Font** and **Legend.Title** options. You can change the legend title alignment by using the TextAlignment option of the legend title.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg
//...
//Customize the legend item text
.Font(font=>font.FontFamily("Segoe UI").FontStyle(ChartFontStyle.Normal)
.FontWeight(ChartFontWeight.Bold).Size("15px"))
.Title(title=>title
.TextAlignment(Syncfusion.JavaScript.DataVisualization.TextAlignment.Center)
//Customize the legend title text
.Font(font=>font.FontFamily("Segoe UI").FontStyle(ChartFontStyle.Italic)
.FontWeight(ChartFontWeight.Bold).Size("12px"))
)
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



LegendItems Text Overflow

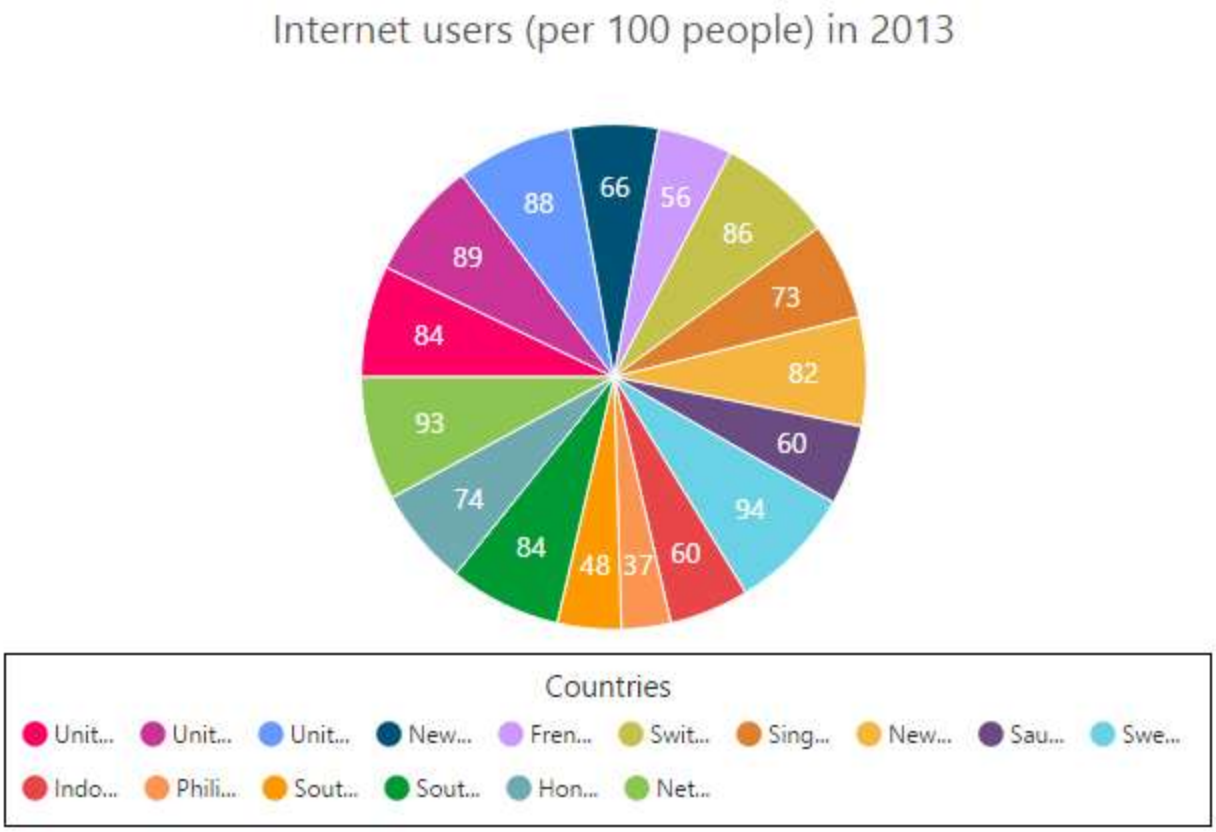
Trim

You can trim the legend item text when its width exceeds the **Legend.TextWidth**, by specifying *TextOverflow* as **Trim**. The original text will be displayed on mouse hover.

ASPX-CS

```
@(Html.EJ().Chart("container")
// ...
//trim the legend text
.Legend(lg=>lg.Visible(true).TextOverflow(TextOverflow.Trim)
.TextWidth(34))
// ...
)
```

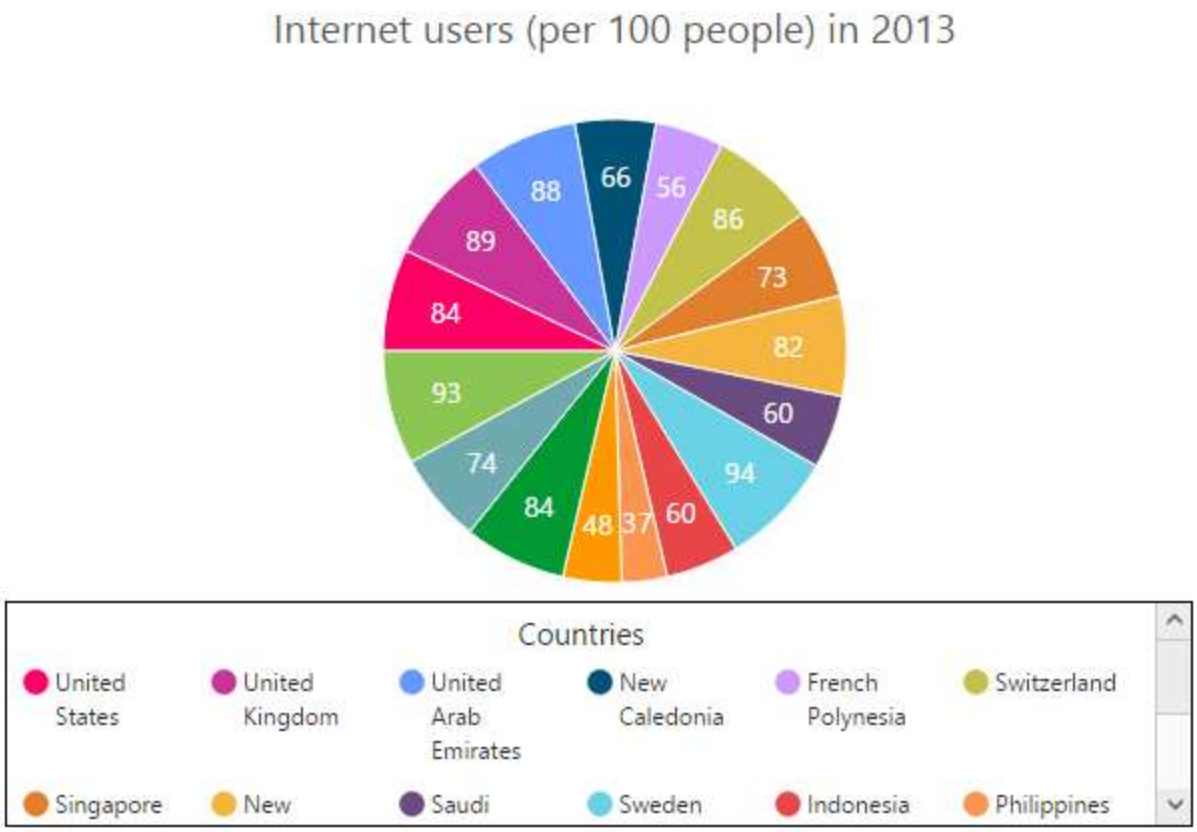
Copyright © 2001 - 2020 Syncfusion Inc.



Wrap

By specifying *TextOverflow* as **Wrap**, you can wrap the legend text by word.

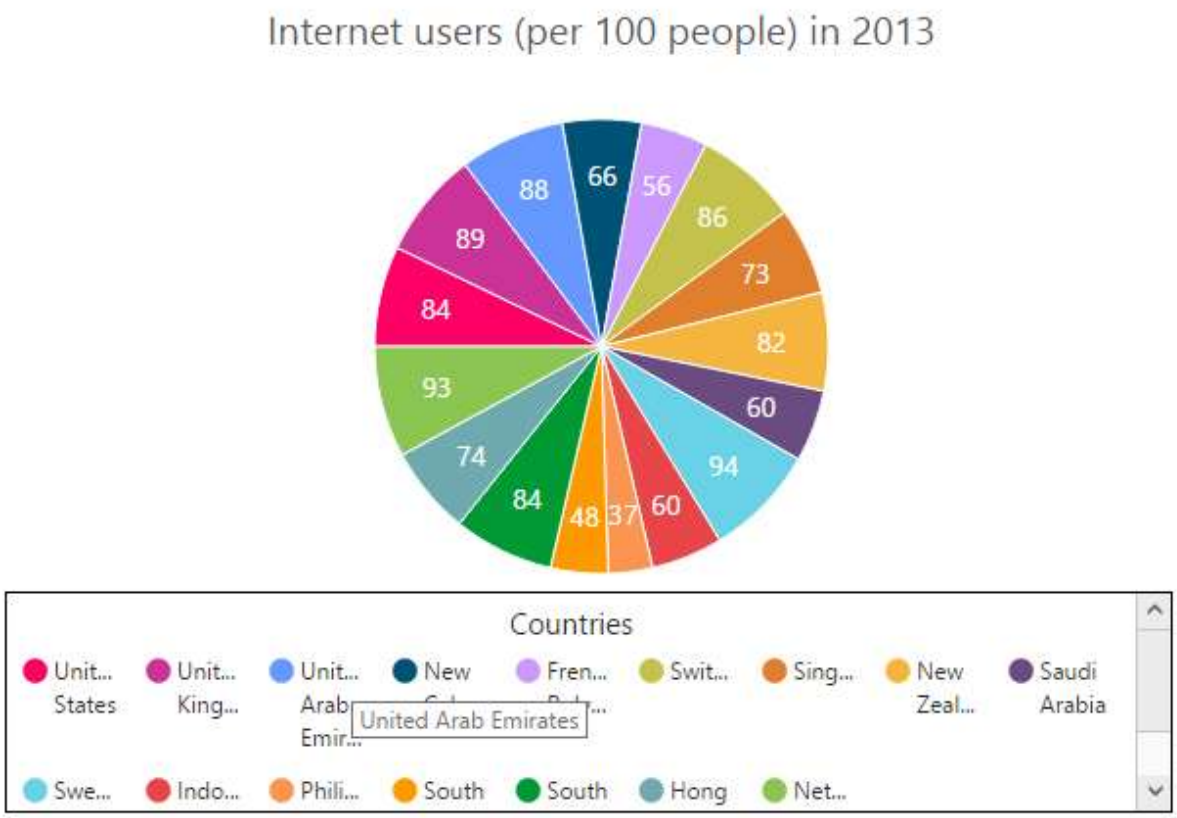
Copyright © 2001 - 2020 Syncfusion Inc.



WrapAndTrim

You can wrap and trim the legend text by specifying *TextOverflow* as **WrapAndTrim**. The original text will be displayed on mouse hover.

Copyright © 2001 - 2020 Syncfusion Inc.



Handle the legend item clicked

You can get the legend item details such as *Index*, *Bounds*, *Shape* and *Series* by subscribing the **LegendItemClick** event on the chart. When the legend item is clicked, it triggers the event and returns the Legend information.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg
.Visible(true)
//...
)
//Subscribe the legend item click event
.LegendItemClick("onLegendClicked")
)
function onLegendClicked(sender) {
//Get legend item details on legend item click.
var legendItem = sender.data;
}
```

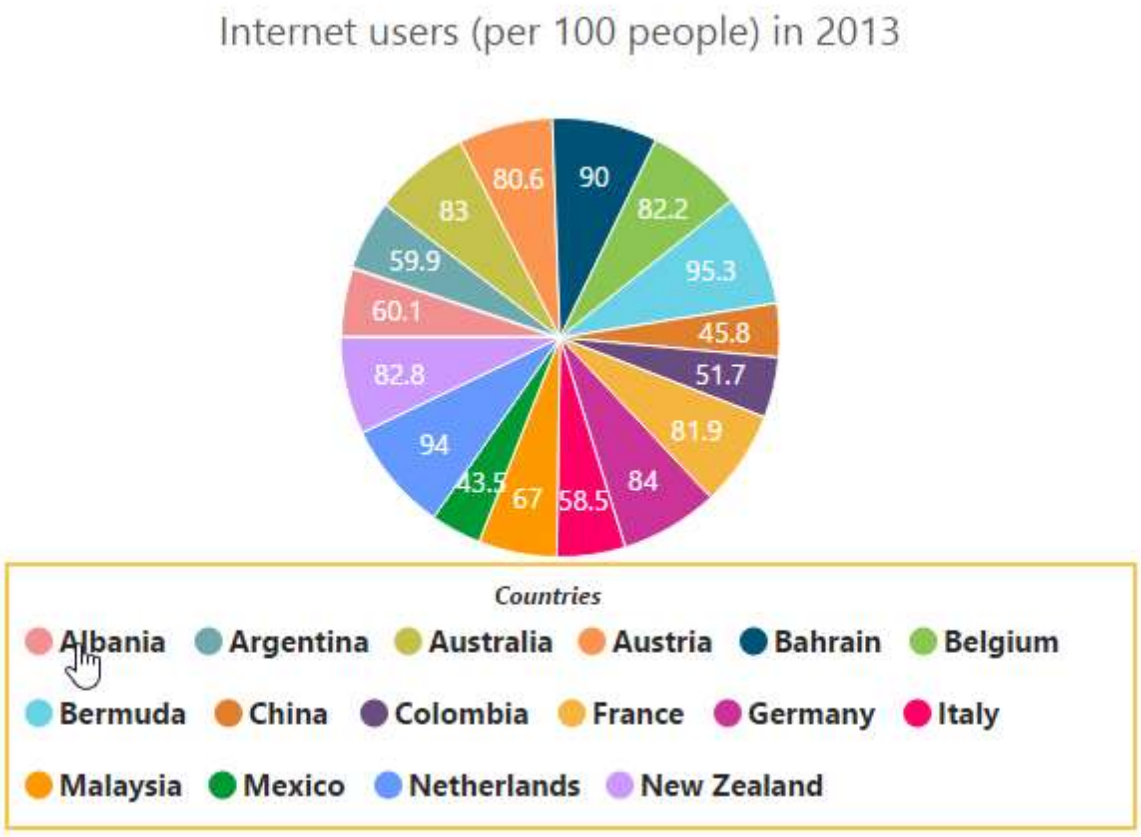
Series selection on legend item click

You can select a specific series or point while clicking on the corresponding legend item through disabling the **ToggleSeriesVisibility** option of the legend. The default value of toggleSeriesVisibility option is **true**. To customize the series selection refer to the series Selection.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Legend(lg=>lg
//Disable series collapsing on legend item clicked
.ToggleSeriesVisibility(false)
//...
)
//...
)
```



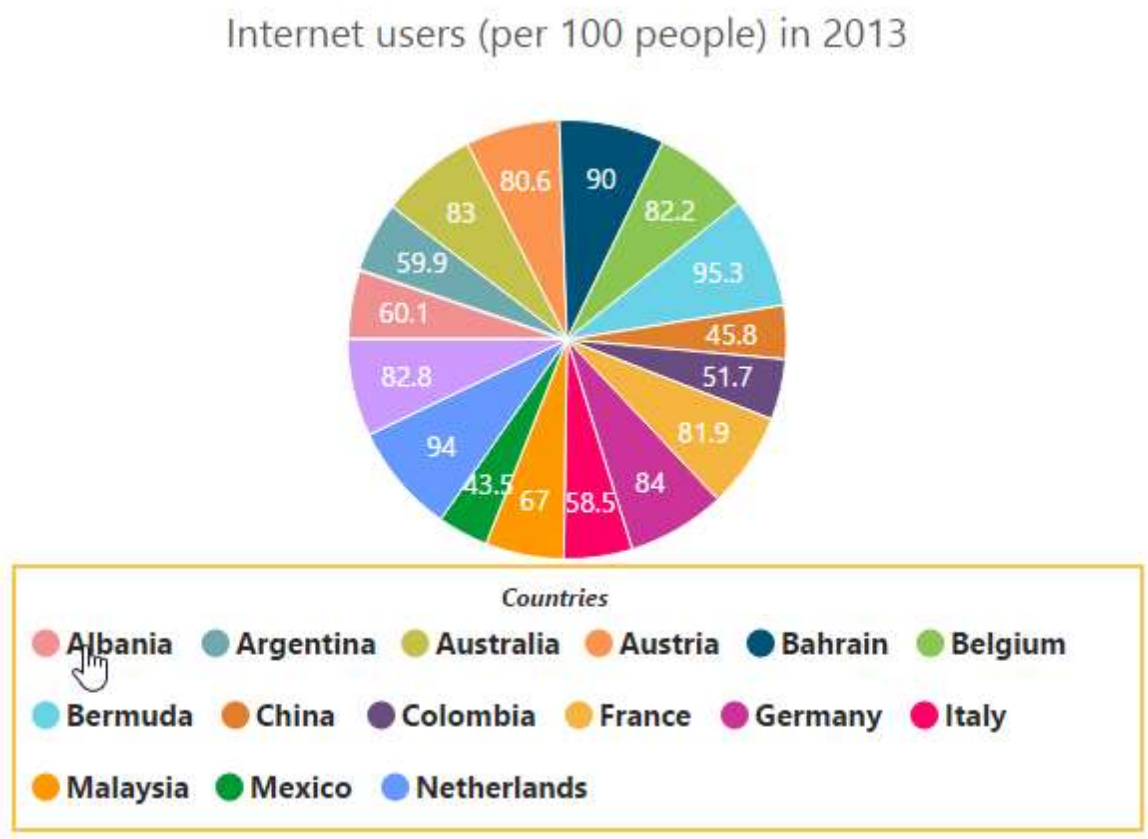
Collapsing legend item

You can collapse the specific series/point legend item displaying in the chart, by setting the **VisibleOnLegend** as *Hidden* in the point or series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
. Series(sr =>{
//Initializing Series
sr.Points(pt => {
pt.X("Albania").Y(60.1).Add();
//...
//Collapse the point's legend item in the legend collection
```

```
pt.X("New Zealand").Y(82.8).VisibleOnLegend(VisibleOnLegend.Hidden).Add();
})// visible the EmptyPointSettings
.EmptyPointSettings(e => e.Visible(true)).Add();
// ...
})
.Legend(lg=>lg.Visible(true))
// ...
)
```



Empty Points

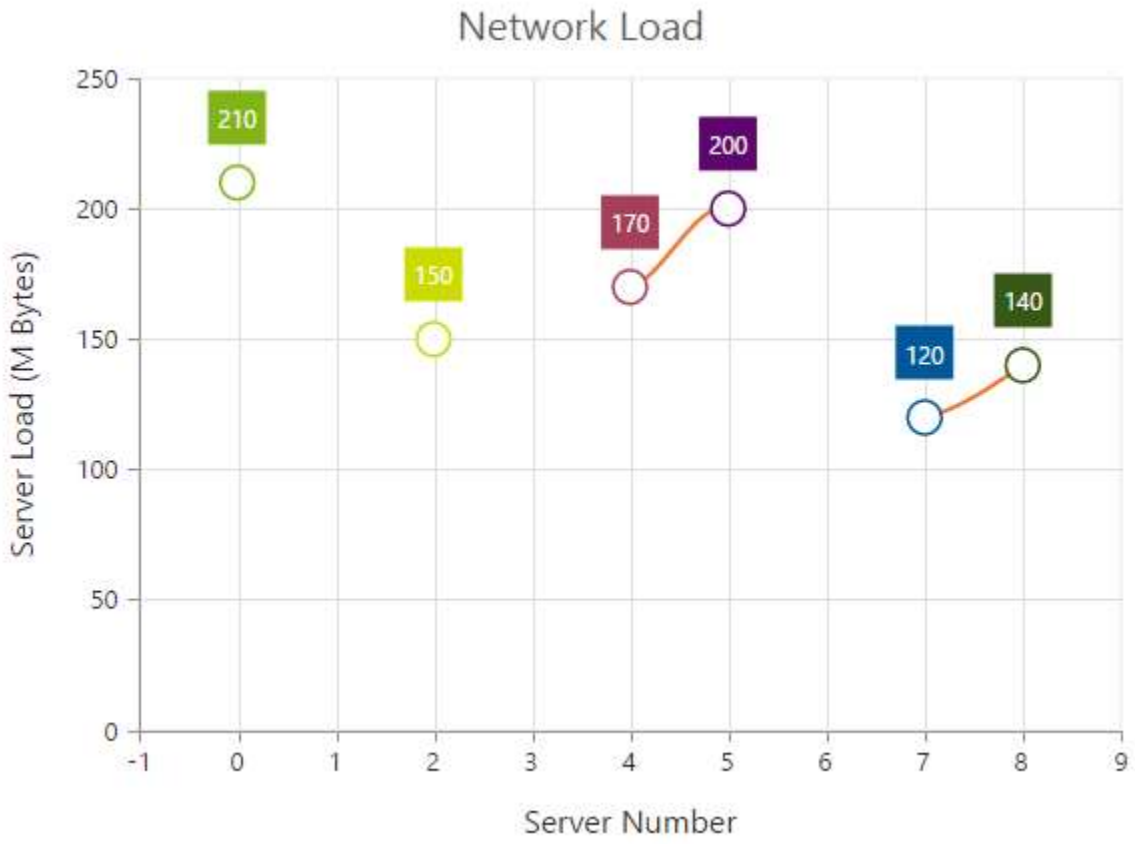
The Data points that uses the **null** or **undefined** as value are considered as empty points. Empty data points are ignored and not plotted in the Chart. When the data is provided by using the Points property, you can set the **IsEmpty** to true to specify that the particular point is an empty point.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
. Series(sr =>{
//Using empty points
sr.Points(pt => {
pt.X("0").Y(210).Add(); pt.X("1").Y(0).Add();
pt.X("2").Y(150).Add(); pt.X("3").Y(180).IsEmpty(true).Add();
pt.X("4").Y(170).Add(); pt.X("5").Y(200).Add();
pt.X("6").Y(140).IsEmpty(true).Add();
pt.X("7").Y(120).Add(); pt.X("8").Y(140).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}).Add();
// ...
})
// ...
)
```



Click here to view the online demo sample for empty points.

EmptyPointSettings

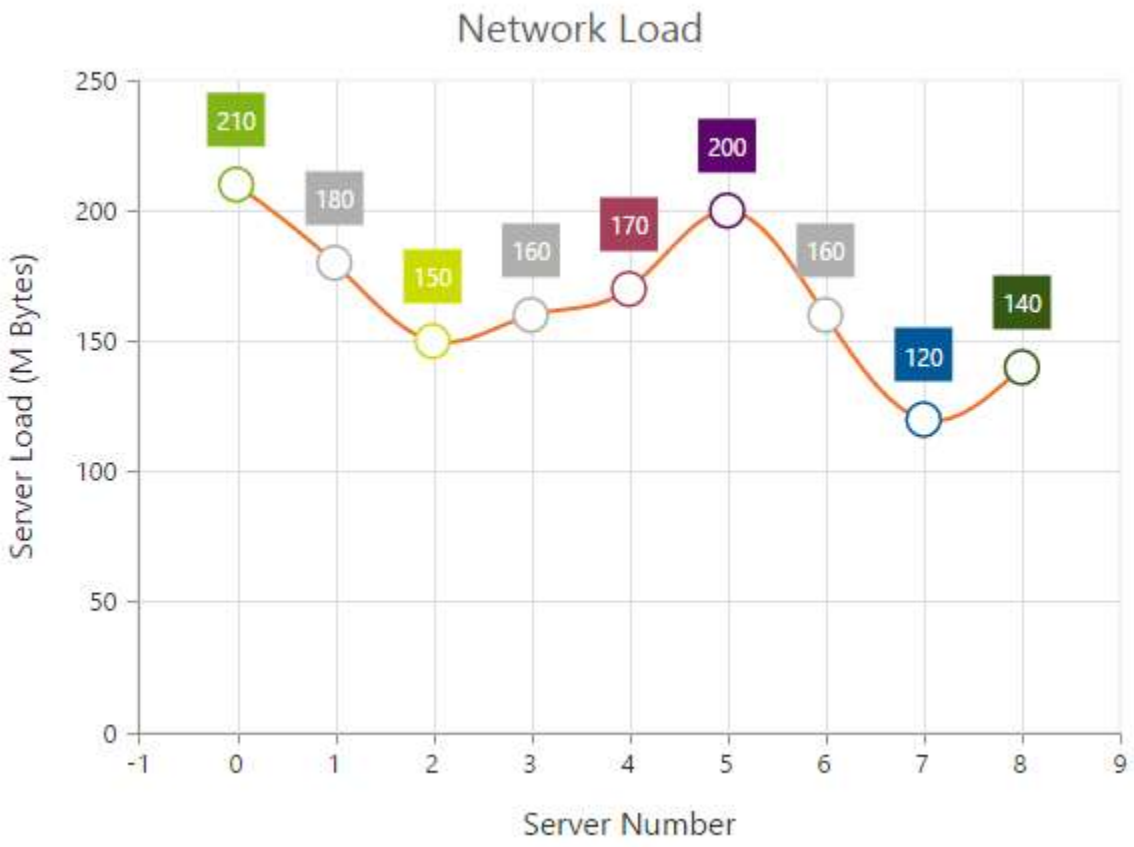
You can customize the empty points visibility and change its **DisplayMode** *(Gap, Zero and Average)* using *EmptyPointSettings* option.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
. Series(sr =>{
//Using empty points
sr.Points(pt => {
pt.X("0").Y(210).Add(); pt.X("1").Y(0).Add();
pt.X("2").Y(150).Add(); pt.X("3").Y(180).IsEmpty(true).Add();
pt.X("4").Y(170).Add(); pt.X("5").Y(200).Add();
pt.X("6").Y(140).IsEmpty(true).Add();
pt.X("7").Y(120).Add(); pt.X("8").Y(140).Add();
})// visible the EmptyPointSettings
.EmptyPointSettings(e => e.Visible(true)
```

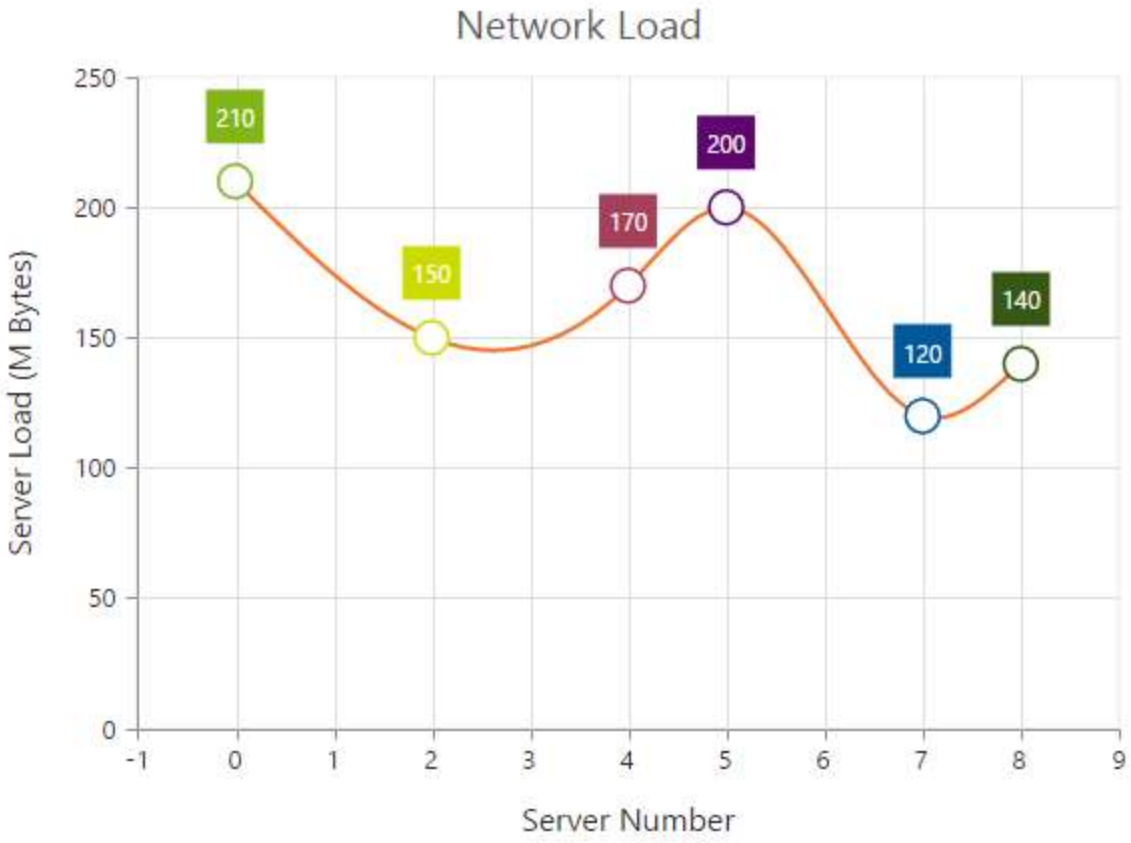
Copyright © 2001 - 2020 Syncfusion Inc.

```
.DisplayMode(ChartEmptyPointMode.Average)
).Add();
// ...
})
// ...
)
```



If the *Visible* property of EmptyPointSettings is *false*, then the empty points has been dropped and chart will be rendered without empty points.

Copyright © 2001 - 2020 Syncfusion Inc.



Customizing Styles

Empty points color and border can be customized using **Style** property of EmptyPointSettings.

ASPX-CS

```
@(Html.EJ().Chart("container")
// ...
. Series(sr =>{
.EmptyPointSettings(e => e.Visible(true)
.Style(s => sl.Color("Pink")
.Border(b => b.Color("gray").Width(2)))
.Add();
// ...
})
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

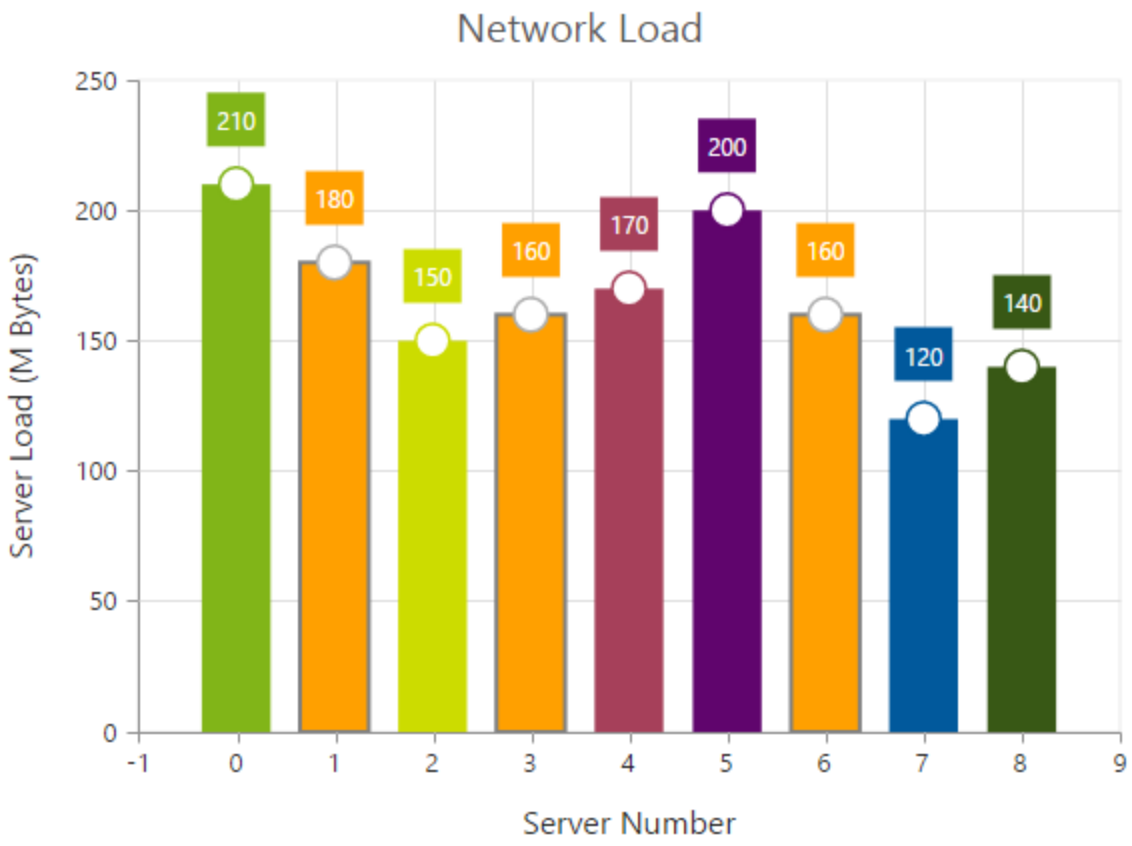


Chart Title & Subtitle

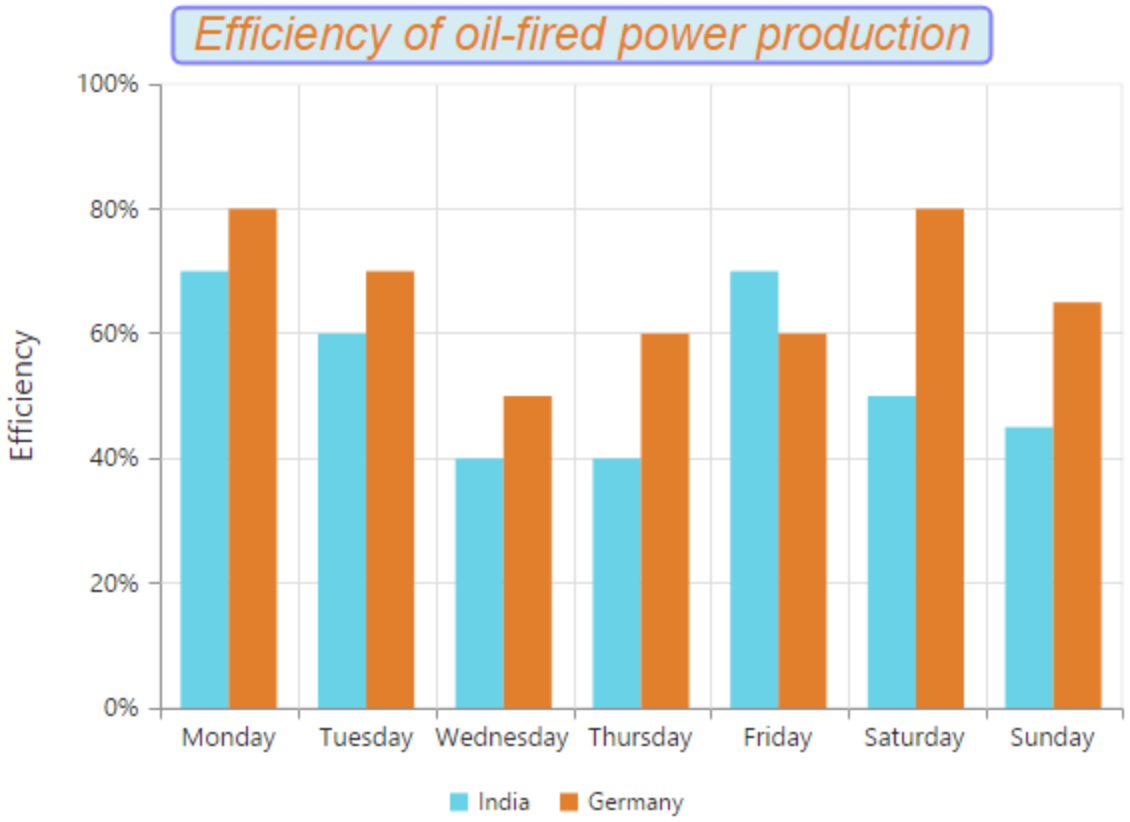
Title

By using the **Title** option, you can add the *Text* as well as customize its *Border, Background and Font*.

ASPX-CS

```
@(Html.EJ().Chart("container")
// ...
//Adding text to chart title
.Title(title => title.Text("Efficiency of oil-fired power production")
//Change the title text background color
.Background("lightblue")
//Customizing Chart title border
.Border(b => b.Color("blue").Width(2).CornerRadius(4.0).Opacity(0.5))
//Customizing Chart title font
.Font(f => f.Opacity(1).FontFamily("Arial").FontStyle("italic
").FontWeight("regular")
.Color("#E27F2D").Size("23px"))
,
// ...
)
```

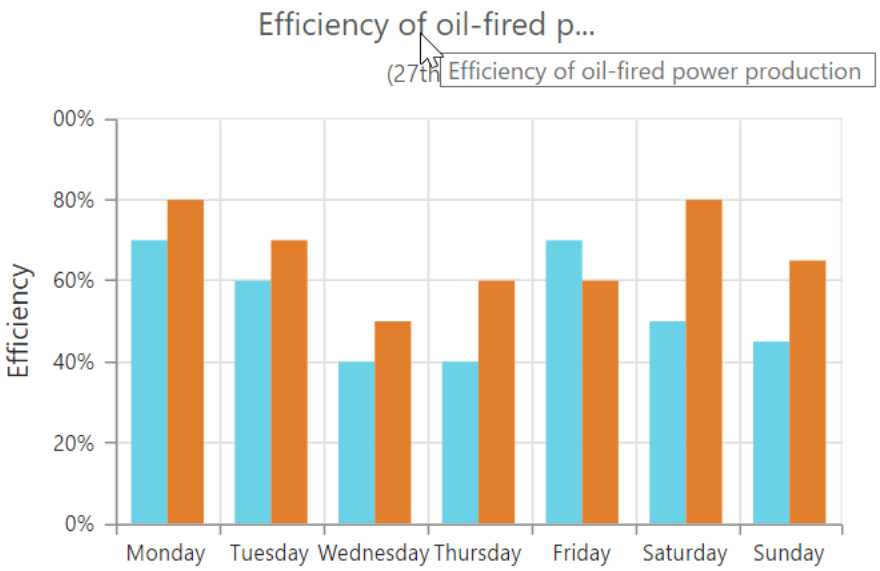


Click here to view the Chart Title online demo sample.

We can trim, wrap and wrapAndTrim to the chart title using textOverflow property. The original text will be displayed as tooltip on mouse hover.

JAVASCRIPT

```
@(Html.EJ().Chart("chartContainer")
//  ..
// To enable title trim and wrap
.Title(title => title.Text("Efficiency of oil-fired power production ")
.EnableTrim("true")
.MaximumWidth(150)
.TextOverflow("trim"))
//  ..
)
```



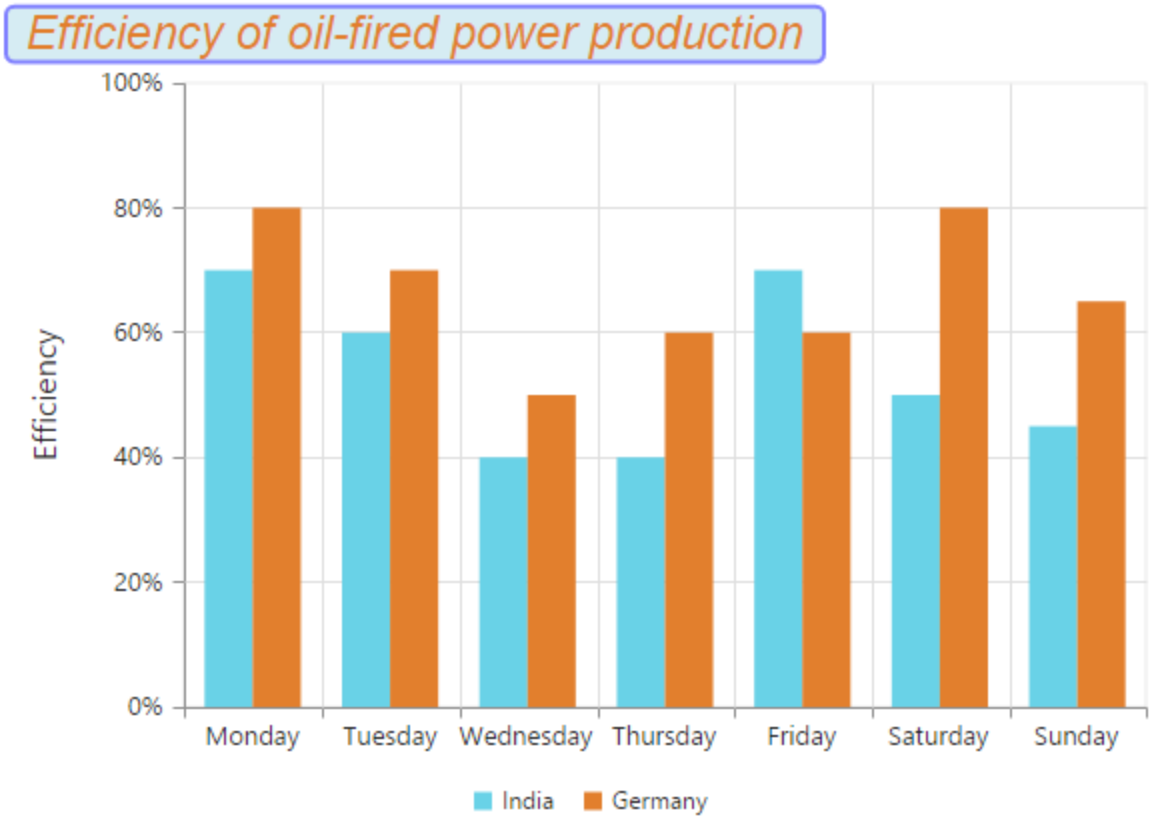
Title Alignment

You can change the title alignment to *Center*, *Far* and *Near* by using the **TextAlignment** property of the chart title.

ASPX-CS

```
@(Html.EJ().Chart("container")
// ...
.Title(title => title.Text("Efficiency of oil-fired power production")
//Change title text alignment
.TextAlignment(Syncfusion.JavaScript.DataVisualization.TextAlignment.Far)
//...
}
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



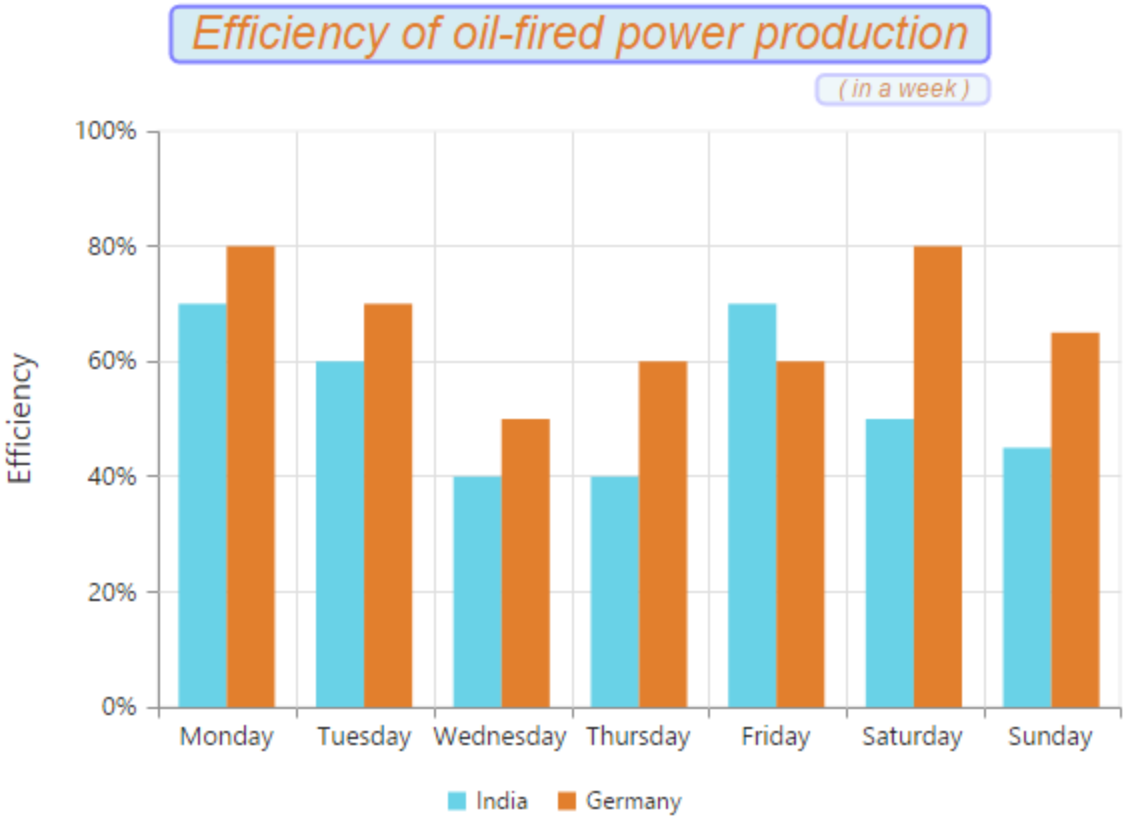
Add Subtitle to the chart

By using the **SubTitle** option, you can add the SubTitle to the chart title and customize its *Border, Background and Font*.

ASPX-CS

```
@(Html.EJ().Chart("container")
// ...
.Title(title => title.Text("Efficiency of oil-fired power production")
//Add subtitle to chart title
.SubTitle(t2 => t2.Text("(in a week)")
//Change the subtitle text background color
.Background("lightblue")
//Customizing Chart subtitle border
.Border(b => b.Color("blue").Width(2).CornerRadius(4.0).Opacity(0.2))
//Customizing Chart subtitle font
.Font(f =>
f.Opacity(1).FontFamily("Arial").FontStyle("italic").FontWeight("regular")
.Color("#E27F2D").Size("12px"))
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

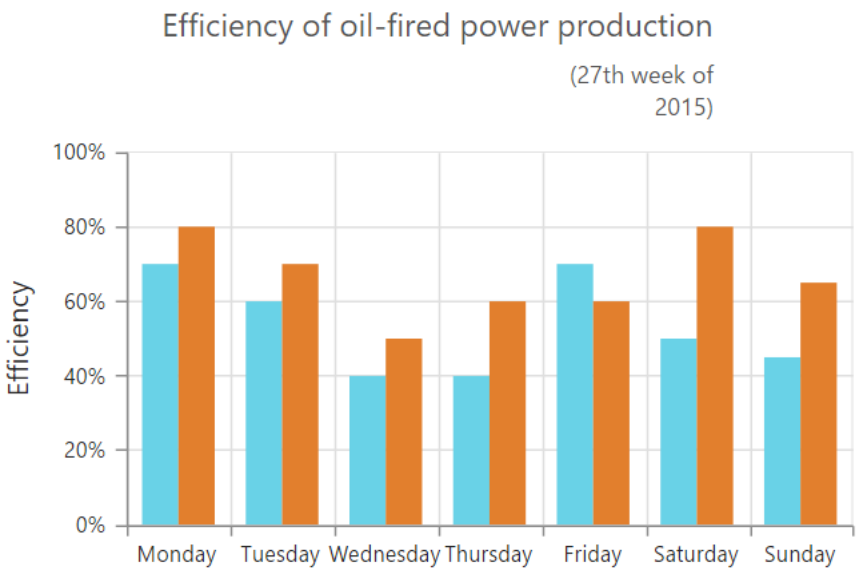


We can trim, wrap and wrapAndTrim to the chart subtitle using textOverflow property. The original text will be displayed as tooltip on mouse hover.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//  ..
// To enable sub-title trim and wrap
.Title(title => title.SubTitle(sTitle => sTitle.Text("(In a Week) ")
.EnableTrim("true")
.MaximumWidth(150)
.TextOverflow("wrap")))
//  ..
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



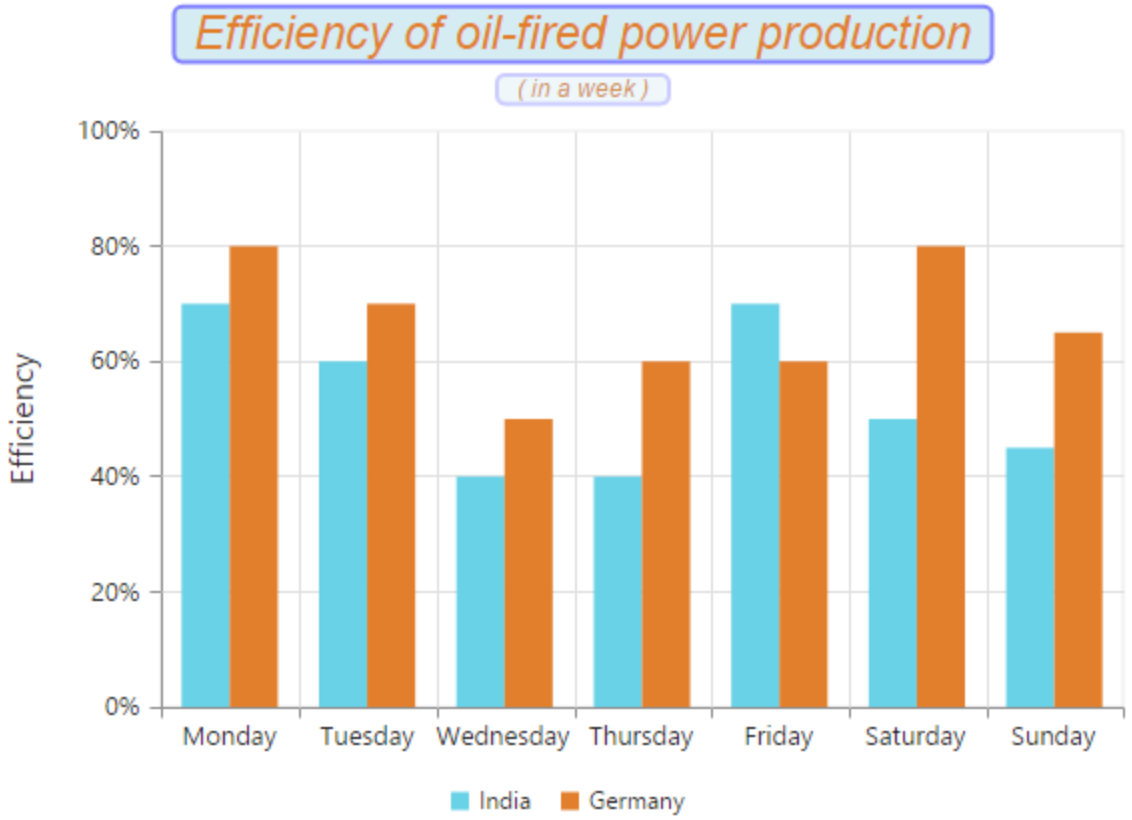
Subtitle Alignment

You can change the SubTitle alignment to *Center*, *Far* and *Near* by using the **TextAlignment** property of the SubTitle.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Title(title = >title
//...
.SubTitle(st=>st
//Change subtitle text alignment
.TextAlignment(Syncfusion.JavaScript.DataVisualization.TextAlignment.Center)
//...
)
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Striplines

EjChart supports horizontal and vertical striplines.

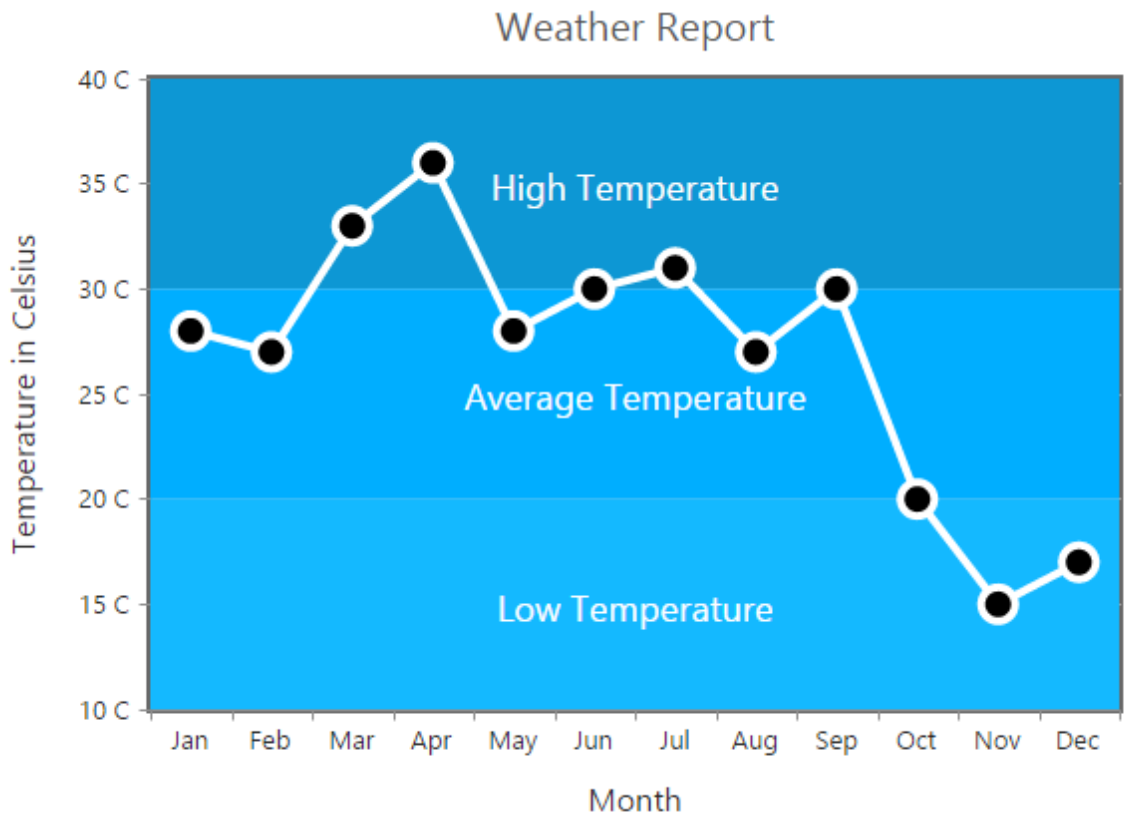
Horizontal Stripline

You can create horizontal stripline by adding the **Stripline** in the *vertical axis* and set **Visible** option to *true*. Striplines are rendered in the specified **Start** to **End** range and you can add more than one stripline for an axis.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Primary Y Axis
.PrimaryYAxis(axis => axis.StripLine(line =>
{
//Enable Stripline
line.Visible(true)
.Start(30).End(40).Add();
}))
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



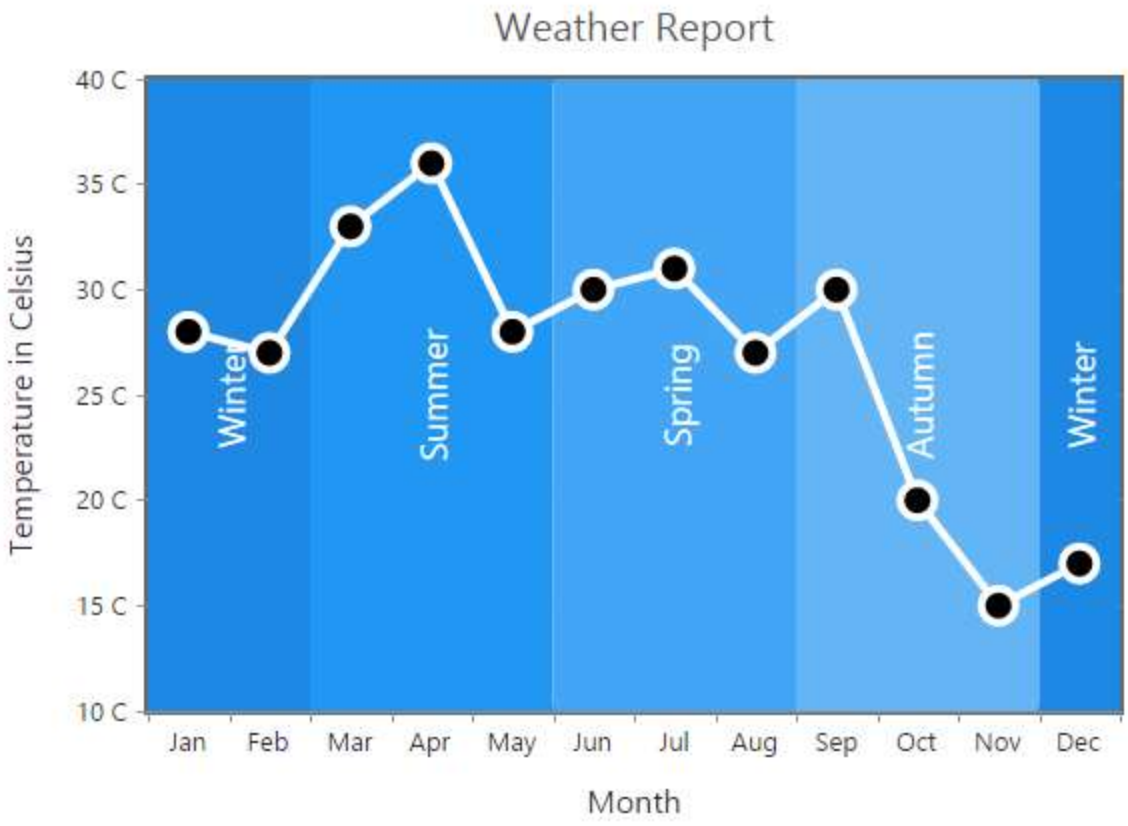
Click here to view the Striplines online demo sample.

Vertical Stripline

You can create vertical stripline by adding the Stripline in the *horizontal axis* and set Visible option to *true*.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Primary X Axis
.PrimaryXAxis(axis => axis.StripLine(line =>
{
//Create vertical Stripline using horizontal Axis
line.Visible(true)
.Start(3).End(7).Add();
}))
//...
)
```

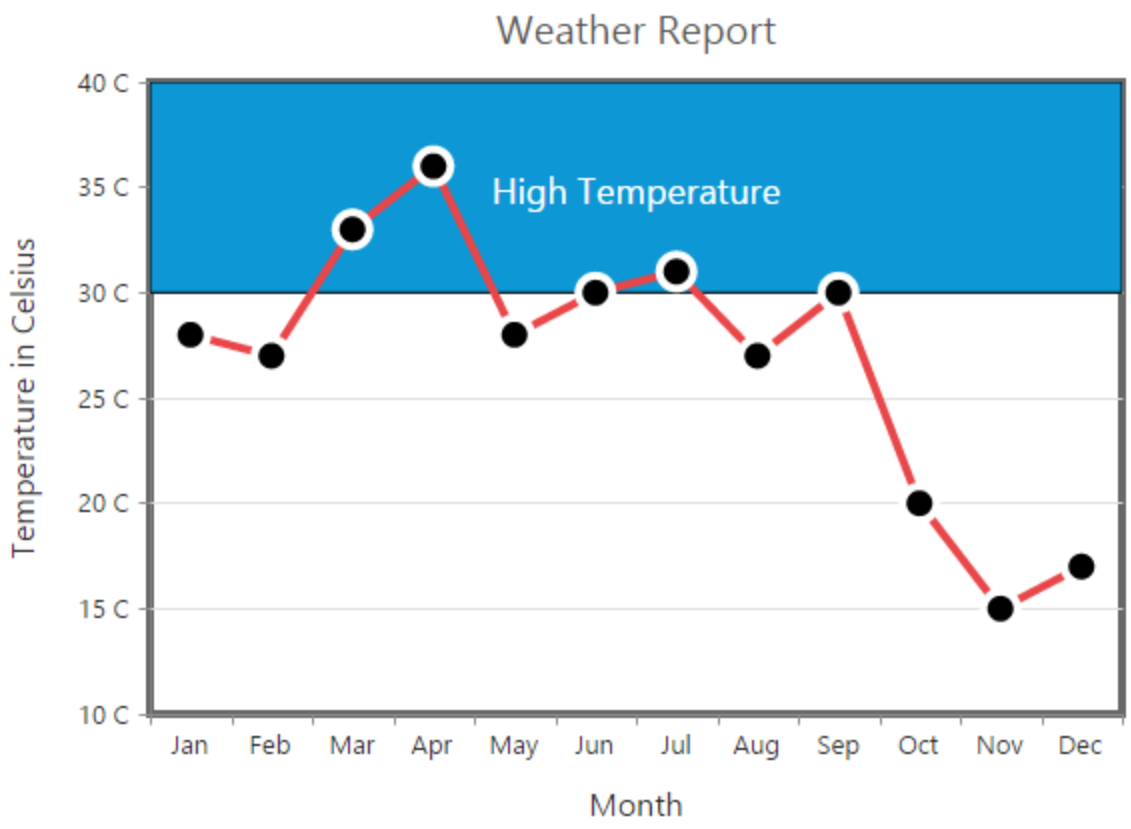


Customize the Text

To customize the stripLine text, use the **Text** and **Font** options.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Primary Y Axis
.PrimaryYAxis(axis => axis.StripLine(line =>
{
//Customize the stripLine text and font styles
line.Text("High Temperature")
.Font(font=>font.Size("18px").Color("white")).Add();
}))
//...
)
```



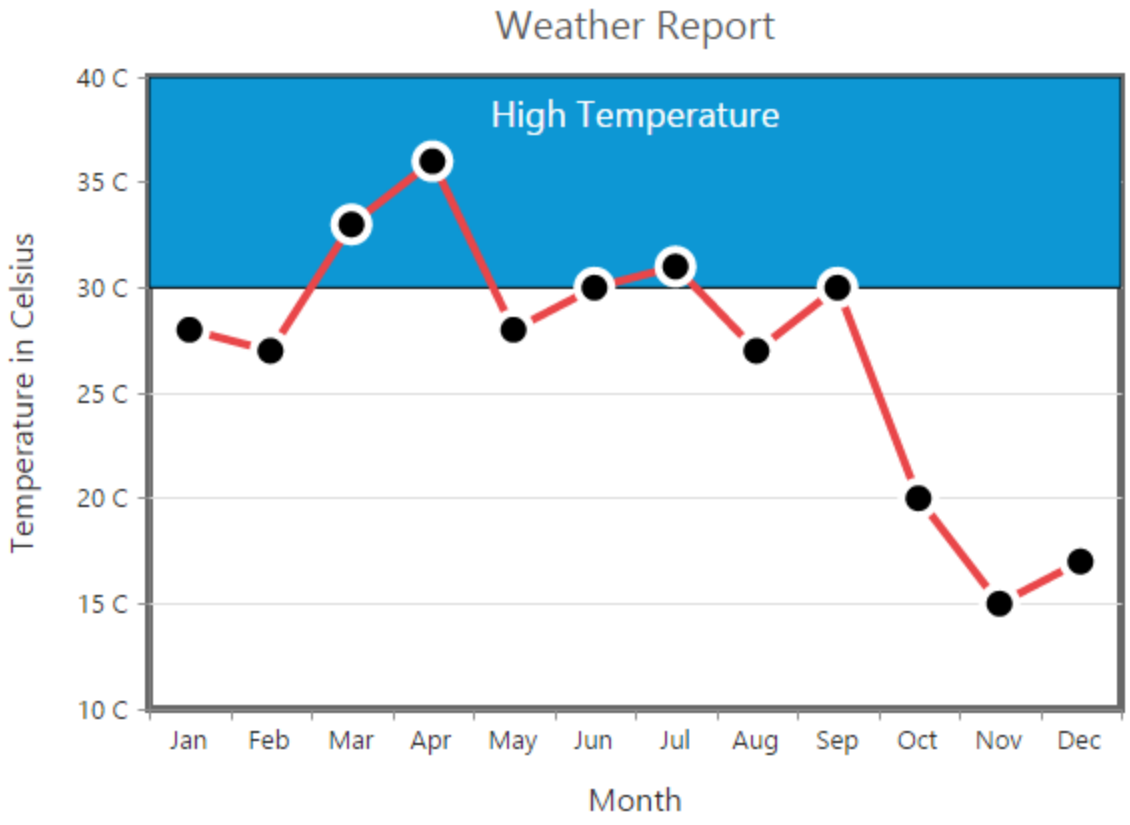
Text Alignment

Stripline text can be aligned by using the **TextAlignment** property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Primary Y Axis
.PrimaryYAxis(axis => axis.StripLine(line =>
{
//Set stripLine text alignment to top position
line.TextAlignment(StriplineTextAlignment.MiddleTop)
.Add();
}))
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



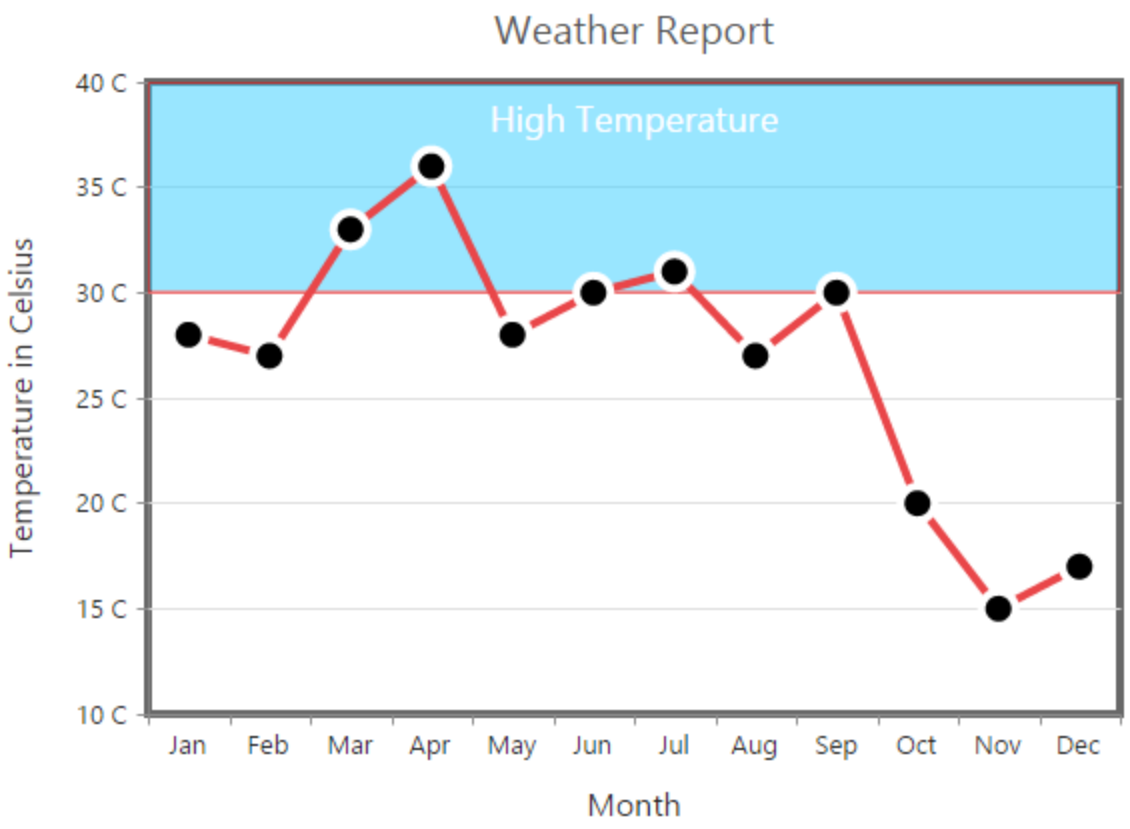
Customize the Stripline

To customize the stripLine styles, use the *Color, Opacity, BorderWidth and BorderColor* properties.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Primary Y Axis
.PrimaryYAxis(axis => axis.StripLine(line =>
{
//Customize the StripLine rectangle
line.Color("#33CCFF").BorderWidth(2).Opacity(0.5).BorderColor("red")
.Add();
}))
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



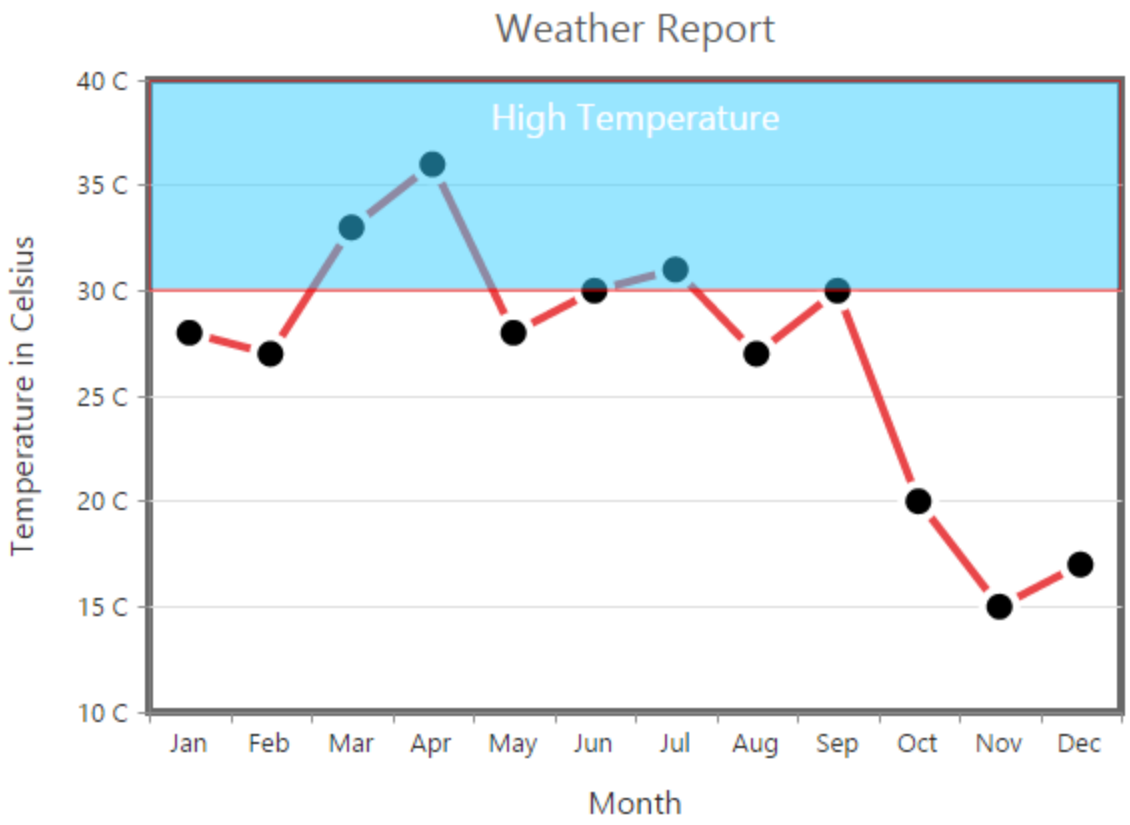
Change the Z-order of the stripline

Stripline **ZIndex** property is used to display the stripLine either behind or over the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Primary Y Axis
.PrimaryYAxis(axis => axis.StripLine(line =>
{
//Change stripLine ZIndex
line.ZIndex(ChartZIndex.Over)
.Add();
}))
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



User Interactions

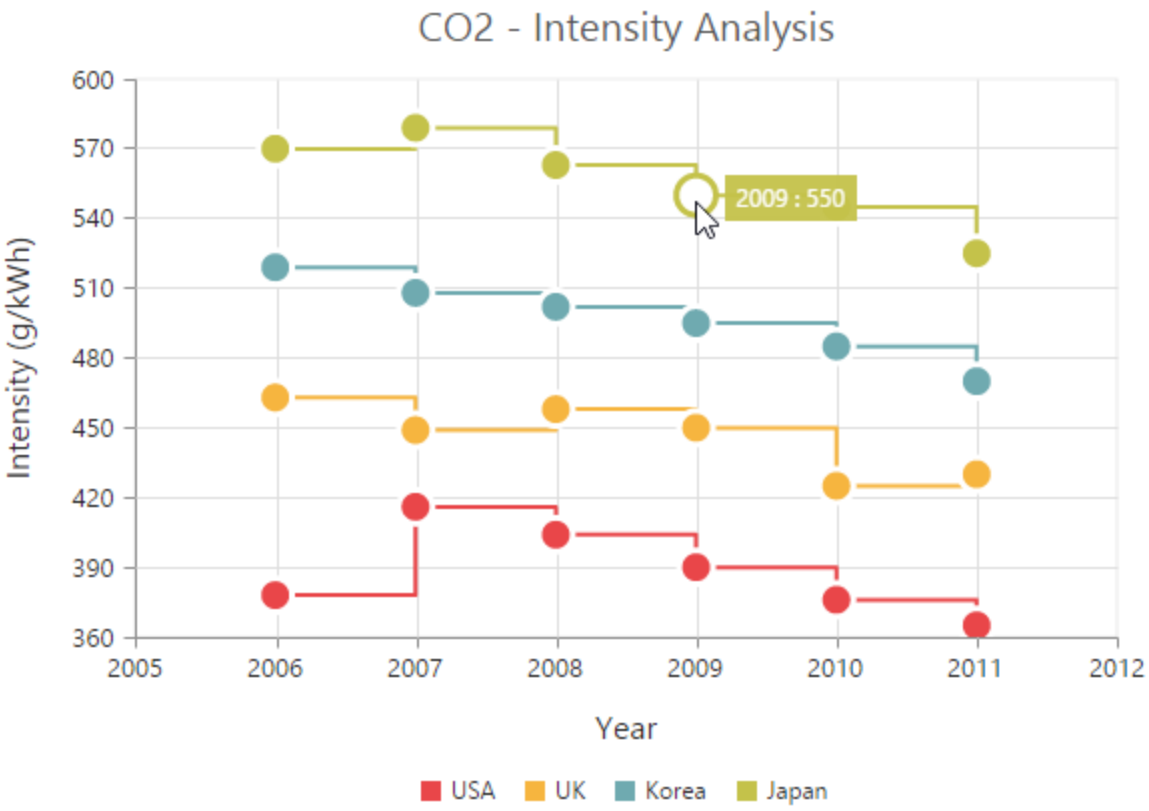
Tooltip

Enable tooltip for data point

Tooltip for the data points can be enabled by using the *Visible* option of the **Tooltip** in the series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(ser =>
{
ser.Tooltip(tooltip=>tooltip
//Enable tooltip for the series
.Visible(true)
).Add();
})
//...
)
```



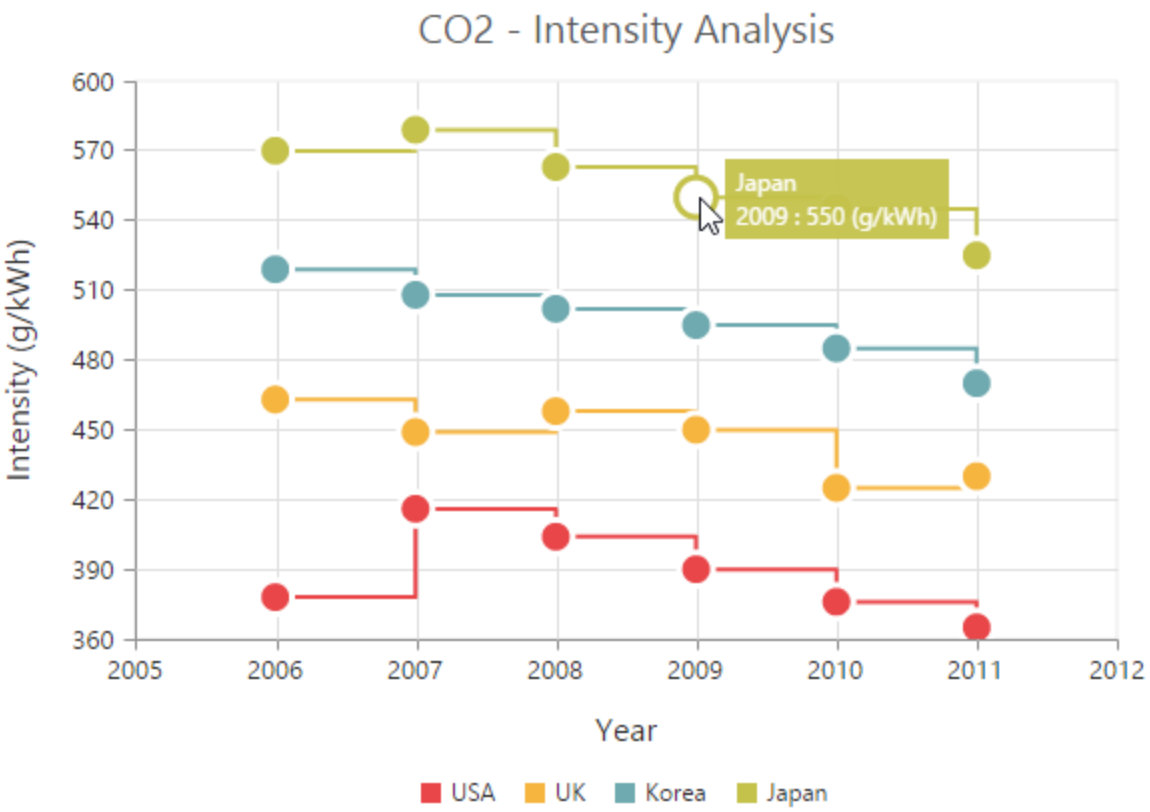
Format the tooltip

Tooltip displays data specified by the **Format** option of the tooltip. The default value of the format option is *#point.x# : #point.y#* . Here, *#point.x#* is the placeholder for x value of the point and *#point.y#* is the placeholder for y value of the point.

You can also use *#series.<optionname>#* as placeholder to display the value of an option in corresponding series and use *#point.<optionname>#* as place holder to display the value of an option in the corresponding point.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(ser =>
{
ser.Tooltip(tooltip=>tooltip
//Displaying tooltip in a format
.Format("#series.name# <br/> #point.x# : #point.y#  (g/kWh)")
).Add();
})
//...
)
```



Tooltip Template

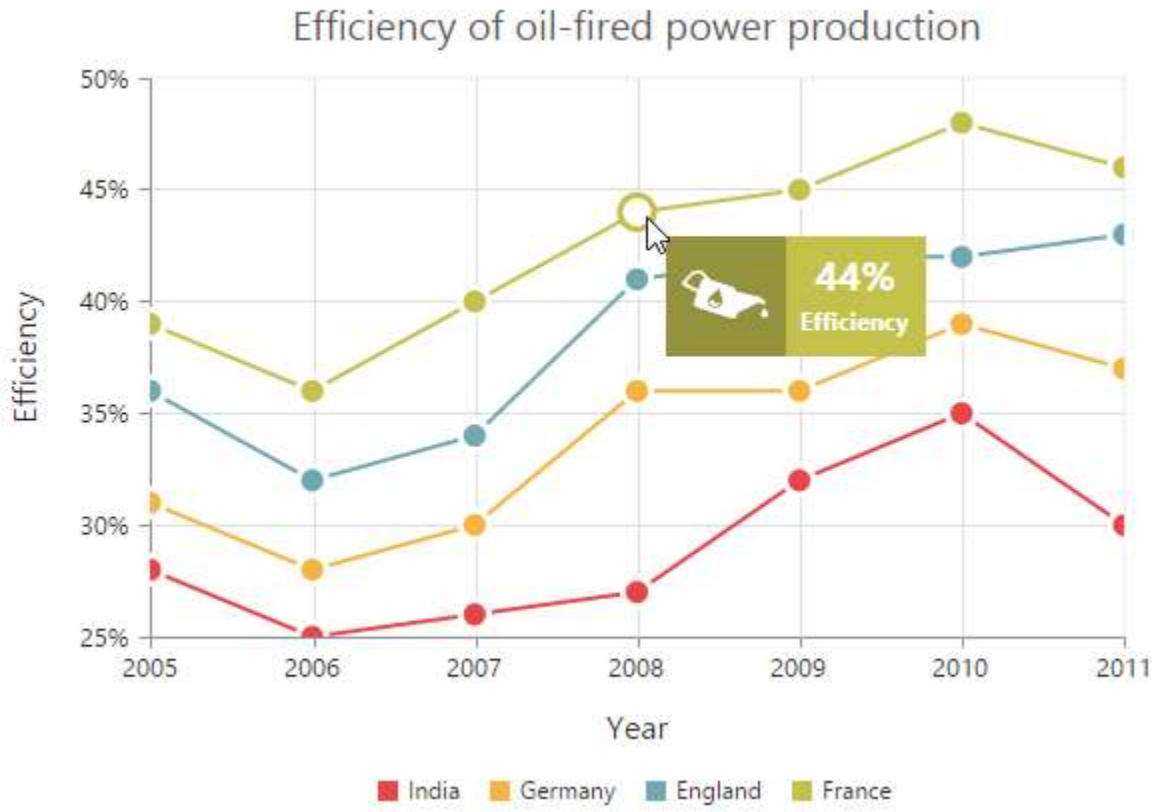
HTML elements can be displayed in the tooltip by using the **Template** option of the tooltip. The template option takes the value of the id attribute of the HTML element. You can use the *#point.x#* and *#point.y#* as place holders in the HTML element to display the x and y values of the corresponding data point.

You can also use *#series.<optionname>#* as place holder to display the value of an option in corresponding series of the tooltip and use *#point.<optionname>#* as place holder to display the value of an option in the corresponding point for which the tooltip is displayed.

ASPX-CS

```
<!-- Create Tooltip template here -->
<div id="Tooltip" style="display: none;">
<div id="icon"> <div id="eficon"> </div>  </div>
<div id="value">
<div>
<label id="efpercentage"> #point.y#% </label>
<label id="ef">Efficiency </label>
</div>
</div>
</div>
@(Html.EJ().Chart("chartContainer")
//...
.Series(ser =>
{
ser.Tooltip(tooltip=>tooltip
```

```
//Set template id to tooltip template
.Template("Tooltip")
).Add();
})
//...
)
```



Click here to view the Tooltip template online demo sample.

Tooltip template animation

You can enable animation by setting the *EnableAnimation* to true. Tooltip animates when the mouse moves from one data point to another point. The Duration property in tooltip specifies the time taken to animate the tooltip. the duration is set to **"500ms"**, by default.

Note: Tooltip is animated only if the template is specified for tooltip.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(ser =>
{
ser.Tooltip(tooltip=>tooltip
//Enable tooltip template animation and set duration time
.EnableAnimation(true).Duration("1000ms")
).Add();
})
```

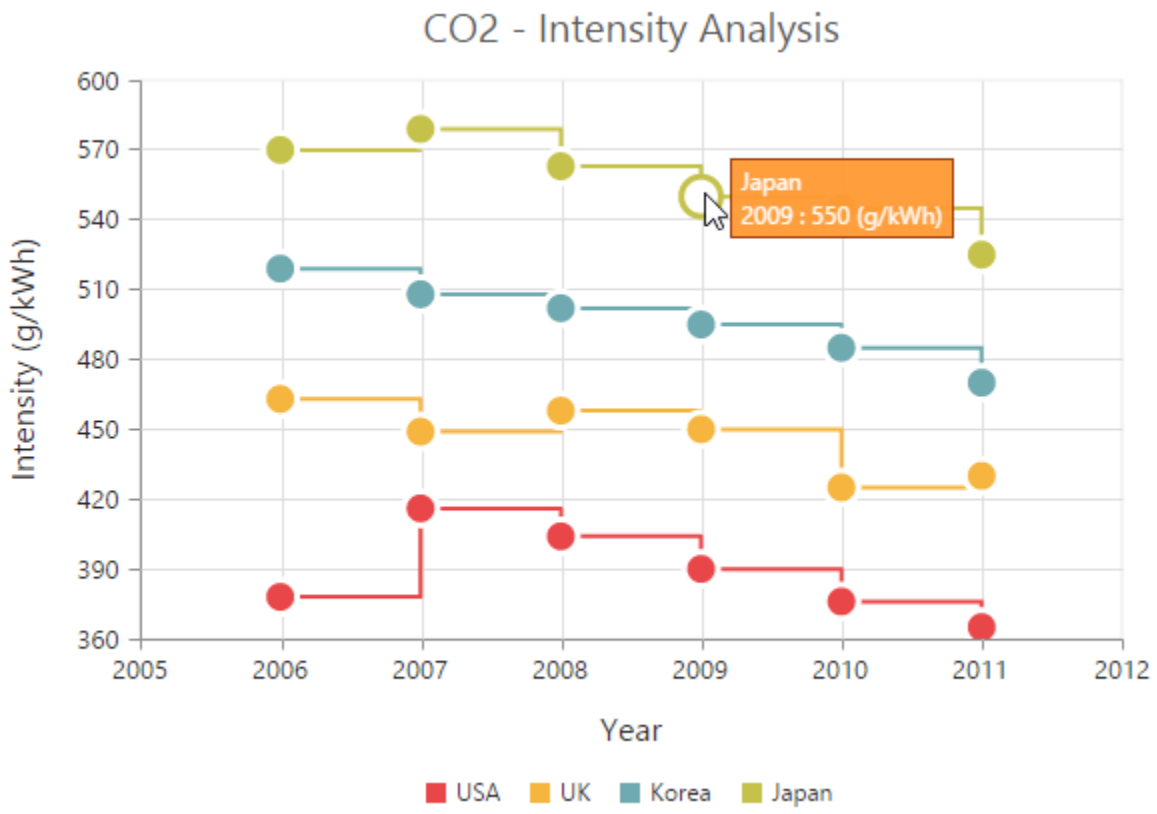
```
//...
)
```

Customize the appearance of tooltip

The *Fill* and *Border* options are used to customize the background color and border of the tooltip respectively. The *Font* option in the tooltip is used to customize the font of the tooltip text.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(ser =>
{
ser.Tooltip(tooltip=>tooltip
//Change tooltip color and border
.Fill("#FF9933")
.Border(br => br.Color("#993300").Width(1))
// ...
).Add();
})
//...
)
```

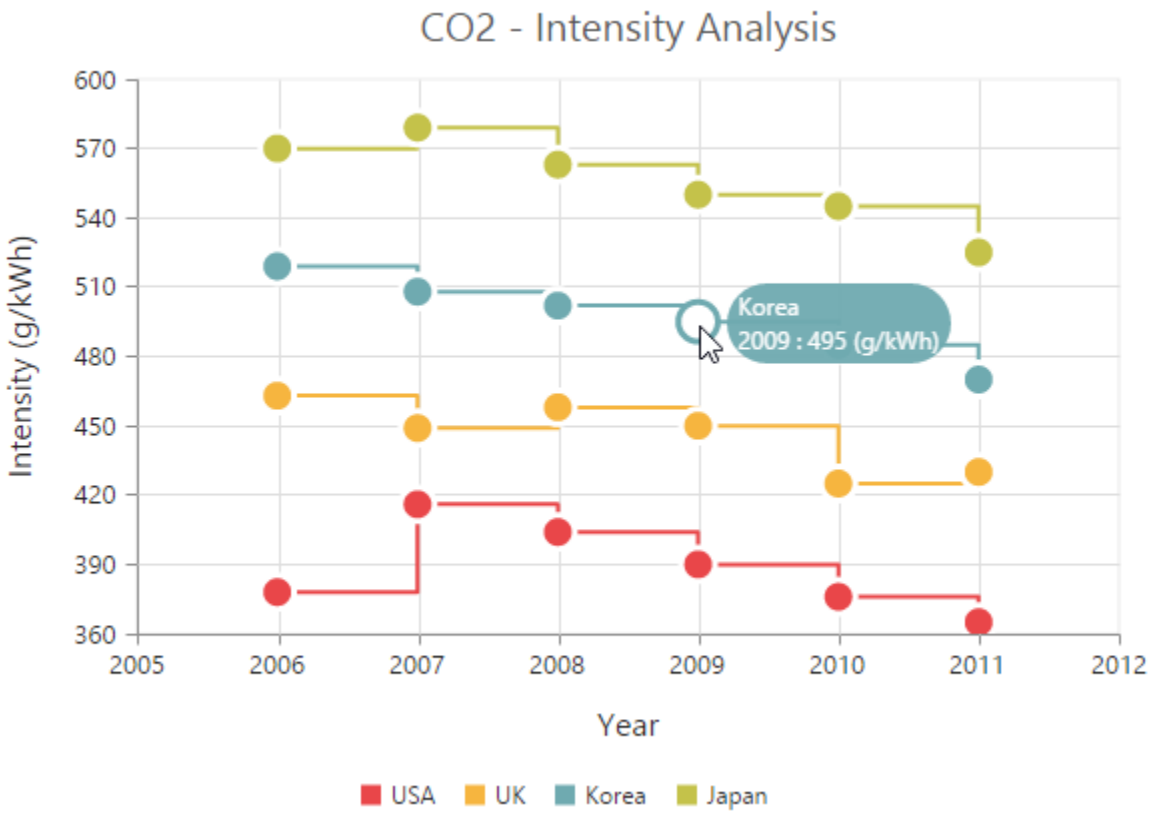


Tooltip with rounded corners

The options *RX* and *RY* are used to customize the corner radius of the tooltip rectangle.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(ser =>
{
ser.Tooltip(tooltip=>tooltip
//Customize the corner radius of the tooltip rectangle.
.RX(50).RY(50)
// ...
).Add();
})
//...
)
```



Zooming and Panning

Enable Zooming

There are two ways you can zoom the chart,

- When the **Zooming.Enable** option is set to true, you can zoom the chart by using the rubber band selection.
- When the **Zooming.EnableMouseWheel** option is set to true, you can zoom the chart on mouse wheel scrolling.

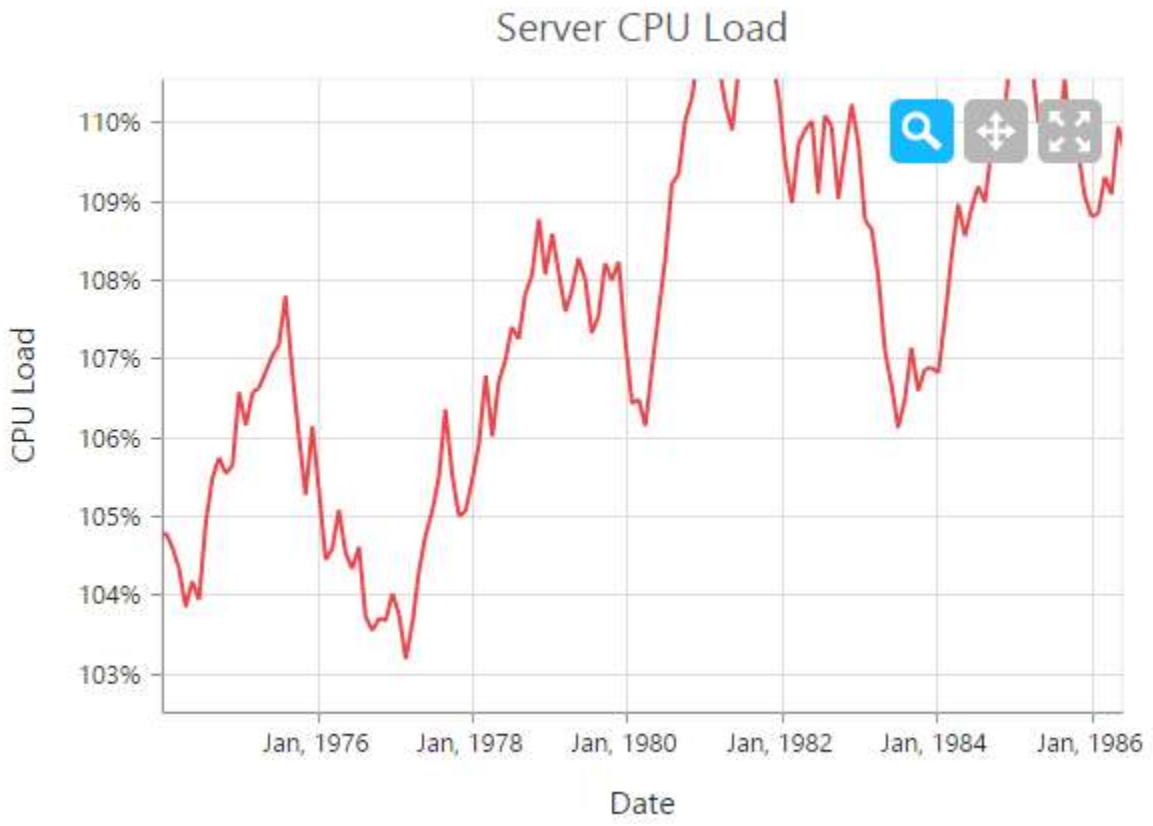
Copyright © 2001 - 2020 Syncfusion Inc.

- When **Zooming.EnablePinching** option is set to *true*, you can zoom the chart through pinch gesture.

Note: Pinch zooming is supported only in browsers that support multi-touch gestures. Currently IE10, IE11, Chrome and Opera browsers support multi-touch in desktop devices.

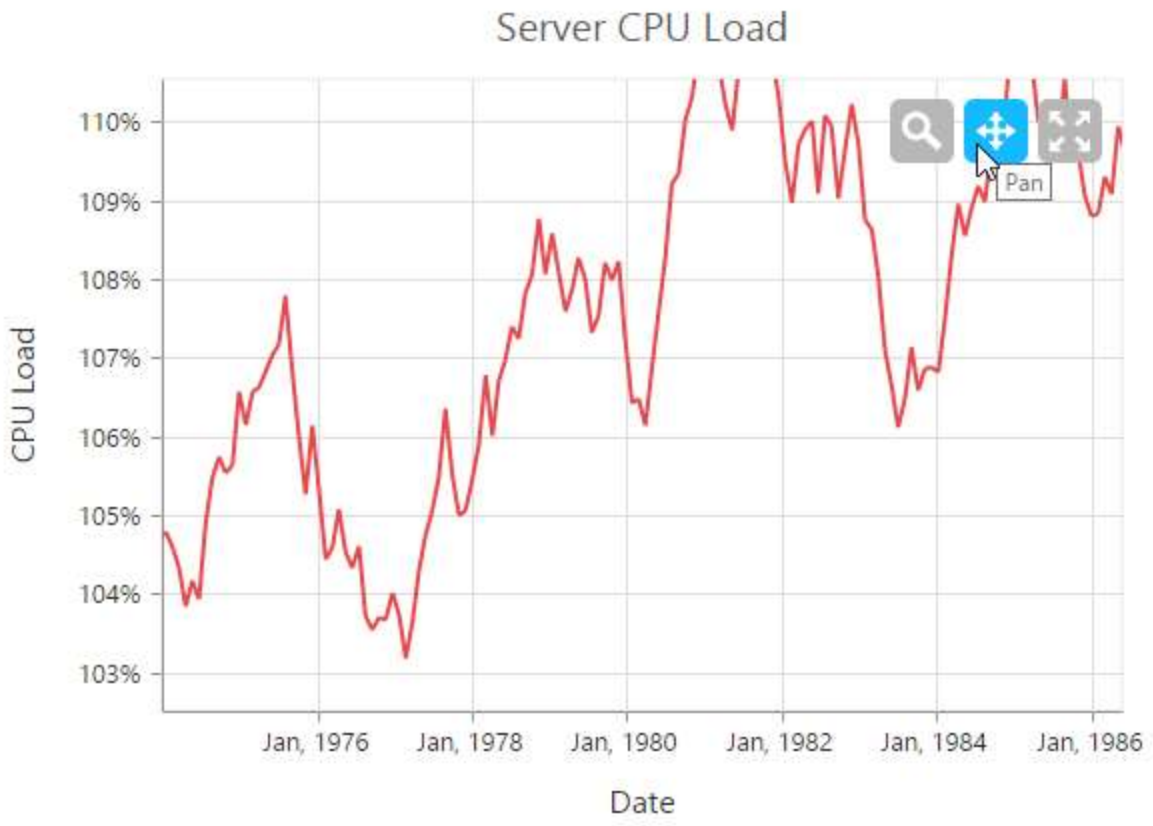
ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Zooming(zoom=>zoom
//Enable zooming in chart
.Enable(true)
)
//...
)
```



After zooming the chart, a zooming toolbar will appear with options to *zoom*, *pan* and *reset*. Selecting the Pan option will allow to pan the chart and selecting the Reset option will reset the zoomed chart.

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Zooming and Panning online demo sample.

Types of zooming

The *Type* option in zooming specifies whether the chart is allowed to scale along the horizontal axis(X) or vertical axis(Y) or along both axis(X,Y). The default value of the Type is **"X,Y"** (both axis).

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Zooming(zoom=>zoom
.Enable(true)
//Enable horizontal zooming
.Type("x")
)
//...
)
```

Customizing zooming toolbar

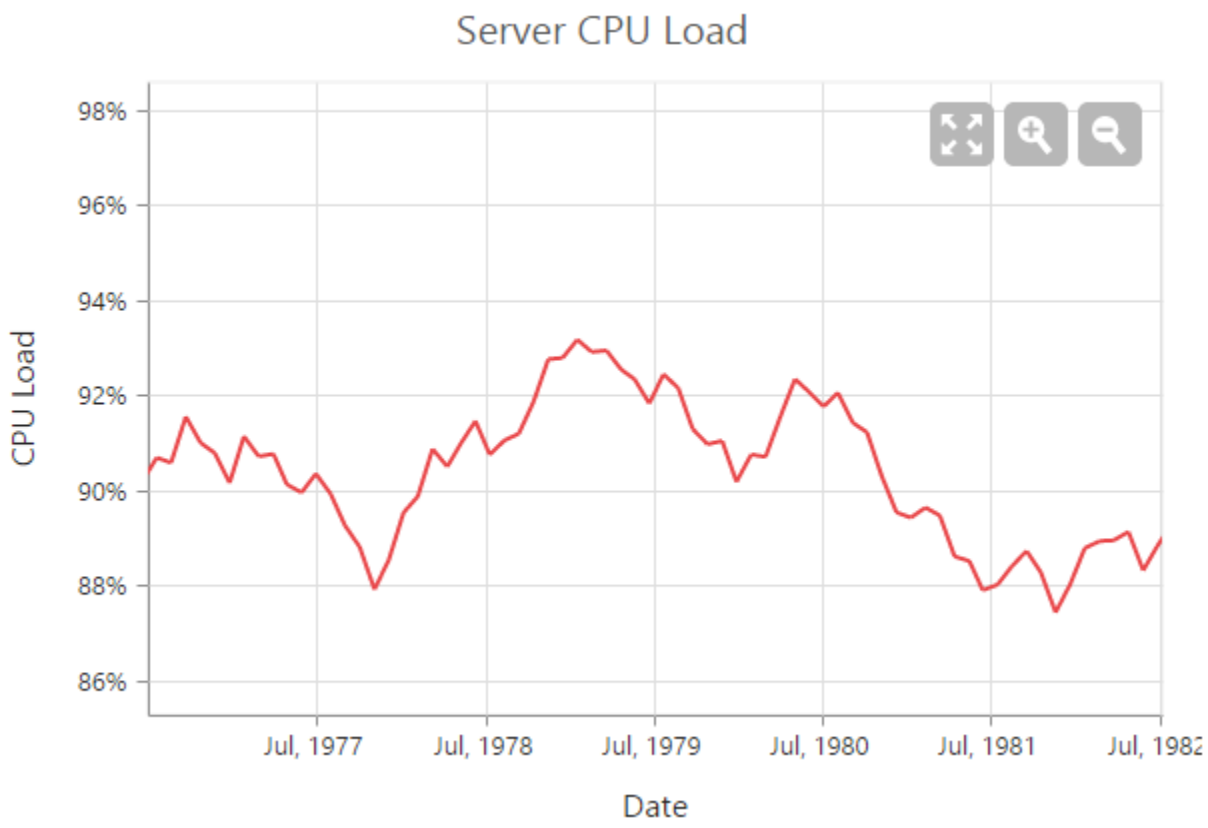
The user can choose the items displayed in the zooming toolbar by specifying the property **ToolBarItems**.

ASPX-CS

```
@(Html.EJ().Chart("container")
//Customizing zooming toolbar
.Zooming(
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
zoom => zoom.Enable(true).ToolbarItems (new List<string>()
{"reset", "zoomIn", "zoomOut"})
)
//...
)
```



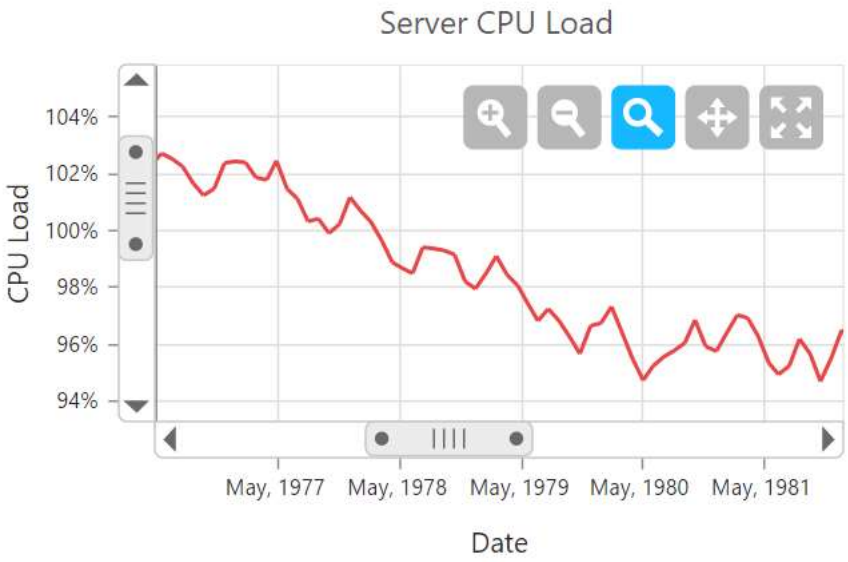
Enable ScrollBar

EjChart provides scrollbar support to view the other portions of chart area which is not shown in the view port when zoomed, by setting true to **EnableScrollbar** option in **Zooming**.

ASPX-CS

```
@(Html.EJ().Chart("container")
//Customizing zooming toolbar
.Zooming(
zoom => zoom.Enable(true)
.EnableScrollbar(true)
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Crosshair

Crosshair is used to view the value of an axis at mouse position or touch contact point.

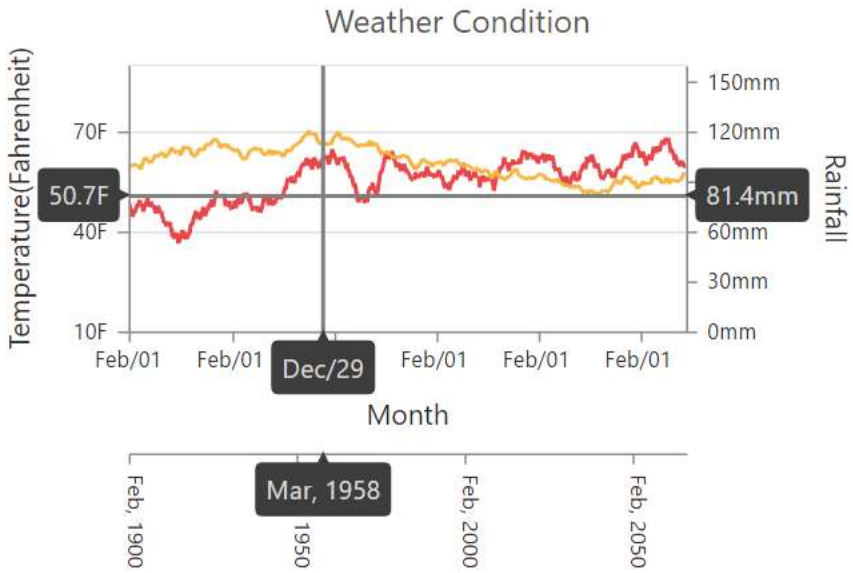
Enable Crosshair and Crosshair label

Crosshair can be enabled by using the **Visible** option in the Crosshair. Crosshair label for an axis can be enabled by using the Visible option of CrosshairLabel in the corresponding axis.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.PrimaryXAxis(axis=>axis.CrosshairLabel(label=>label
//Enable crosshairLabel to X-Axis
.Visible(true))
)
.PrimaryYAxis(axis=>axis.CrosshairLabel(label=>label
//Enable crosshairLabel to Y-Axis
.Visible(true))
)
//Initializing Crosshair
.Crosshair(crosshair=>crosshair.Visible(true))
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



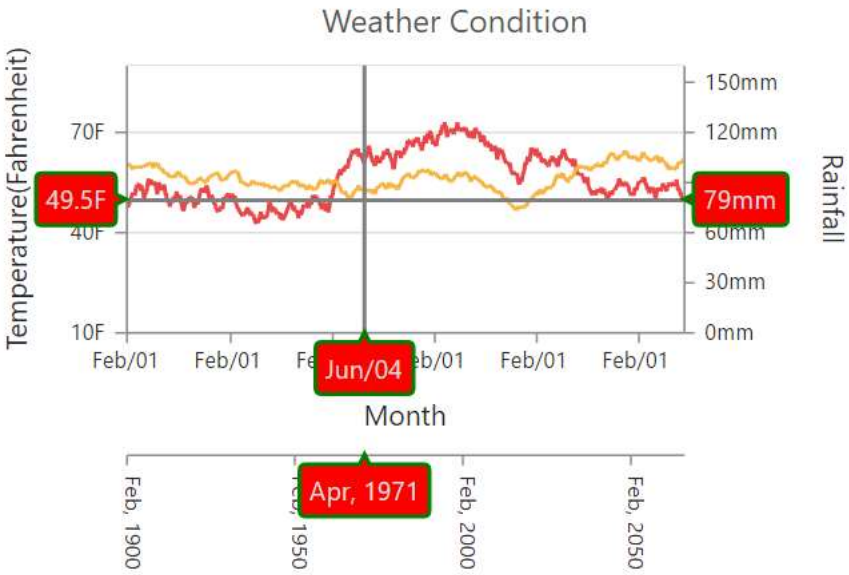
Click here to view the Crosshair online demo sample.

Customize the Crosshair line and Crosshair label

The *Fill* and *Border* options of the **CrosshairLabel** is used to customize the background color and border of the crosshair label respectively. Color and width of the crosshair line can be customized by using the **Line** option in the Crosshair.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.PrimaryYAxis(axis=>axis.CrosshairLabel(label=>label
//Customizing the crosshair label background color and border
.Fill("red").Border(br=>br.Color("green").Width(2))
))
//Initializing Crosshair
.Crosshair(crosshair=>crosshair
.Visible(true)
//Customizing the crosshair line
.Line(line=>line.Color("grey").Width(2))
)
//...
)
```



Trackball

Trackball is used to track a data point close to the mouse position or touch contact point. Trackball marker indicates the closest point and trackball tooltip displays the information about the point.

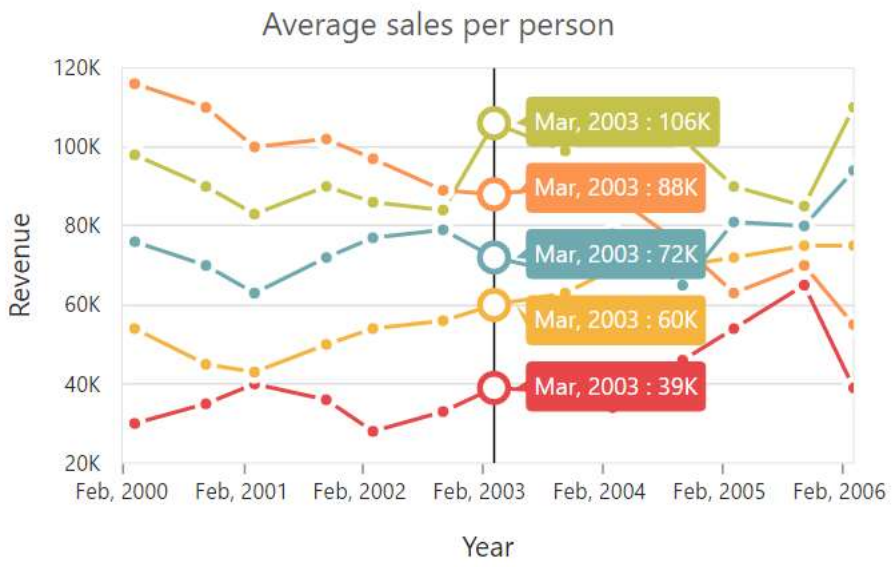
Enable Trackball

Trackball can be enabled by setting the *Visible* option of the crosshair to *true* and then set the **Type** as *Trackball*. The default value of type is *Crosshair*.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
//Initializing Crosshair
.Crosshair(crosshair=>crosshair
.Visible(true)
//Change crosshair type to trackball
.Type(CrosshairType.Trackball)
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Trackball online demo sample.

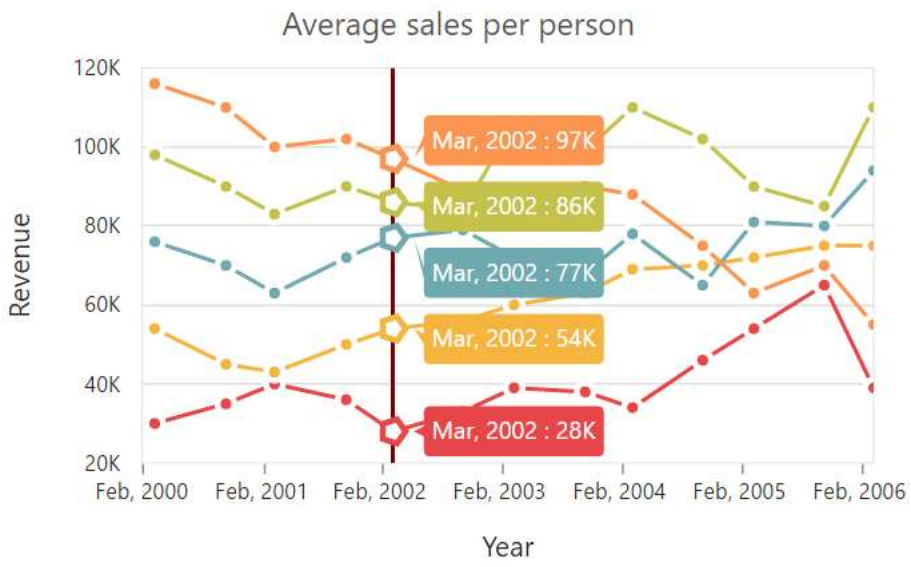
Customize trackball marker and trackball line

Shape and size of the trackball marker can be customized by using the *Shape* and *Size* options of the Crosshair marker. Color and width of the trackball line can be customized by using the *Line* option in the crosshair.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
//Initializing Crosshair
.Crosshair(crosshair=>crosshair
.Visible(true)
//Customize the trackball line color and width
.Line(line=>line.Color("#800000").Width(2))
//Customize the trackball marker shape size and visibility
.Marker(mr=>mr
//Enable/disable trackball marker
.Visible(true).Shape(ChartShape.Pentagon).Size(size=>size.Width(9).Height(9)
)
)
//...
)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



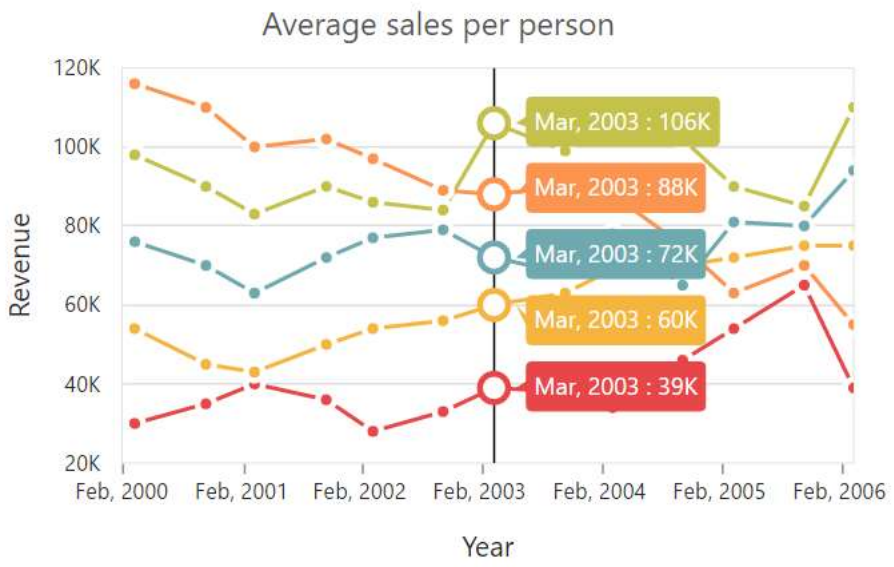
Format Trackball tooltip

X and Y values displayed in the trackball tooltip are formatted based on its axis *LabelFormat*.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
//Add format to crosshair label
.PrimaryXAxis(axis=>axis.LabelFormat("MMM, yyyy"))
.PrimaryYAxis(axis=>axis.LabelFormat("{value}K"))
//Initializing Crosshair
.Crosshair(crosshair=>crosshair
.Visible(true)
//...
)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

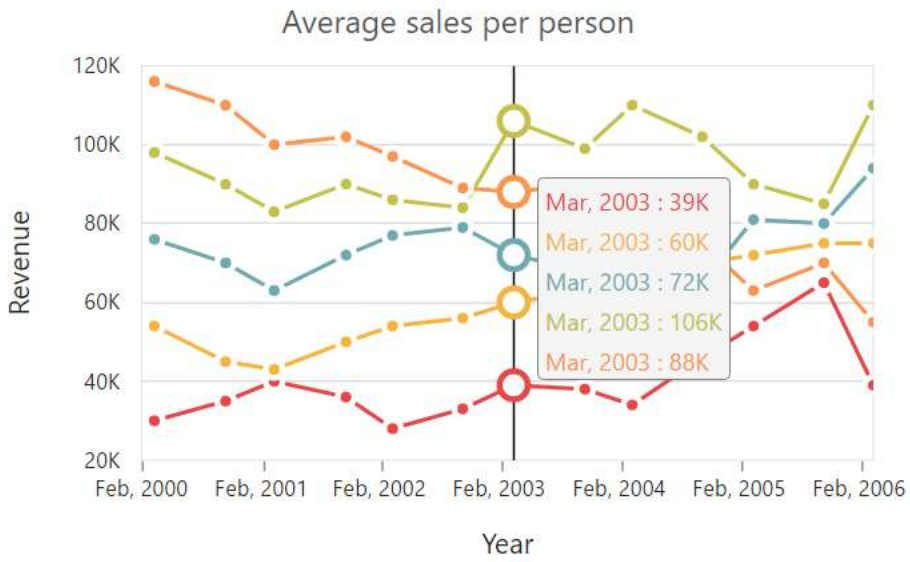


You can able to show the trackball tooltip in two modes, using trackballTooltipSettings.

1. Grouping. 2. Float.

JAVASCRIPT

```
@(Html.EJ().Chart("chartContainer")
//  ..
.Crosshair(crosshair =>
crosshair.Visible(true).type(CrosshairType.Trackball)
.TrackballTooltipSettings(trackball => trackball.Rx("3")
.Ry("3").Fill("whitesmoke").Mode(TrackballDisplayMode.Grouping)
.Border(br => br.Width("1").Color("grey")))
//  ..
)
```



Highlight

EjChart provides highlighting support for the series and data points on mouse hover. To enable the highlighting option, set the *Enable* property to *true* in the **HighlightSettings** of the series.

Note: When hovering mouse on the data points, the corresponding series legend also will be highlighted.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the highlight settings
.Series(sr =>
{
sr
.HighlightSettings(highlight => highlight
// enable the highlight settings
.Enable(true)).Add();
})
)
```

Click here to view the highlight and selections online demo sample.

Highlight Mode

You can set three different highlight mode for the highlighting data point and series by using the **Mode** property of the *HighlightSettings*.

- Series
- Points
- Cluster

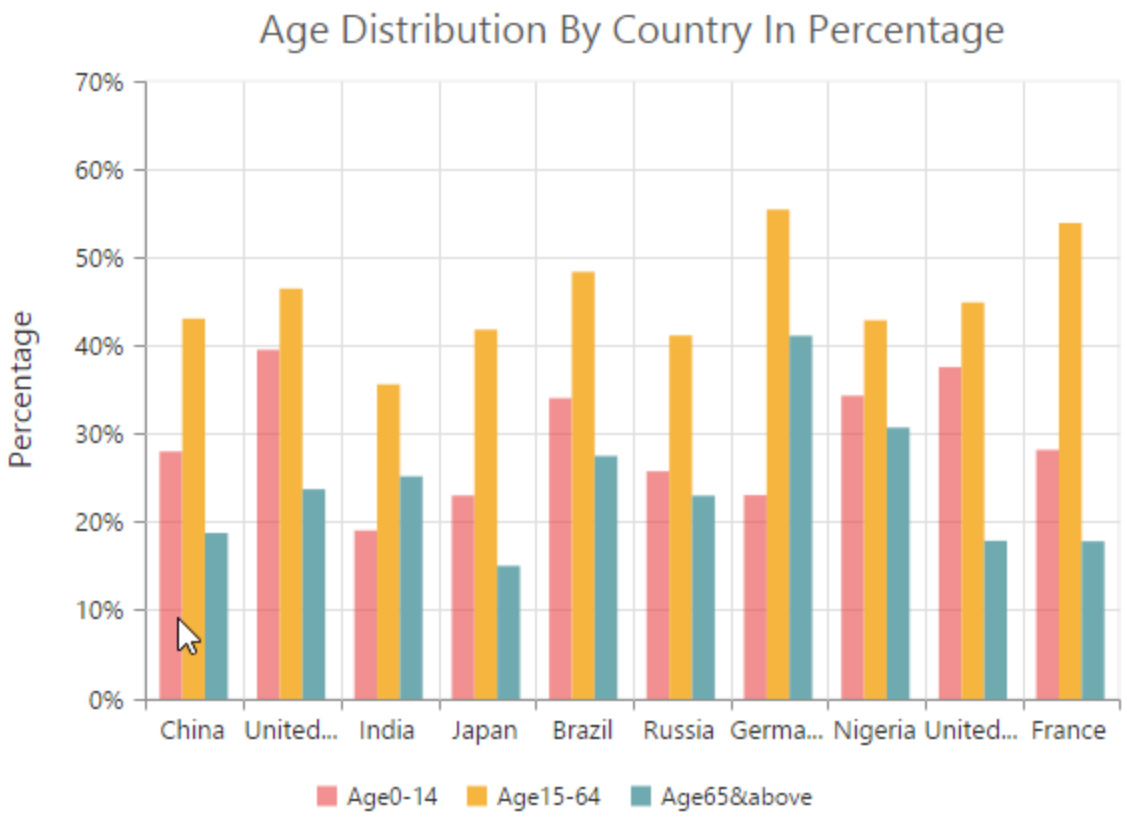
Series mode

To highlight all the data points of the specified series, you can set the **Series** value to the *Mode* option in the HighlightSettings.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the highlight settings
.Series(sr =>
{
sr
.HighlightSettings(highlight => highlight
//Change highlight mode
.Mode(ChartMode.Series)
).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



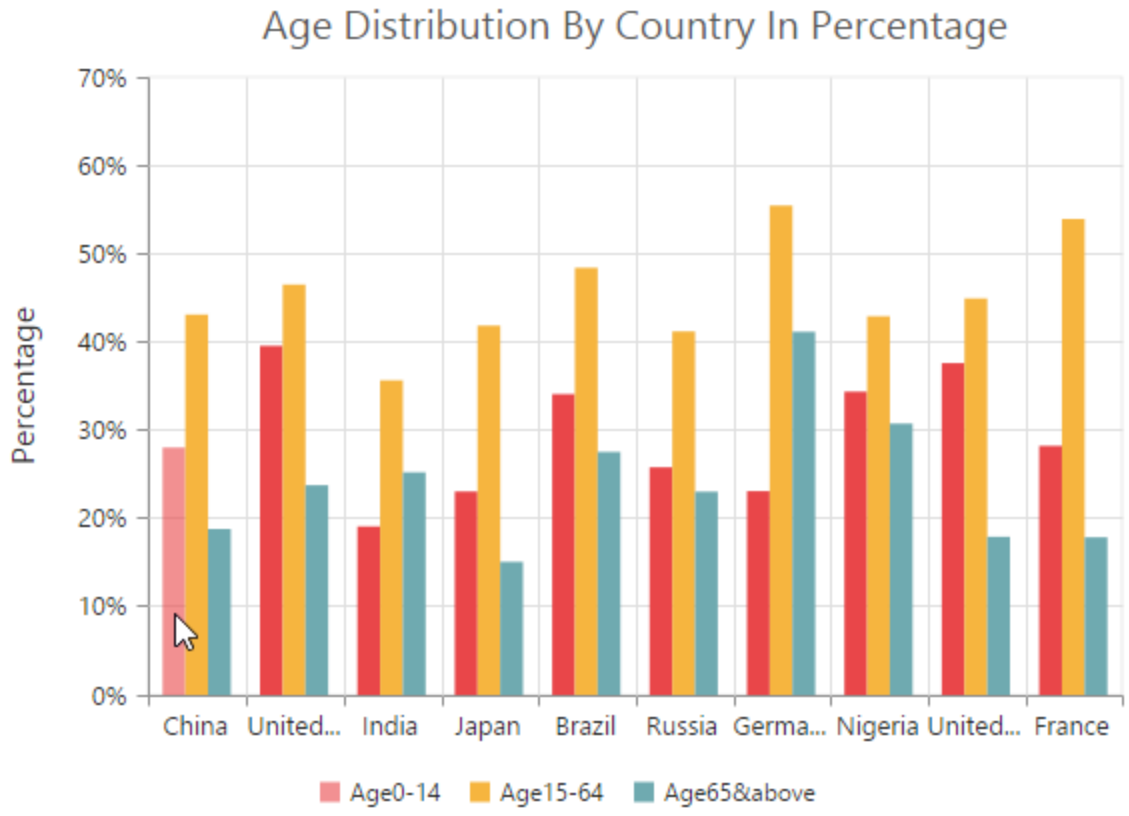
Point mode

To highlight a single point, you can set the **Point** value to the *Mode* option.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the highlight settings
.Series(sr =>
{
sr
.HighlightSettings(highlight => highlight
//Change highlight mode
.Mode(ChartMode.Point)
).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



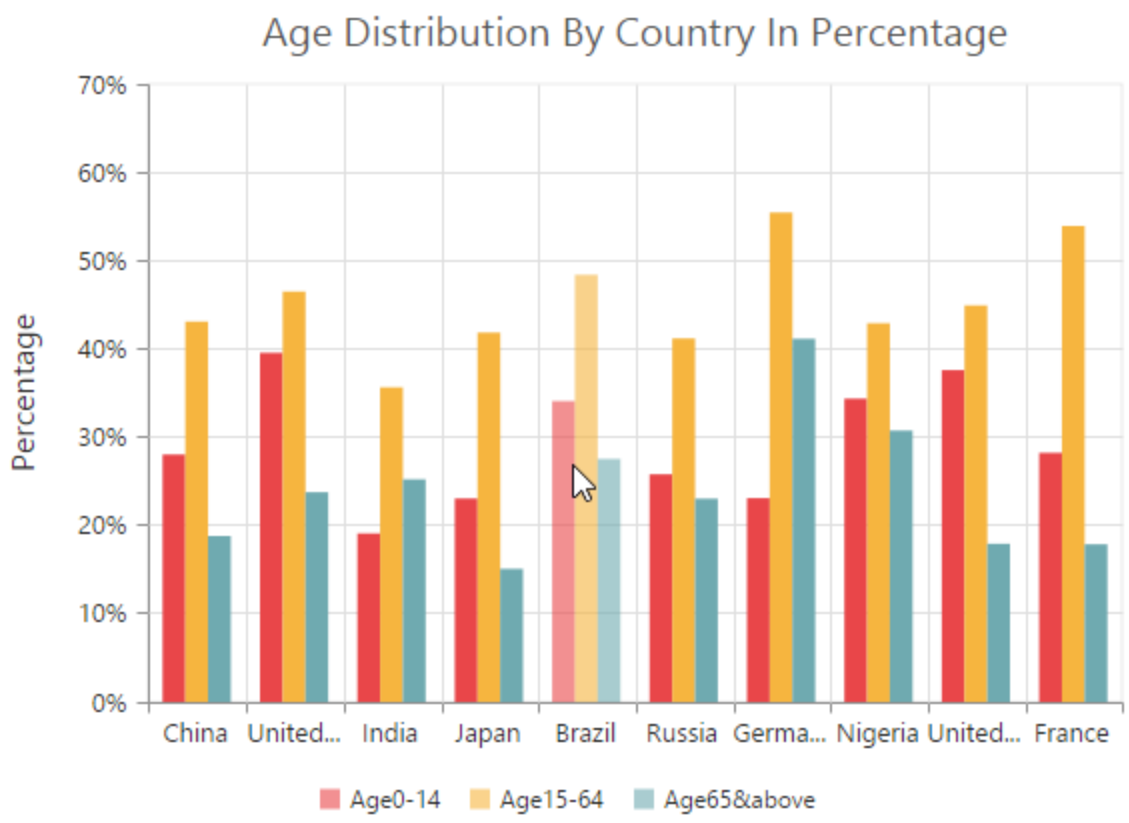
Cluster mode

To highlight the points that corresponds to the same index in all the series, set the **Cluster** value to the *Mode* option.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the highlight settings
.Series(sr =>
{
sr
.HighlightSettings(highlight => highlight
//Change highlight mode
.Mode(ChartMode.Cluster)
).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



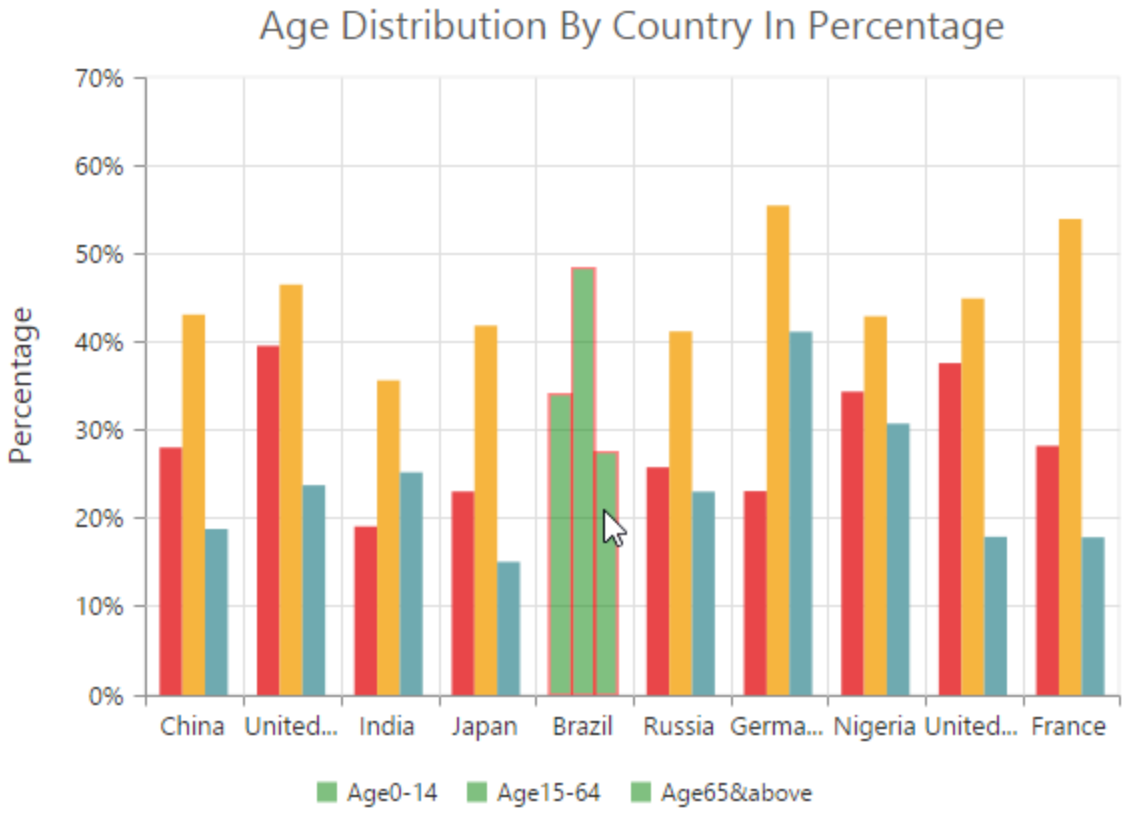
Customize the highlight styles

To customize the highlighted series, use the *Color*, *Border* and *Opacity* options in the HighlightSettings.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the highlight settings
.Series(sr =>
{
sr
.HighlightSettings(highlight => highlight
//Customizing styles
.Border(br=>br.Color("red").Width(1.5))
.Opacity(0.5).Color("green")
).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



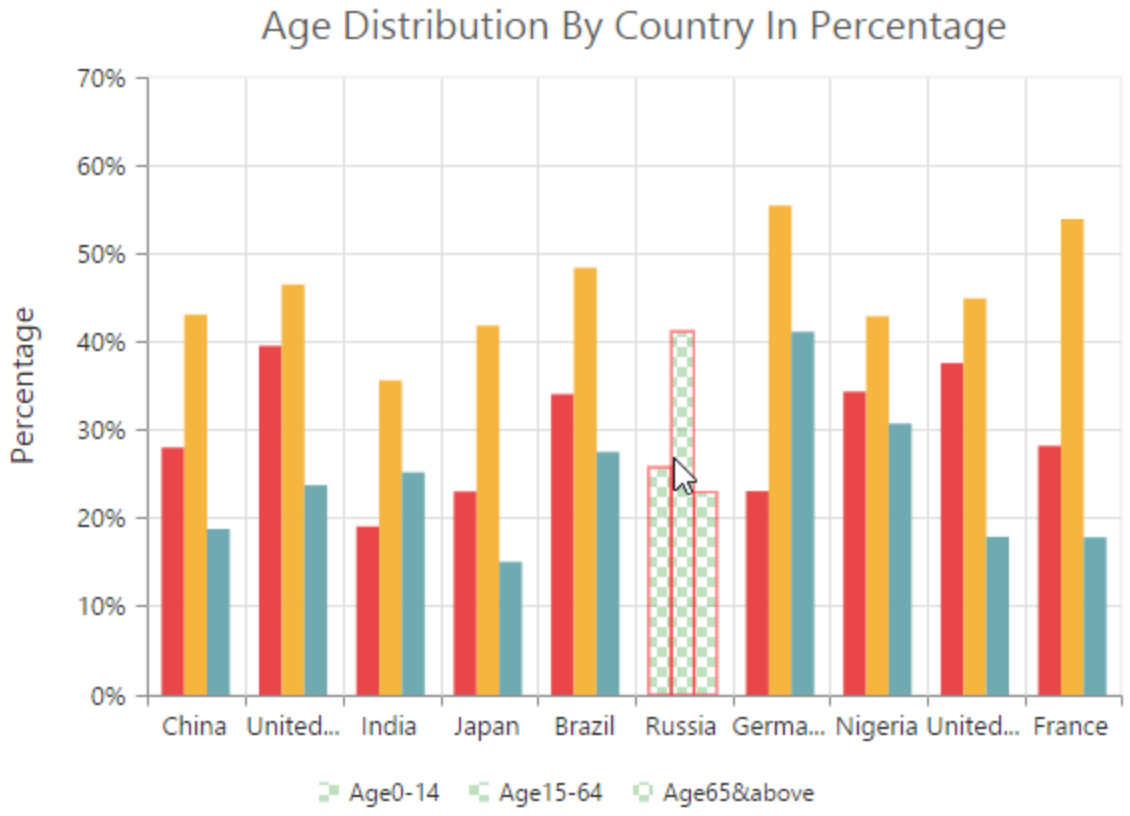
Patterns to highlight

EjChart provides pattern support for highlighting the data by setting the value to the **Pattern** property of the HighlightSettings. The different types of highlight patterns are as follows.

1. Chessboard 2. Crosshatch 3. Dots 4. Pacman 5. Grid 6. Turquoise 7. Star 8. Triangle 9. Circle 10. Tile 11. HorizontalDash 12. VerticalDash 13. Rectangle 14. Box 15. VerticalStripe 16. HorizontalStripe 17. Bubble 18. DiagonalBackward 19. DiagonalForward

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the highlight settings
.Series(sr =>
{
sr
.HighlightSettings(highlight => highlight
.Pattern(ChartPattern.Chessboard)
).Add();
})
)
```



Custom pattern

To create a custom pattern for the highlighting data points, set the pattern type as **Custom** and add the custom pattern *Id* in the **CustomPattern** option of the HighlightSettings.

ASPX-CS

```
<svg>
<pattern id="dots_a" patternUnits="userSpaceOnUse" width="6" height="6">
<rect x="0" y="0" width="6" height="6" transform="translate(0,0)"
fill="black" opacity="1"></rect>
<path d='M 3 -3 L -3 3 M 0 6 L 6 0 M 9 3 L 3 9'stroke-width="1"
stroke="white"></path>
</pattern>
</svg>
@(Html.EJ().Chart("chartContainer")
//...
// enable the highlight settings
.Series(sr =>
{
sr
.HighlightSettings(highlight => highlight
//Add custom pattern for highlighting data
.Pattern(ChartPattern.Custom)
.CustomPattern("dots_a")
//...
.Enable(true)
).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
)
```

Selection

EjChart provides selection support for the series and data points on mouse click. To enable the selection option, set the *Enable* property to *true* in the SelectionSettings* of the series.

Note: When mouse is clicked on the data points, the corresponding series legend also will be selected.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the selection settings
.Series(sr =>
{
sr
.SelectionSettings(ss => ss
// enable the selection settings
.Enable(true)
).Add();
})
)
```

Click here to view the highlight and selections online demo sample.

Selection Mode

You can set four different selection mode for highlighting the data point and series by using the **Mode** property of the SelectionSettings.

- Series
- Points
- Cluster
- Range

Series mode

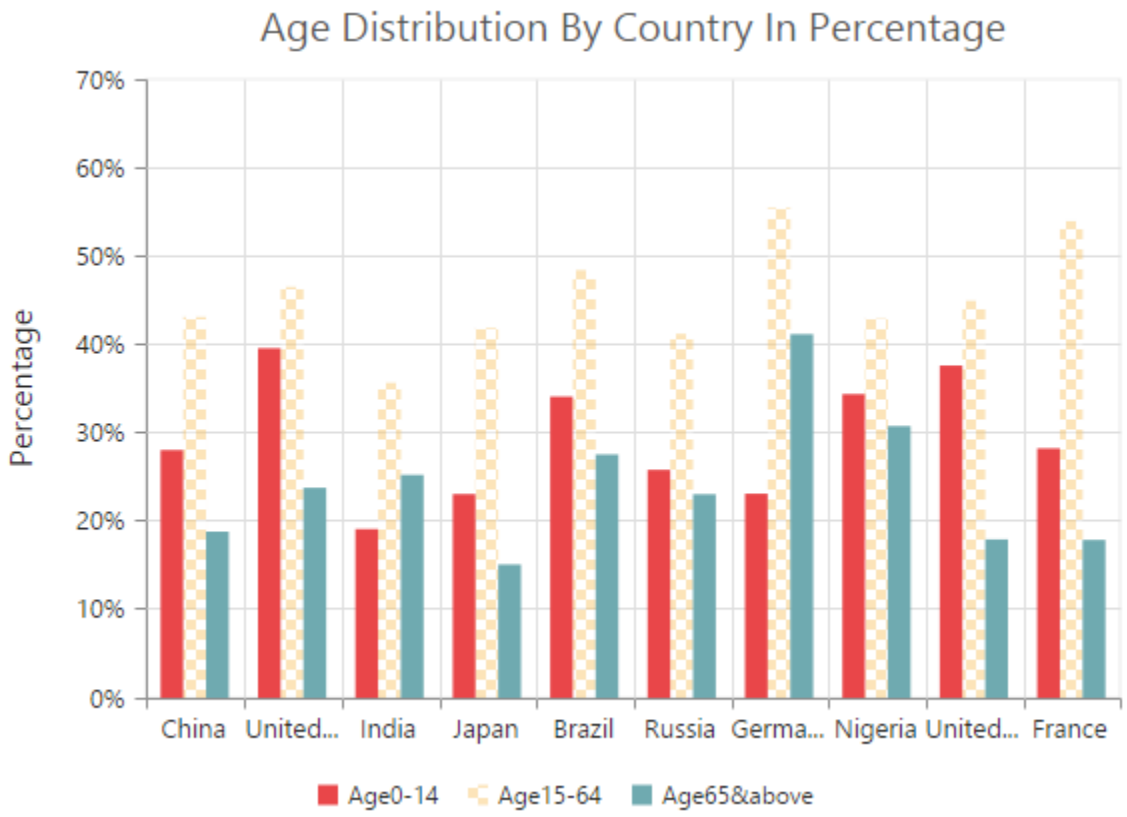
To select all the data points of the specified series, you can set the **Series** value to the *Mode* option in the SelectionSettings.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the selection settings
.Series(sr =>
{
sr
.SelectionSettings(ss => ss
//Change selection mode
.Mode(ChartMode.Series)
.Pattern(ChartPattern.Chessboard)
.Enable(true)
).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
)
```

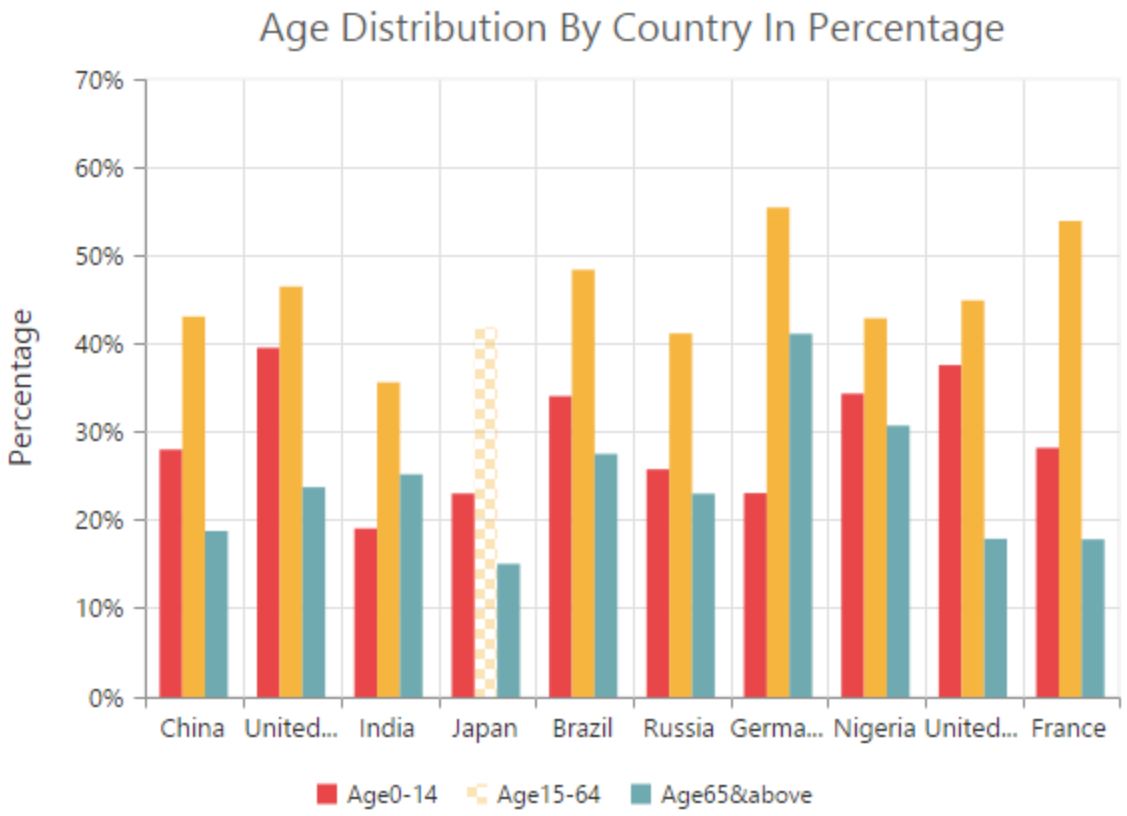


Point mode

To highlight a single point, you can set the **Point** value to the *Mode* option.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the selection settings
.Series(sr =>
{
sr
.SelectionSettings(ss => ss
//Change selection mode
.Mode(ChartMode.Point)
//...
.Enable(true)
).Add();
})
)
```



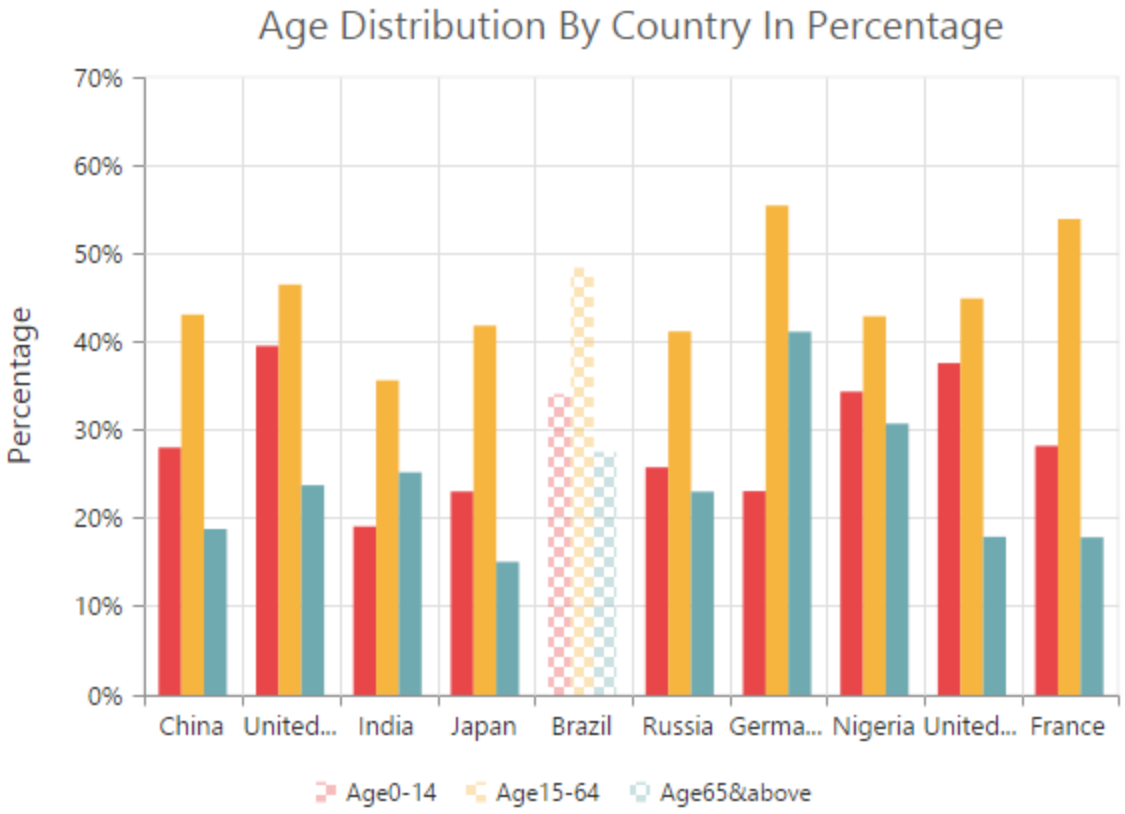
Cluster mode

To select the points that corresponds to the same index in all the series, set the **Cluster** value to the *Mode* option.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the selection settings
.Series(sr =>
{
sr
.SelectionSettings(ss => ss
//Change selection mode
.Mode(ChartMode.Cluster)
//...
.Enable(true)
).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Range mode

To fetch the selected area data points value, you can set the selectionSettings Mode as **Range** in the chart series. The selection rectangle can be drawn as horizontally, vertically or in both direction by using **RangeType** property and the selected data's are returned as an array collection in the **RangeSelected** event.

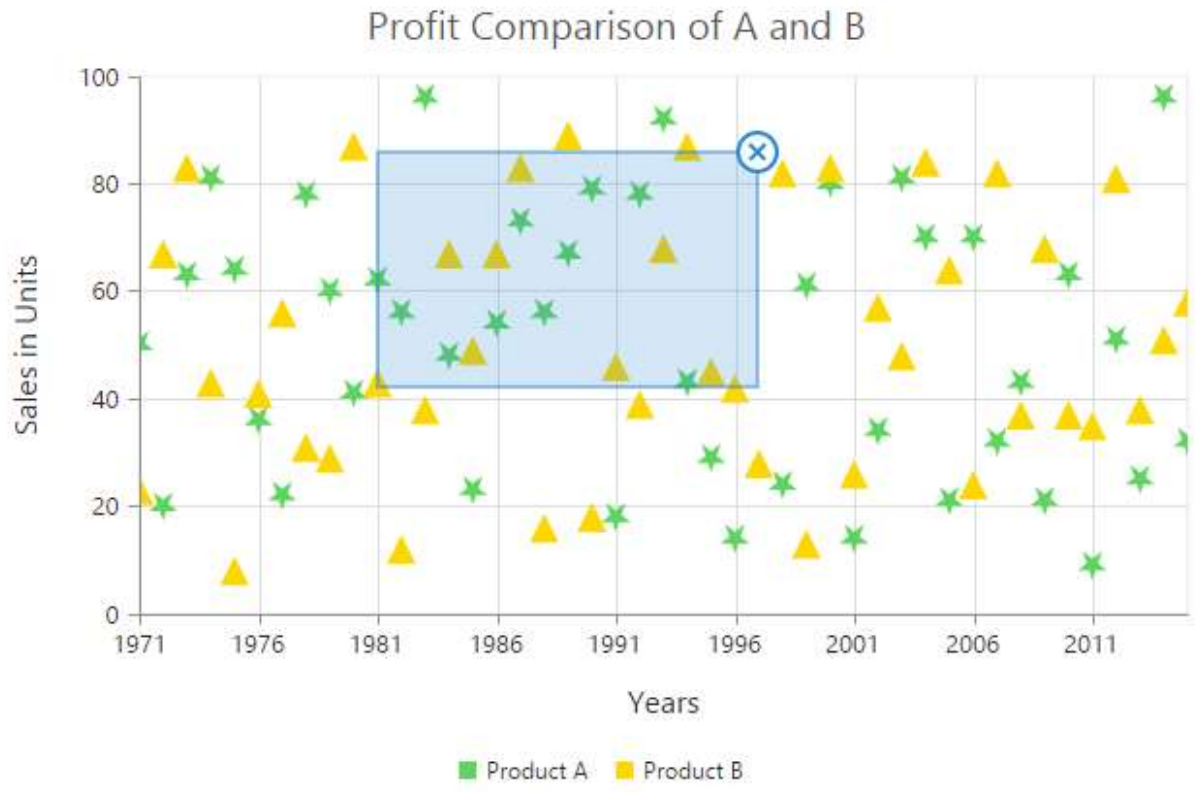
ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the selection settings
.Series(sr =>
{
sr
.SelectionSettings(ss => ss
//Change selection mode
.Mode(ChartMode.Range)
.RangeType(MultiSelectType.XY)
//...
.Enable(true)
).Add();
})
//Subscribe the rangeSelected event.
.RangeSelected("rangeSelection")
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
//event to fetch the selected data point values
rangeSelection:function (sender){
var selectedData = sender.data.selectedDataCollection;
//...
}
```



Click here to view the Multiple data selection online demo sample.

Selection Type

You can set two different selection type for selecting the data point and series on mouse click by using the **Type** property of the SelectionSettings.

- Single
- Multiple

Single Type

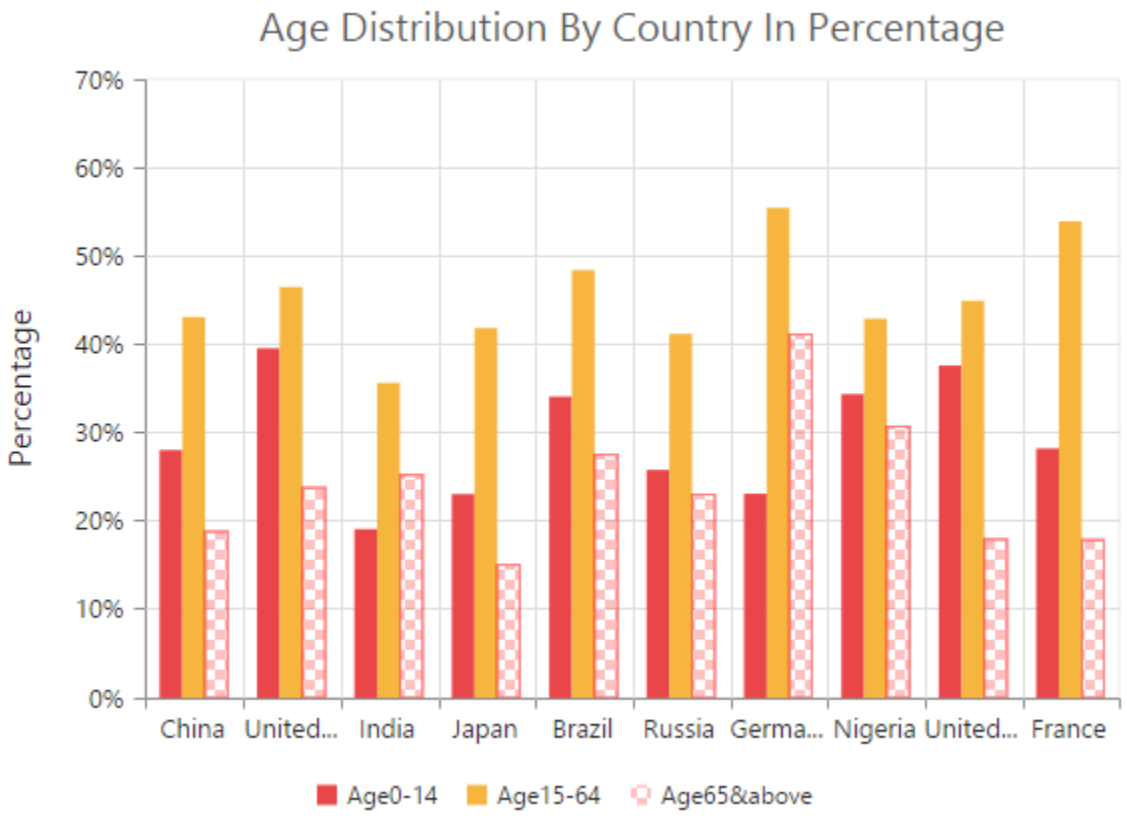
To select a data point or a series on mouse click based on the **SelectionSettings.Mode**, set **SelectionSettings.Type** as **Single** in the series.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.CommonSeriesOptions(
cm => cm.SelectionSettings(
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
selection => selection.Enable(true)
//Selection mode is series or point ,cluster
.Mode(ChartMode.Series)
//Selection type is single
.Type(ChartSelectionType.Single))
)
//...
)
```



Multiple Type

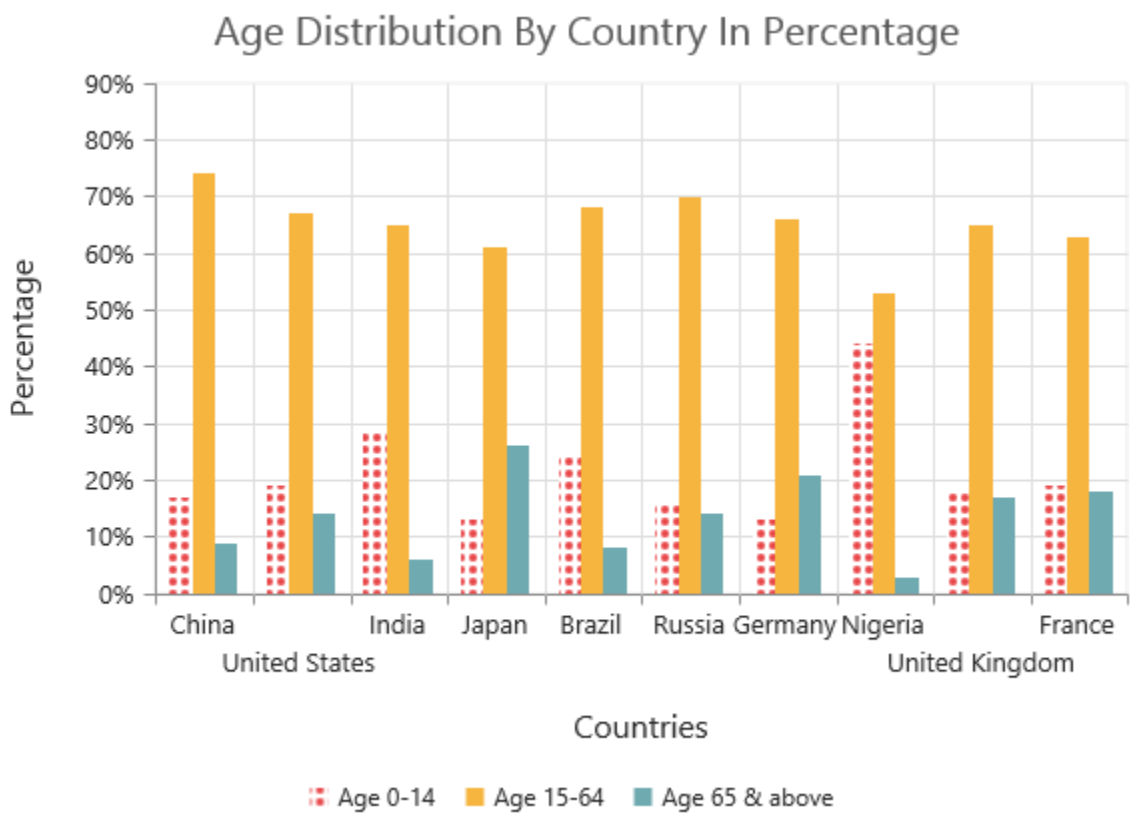
For selecting multiple data points or series on mouse click, set **SelectionSettings.Type** as **Multiple** in the series.

ASPX-CS

```
@(Html.EJ().Chart("container")
//...
.CommonSeriesOptions(
cm => cm.SelectionSettings(
selection => selection.Enable(true)
//Selection mode is series or point, cluster
.Mode(ChartMode.Series)
//Selection type is multiple
.Type(ChartSelectionType.Multiple))
)
//...
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

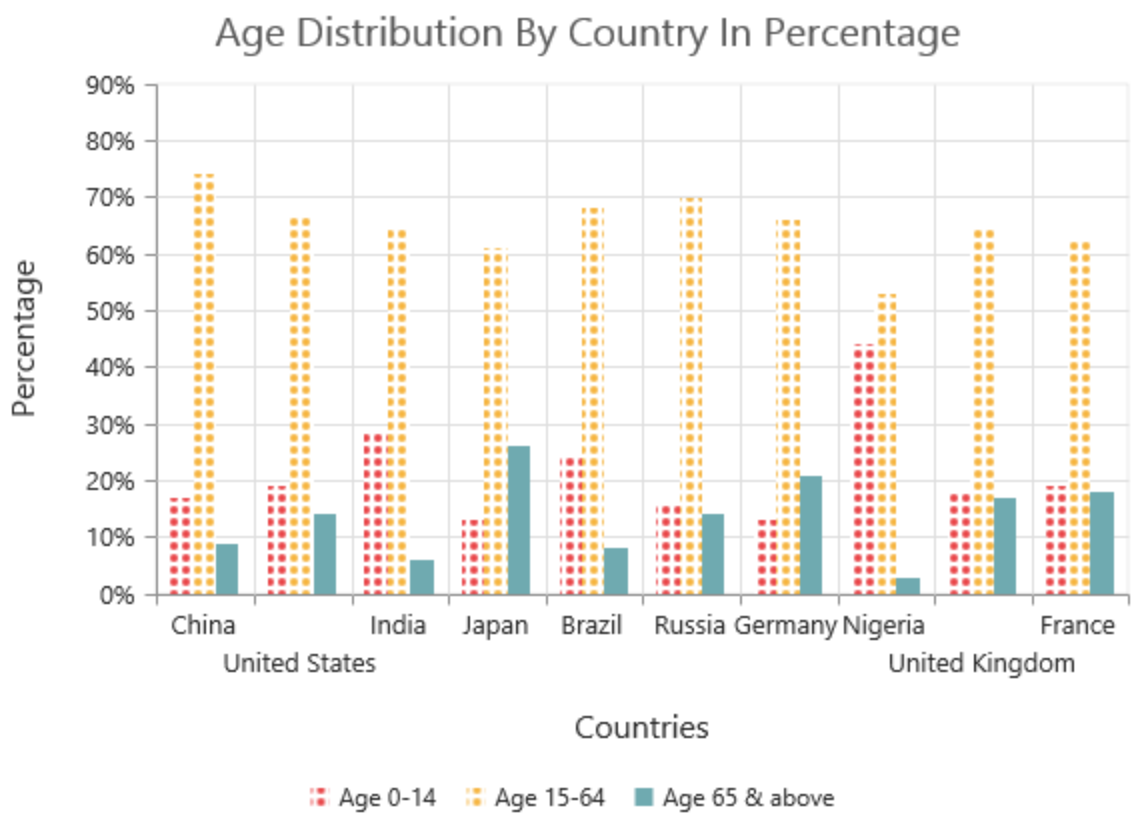


Customizing selection styles

To customize the selection styles, use the *Color*, *Border* and *Opacity* options in the SelectionSettings.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the selection settings
.Series(sr =>
{
sr
.SelectionSettings(ss => ss
//Customizing selection rectangle styles
.Border(br=>br.Width(1.5).Color("red"))
.Opacity(0.5).Color("red")
.Enable(true)
).Add();
})
)
```



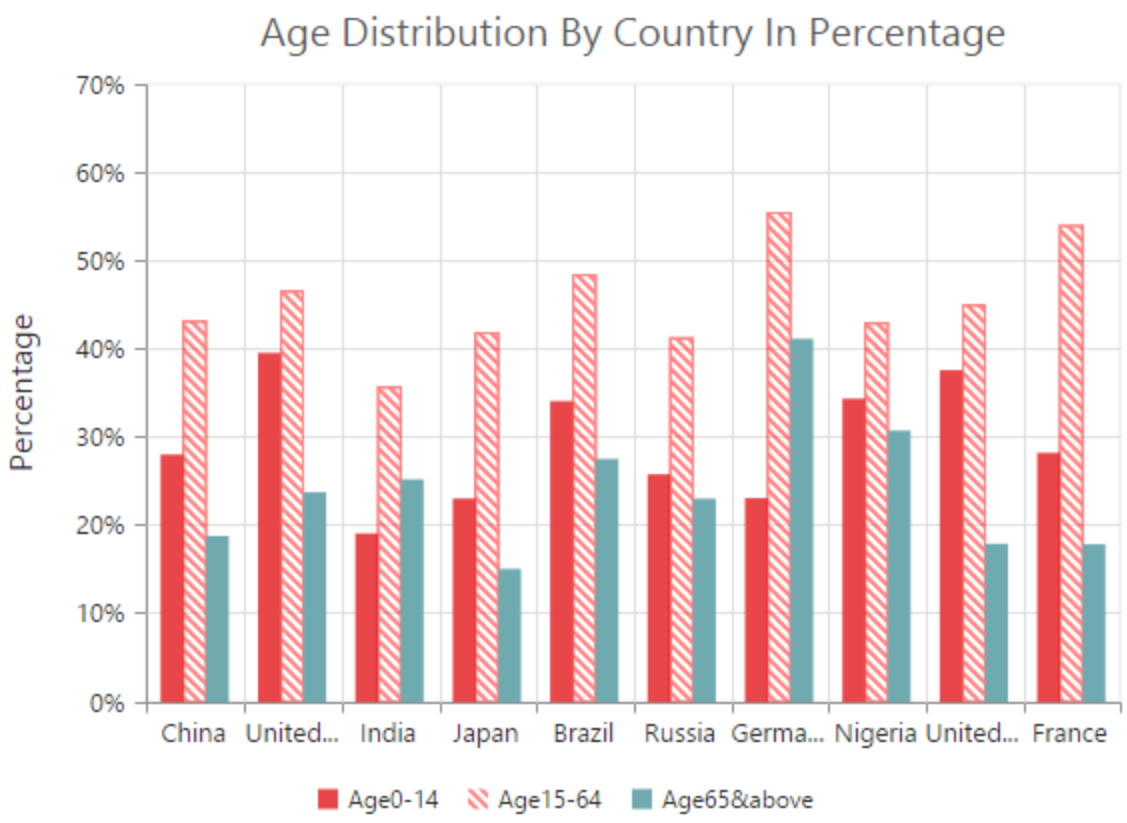
Patterns for selection

EjChart provides pattern support for the data selection by setting the value to the **Pattern** property of the SelectionSettings. The different types of selection patterns are as follows.

1. Chessboard 2. Crosshatch 3. Dots 4. Pacman 5. Grid 6. Turquoise 7. Star 8. Triangle 9. Circle 10. Tile 11. HorizontalDash 12. VerticalDash 13. Rectangle 14. Box 15. VerticalStripe 16. HorizontalStripe 17. Bubble 18. DiagonalBackward 19. DiagonalForward

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the selection settings
.Series(sr =>
{
sr
.SelectionSettings(ss => ss
//Change selection pattern
.Pattern(ChartPattern.DiagonalForward)
.Enable(true)
).Add();
})
)
```



Custom pattern

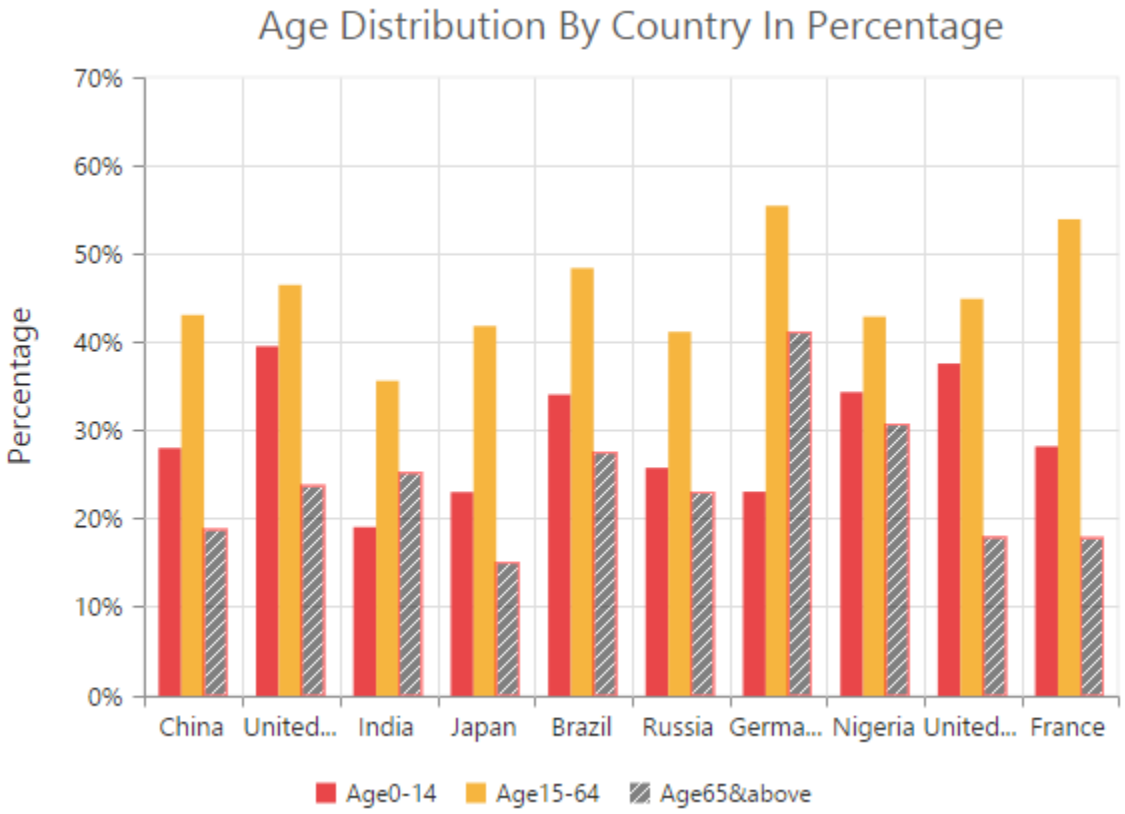
To create a custom pattern for selecting the data points, set the *Pattern* type as **Custom** and add the custom pattern *id* in the **CustomPattern** option of the SelectionSettings.

ASPX-CS

```
<div id="container"></div>
<svg>
<pattern id="dots_a" patternUnits="userSpaceOnUse" width="6" height="6">
<rect x="0" y="0" width="6" height="6" transform="translate(0,0)"
fill="black" opacity="1"></rect>
<path d='M 3 -3 L -3 3 M 0 6 L 6 0 M 9 3 L 3 9'stroke-width="1"
stroke="white"></path>
</pattern>
</svg>
@(Html.EJ().Chart("chartContainer")
//...
// enable the selection settings
.Series(sr =>
{
sr
.SelectionSettings(ss => ss
//Add custom pattern for selection data
.Pattern(ChartPattern.Custom)
.CustomPattern("dots_a")
.Enable(true)
).Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```



Handling Series Selection

To get the series information when selecting the specific series, subscribe to the **SeriesRegionClick** event and set the **SelectionSettings.Mode** as *Series*.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
// enable the selection settings
.Series(sr =>
{
sr
.SelectionSettings(ss => ss
//Change selection mode
.Mode(ChartMode.Series)
//...
.Enable(true)
).Add();
})
//Subscribe series selection event
.SeriesRegionClick("seriesSelection")
)
```

JS

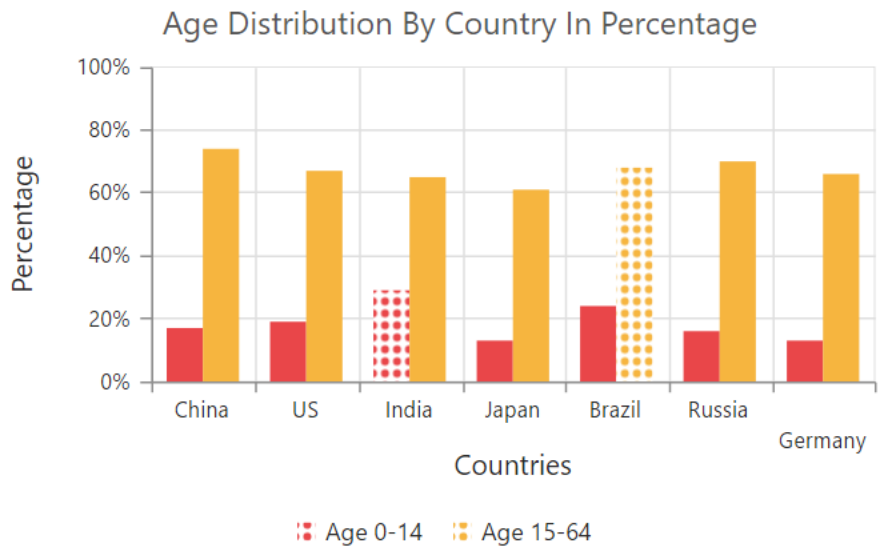
```
function seriesSelection(sender) {
//Get Series information on series selection
var seriesData = sender.series;
}
```

Selection on Load

We can able to select the point/series programmatically on chart load, by setting series and point index in the selectedDataPointIndexes property.

JAVASCRIPT

```
@(Html.EJ().Chart("chartContainer")
//.... . .
.SelectedDataPointIndexes(sr => {
//Adding Selected Data point indexes
sr.SeriesIndex("0").PointIndex("2")
sr.SeriesIndex("1").PointIndex("4")
//.... . .
}).Add();
//.... . .
})
)
```



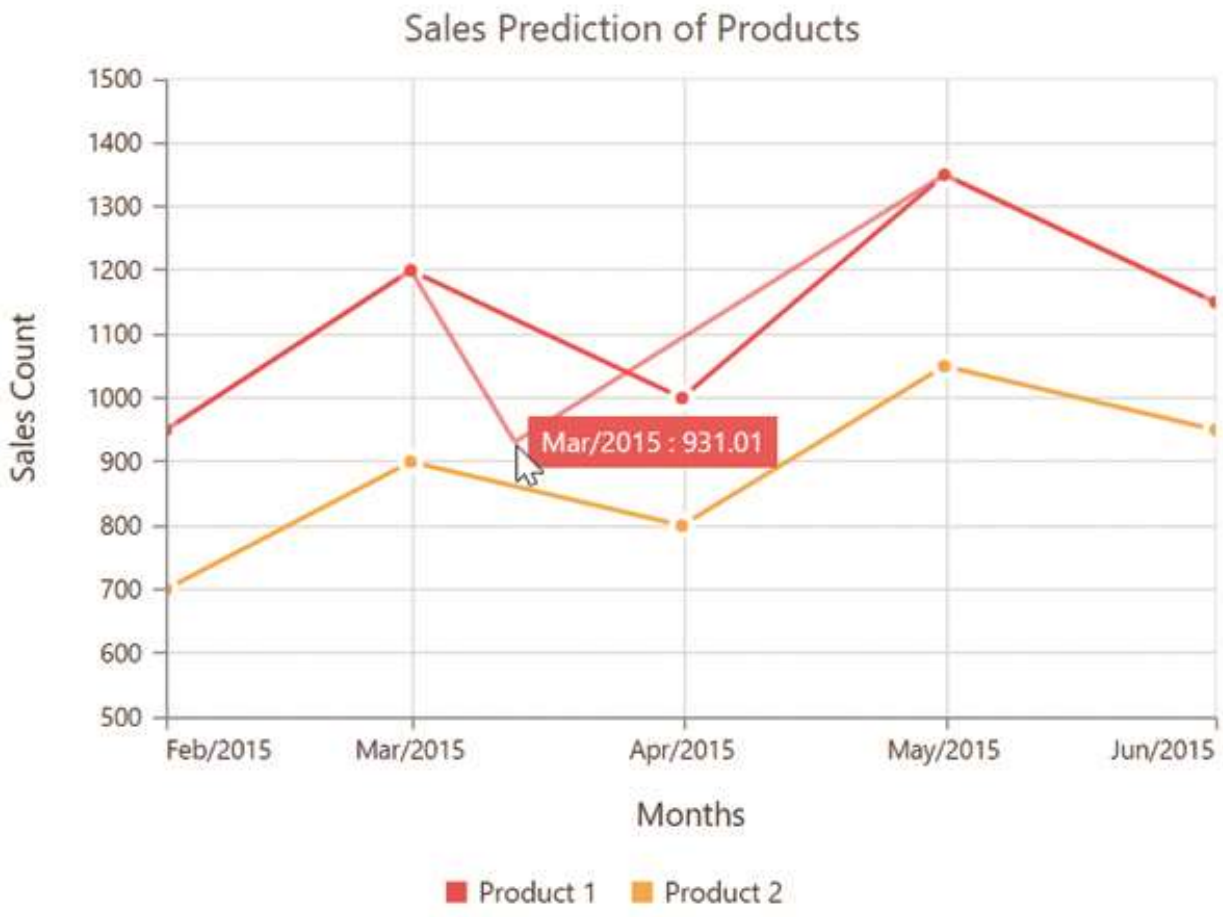
Data Editing

EjChart provides support to change the location of the rendered points. This can be done by dragging the point and dropping it on another location in chart. To enable the data editing, set the **enable** property to true in the *dragSettings* of the series.

ASPX-CS

```
@(Html.EJ().Chart("container")
.CommonSeriesOptions(options => options.DragSettings(drag =>
drag.Enable(true)))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the data editing online demo sample.

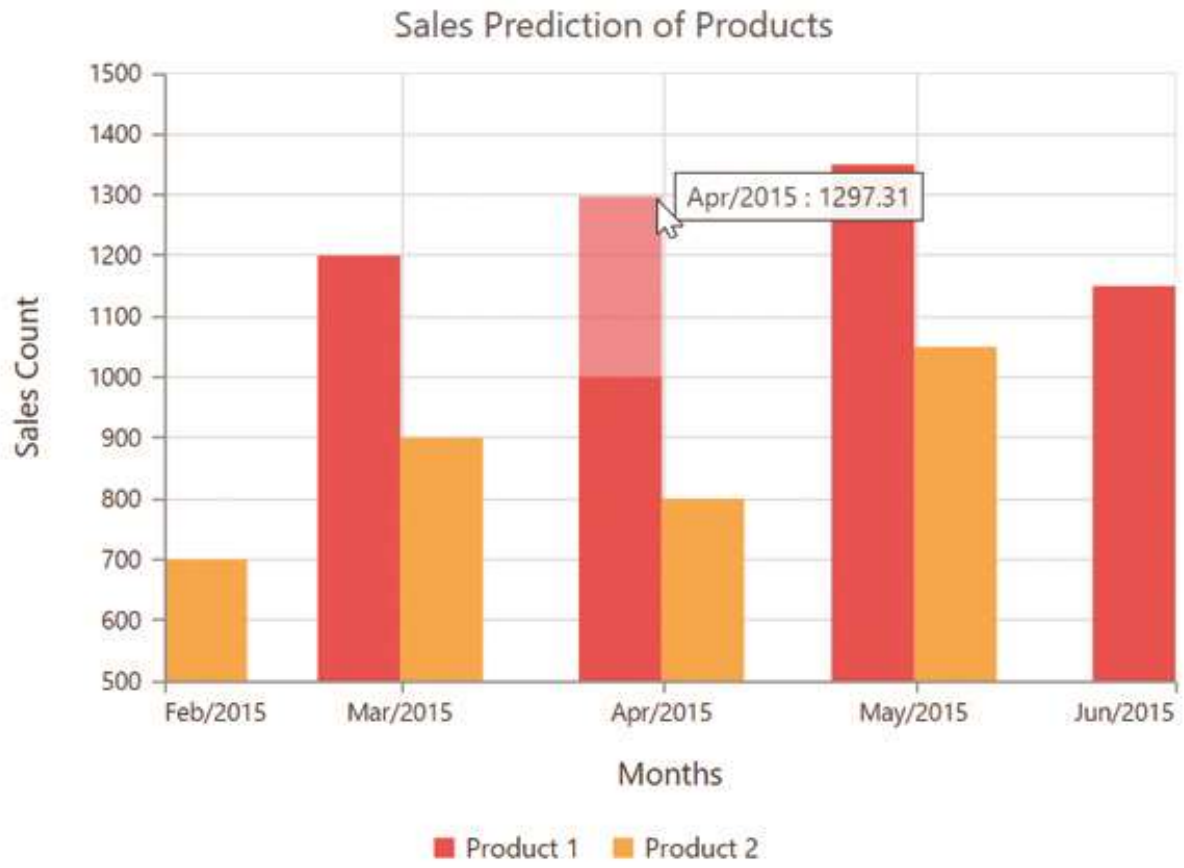
Customize Dragging direction

To drag the point along x and y axes, you can specify **type** as xy in *dragSettings*. And to drag along x axis alone, specify the type as x and to drag along y axis, specify type as y.

ASPX-CS

```
@(Html.EJ().Chart("container")
.CommonSeriesOptions(options => options.DragSettings(drag =>
drag.Type(DragType.Y)))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Performance

- When there are large number of points to load, you can enable canvas rendering mode in chart. Canvas rendering is faster than SVG because it does not involve manipulating DOM elements as much as SVG rendering.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Enable Canvas rendering mode
.EnableCanvasRendering(true)
//...
)
```

Click here to view the online demo sample that shows Chart performance with 100,000 data points.

- Instead of enabling data markers and labels when there are large number of data points, you can use **Trackball** and **Tooltip** to view point information.

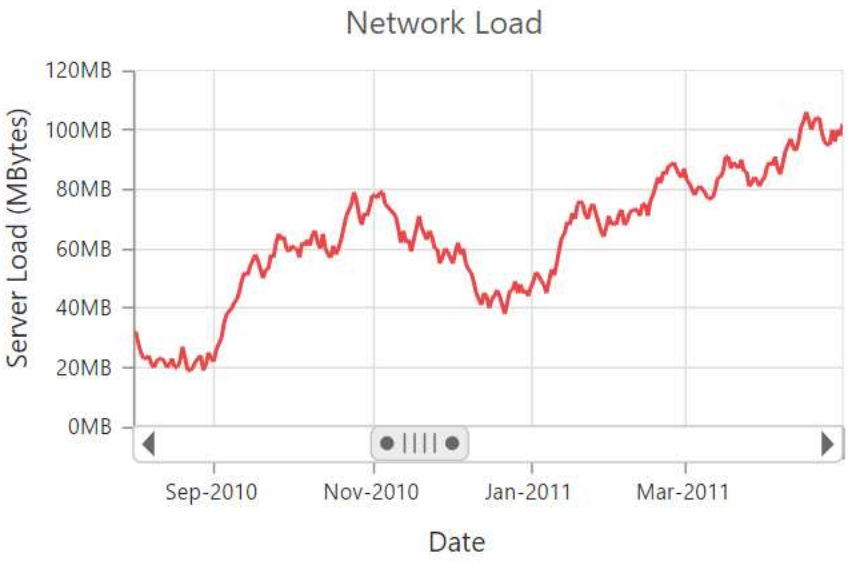
Copyright © 2001 - 2020 Syncfusion Inc.

Lazy Loading

Lazy loading feature provides an effective way for loading data on demand by scrolling and viewing a smaller range of data from a larger collection.

JAVASCRIPT

```
@(Html.EJ().Chart("chartContainer")
// Enable to zoom and scrollbar option
.PrimaryXAxis(axis => axis.ScrollbarSettings(scroll =>
scroll.Visible("true")
.CanResize("true")
.Range(range => range.Min("2009/1/1").Max("2014/1/1"))))
//  ..
)
```



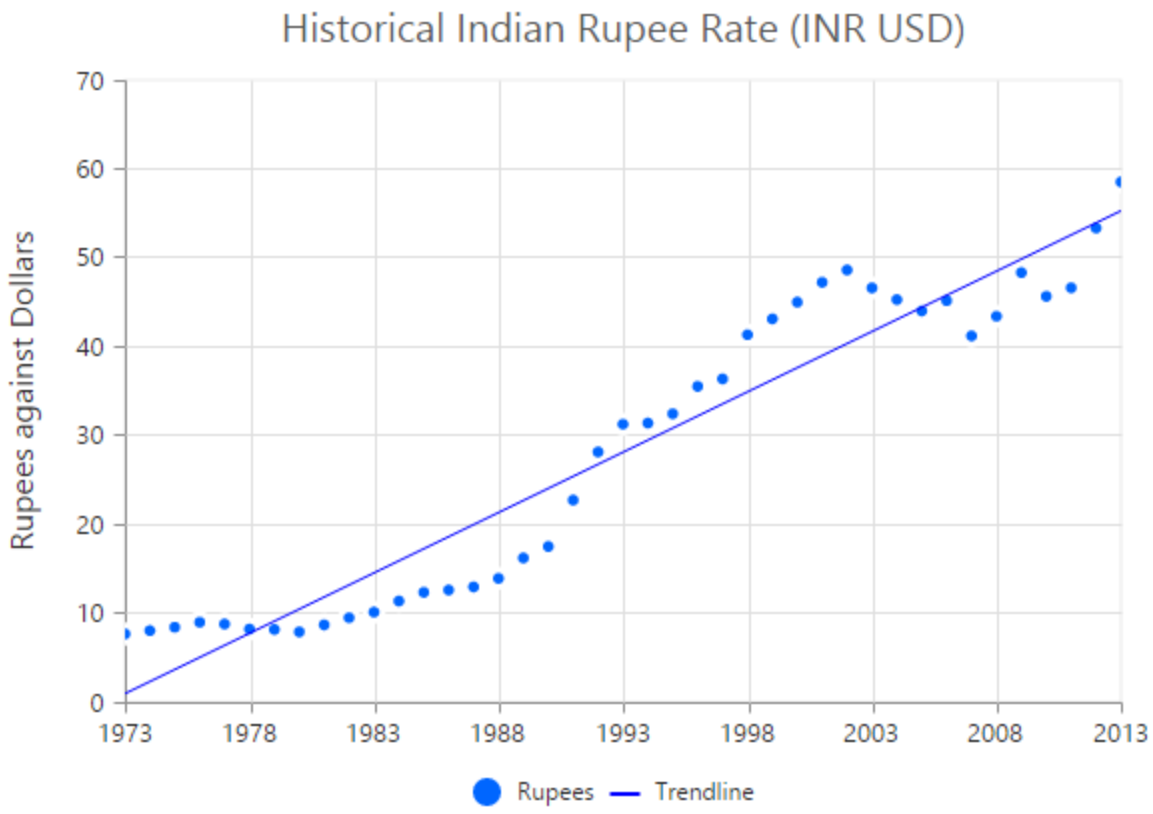
Trendlines

EjChart can generate Trendlines for Cartesian type series *(Line, Column, Scatter, Area, Candle, HiLo etc.)* except Bar type series. You can add more than one trendline object to the **Trendlines** option.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Enable Trendline to chart series
.Visibility("visible").Add();
}).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



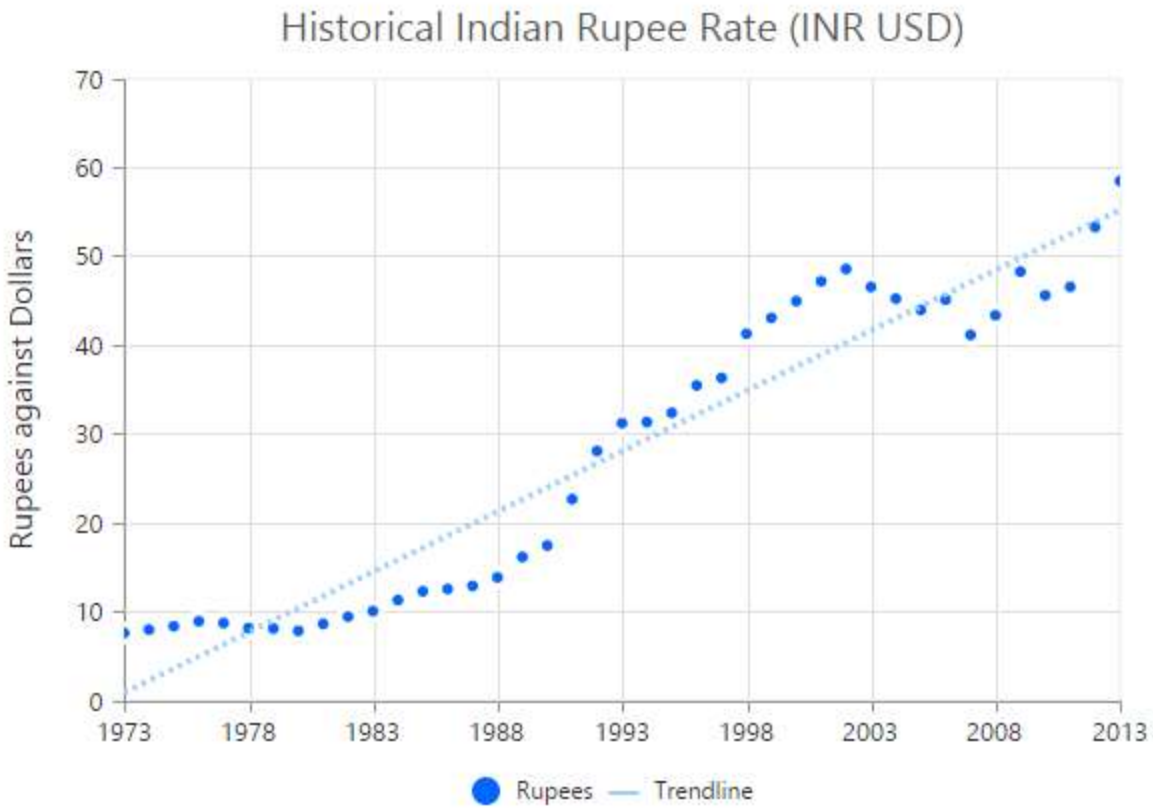
Click here to view the Trendlines online demo sample.

Customize the trendline styles

A trendline can be customized by using the properties such as *Fill*, *Width*, *DashArray* and *Opacity*. The default type of Trendline is **Linear**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Customize the Trendline styles
.Fill("#99CCFF").Width(3).Opacity(1).DashArray("2,3").Add();
}).Add();
})
//...
)
```



Types of Trendline

EjChart supports the following type of Trendlines.

- Linear
- Exponential
- Logarithmic
- Power
- Polynomial
- MovingAverage

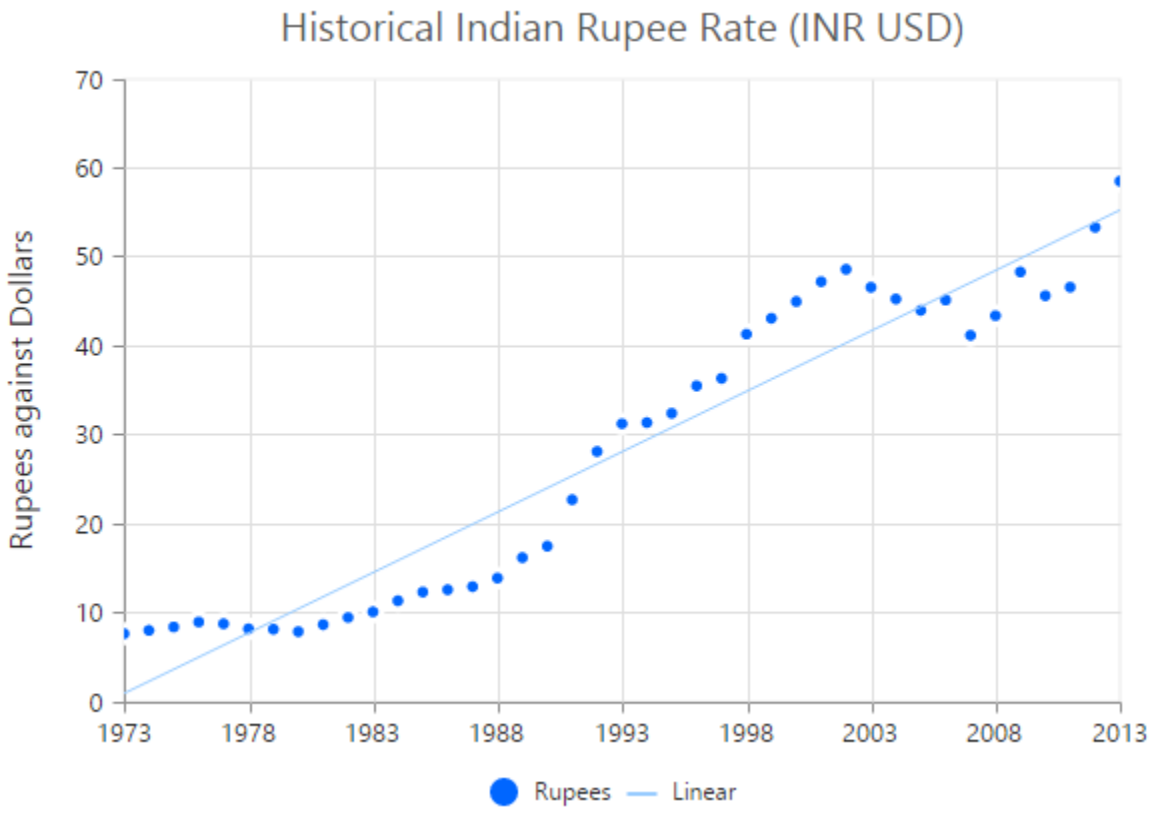
Linear

To render Linear Trendline, you have to set the **Type** as *Linear*.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Change Trendline type
.Type(TrendlineType.Linear).Add();
```

```
}).Add();
})
//...
)
```

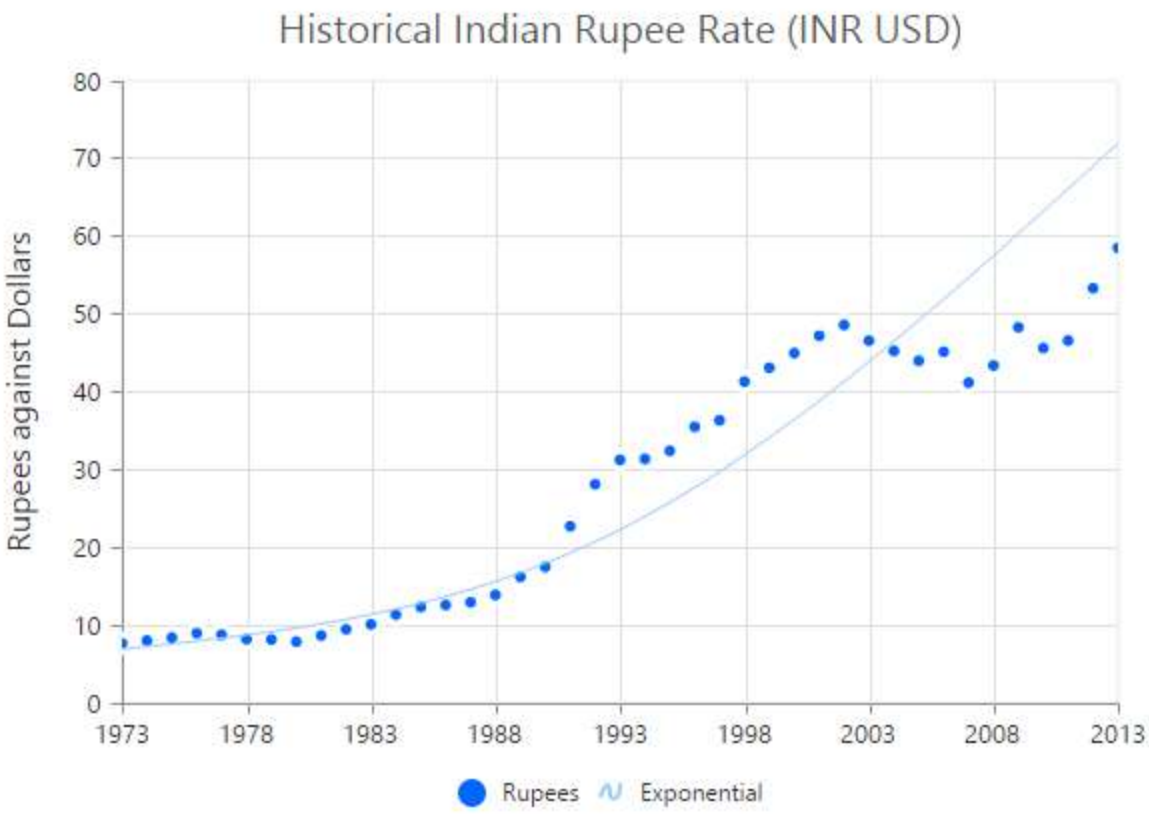


Exponential

Exponential Trendline can be rendered by setting the *Type* as Exponential.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Change Trendline type
.Type(TrendlineType.Exponential).Add();
}).Add();
})
//...
)
```



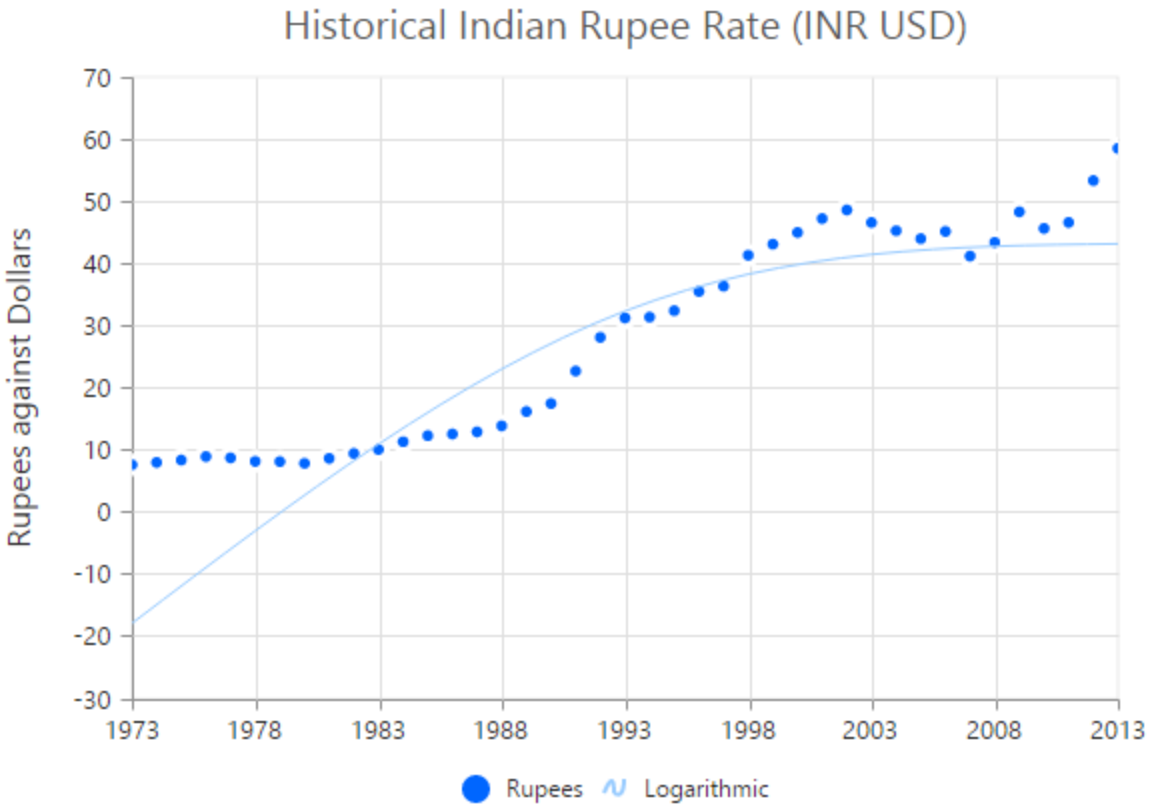
Logarithmic

Logarithmic Trendline can be rendered by setting the *Type* as Logarithmic.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Change Trendline type
.Type(TrendlineType.Logarithmic).Add();
}).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



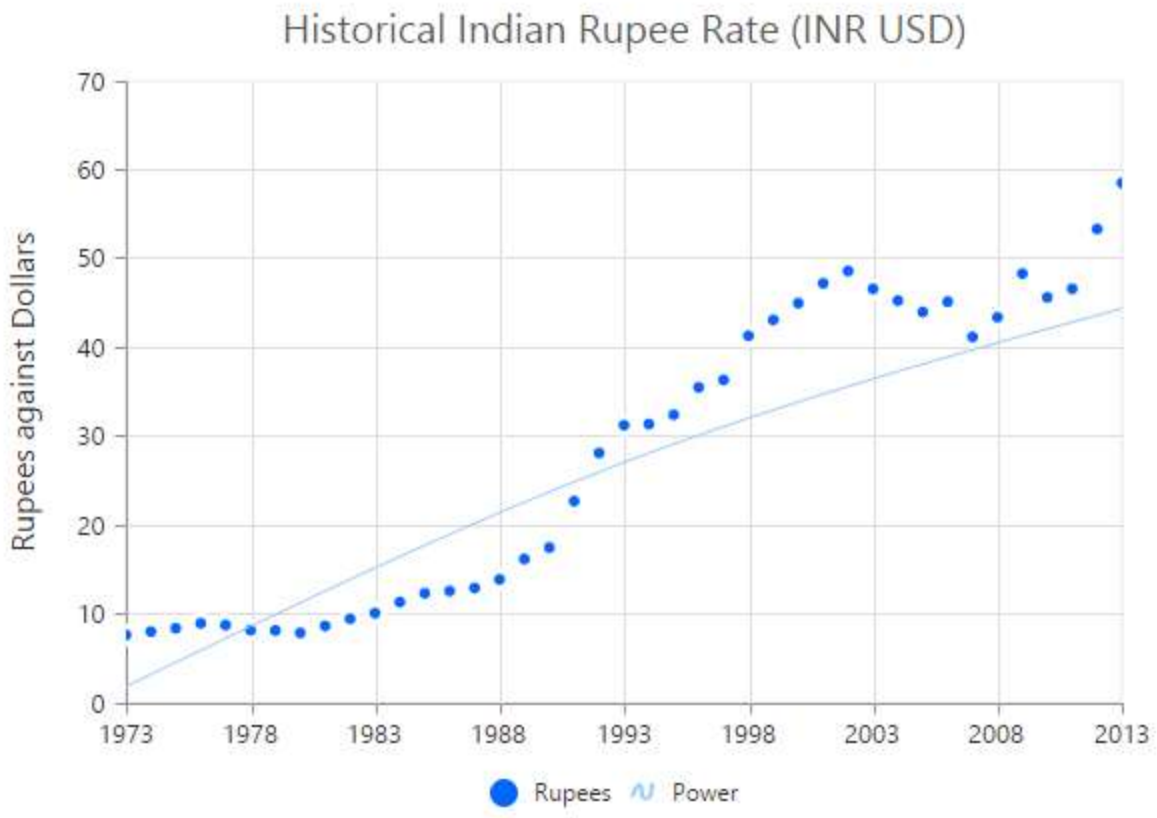
Power

Power Trendline can be rendered by setting the *Type* of the trendline as Power.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Change Trendline type
.Type(TrendlineType.Power).Add();
}).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

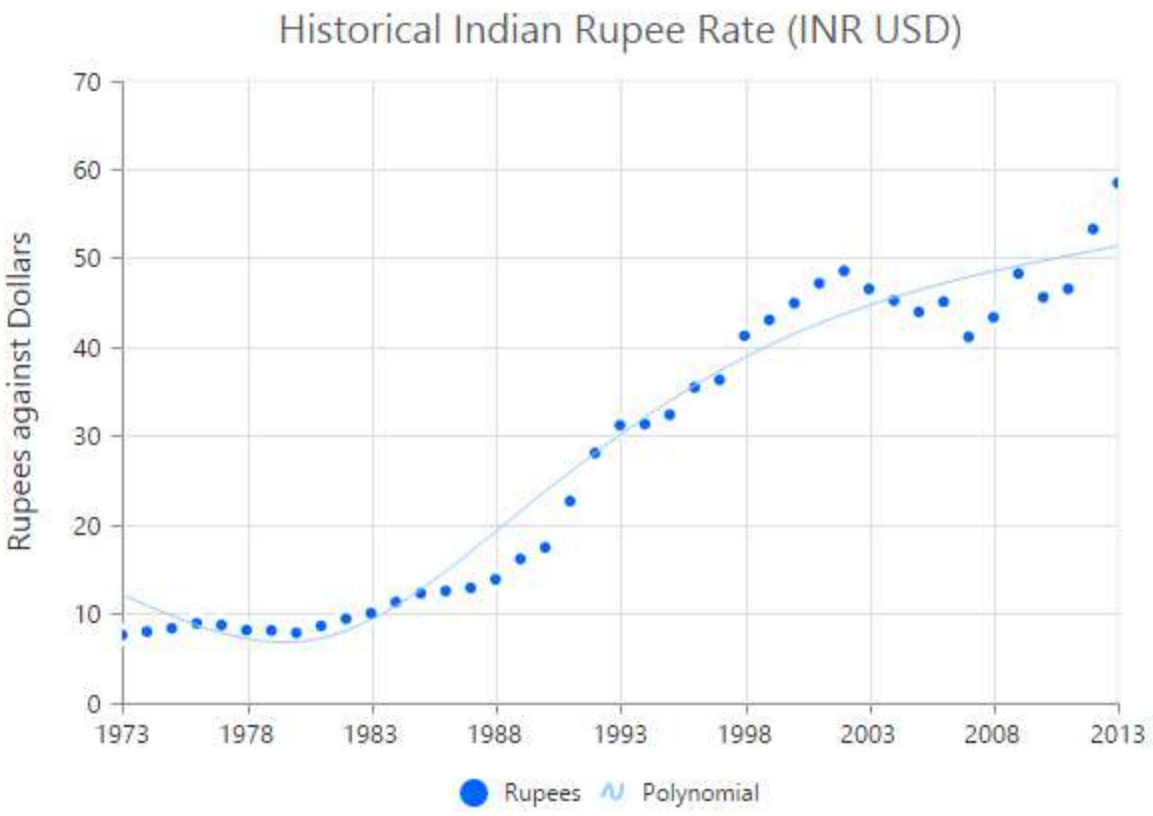


Polynomial

Polynomial Trendline can be rendered by setting the trendline *Type* as Polynomial. You can change the polynomial order by using the **PolynomialOrder** of the trendlines. It ranges from 2 to 6.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Change Trendline type
.Type(TrendlineType.Polynomial).Add();
}).Add();
})
//...
)
```

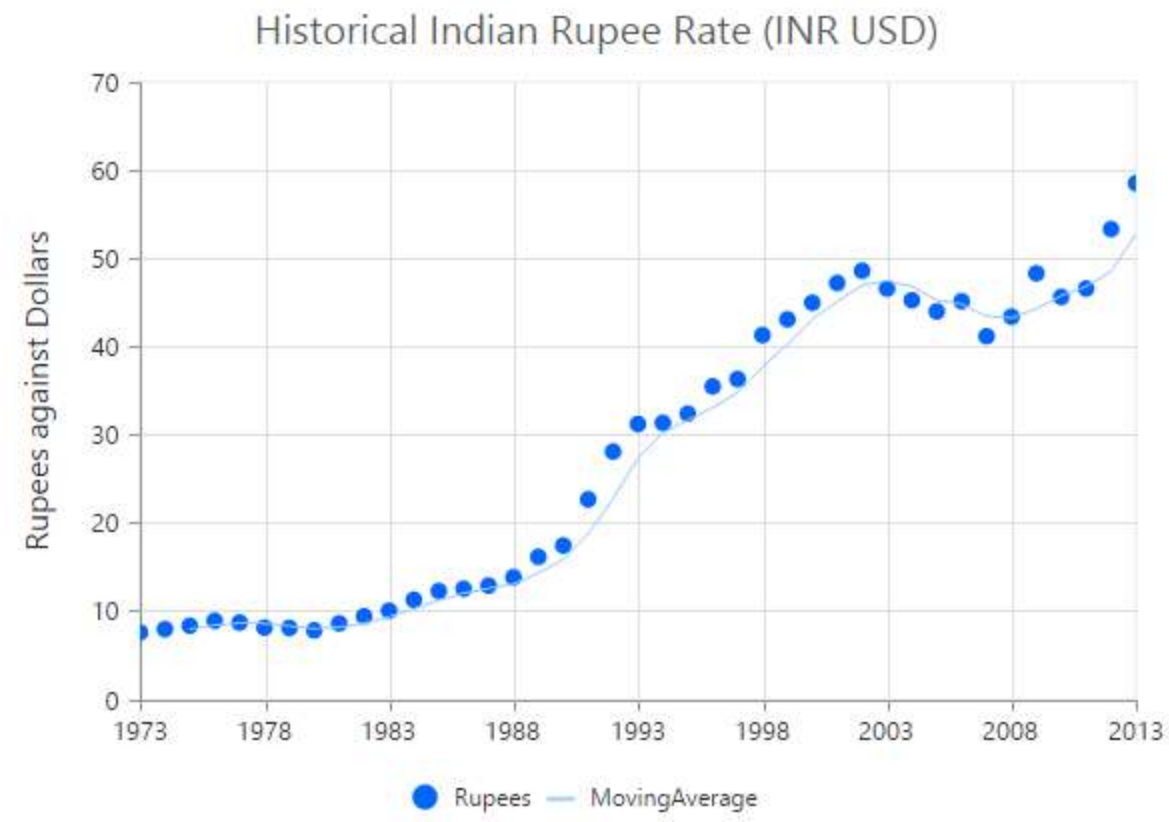


MovingAverage

MovingAverage Trendline can be rendered by setting the Type of the trendline as **MovingAverage**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Change Trendline type
.Type(TrendlineType.MovingAverage).Add();
}).Add();
})
//...
)
```



Forecasting

Trendline forecasting is the prediction of future/past situations. **Forecasting** can be classified into two types as follows.

- Forward Forecasting
- Backward Forecasting

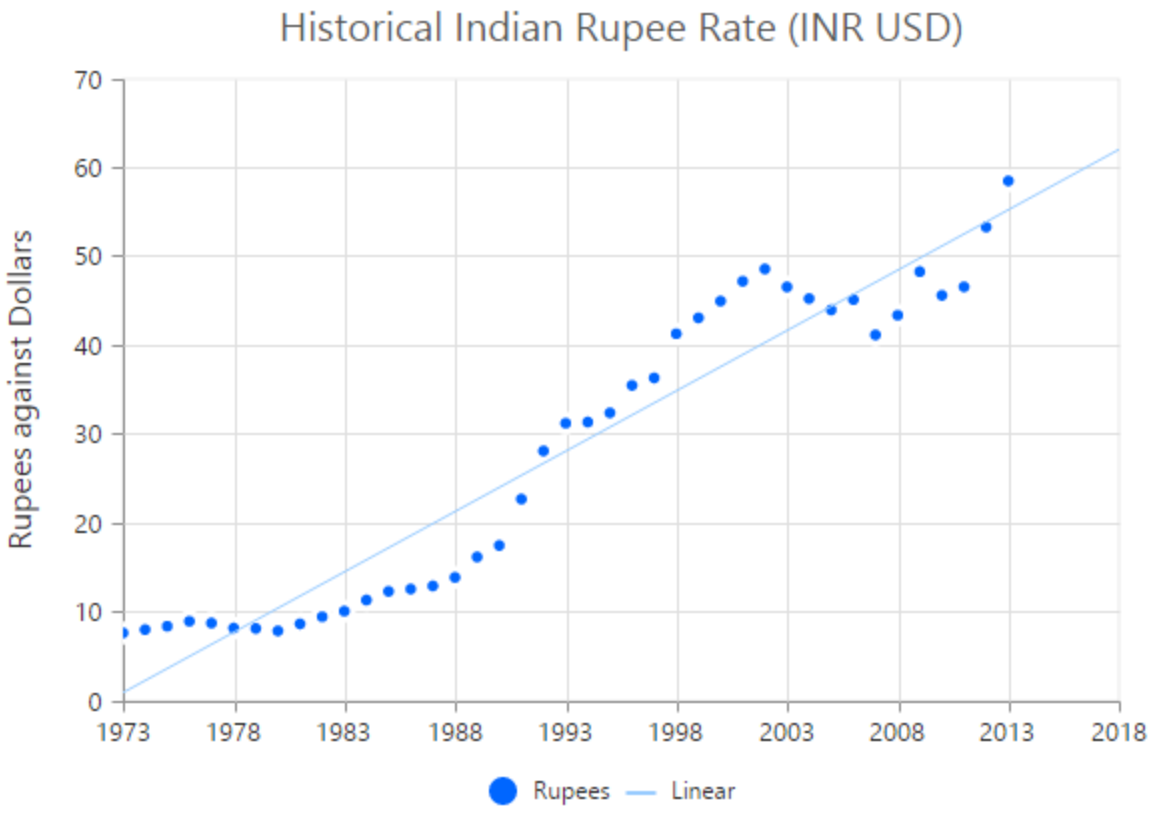
Forward Forecasting

The value set for **ForwardForecast** is used to determine the distance moving towards the future trend.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Set forward forecasting value
.ForwardForecast(5).Add();
}).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



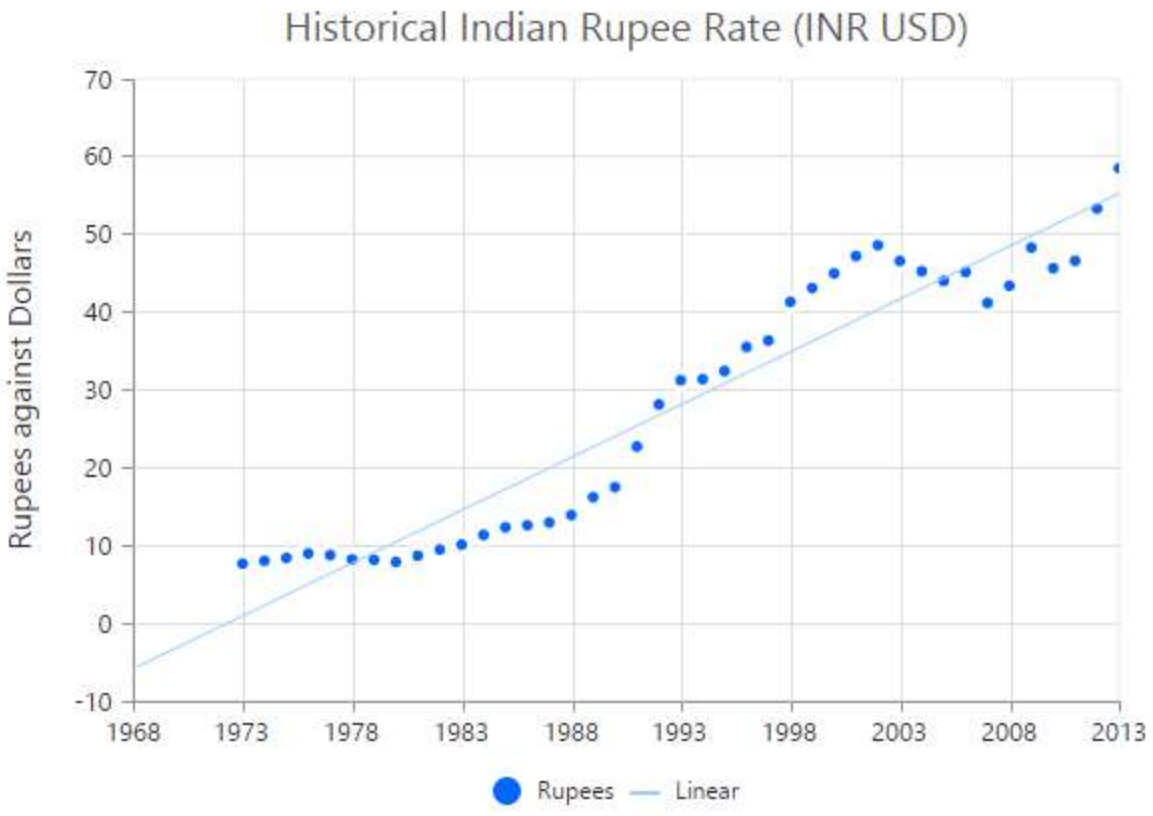
Backward Forecasting

The value set for the **BackwardForecast** is used to determine the past trends.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Set backward forecasting value
.BackwardForecast(5).Add();
}).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



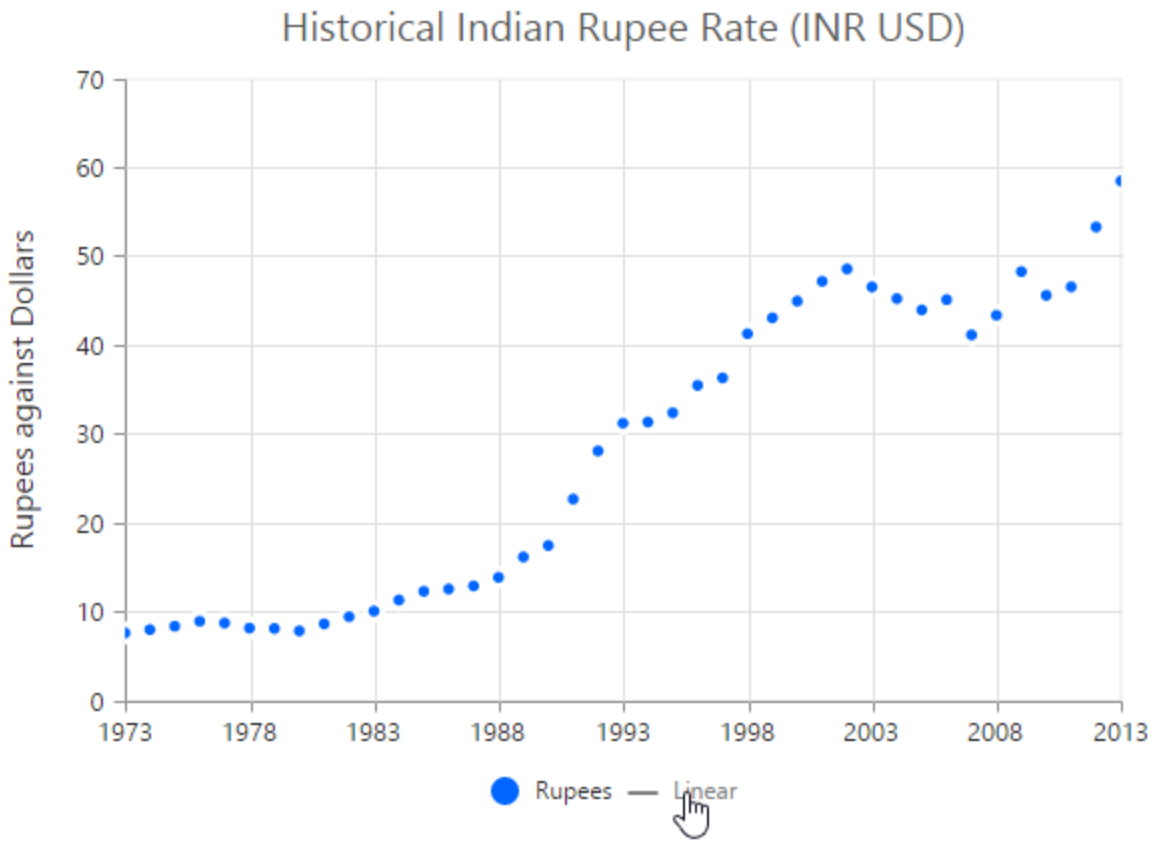
Trendlines Legend

To display the legend item for trendline, use the **Name** property. You can interact with the trendline legends similar to the series legends *(show/hide trendlines on legend click)*.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//...
.Series(sr =>
{
sr
.Trendlines(trendline =>
{
trendline
//Set Trendline name to display in the legend
.Name("Linear").Add();
}).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Technical Indicators

EjChart control supports 10 types of technical indicators.

Bind data to render the indicator

You can bind the series **DataSource** to the indicator by setting the specific series name to the indicator by using the *Indicators.SeriesName* property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
sr
.XName("XDate").High("High").Low("Low").Open("Open").Close("Close")
//Set name to series
.Name("Hilo")
.DataSource(ViewBag.ChartData).Add();
})
//Initializing Indicators
.Indicators(ind => { ind
//Set HiLo series dataSource to indicator using seriesName
.SeriesName("Hilo").Add();
})
//...
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

CSHARP

```
//// Create dataSource to chart
List<ChartData> data = new List<ChartData>();
data.Add(new ChartData("2010/7/1", 38, 10, 58, 27));
data.Add(new ChartData("2010/7/8", 28, 15, 48, 58));
data.Add(new ChartData("2010/7/9", 54, 35, 85, 98));
data.Add(new ChartData("2010/7/10", 52, 21, 38, 85));
///...
ViewBag.ChartData = data;
```

Also, you can add data to the indicator directly by using the DataSource option of the indicator.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Indicators
.Indicators(ind => { ind
//Add dataSource to indicator directly
.XName("XDate").High("High").Low("Low").Open("Open").Close("Close")
.DataSource(ViewBag.ChartData).Add();
})
//...
)
```

Indicator Types

Accumulation Distribution

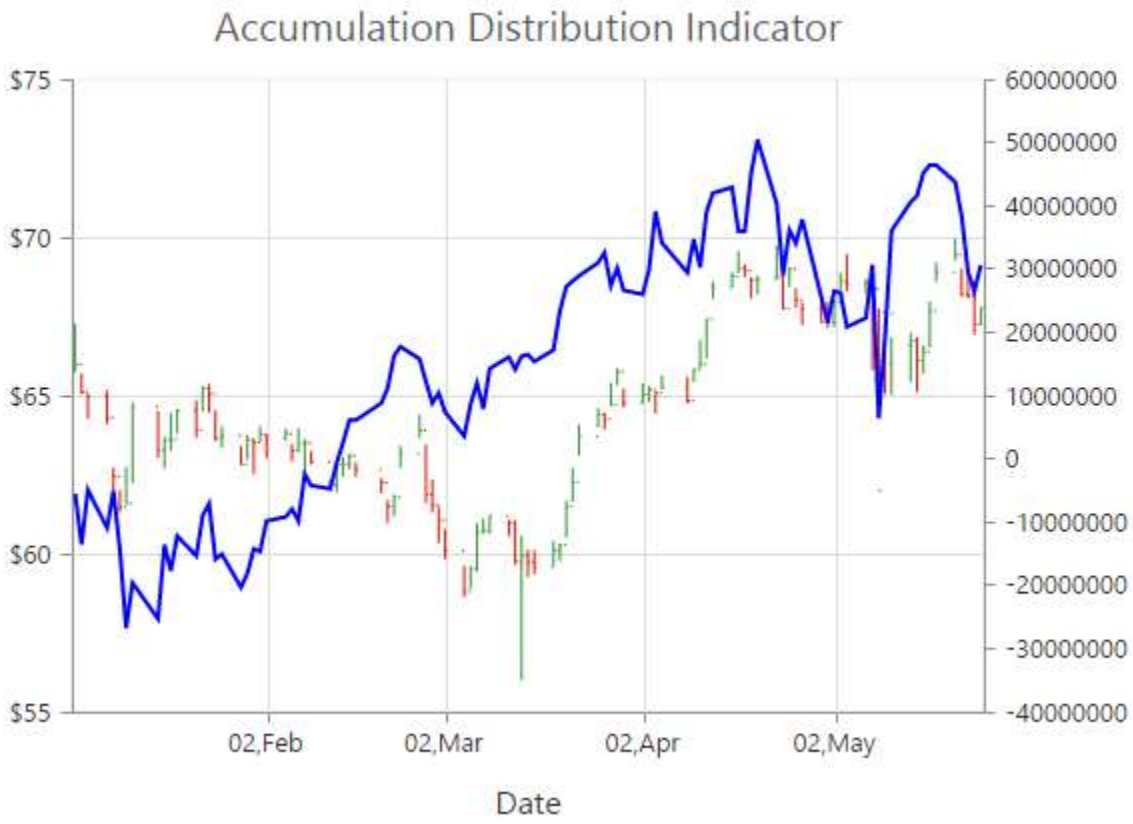
To create an Accumulation Distribution indicator, set the *Indicators.Type* as **AccumulationDistribution**. Accumulation Distribution require **Volume** field additionally with the DataSource to calculate the signal line.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
sr
.XName("XDate").High("High").Low("Low").Open("Open").Close("Close").Volume("
Volume")
//Set name to series
.Name("Hilo")
.DataSource(ViewBag.ChartData).Add();
})
//Initializing Indicators
.Indicators(ind => { ind
//Set indicator type
.Type(ChartIndicatorType.AccumulationDistribution)
.SeriesName("Hilo").Add();
})
//...
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```



Click here to view the Accumulation Distribution indicator online demo sample.

Average True Range (ATR)

You can create an ATR indicator by setting the Indicators.Type as **ATR** in the Indicators.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
//Set indicator type
.Type(ChartIndicatorType.ATR).Add();
})
//...
)
```

Click here to view the ATR indicator online demo sample.

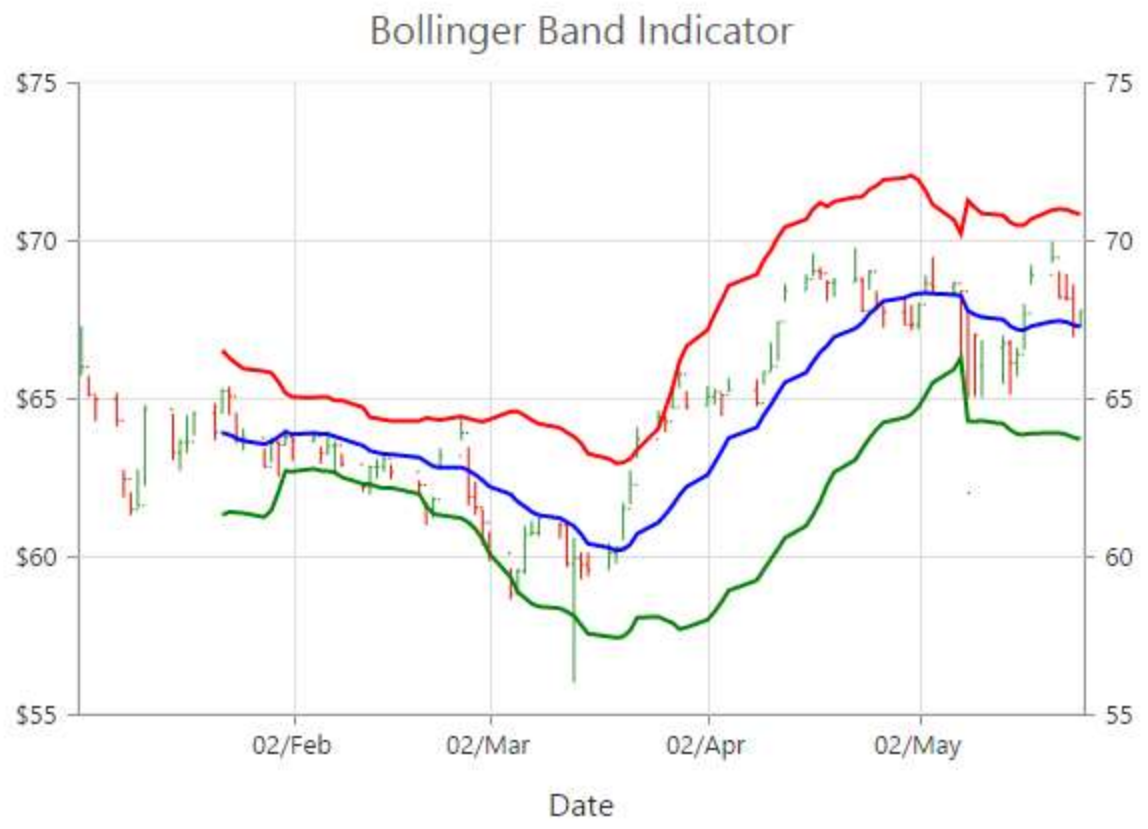
Bollinger Band

Bollinger Band indicator is created by setting the Indicators.Type as **BollingerBand**. It contains three lines, namely upper band, lower band and signal line. Bollinger Band default value of the *Period* is 14 and *StandardDeviations* is 2.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
//Set indicator type
.Type(ChartIndicatorType.BollingerBand).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Bollinger Band indicator online demo sample.

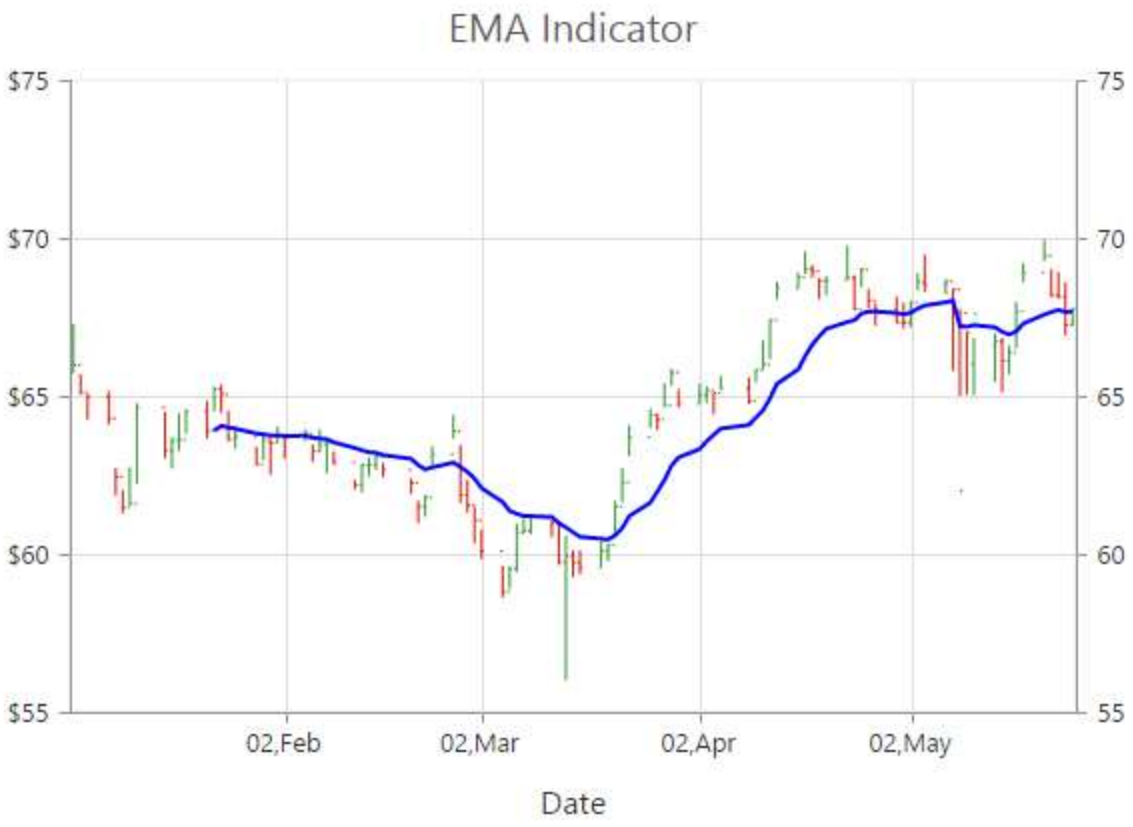
Exponential Moving Average (EMA)

To render an EMA indicator, you have to set the Indicators.Type as **EMA**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
//Set indicator type
.Type(ChartIndicatorType.EMA).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the EMA indicator online demo sample.

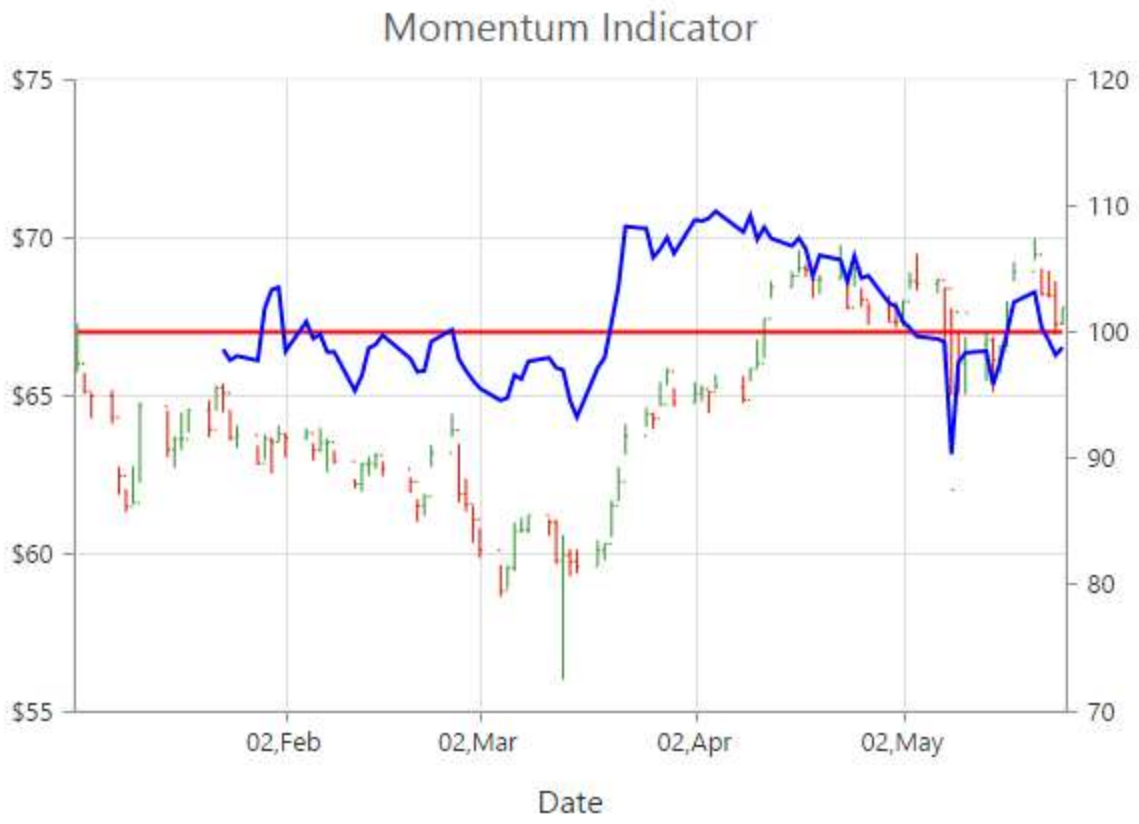
Momentum

Momentum Technical indicator is created by setting the Indicators.Type as **Momentum**. The momentum indicator renders two lines, namely upper band and signal line. Upper band always rendered at the value 100 and the signal line is calculated based on the momentum of the data.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
//Set indicator type
.Type(ChartIndicatorType.Momentum).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Momentum indicator online demo sample.

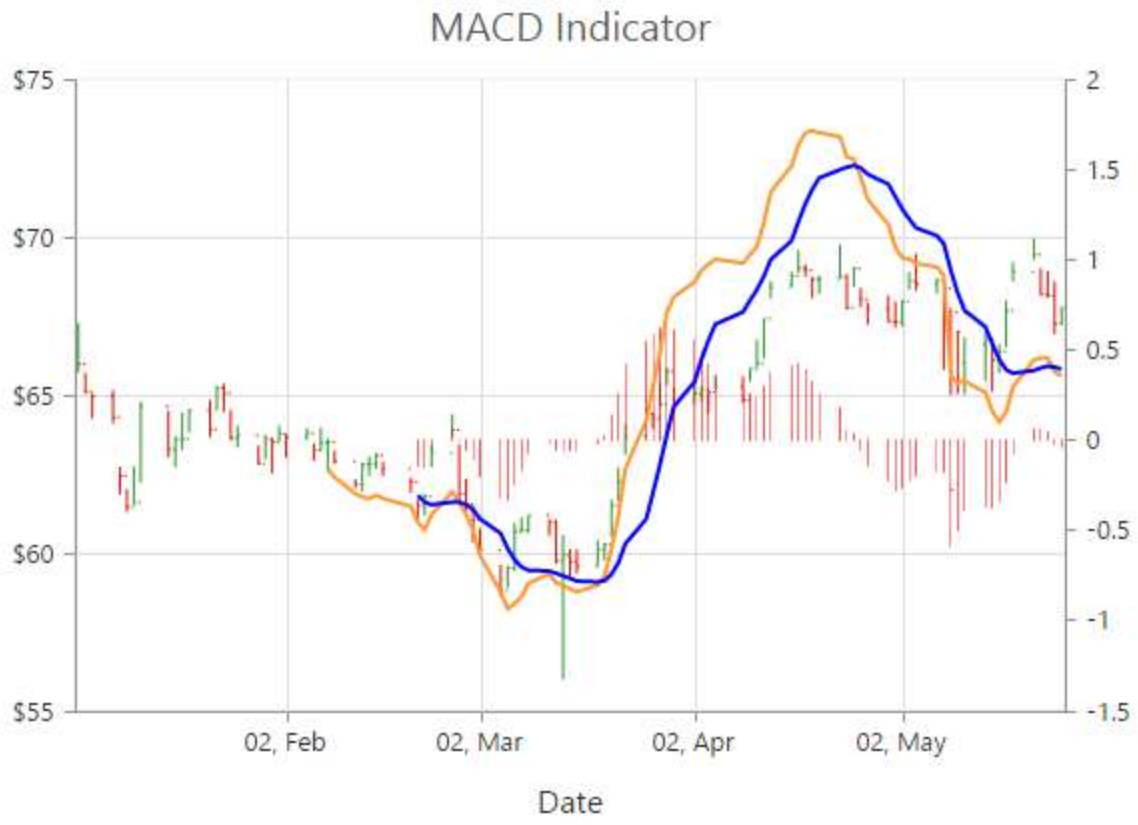
Moving Average Convergence Divergence (MACD)

To render an MACD indicator, you have to set the Indicators.Type as **MACD**. MACD indicator contains MACD line, Signal line and Histogram column. Histogram is used to differentiate MACD and signal line.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
//Set indicator type
.Type(ChartIndicatorType.MACD).Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



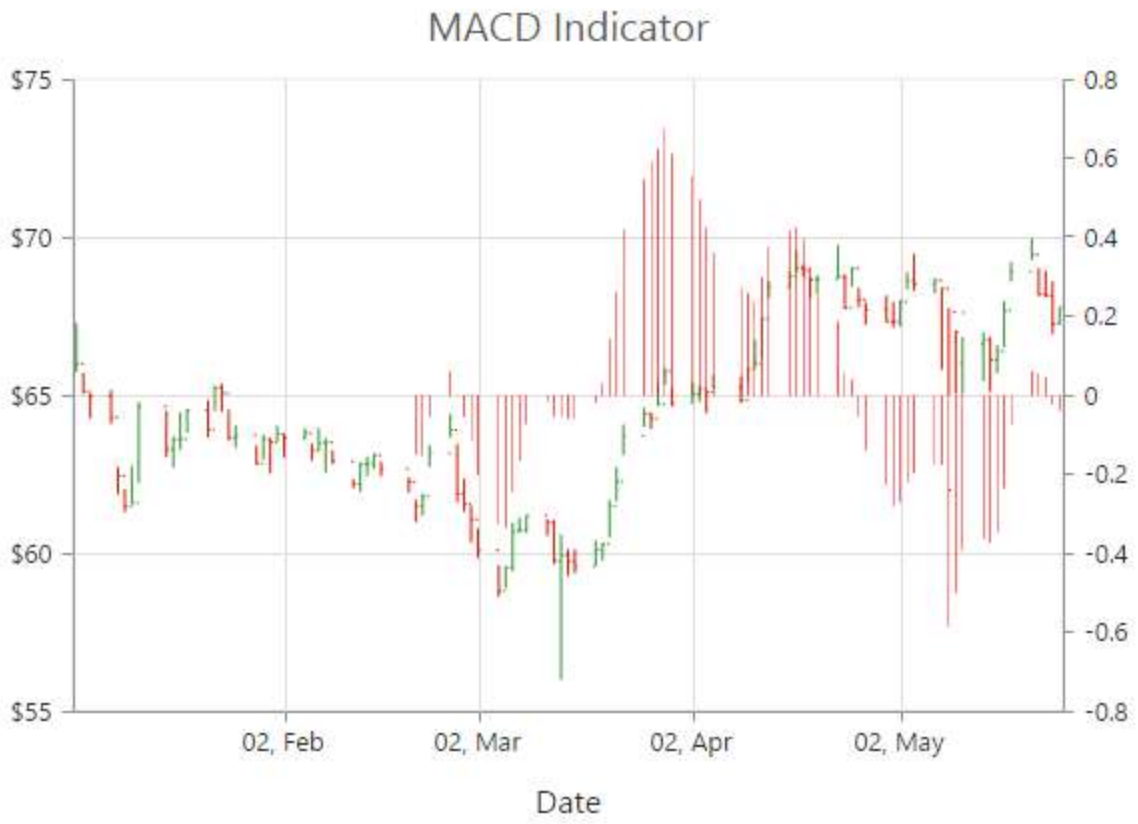
Click here to view the MACD indicator online demo sample.

MacdType

By using the **MacdType** enumeration property, you can change the MACD rendering as *Line*, *Histogram* or *Both*.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
.Type(ChartIndicatorType.MACD)
//Set MACD draw type
.MacdType(MacdType.Histogram)
.Add();
})
//...
)
```



Relative Strength Index (RSI)

To render the RSI indicator, set the Indicators.Type as **RSI**. It contains three lines, namely upper band, lower band and signal line. Upper and lower band always render at value 70 and 30 respectively and signal line is calculated based on the *RSI* formula.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
//Set indicator type
.Type(ChartIndicatorType.RSI)
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Click here to view the RSI indicator online demo sample.

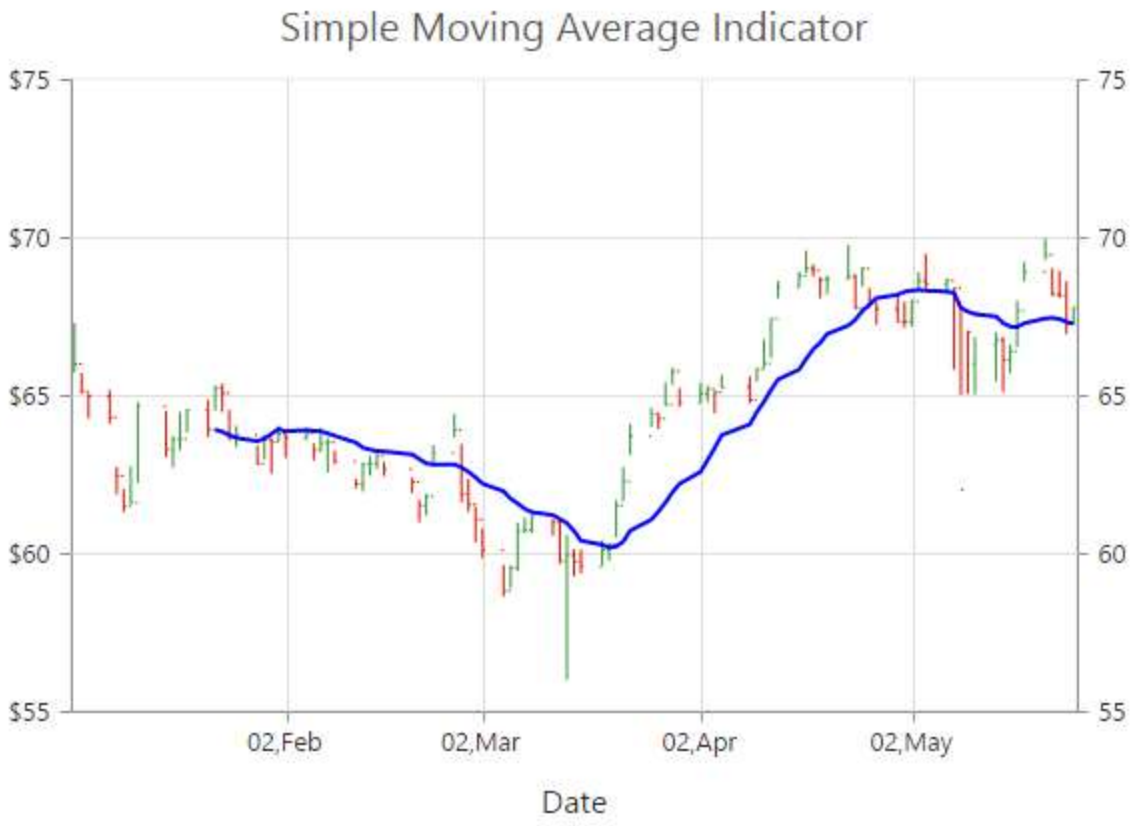
Simple Moving Average (SMA)

To render the SMA indicator, you should specify the Indicators.Type as **SMA**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
//Set indicator type
.Type(ChartIndicatorType.SMA)
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the SMA indicator online demo sample.

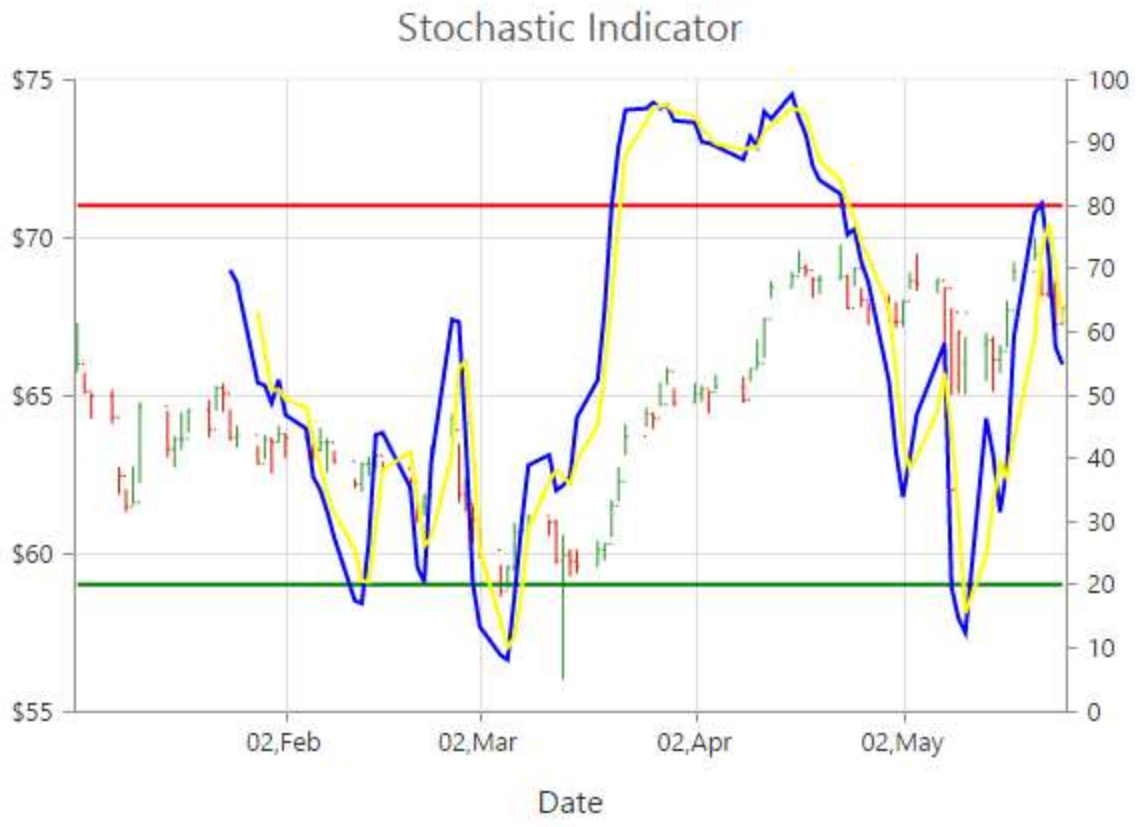
Stochastic

For the Stochastic indicator, you need to set the Indicators.Type as **Stochastic**. The Stochastic indicator renders four lines namely, upper line, lower line, stochastic line and the signal line. Upper line always rendered at value 80 and the lower line is rendered at value 20. Stochastic and Signal Lines are calculated based on the stochastic formula.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
//Set indicator type
.Type(ChartIndicatorType.Stochastic)
.Add();
})
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the stochastic indicator online demo sample.

Triangular Moving Average (TMA)

To render the TMA indicator, you should specify the Indicators.Type as **TMA**.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
//Set indicator type
.Type(ChartIndicatorType.TMA)
.Add();
})
//...
)
```

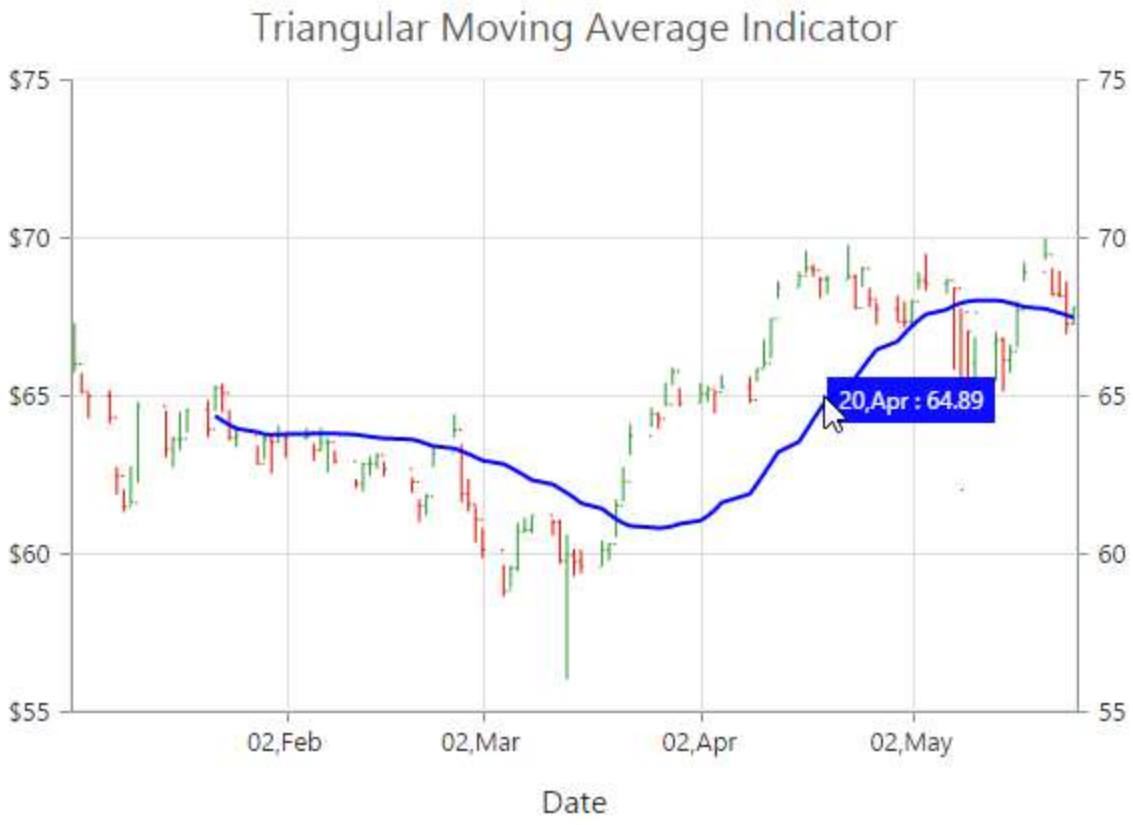
Click here to view the TMA indicator online demo sample.

Enable Tooltip

To display the indicator tooltip, use *Visible* option of the **Indicators.Tooltip**. Also, you can change and customize the tooltip color, border, format and font properties similar to the series tooltip.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Initializing Series
.Series(sr =>
{
//...
})
//Initializing Indicators
.Indicators(ind => { ind
//...
.Tooltip(tooltip=>tooltip.
//Enable tooltip for indicator
Visible(true))
.Add();
})
//...
)
```



Annotations

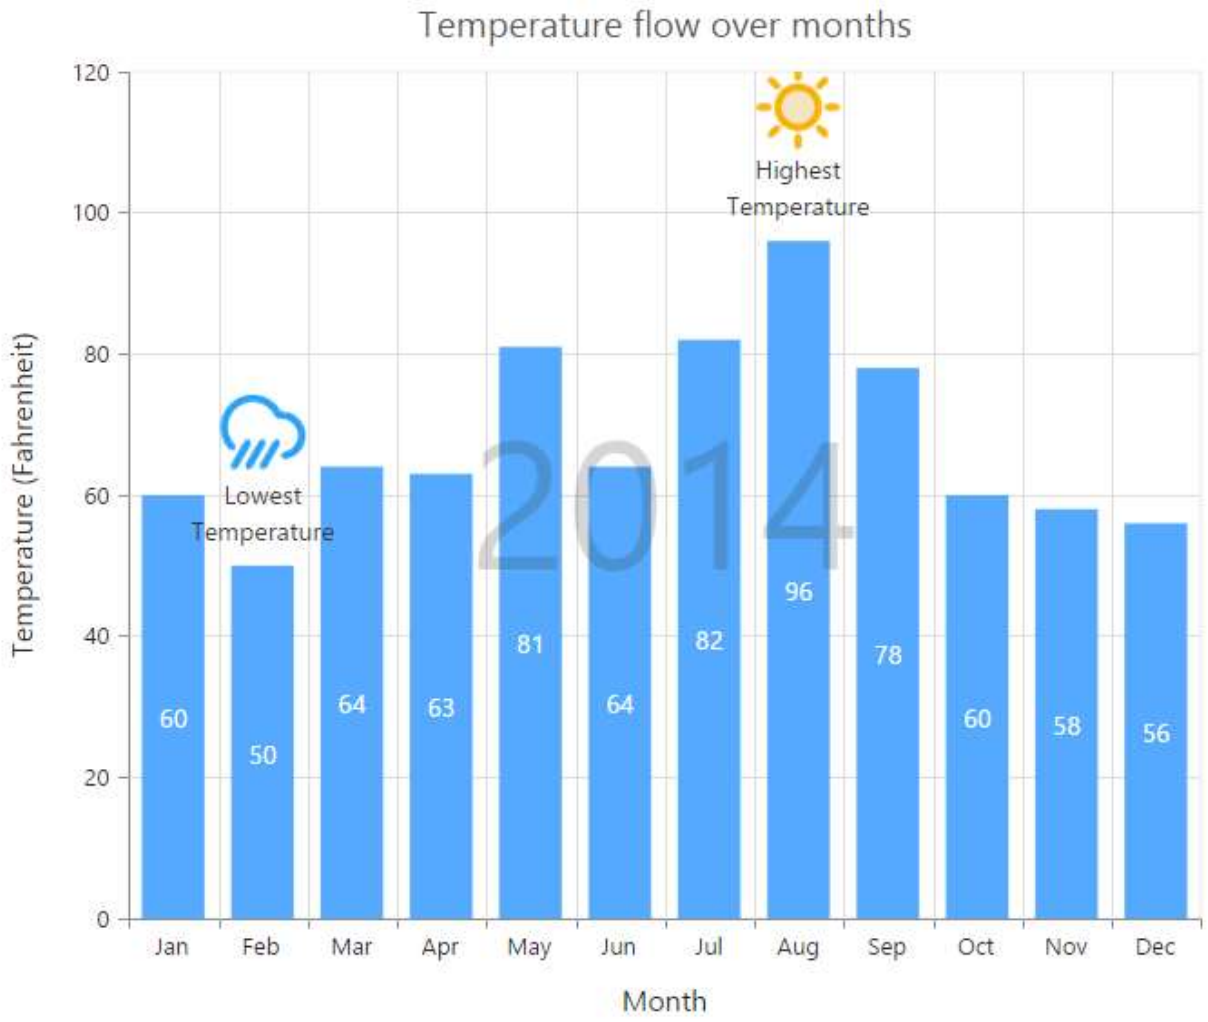
annotations are used to mark the specific area of interest in the chart area with texts, shapes or images.

You can add annotations to the chart by using the **Annotations** option. By using the **Content** option of annotation object, you can specify the id of the element that needs to be displayed in the chart area.

ASPX-CS

```
<div id= "watermark" style="font-size:100px; display:none">2014</div>
<div>
@(Html.EJ().Chart("chartContainer")
.Annotations(an => {
//Add Annotation content here
an.Visible(true).Content("watermark").Opacity(0.2).Region(Region.Series).Add
();
})
// ...
)
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Annotations online demo sample.

Note: Annotations are not supported in 3D chart types.

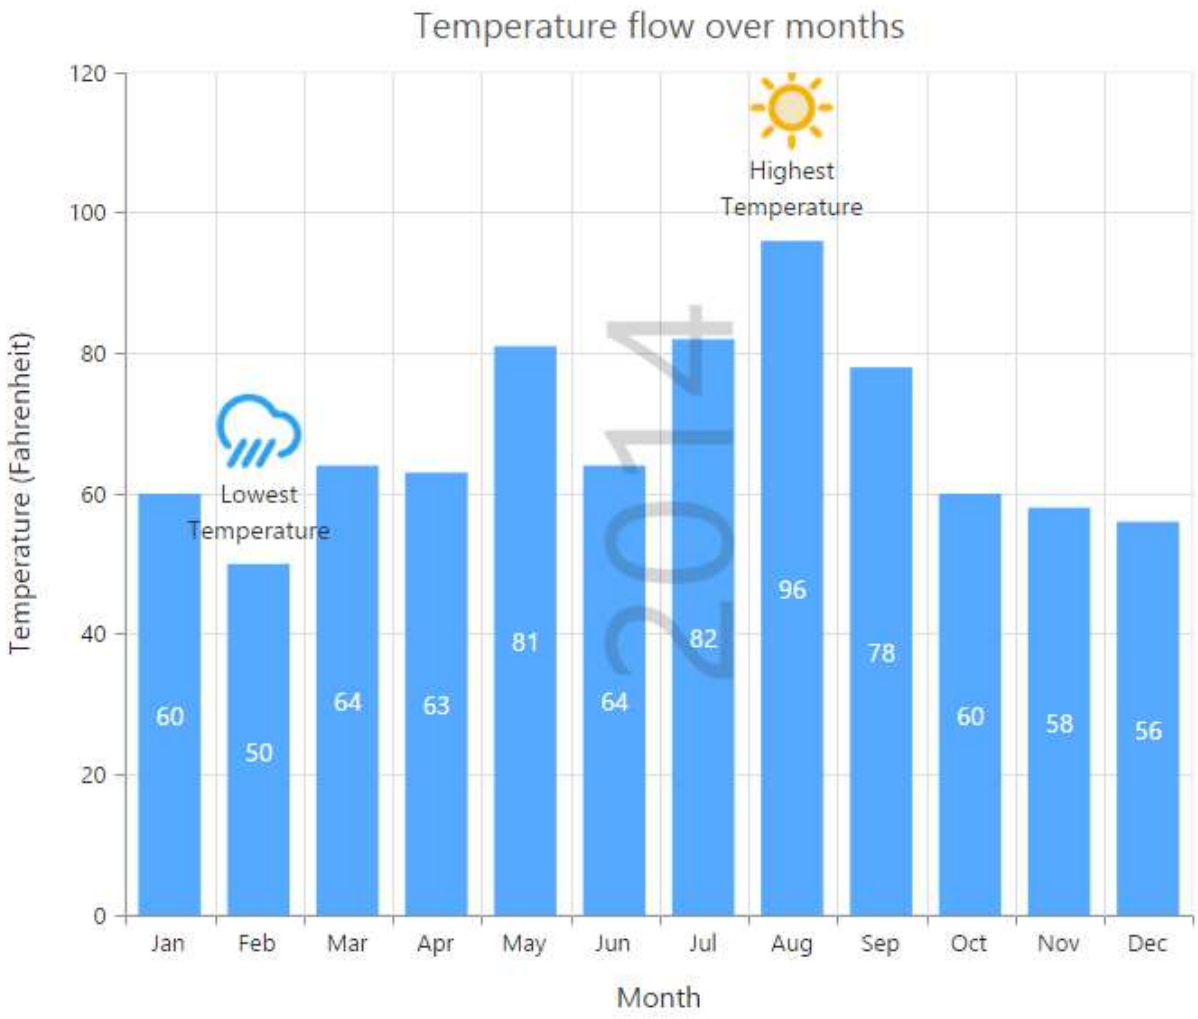
Rotate the annotation template

To rotate the annotation template, you can use the **Angle** property of the annotations.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Annotations(an => {
an.Visible(true)
// ...
//Rotate the Annotation template
.Angle(270).Add();
})
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Positioning Annotation

You can position annotations either by using the coordinates (**X** and **Y**) options or by using the alignment options **HorizontalAlignment** and **VerticalAlignment**.

By using the **CoordinateUnit** option, you can specify whether the value provided in the X and Y options are relative to the chart or axis.

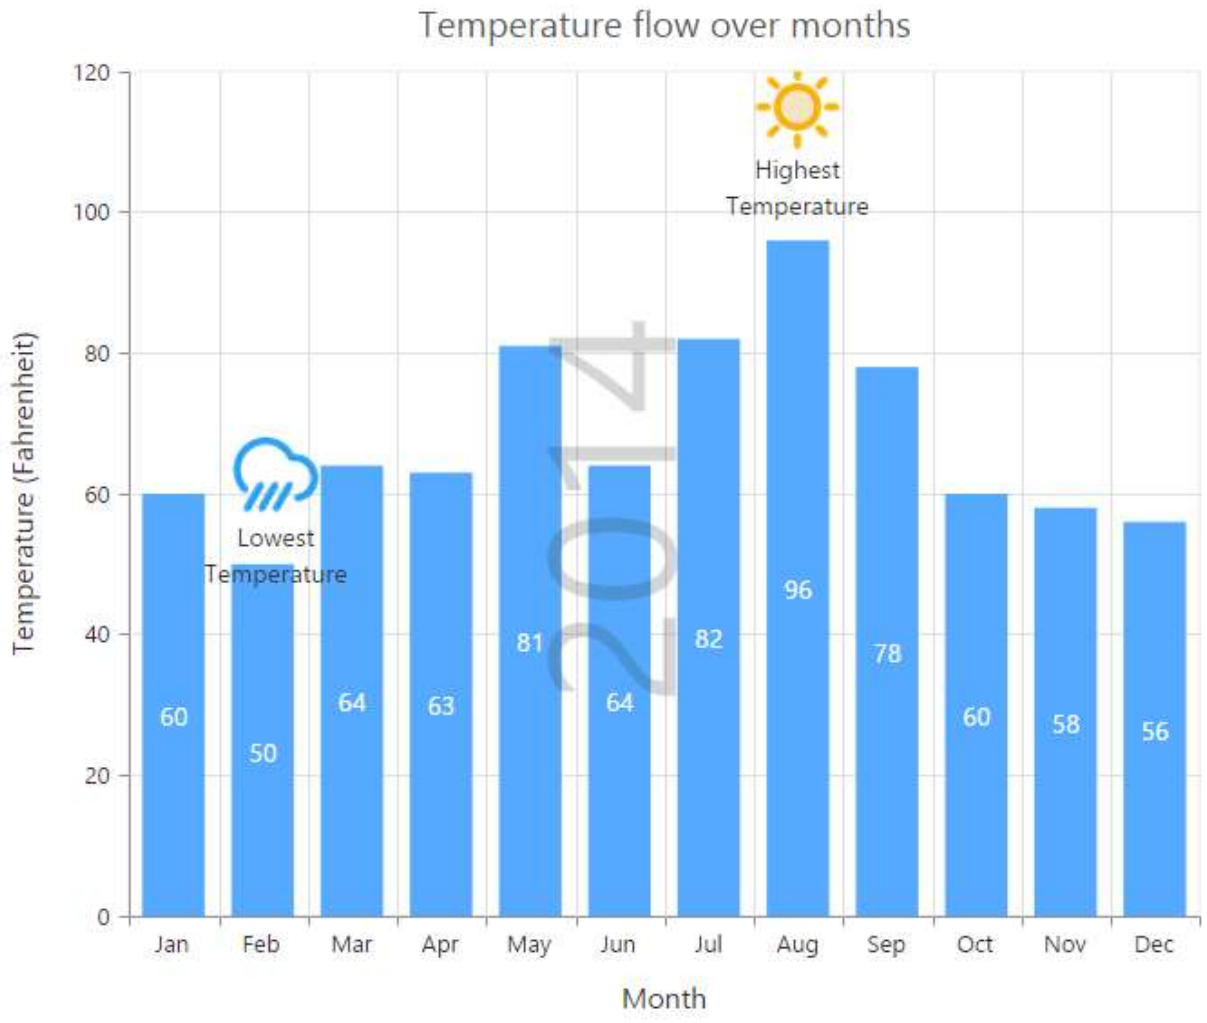
- If the CoordinateUnit is set to None, the annotations are placed relative to the chart/plot area by using the HorizontalAlignment and VerticalAlignment options.
- If the coordinateUnit is set to points, the x and y values of the annotation are the coordinates relative to the axis and annotation is positioned relative to the axis. By default, the x and y values are associated with the **PrimaryXAxis** and **PrimaryYAxis**. In case, when the chart contains multiple axis and you want to associate the annotation with a particular axis, you can specify the **XAxisName** and **YAxisName** options of the annotation object.
- If the coordinateUnit is set to Pixels, the X and Y values are coordinates relative to the top-left corner of the chart/plot area.

Note: By using the **Region** option, you can specify whether the annotation is placed relative to the entire chart or plot area.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Annotations(an => {
an.Visible(true)
// ...
//Change coordinateUnit type to pixels
.CoordinateUnit(CoordinateUnit.Pixels).X(170).Y(350).Add();
})
// ...
)
```



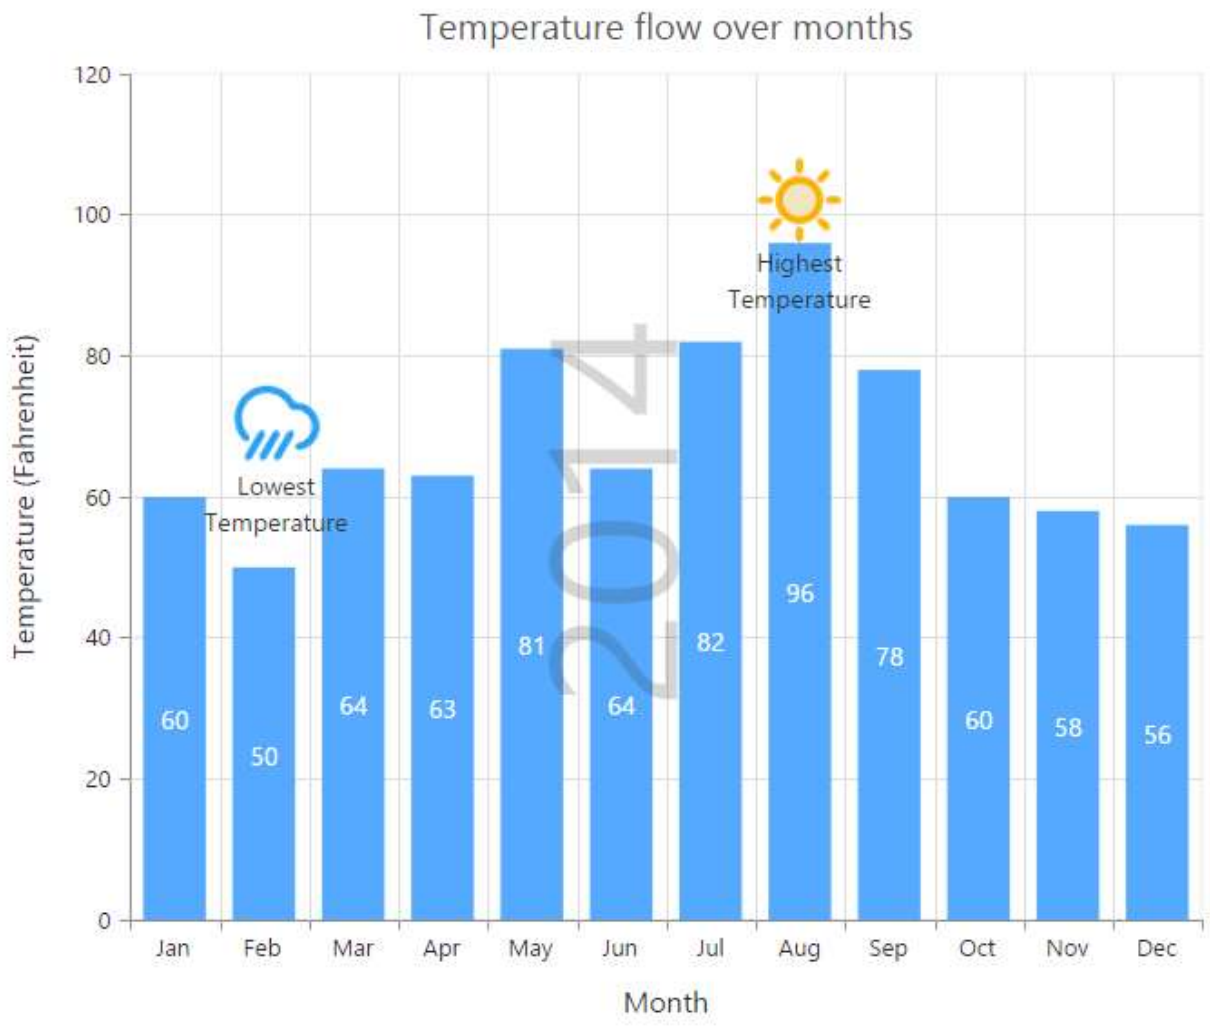
Annotation alignments

When the coordinateUnit is set to pixels or points, you can align the annotation relative to the coordinates by using the **HorizontalAlignment** and **VerticalAlignment** options.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Annotations(an => {
an.Visible(true)
```

```
// ...
//Change alignment of annotation template
.VerticalAlignment(VerticalAlignment.Middle).HorizontalAlignment(HorizontalA
lignment.Left)
.Margin(mr=>mr.Right(40)).Add();
})
// ...
)
```



Appearance

Custom Color Palette

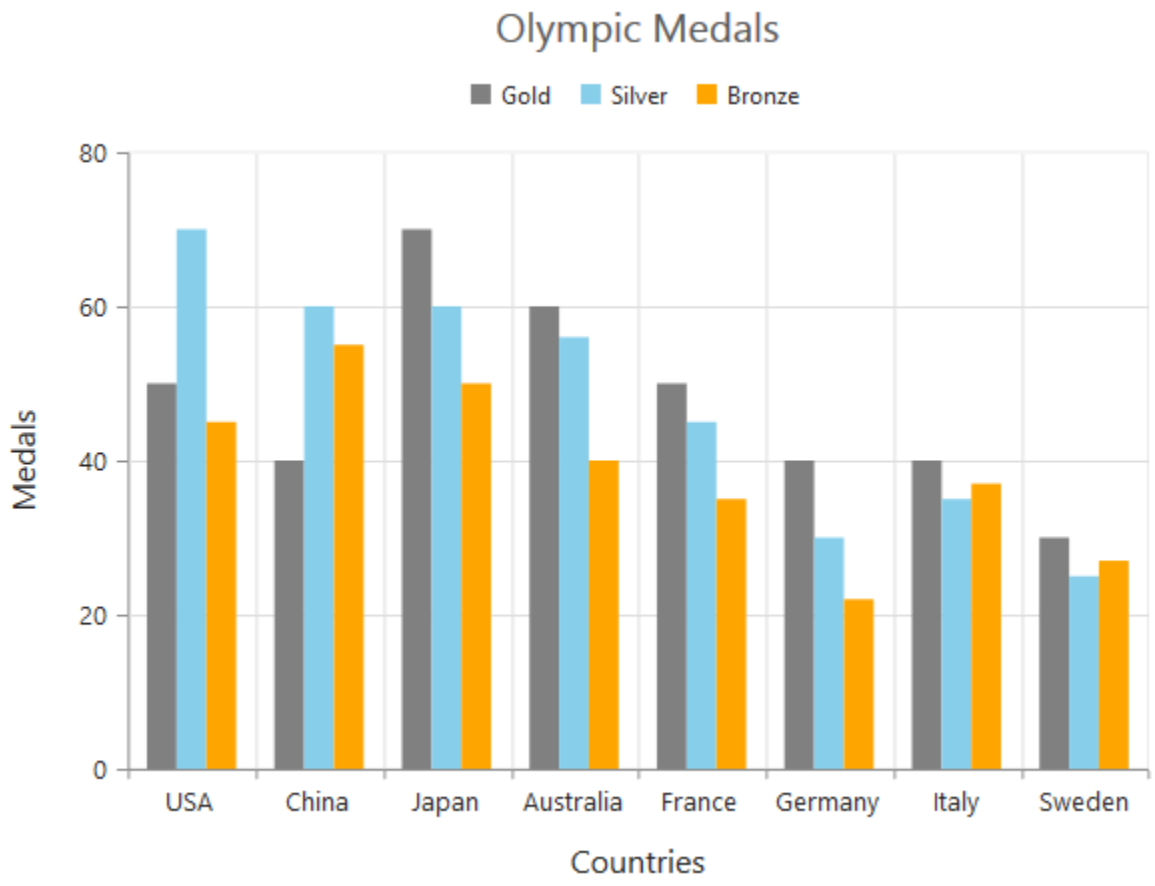
The Chart displays different series in different colors by default. You can customize the color of each series by providing a custom color palette of your choice by using the **Palette** property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//Providing a custom palette
.Palette(pl => { pl.Add("grey"); pl.Add("skyblue"); pl.Add("orange"); })
// ...
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```



Note: The Color palette is applied to the points in accumulation type series

Built-in Themes

Following are the built-in themes available in the Chart

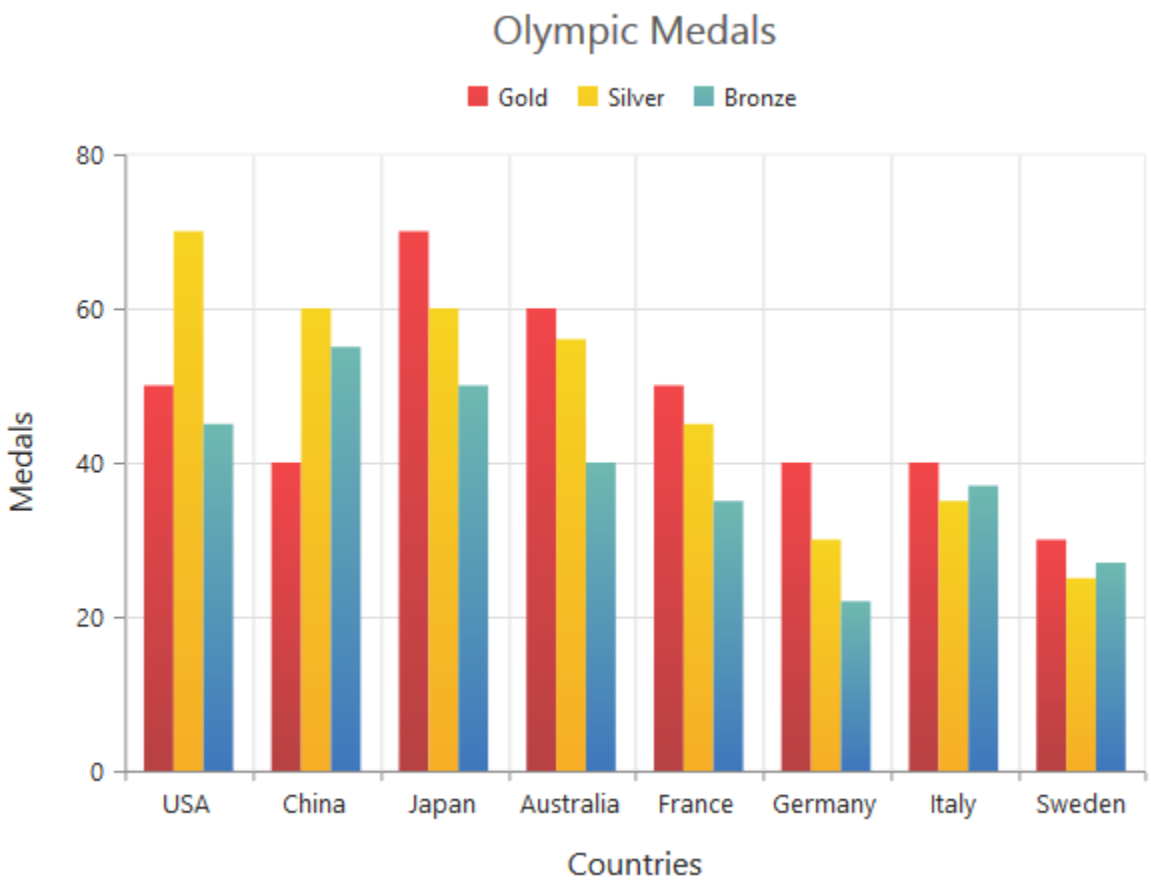
- Azure
- Azuredark
- Flatdark
- Flatlight
- GradientDark
- GradientLight
- Lime
- LimeDark
- Saffron
- SaffronDark

You can set your desired theme by using the **Theme** property. FlatLight is the default theme used in the Chart.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().Chart("chartContainer")
//Using gradient theme
.Theme(Syncfusion.JavaScript.DataVisualization.ChartTheme.GradientLight)
// ...
)
```



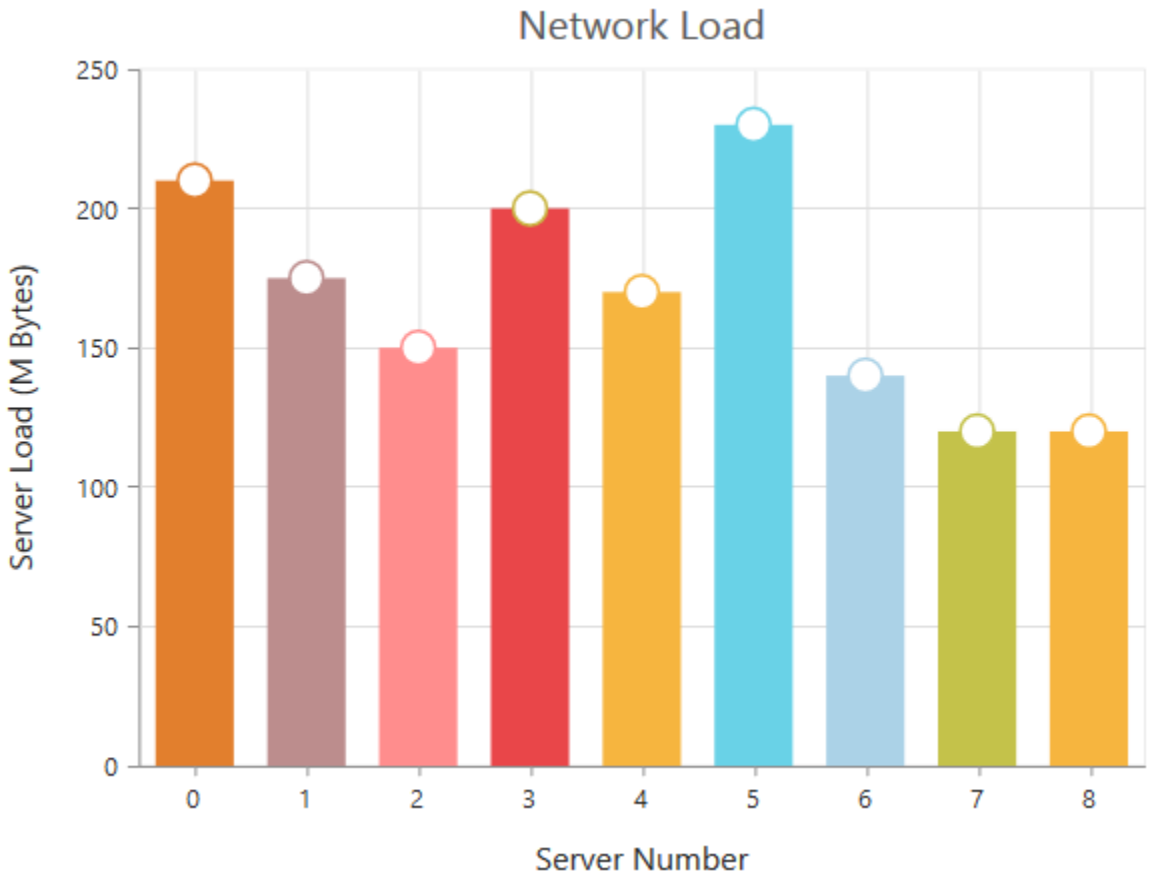
Point level customization

Marker, DataLabel and Fill color of each point in a series can be customized individually by using the **Points** collection.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
sr.Points(pt => {
//Customizing marker and fill color of a point
pt.X("0").Y(210).Fill("#E27F2D").Marker(mr => mr.Visible(true)).Add();
//...
})
.Add();
//...
})
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Series border customization

To customize the series border color, width and dashArray, you can use **Series.Border** option. The series border styles can be applied only to the column, bar and area type of series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr =>
{
sr.Border(border=>border.Color("blue").Width(2).DashArray("5,3")).Add();
//...
})
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

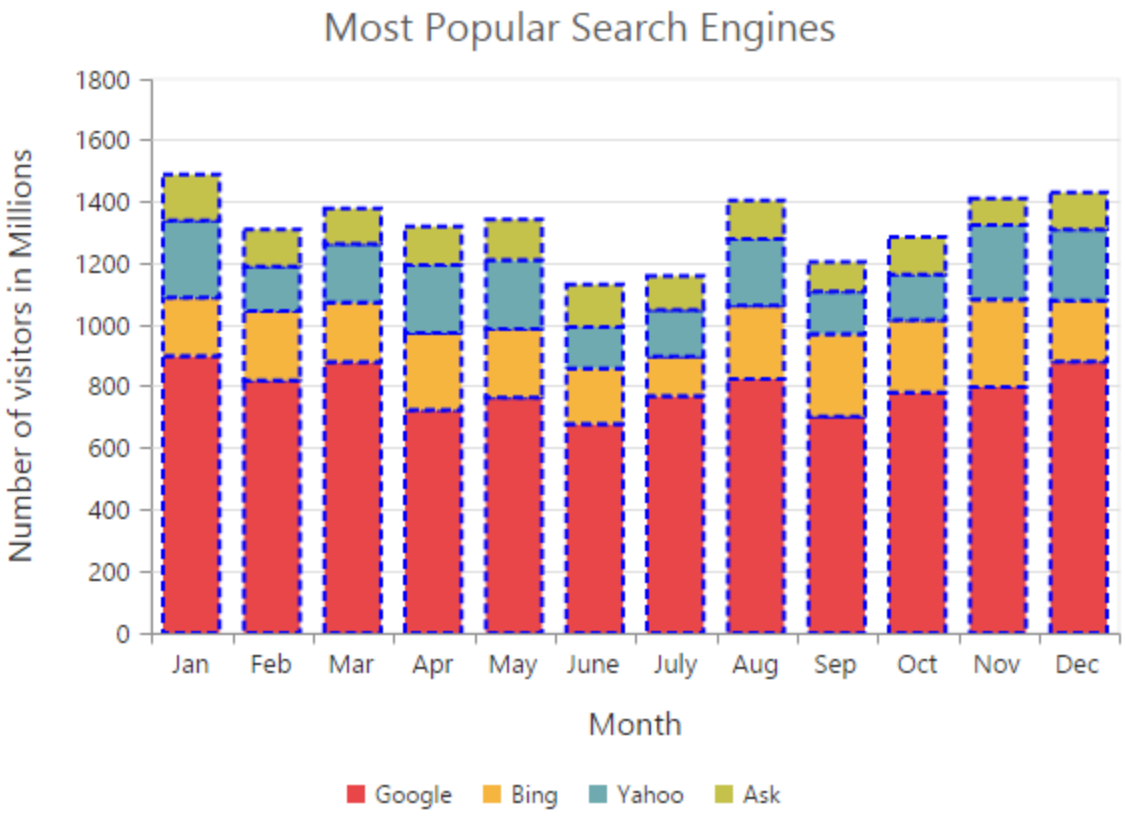


Chart area customization

Customize chart background

The Chart background can be customized by using the **Background** property of the Chart. To customize the chart border, use **Border** option of the chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//Customizing Chart background
.Background("skyblue")
//Customize the chart border and opacity
.Border(br=>br.Color("#FF0000").Width(2).Opacity(0.35))
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

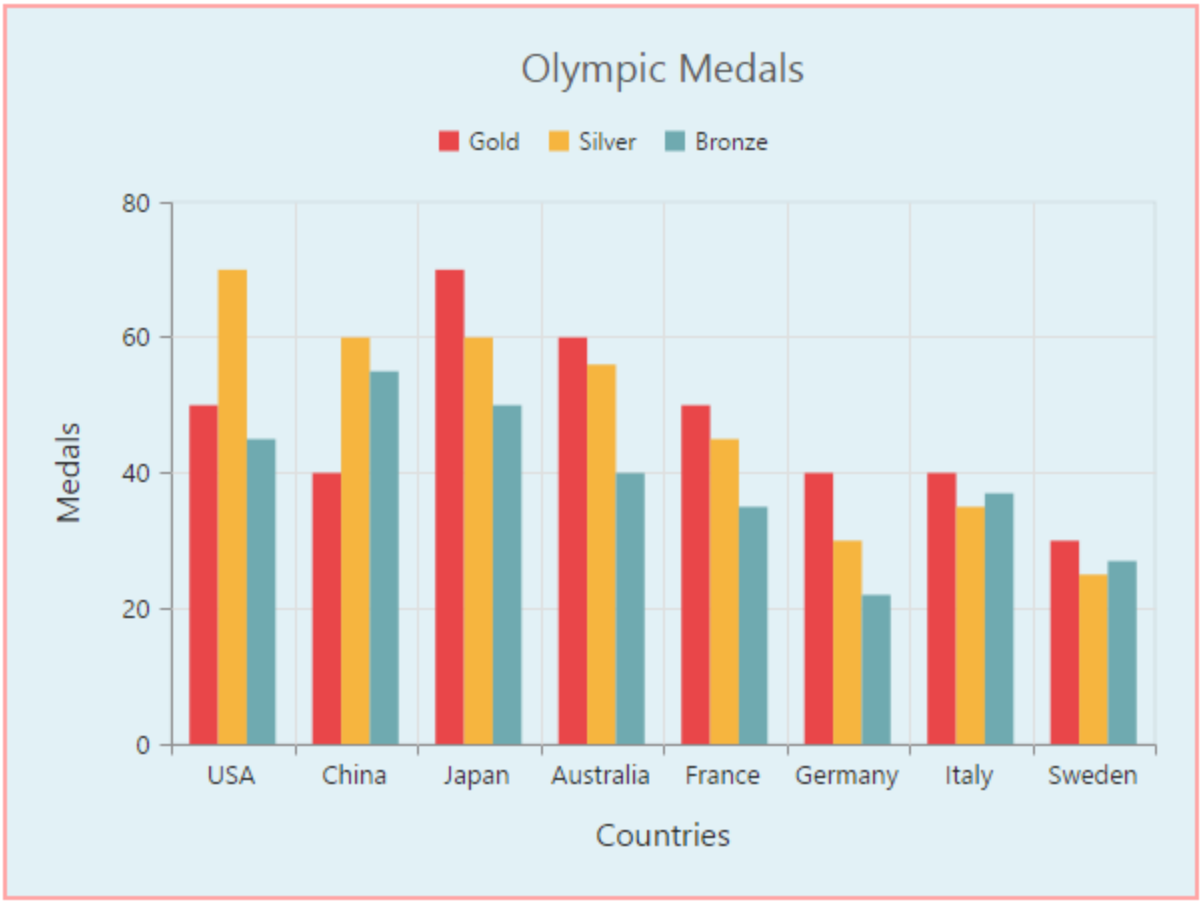

Chart Margin

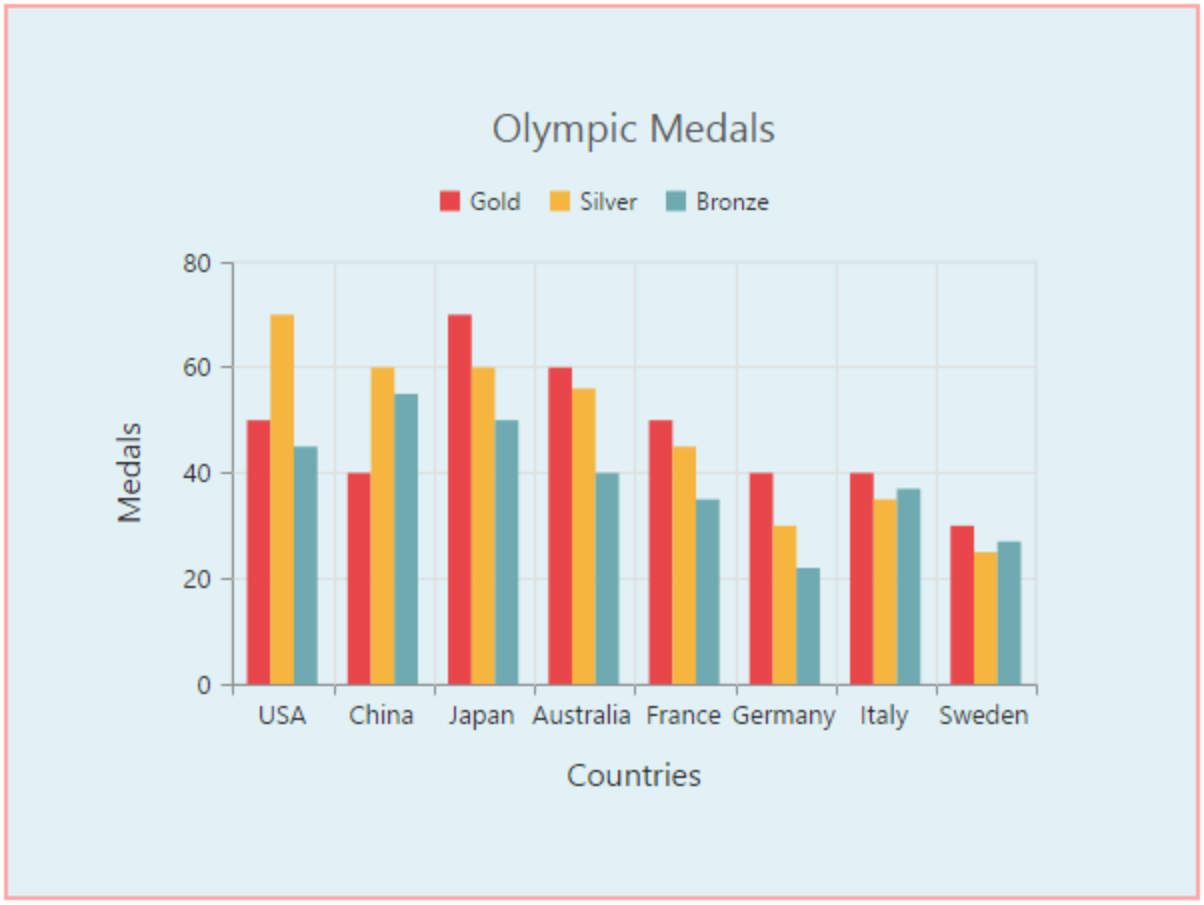
The Chart **Margin** property is used to add the margin to the chart area at the Left, Right, Top and Bottom position.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
//Change chart margin to left, right, top and bottom
.Margin(mr=>mr.Left(40).Right(40).Bottom(40).Top(40))
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



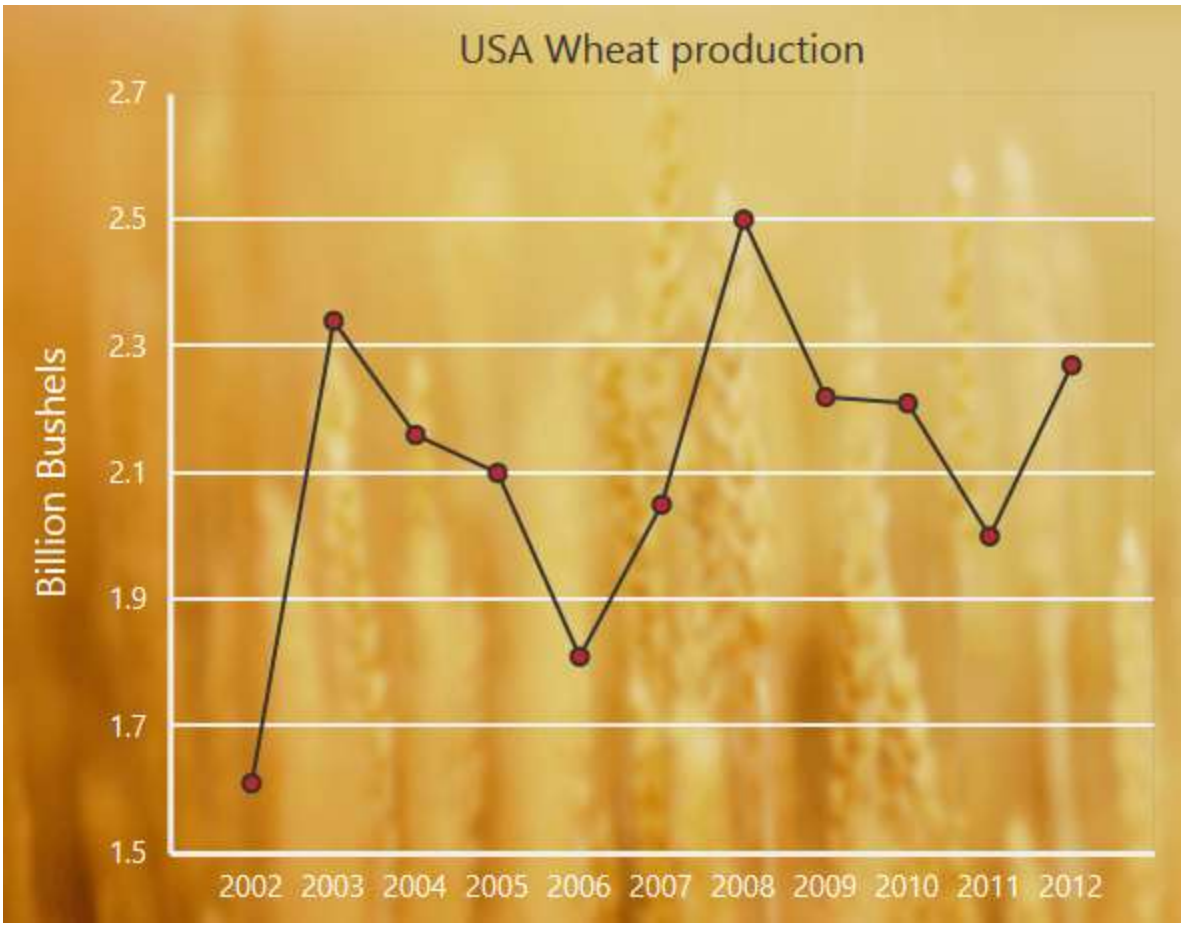
Setting background image

Background image can be added to the chart by using the **BackGroundImageUrl** property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Setting an image as Chart background
.BackGroundImageUrl("images/chart/wheat.png")
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view our online demo sample for setting Chart background image.

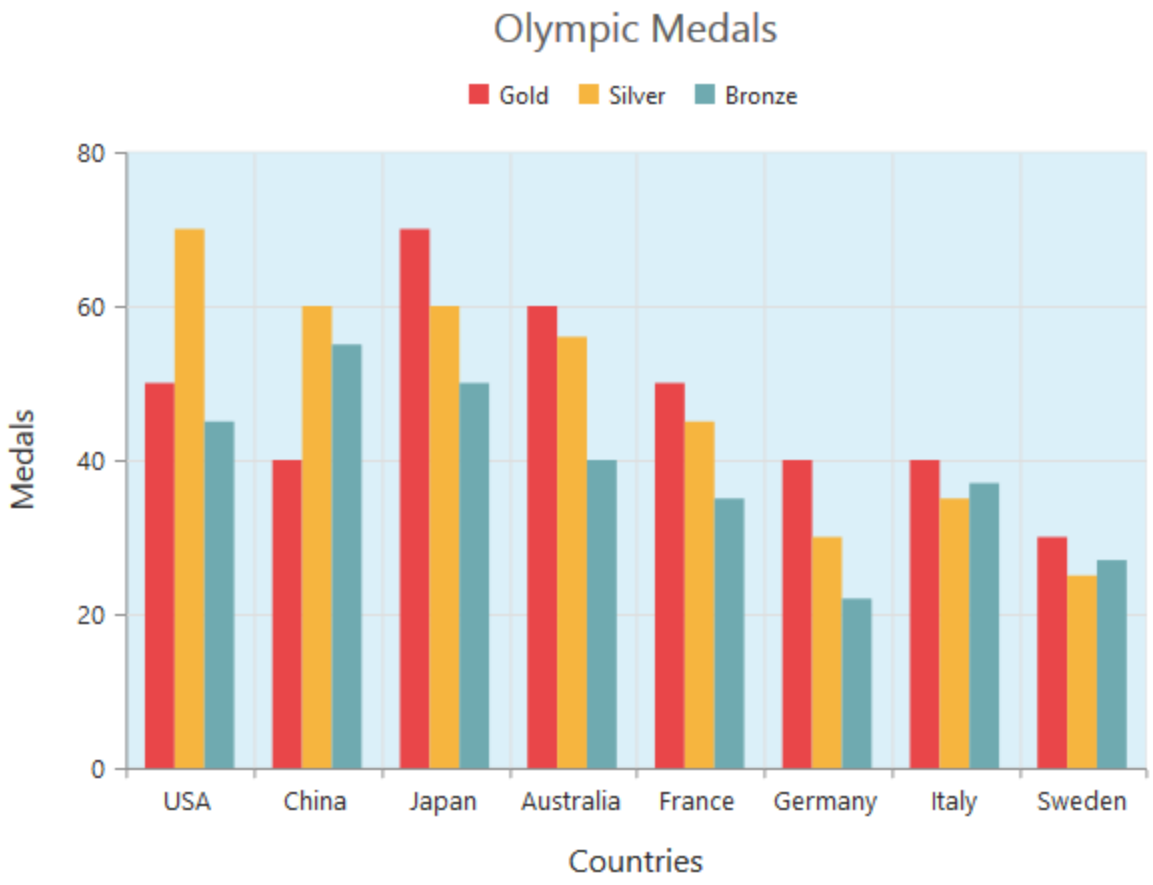
Chart area background

The Chart area background can be customized by using the **Background** property in the chart area.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.ChartArea(ca=>
//Setting background for Chart area
ca.Background("skyblue")
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



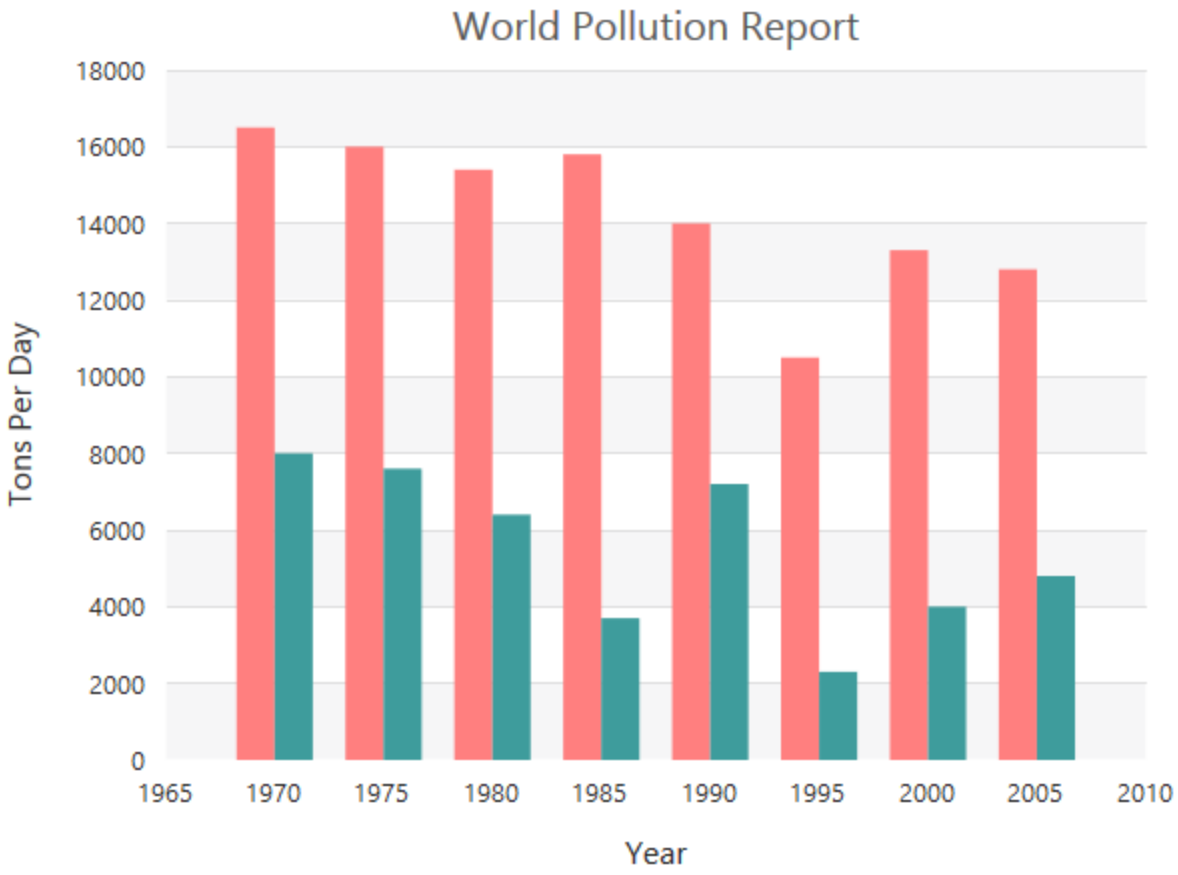
Customize chart area grid bands

You can provide different color for alternate grid rows and columns formed by the grid lines in the chart area by using the **AlternateGridBand** property of the axis. The properties **Odd** and **Even** are used to customize the grid bands at odd and even positions respectively.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.PrimaryYAxis(axis=>
//Customizing horizontal grid bands at even position
axis.AlternateGridBand(band=>band.Even(en=>en.Fill("#A7A9AB").Opacity(0.1)))
)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the AlternateGridBand online demo sample.

Animation

You can enable animation by using the **EnableAnimation** property of the series. This animates the chart series on two occasions – when the chart is loaded for the first time or whenever you change the series type by using the type property.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(
//Enabling animation of series
sr => { sr.EnableAnimation(true).Add();
})
// ...
)
```

However, you can force the chart to animate series by calling the animate method as illustrated in the following code example,

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
.Series(
//Enabling animation of series
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
sr => { sr.EnableAnimation(true).Add();
})
// ...
)
```

JS

```
//Dynamically animating Chart
function animateChart(){
//Calling the animate method for dynamic animation
$("#chartContainer").ejChart("animate");
}
```

Rendering Modes

Chart uses following three rendering technologies

- VML
- SVG
- HTML5 Canvas

VML

VML is used to render chart in IE lower versions such as IE7 and IE8. VML is used by default in these two browsers, as SVG and Canvas are not supported in these browsers.

Limitations:

- Label rotation is not supported.
- Animation is not supported.
- Patterns are not supported.
- Zooming and panning features are not supported.

SVG

SVG is used to render Chart by default for all browsers other than IE7 and IE8.

Canvas

You can switch between SVG and Canvas rendering by using the **EnableCanvasRendering** option. The canvas mode rendering is used in the following scenarios,

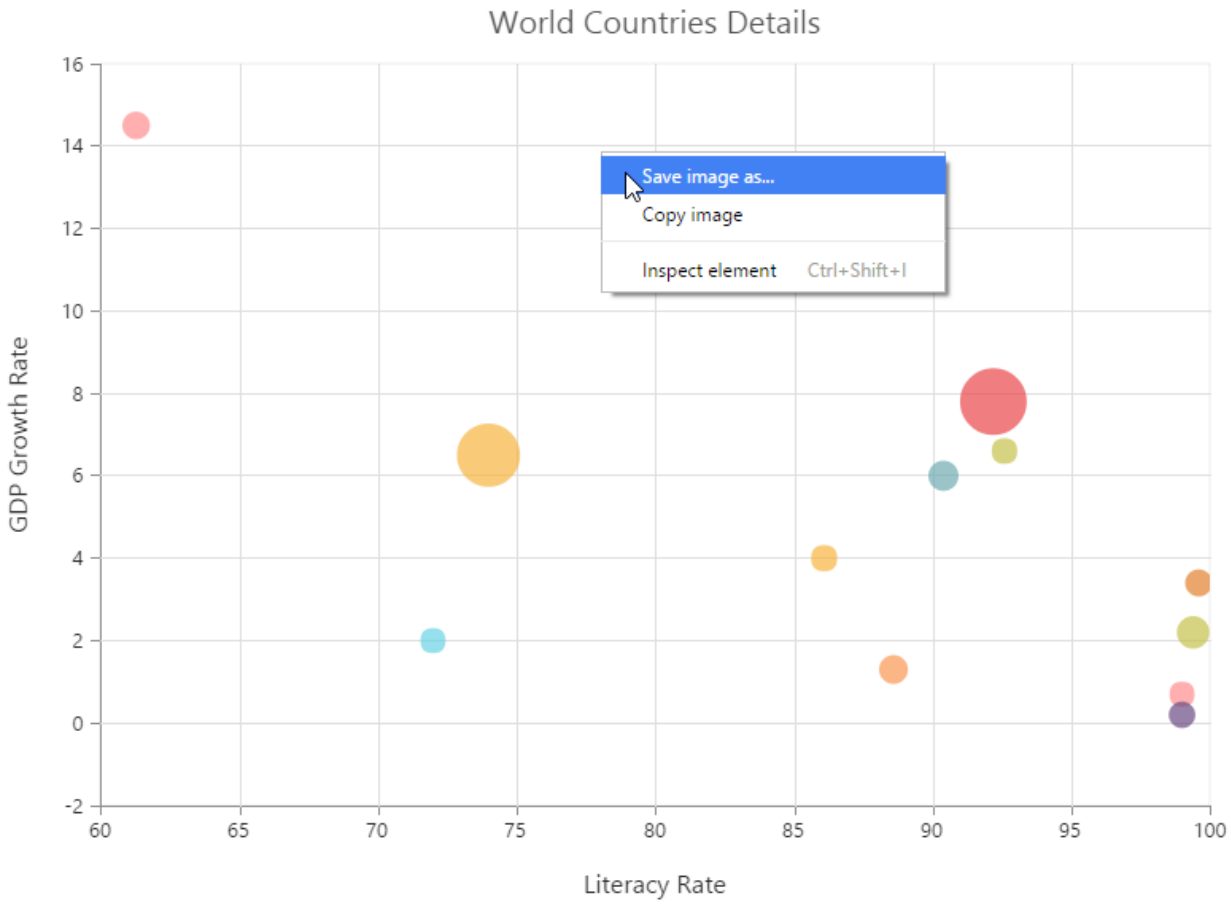
- Plotting large number of data points.
- Performing high frequency live updates.

The following code example shows how to enable HTML5 Canvas rendering in chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Rendering chart in canvas mode
.EnableCanvasRendering(true)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Limitations:

- Animation is not supported.
- 3D charts are not supported.

Real-Time Chart

Chart can be updated dynamically with the real time data. Whenever you add a point or remove a point from the dataSource, you can call the **redraw** method to request the chart to redraw its content.

Note: You can get the chart **instance** using instance method.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Rendering empty Chart without data
.Series(sr =>
{
sr.Points(pt =>
{
}).Add();
})
//...
```

```
)
```

JS

```
//Using set interval to update chart dynamically
window.setInterval(updateChart, 200);
//Function that updates chart dynamically
function updateChart(){
//Creating chart instance
var chart =  $("#chartContainer").ejChart("instance");
if (chart.model.series[0].points.length > 10)
chart.model.series[0].points.splice(0, 1);
var point = chart.model.series[0].points;
var xValue = point.length > 0 ? point[point.length - 1].x + 1 : 1;
point[point.length] = { x:  xValue, y: getRandomNumber( 1000 ) }
//Update Chart dynamically using redraw option
//chart.redraw() can also be used here instead of redraw option
$("#chartContainer").ejChart("redraw");
}
```

Click here to view the online demo sample for real-time Chart.

Exporting Chart

Exporting a chart can be done in both client-side and in server-side. This can be modified by setting values to the property “mode” in exporting. Default value for mode is client.

Client-side Exporting

In client-side rendered chart can be exported as PNG image or as SVG file.

- Export as PNG - The chart can be exported to image when it is rendered in HTML5 Canvas. To render a chart in canvas, set the *EnableCanvasRendering* option to true. To export the chart, you can use the export method of the chart. Refer to the online KB link of exporting chart to know more about chart exporting.
- Export as SVG - Chart can be exported as SVG if it is rendered as a scalable vector graphics element. By default chart will be rendered as SVG.

ASPX-CS

```
<!--Chart download link-->
<a id="download" style="cursor: pointer; position: absolute;right:
150px;">ExportChart</a>
@(Html.EJ().Chart("container").ChartArea(area => area.Border(ab =>
ab.Color("transparent")))
.EnableCanvasRendering(true)
.ExportSettings(ex
=>ex.FileName("ChartSnapshot").Type(ChartExportingType.PNG)))
<script>
function download() {
var canvas = $("#container").ejChart("export");
this.href = canvas;
}
if (document.getElementById('download').addEventListener)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
document.getElementById('download').addEventListener('click', download,
false);
else
document.getElementById('download').attachEvent('onclick', download, false);
</script>
```

Click here to view the Export chart online demo sample.

Server-side Exporting

Server-side operations can be done at the controller page.

Server side implementation

To convert the chart data from client to server-side, refer to the following steps.

1. Create an MVC application and add a controller.
2. Add Syncfusion.EJ, Syncfusion.EJ.MVC, Syncfusion.EJ.Export, Syncfusion.XlsIO, Syncfusion.DocIO and Syncfusion.PDF.Base dll's as references to the application.
3. Specify the name of the method defined in the controller in the property "action" in exporting
4. Currently, the chart data can be exported at server-side only through the helper functions in the ".Net". So to use exporting in your projects, it is required to create a server with any of the following.

i). ASP.NET MVC Controller

ii). ASP.NET Web Form

iii). WebAPI

iv). WCF Service

ASPX-CS

```
<!--Export Chart-->
<button onclick="download()" value="Export">Export</button>
@(Html.EJ().Chart("container").ChartArea(area => area.Border(ab =>
ab.Color("transparent")))
.EnableCanvasRendering(true)
.ExportSettings(ex =>
ex.Type(ChartExportingType.JPG).Action("ExportToImage").Mode(ChartExportingM
ode.Server))
)
<script>
//Export chart to excel
function download() {
$("#container").ejChart("export");
}
</script>
```

At the server side the chart can be exported as JPG, PNG, SVG, PDF, word document and as excel documents. For this the following code have to place in the controller

CSHARP

```
public void ExportChart(string Data, string ChartModel)
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
// declaration
ChartProperties obj = ConvertChartObject(ChartModel);
string type = obj.ExportSettings.Type.ToString().ToLower();
string fileName = obj.ExportSettings.FileName;
string orientation = obj.ExportSettings.Orientation.ToString();
if (type == "svg")       // for SVG export
{
StringWriter oStringWriter = new StringWriter();
string data = HttpUtility.HtmlDecode(Data);
data = HttpUtility.UrlDecode(Data);
data = System.Uri.UnescapeDataString(Data);
oStringWriter.WriteLine(System.Uri.UnescapeDataString(Data));
Response.ContentType = "text/plain";
Response.AddHeader("Content-Disposition",
String.Format("attachment;filename={0}", (obj.ExportSettings.FileName +
".svg")));
Response.Clear();
using (StreamWriter writer = new StreamWriter(Response.OutputStream))
{
data = oStringWriter.ToString();
writer.Write(oStringWriter.ToString());
}
Response.End();
}
else if (type == "xlsx")        // to export chart as excel
{
List<ExportChartData> chartData = new List<ExportChartData>();
chartData.Add(new ExportChartData("John", 10));
chartData.Add(new ExportChartData("Jake", 12));
chartData.Add(new ExportChartData("Peter", 18));
chartData.Add(new ExportChartData("James", 11));
chartData.Add(new ExportChartData("Mary", 9.7));
ExcelExport exp = new ExcelExport();
exp.Export(obj, (IEnumerable)chartData, fileName + ".xlsx",
ExcelVersion.Excel2010, null, null);
}
else
{
Data = Data.Remove(0, Data.IndexOf(',') + 1);
MemoryStream stream = new MemoryStream(Convert.FromBase64String(Data));
if (type == "docx")         // to export as word document
{
WordDocument document = new WordDocument();
IWSection section = document.AddSection();
IWParagraph paragraph = section.AddParagraph();
if (obj.ExportSettings.Orientation.ToString() == "Landscape")
section.PageSetup.Orientation = PageOrientation.Landscape;
else
section.PageSetup.Orientation = PageOrientation.Portrait;
paragraph.AppendPicture(Image.FromStream(stream));
document.Save(fileName + ".doc", Syncfusion.DocIO.FormatType.Doc,
HttpContext.ApplicationInstance.Response,
Syncfusion.DocIO.HttpContentDisposition.Attachment);
}
else if (type == "pdf")       // to export as PDF
{
PdfDocument pdfDoc = new PdfDocument();
```

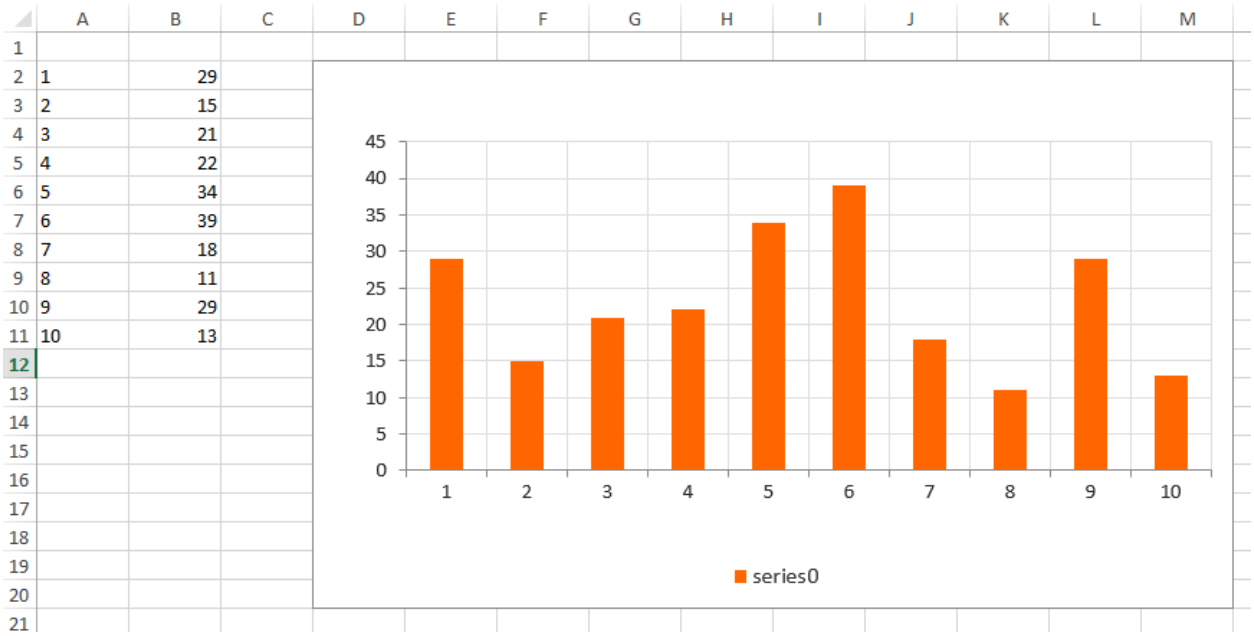
Copyright © 2001 - 2020 Syncfusion Inc.

```
pdfDoc.Pages.Add();
if (obj.ExportSettings.Orientation.ToString() == "Landscape")
pdfDoc.Pages[0].Section.PageSettings.Orientation =
PdfPageOrientation.Landscape;
else
pdfDoc.Pages[0].Section.PageSettings.Orientation =
PdfPageOrientation.Portrait;
pdfDoc.Pages[0].Graphics.DrawImage(PdfImage.FromStream(stream), new
PointF(10, 30));
pdfDoc.Save(obj.ExportSettings.FileName + ".pdf",
HttpContext.ApplicationInstance.Response, HttpReadType.Save);
pdfDoc.Close();
}
else                          // to export as image
{
stream.WriteTo(Response.OutputStream);
Response.ContentType = "application/octet-stream";
Response.AddHeader("Content-Disposition",
String.Format("attachment;filename={0}", fileName + "." + type));
Response.Flush();
stream.Close();
stream.Dispose();
}
}
}
private ChartProperties ConvertChartObject(string ChartModel)
{
JavaScriptSerializer serializer = new JavaScriptSerializer();
IEnumerable div = (IEnumerable)serializer.Deserialize(ChartModel,
typeof(IEnumerable));
ChartProperties chartProp = new ChartProperties();
foreach (KeyValuePair<string, object> d in div)
{
var property = chartProp.GetType().GetProperty(d.Key, BindingFlags.Instance
| BindingFlags.Public | BindingFlags.IgnoreCase);
if (property != null)
{
Type type = property.PropertyType;
string serialize = serializer.Serialize(d.Value);
object value = serializer.Deserialize(serialize, type);
property.SetValue(chartProp, value, null);
}
}
return chartProp;
}
```

Excel Exporting

Excel exporting is a server-side operation. In addition have to refer Syncfusion.XlsIO assembly to export as excel.

Copyright © 2001 - 2020 Syncfusion Inc.



Multiple Chart Excel Exporting

EjChart supports exporting more than one charts in a page, with the *third* argument for the **export** method.

Note: Refer to the MultipleExportType.AppendToSheet, MultipleExportType.NewSheet.

ASPX-CS

```
//Render Chart1
$("#container1").ejChart();
//Render Chart2
$("#container2").ejChart();
//Export multiple chart to excel
function downloadExcel() {
var chart = $("#container1").ejChart("instance");
chart.export('Excel',
'http://js.syncfusion.com/ExportingServices/api/JSChartExport/ExcelExport',
true);
}
```

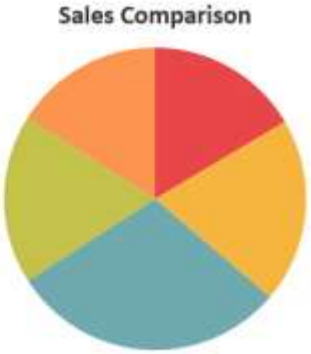
Export multiple chart to excel at server-side

CSHARP

```
public class JSChartExportController : ApiController
{
[System.Web.Http.ActionName("ExcelExport")]
[AcceptVerbs("POST")]
public void ExcelExport()
{
string chartModel = HttpContext.Current.Request.Params["ChartModel"];
IWorkbook book = null;
foreach (string chartProperty in ChartModel)
{
if (chartProperty != null)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
ExcelExport exp = new ExcelExport();
ChartProperties obj = ConvertChartObject(chartProperty);
if (initial)
{
book = exp.Export((obj as ChartProperties), (IEnumerable)data,
"Export1.xlsx",
ExcelVersion.Excel2010, true, null, null);
initial = false;
}
else
{
exp.Export((obj as ChartProperties), (IEnumerable)data, "Export.xlsx",
ExcelVersion.Excel2010, false, book, MultipleExportType.NewSheet, null,
null);
}
}
}
}
}
```



Naming the exported file

EjChart provides options to customize the name of the file to be exported. This can be done by setting the name of the file to the property “fileName” in exporting.

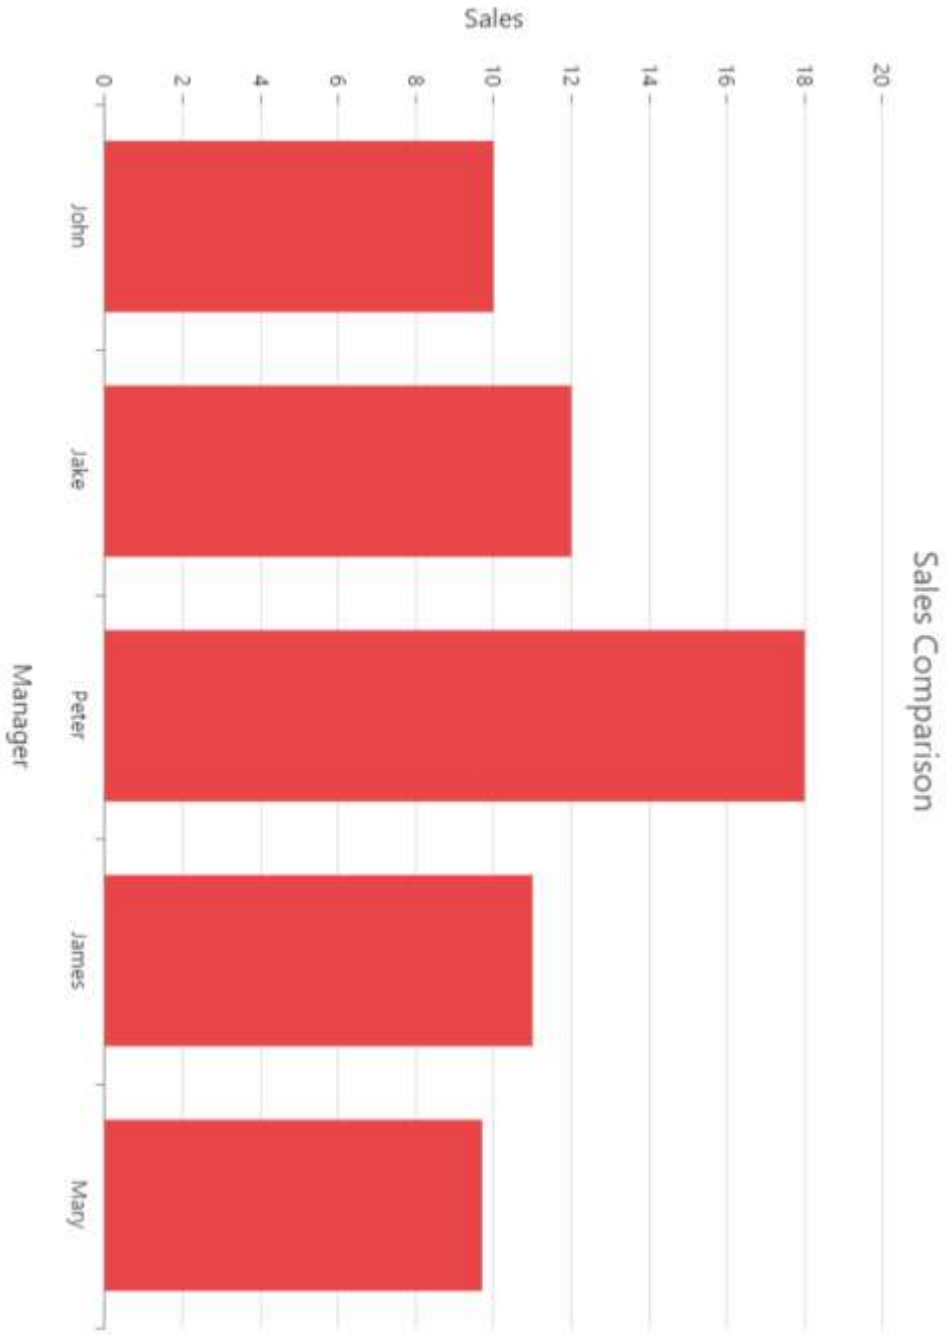
Rotating the chart

We can also rotate the chart and can export it. Possible angles of rotation are 0, 90, -90 and 180 degree. This can be achieved by setting values to the “angle” property in exporting.

ASPX-CS

```
@(Html.EJ().Chart("container")
.ExportSettings(ex => ex.Angle(180).Action("ExportToImage"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Setting orientation for the document

This is applicable for PDF, excel and word documents. By setting values to the “orientation” property in exporting, we can change the orientation of those documents. By default it will export with portrait orientation.

Printing Chart

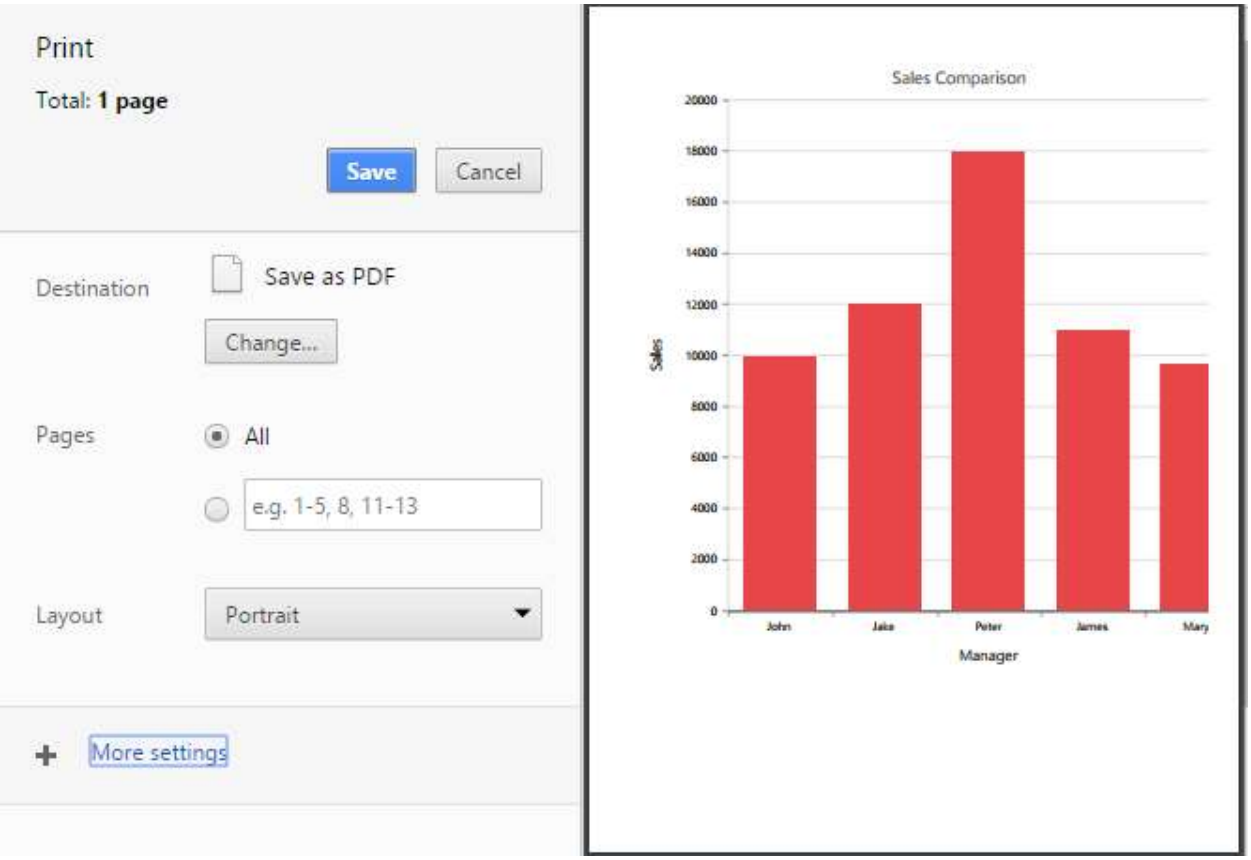
The rendered chart can be printed directly from the browser by calling the public method **print**. ID of the chart div element must be passed as argument to that method.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
<button type="button" onclick="print()" ></button>
@(Html.EJ().Chart("container"))
<script>
function print() {
var chartObj = $("#container").ejChart("instance");
chartObj.print("container");
}
</script>
```

This print method can be called by performing any action on the web page. For example, by clicking a button. While calling the print method in chart, print preview will be displayed in the browser.



Click here to view the Printing chart online demo sample

Printing Multiple chart

Multiple charts in a web page can be printed together. For printing multiple charts, ID of the chart div elements have to be passed as shown in the below code

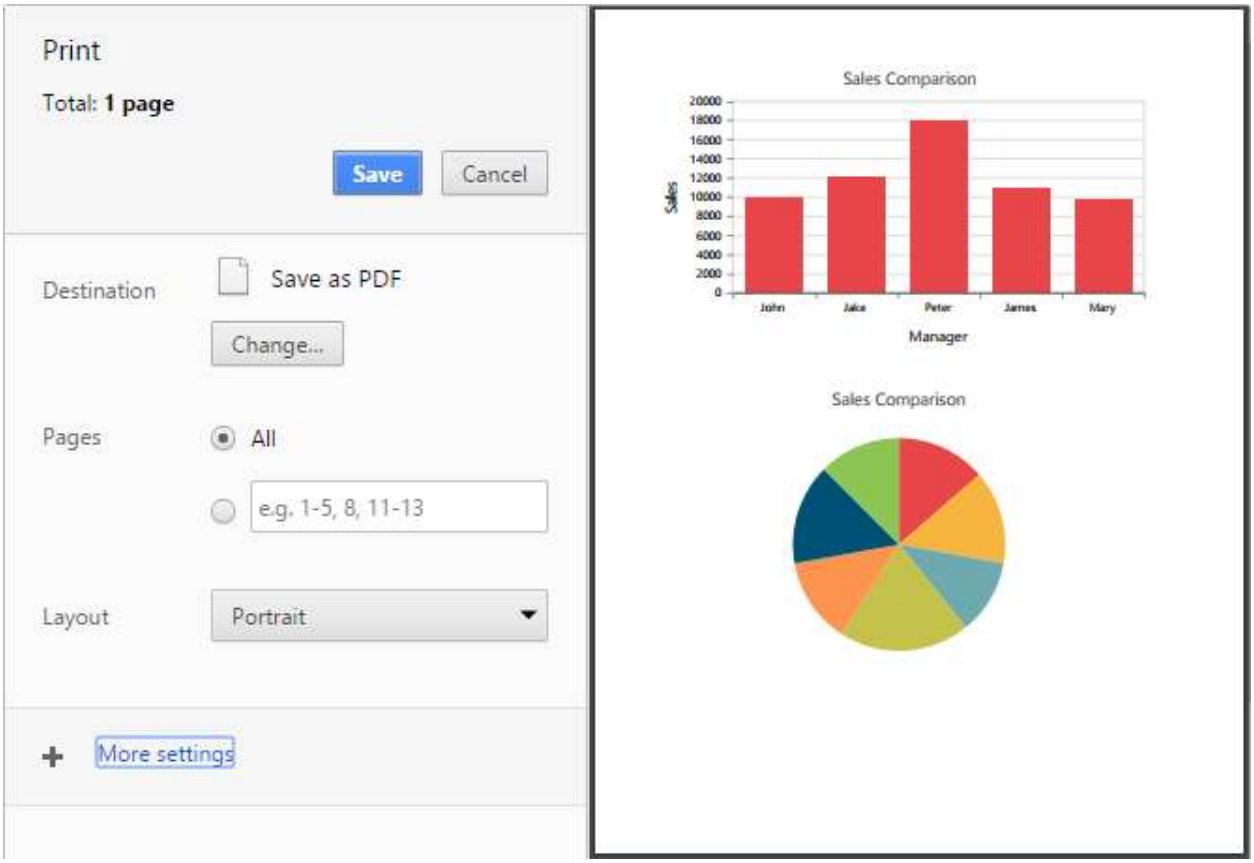
ASPX-CS

```
<button type="button" onclick="print()" ></button>
@(Html.EJ().Chart("container1"))
@(Html.EJ().Chart("container2"))
<script>
function print() {
var chartObj = $("#container1").ejChart("instance");
chartObj.print("container1","container2");
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</script>
```

The Print preview of multiple Charts is shown below



Page Setup

Some of print options are not configurable through JavaScript code. You need to customize layout, paper size, margins options through browser's page setup dialog. Please find the following guidelines link to browser page setup.

- Chrome
- Firefox
- Safari
- IE

3D Chart

Essential 3D Chart for ASP.NET MVC allows you to view 8 chart types in 3D view such as Bar, StackingBar, StackingBar100, Column, Stacked Column, 100% Stacked Column, Pie, Doughnut.

3D Column Chart

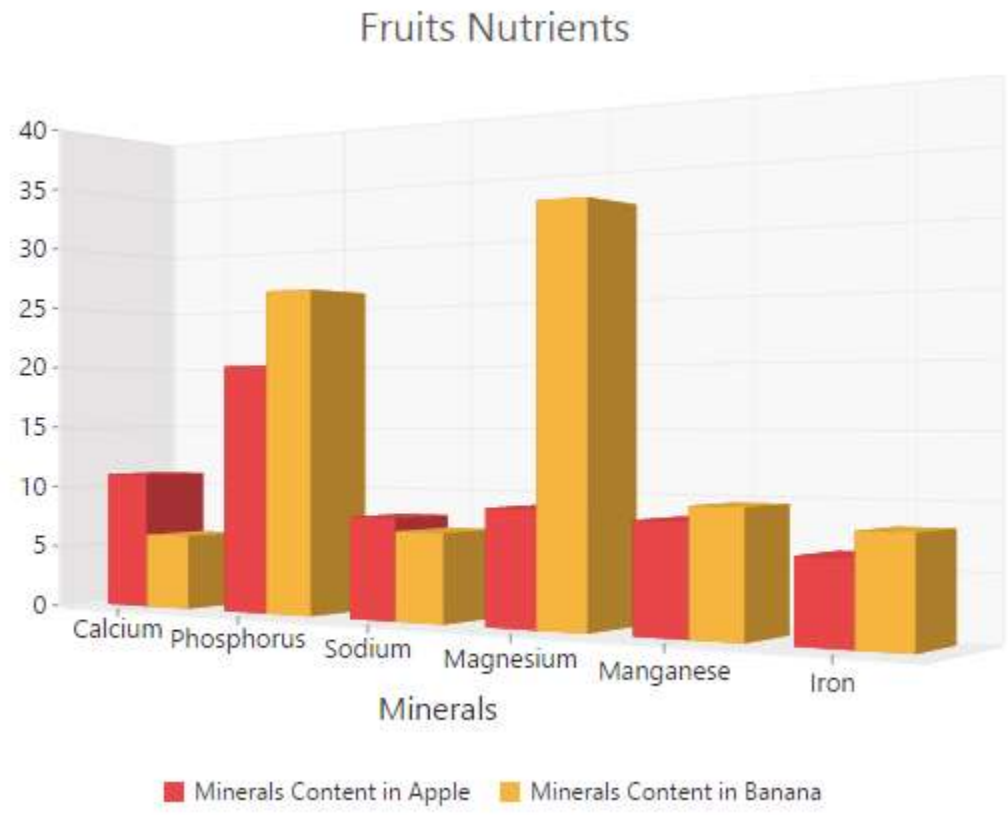
For rendering a 3D Column Chart, specify the series **Type** as **Column** in the chart series and set **Enable3D** option as **true** in the chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Series(sr => { sr.Type(SeriesType.Column).Add(); })
// Enable 3D Chart
.Enable3D(true)
// ...
)
```



Click here to view the Column 3DChart online demo sample.

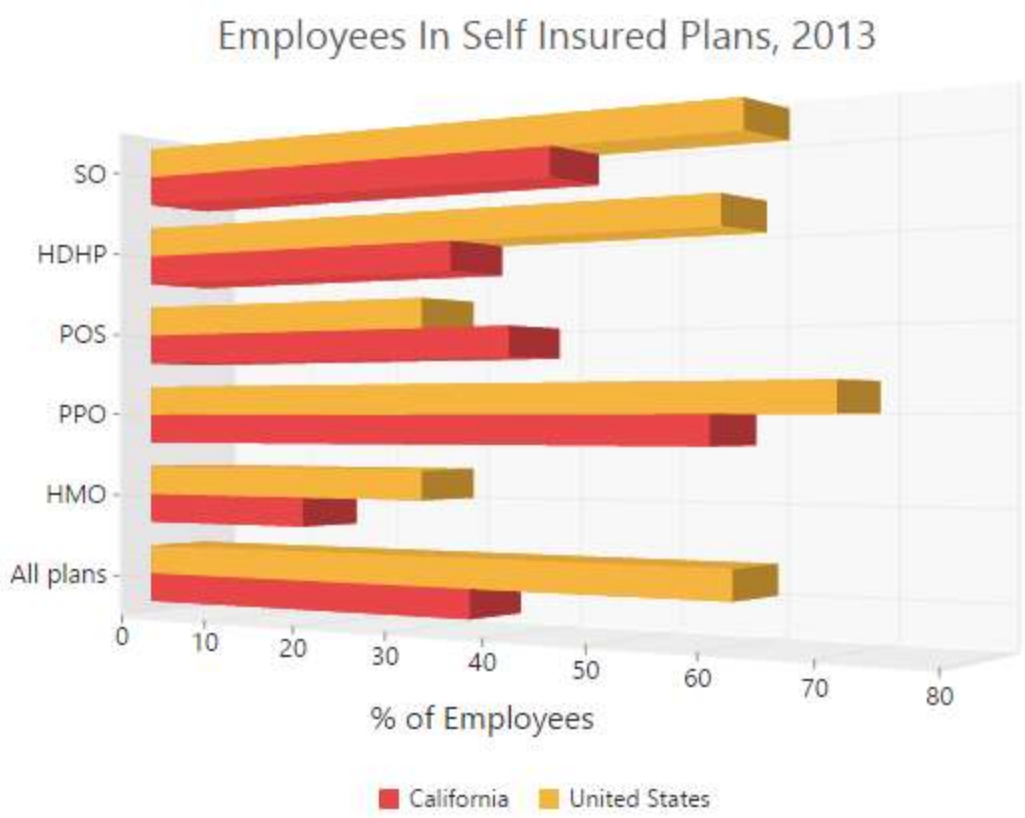
3D Bar Chart

You can create a 3D Bar Chart by setting the series **Type** as **Bar** in the chart series and enable Enable3D option in the chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr => { sr.Type(SeriesType.Bar).Add(); })
// Enable 3D Chart
.Enable3D(true)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Bar 3DChart online demo sample.

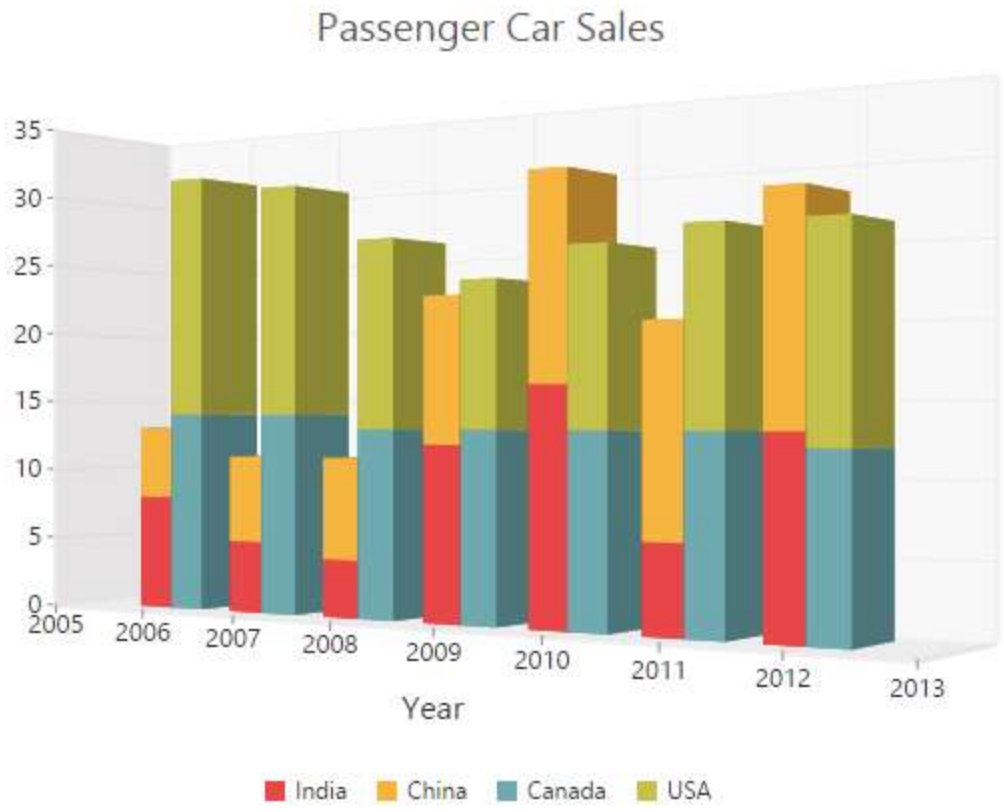
3D Stacked Column Chart

You can create a 3D Stacked Column Chart by setting the series **Type** as **StackingColumn** in the chart series and enable Enable3D option in the chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr => {
//Add First Series
sr.Type(SeriesType.StackingColumn).Add();
//Add Second Series
sr.Type(SeriesType.StackingColumn).Add();})
// Enable 3D Chart
.Enable3D(true)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Stacked Column 3DChart online demo sample.

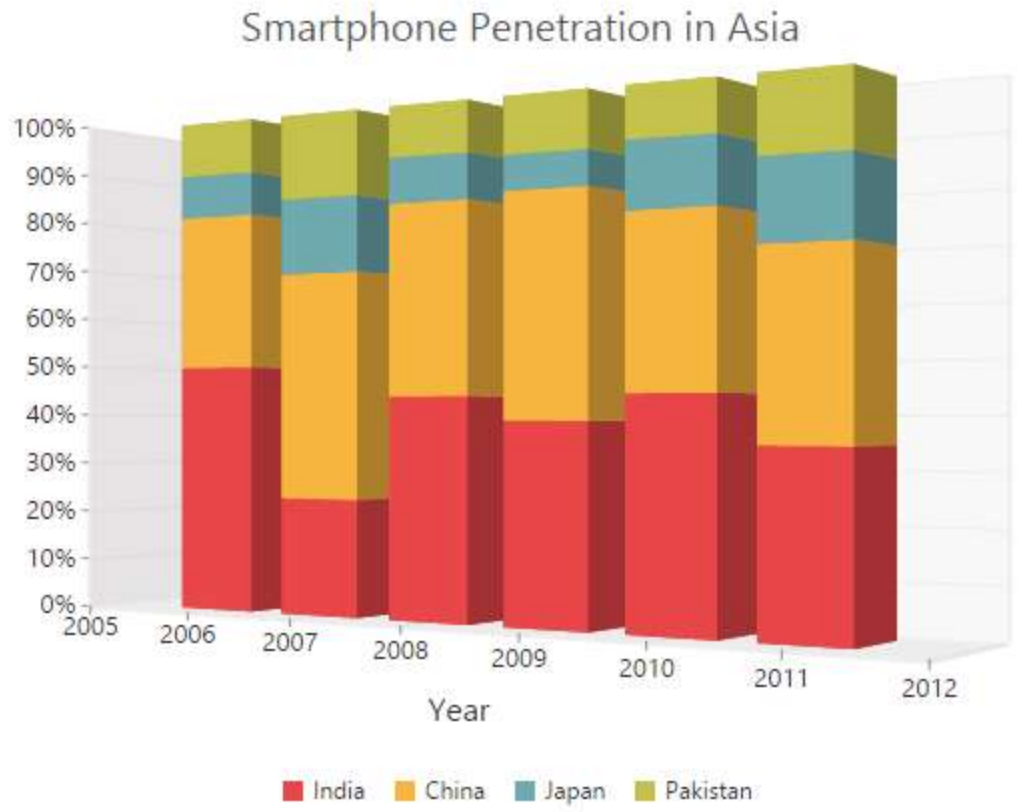
3D 100% Stacked Column Chart

100% Stacking Column 3DChart is rendered by specifying the series **Type** as **StackingColumn100** in the chart series and enable Enable3D option in the chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr => {
//Add First Series
sr.Type(SeriesType.StackingColumn100).Add();
//Add Second Series
sr.Type(SeriesType.StackingColumn100).Add();})
// Enable 3D Chart
.Enable3D(true)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the 100% Stacked Column 3DChart online demo sample.

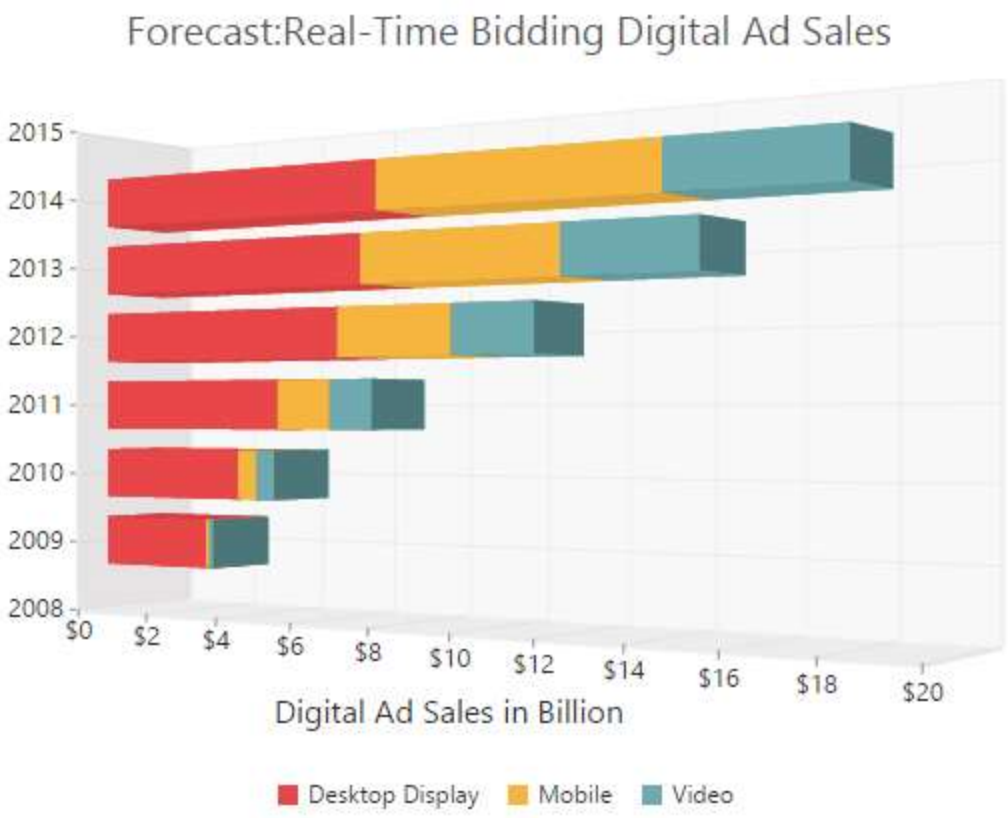
3D Stacked Bar Chart

To create Stacking Bar 3DChart, set the series **Type** as **StackingBar** in the chart series and enable Eenable3D option in the chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr => {
//Add First Series
sr.Type(SeriesType.StackingBar).Add();
//Add Second Series
sr.Type(SeriesType.StackingBar).Add();})
// Enable 3D Chart
.Enable3D(true)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Stacked Bar 3DChart online demo sample.

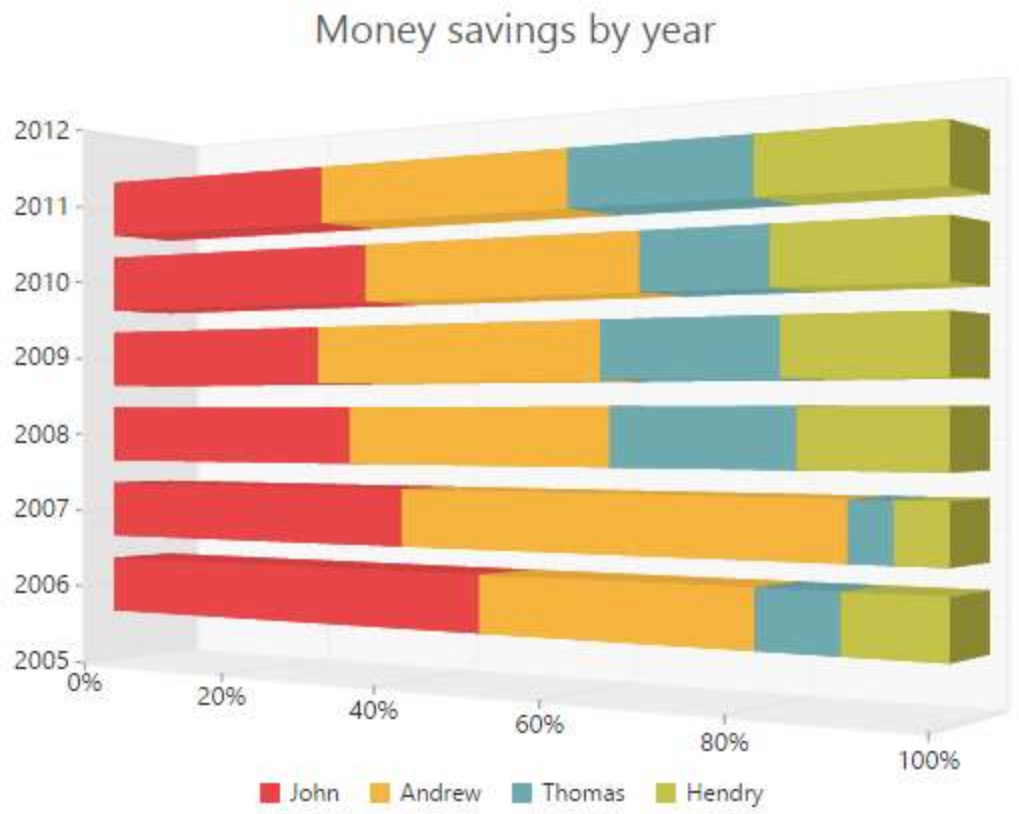
3D 100% Stacked Bar Chart

You can create 100% Stacking Bar 3DChart by setting the series **Type** as **StackingBar100** in the chart series and enable Eenable3D option in chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr => {
//Add First Series
sr.Type(SeriesType.StackingBar100).Add();
//Add Second Series
sr.Type(SeriesType.StackingBar100).Add();})
// Enable 3D Chart
.Enable3D(true)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the 100% Stacked Bar 3DChart online demo sample.

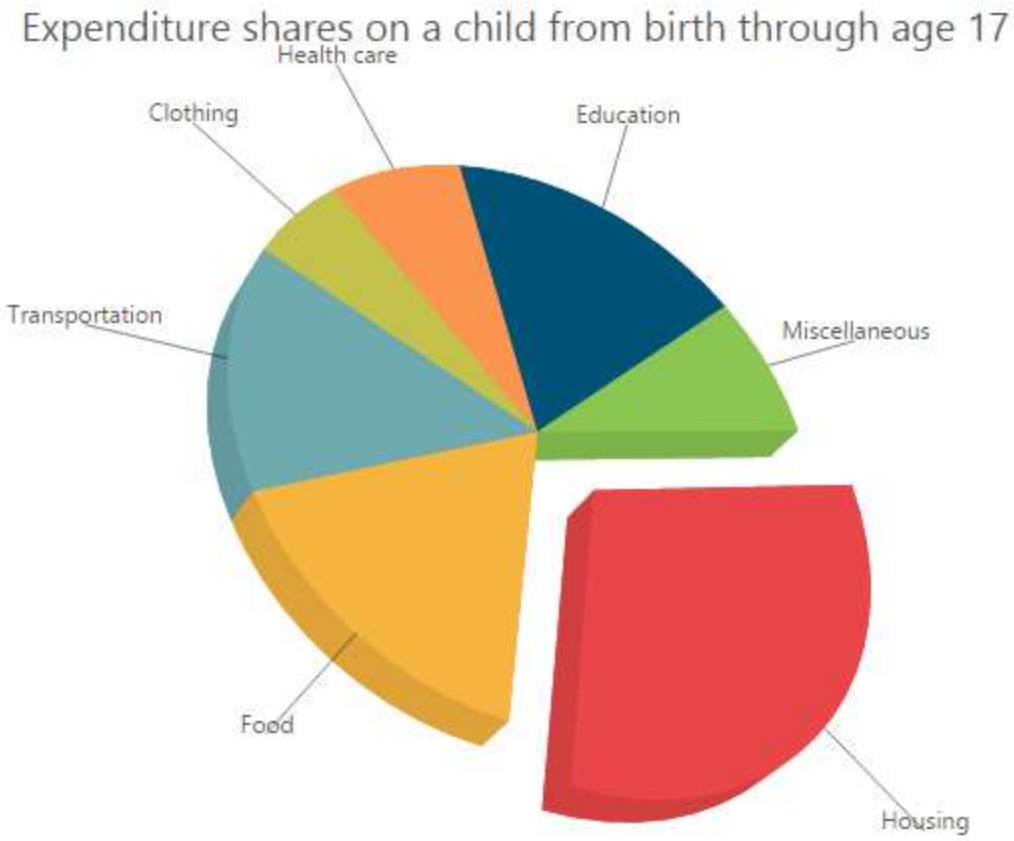
3D Pie Chart

To render the Pie Chart in 3D view, enable the **Enbel3D** option in the chart and set the series **Type** as **Pie** in the chart series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr => {
//Set chart type to series
sr.Type(SeriesType.Pie).Add();})
// Enable 3D Chart
.Enable3D(true)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Pie 3DChart online demo sample.

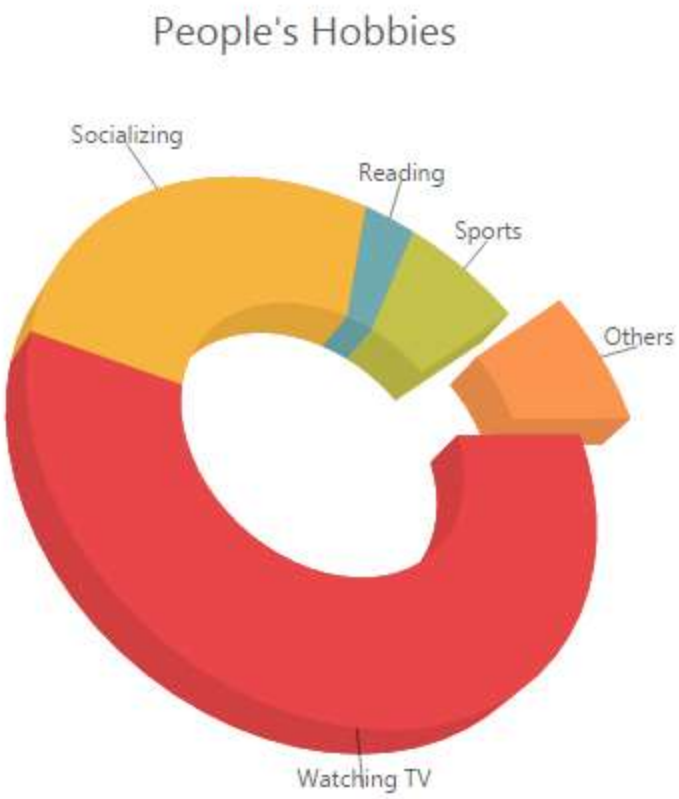
3D Doughnut Chart

To render the Doughnut Chart in 3D view, enable the **Enbel3D** option in the chart and set the series **Type** as **Doughnut** in the chart series.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
.Series(sr => {
//Set chart type to series
sr.Type(SeriesType.Doughnut).Add();})
// Enable 3D Chart
.Enable3D(true)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the Doughnut 3DChart online demo sample.

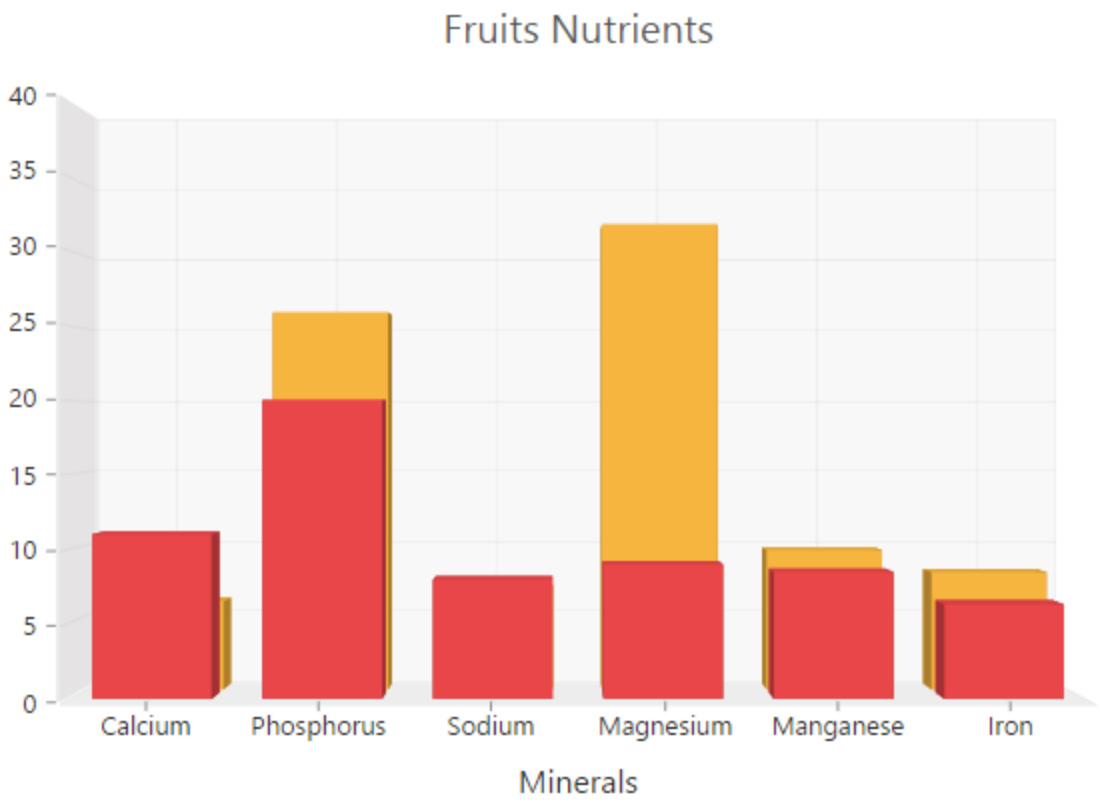
Configure 3D Chart

3D View

To render the EjChart in 3D view, set the **Enable3D** option as **true** in the chart.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// Enable 3D Chart
.Enable3D(true)
// ...
)
```



Click here to view the 3DChart online demo sample.

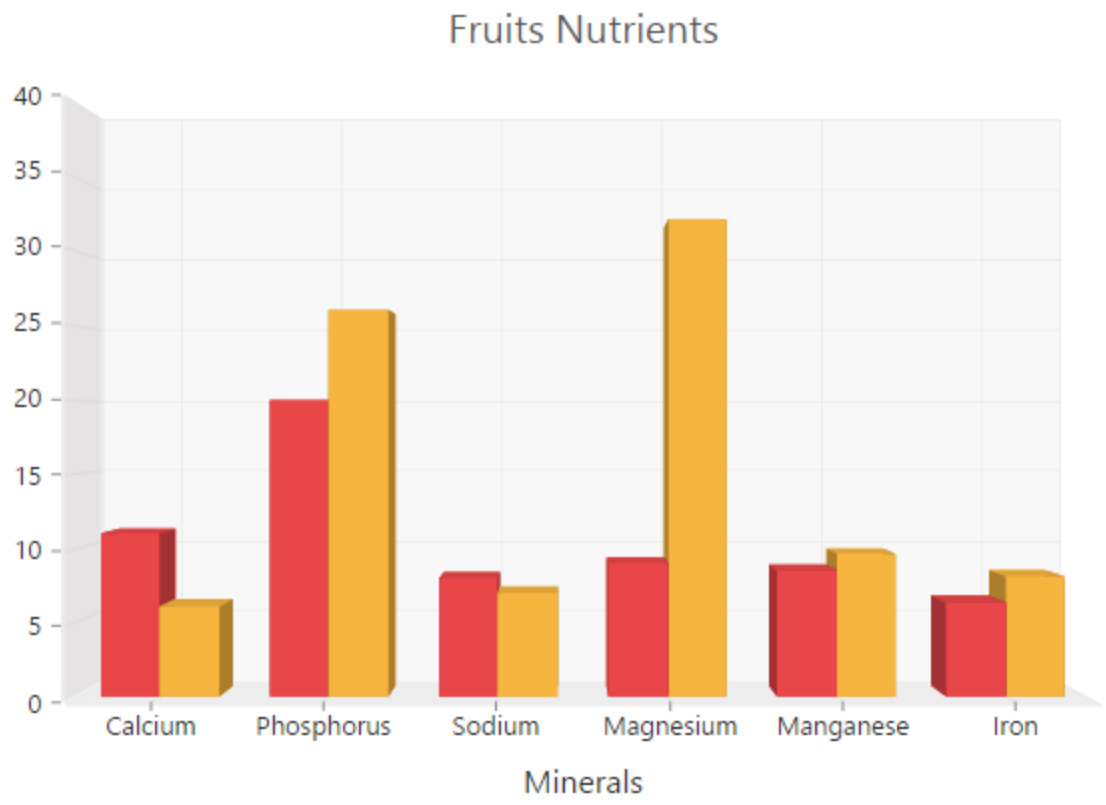
Placing Bar / Column kind of series side-by-side

The **SideBySideSeriesPlacement** defines the appearance of the different sets of data on the 3D Chart. When this property is enabled, the data is displayed side by side, otherwise it is displayed along the depth of the axis.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Enable SideBySideSeriesPlacement for 3DChart
.SideBySideSeriesPlacement(true)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



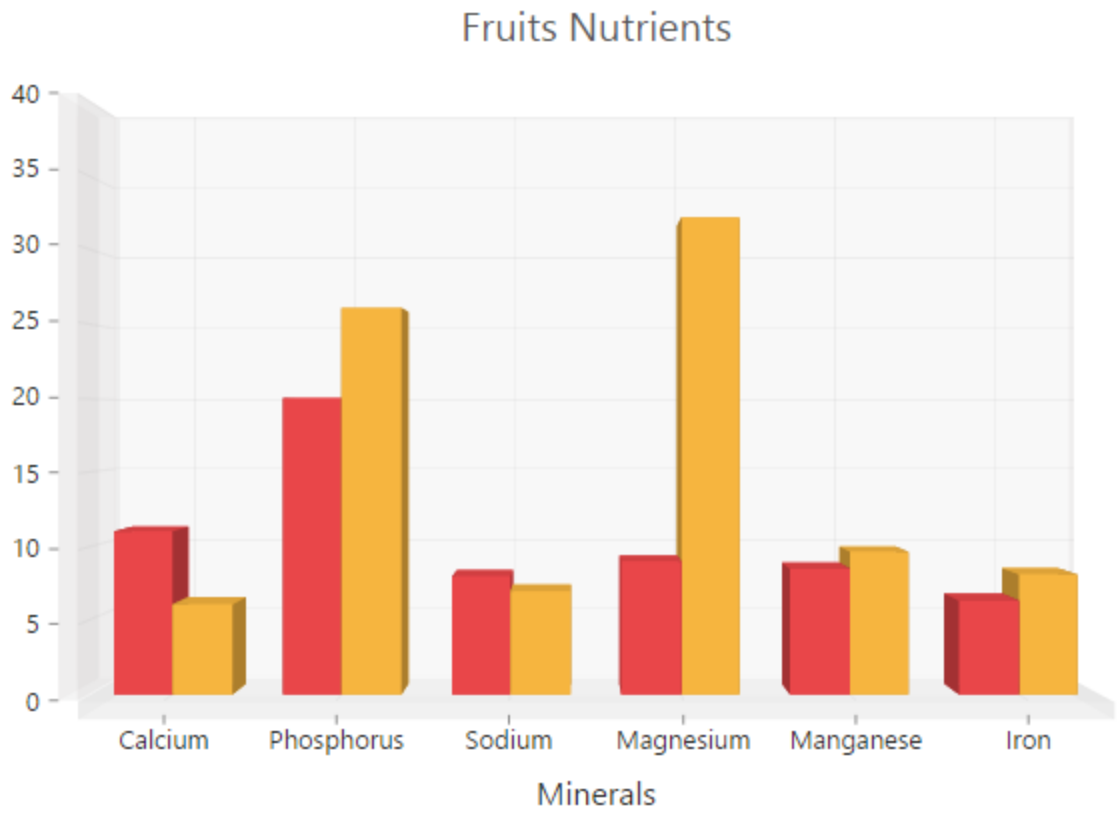
Setting Axis Wall Size

In 3DChart, Cartesian axes lines are represented as walls and it defines the width of the 3D wall. 3D Pie and Doughnut Chart does not support **WallSize** because they don't have axes.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Change 3DChart axis wall size
.WallSize(10)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

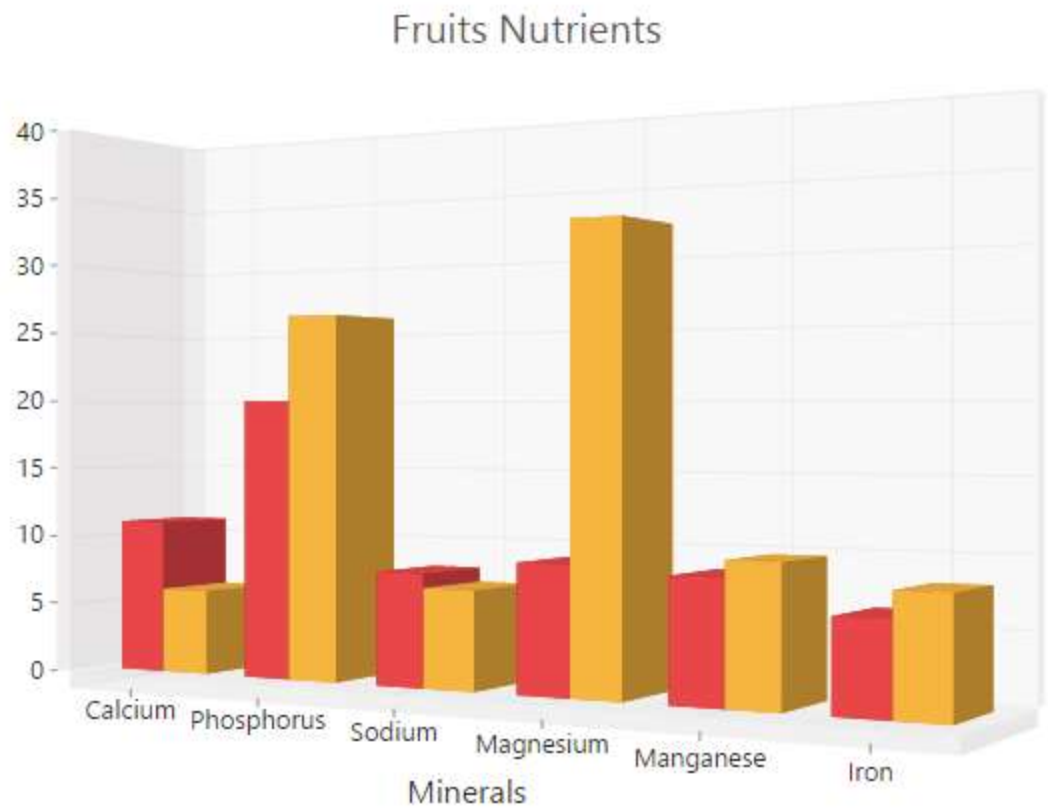


3D Depth

By using the **Depth** property, you can view the 3D Chart from the front view of the series to the background wall.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Change 3DChart depth value
.Depth(120)
// ...
)
```



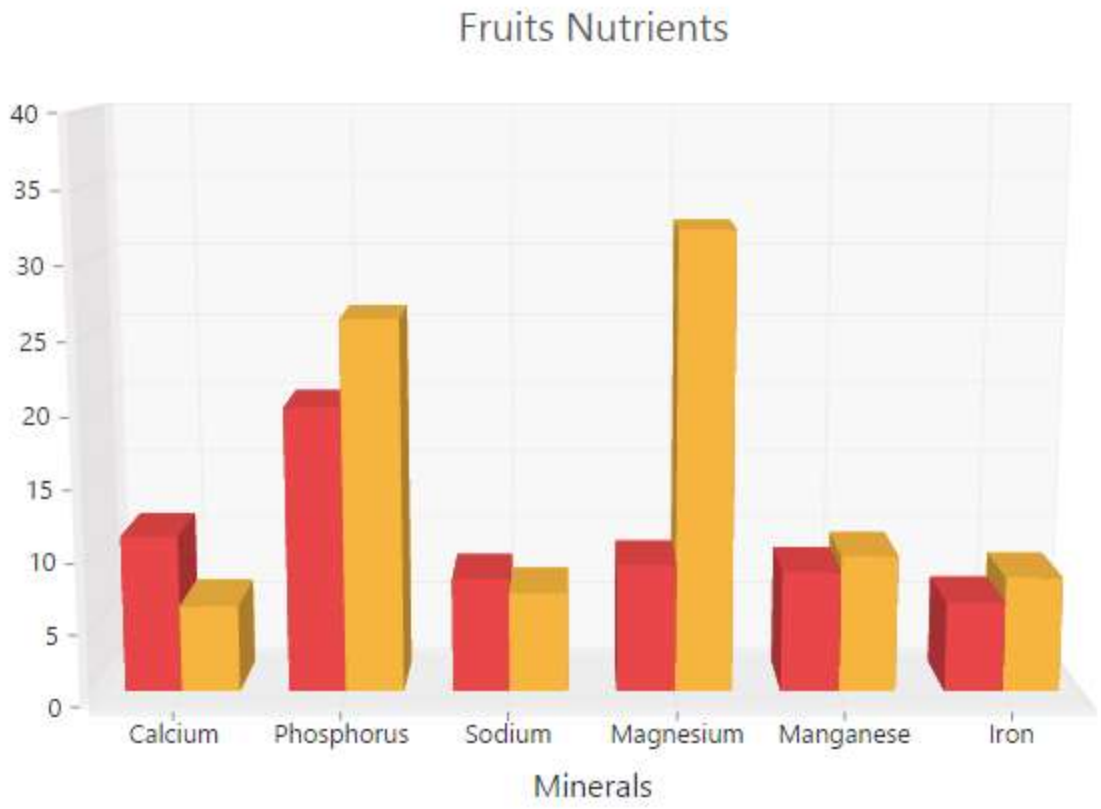
Rotating and Tilting 3D Chart

To spin the 3D Chart on mouse dragging, enable **EnableRotation** option in the chart. The **Tilt** property specifies the angle of the slope of the 3D Chart. The positive and negative values are declared to the side where the slope is present. The **Rotation** option is used to rotate the 3D chart towards left or right side of the chart. The direction of the chart depends upon the positive and negative values of the angle.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Change 3DChart tilt value
.Tilt(10)
//Enable 3DChart  rotation  on mouse dragging
.EnableRotation(true)
//Change 3DChart rotation on chart load
.Rotation(40)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



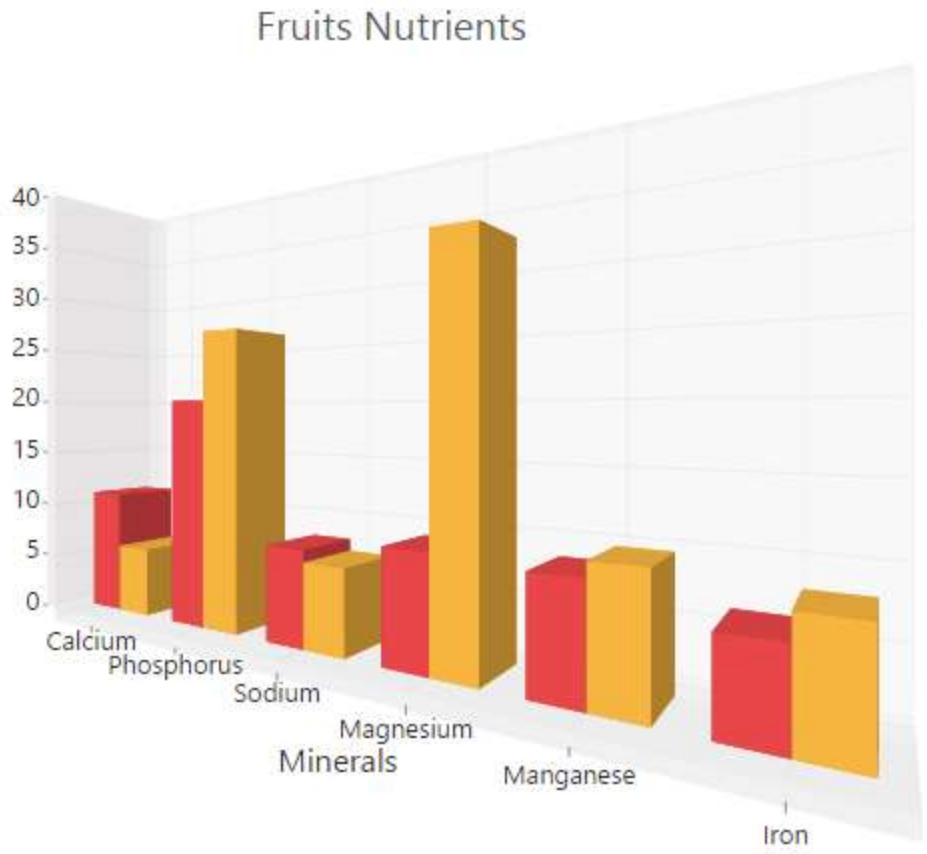
PerspectiveAngle

The **PerspectiveAngle** specifies the appearance of the height, width, depth and wall of the 3D Chart. When the PerspectiveAngle is decreased, the 3D object appears very close to the viewer. But when it is increased, the 3D object appears far away from the viewer.

ASPX-CS

```
@(Html.EJ().Chart("chartContainer")
// ...
//Change 3DChart perspective angle
.PerspectiveAngle(150)
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



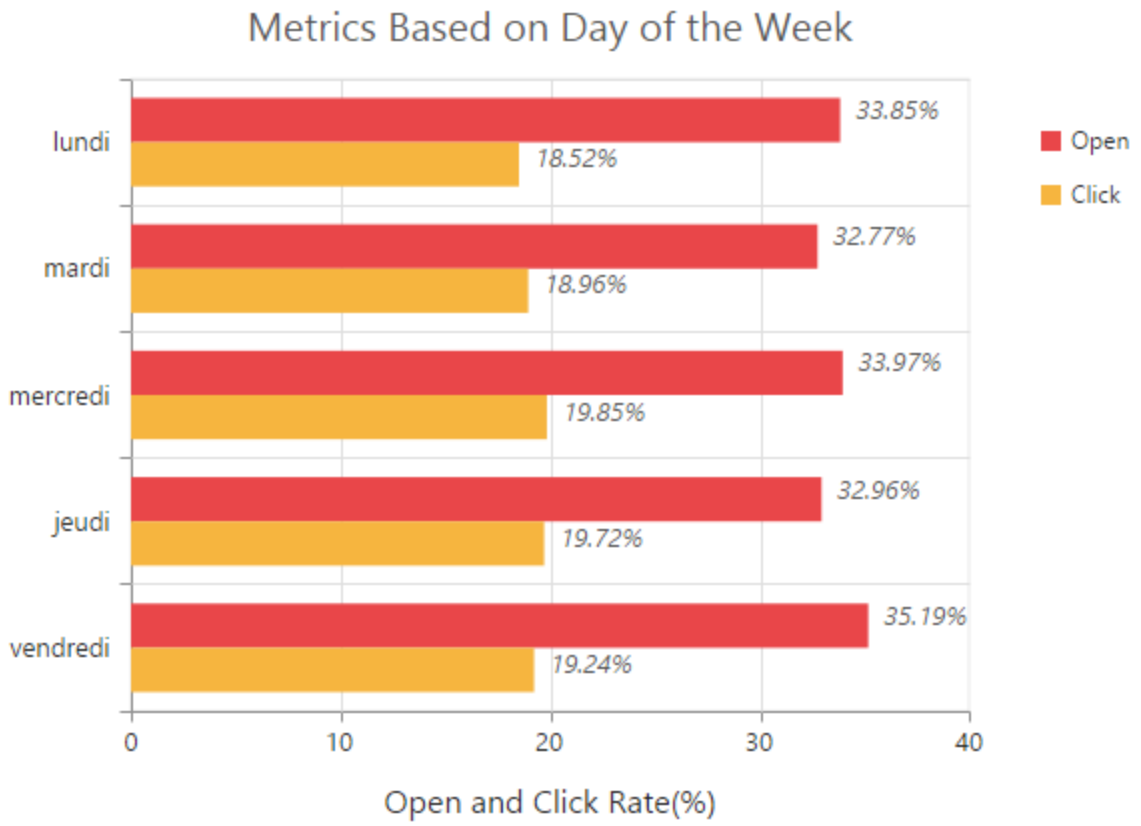
Localization

EjChart supports localization for its axis labels and tooltip. To render the chart with specific culture you have to refer the corresponding **globalize** culture script and need to specify the culture name in **Locale** property of chart.

ASPX-CS

```
<!--Refer french globalize culture script-->
<script src="../scripts/cultures/globalize.culture.fr-FR.min.js"></script>
@(Html.EJ().Chart("chartContainer")
// ...
//Render chart in French locale
.Locale("fr-FR")
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the localization chart online demo sample.

Checkbox

Checkbox

The Essential ASP.NET MVC Checkbox control allows you to check an option to perform an action. This control allows you to select true, false or an intermediate option. These checkboxes are supported with themes. The HTML check box control is rendered as Essential ASP.NET MVC Checkbox control.

Key Features

- Trendy Look : Rich Appearance with Theme Support
- RTL : Supports for Right to Left alignment
- Tri-State: Supports Checkbox with three states.
- Easy Customization: The customization of Checkbox is made simple

Getting Started

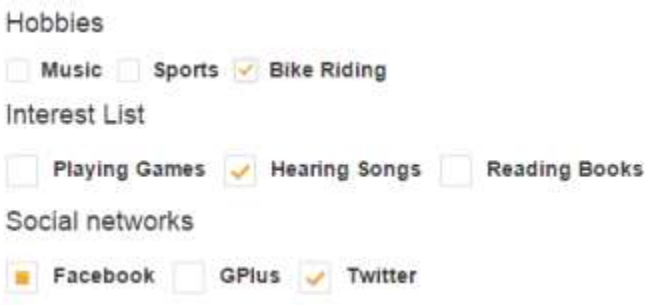
This section explains briefly about how to create a Checkbox in your application with ASP.NET MVC.

Create your first Checkbox in MVC

Essential ASP.NET MVC Checkbox provides support to multiple selections within your web page, and allows you to select options from the list. Refer the following guidelines to create multiple or single

Copyright © 2001 - 2020 Syncfusion Inc.

selection List Receiving App using Checkbox that helps you to get the value of checked Checkbox using the button. The following screenshot illustrates the functionality of Checkbox with button action.



Checkboxes Control

In the above screenshot, you can select hobbies, interest list and social networks receiving app using Checkbox. The Checkbox performs the action to render the checked values when button clicked.

Create a Checkbox

ASP.NET MVC Checkbox widget has built-in features like multiple selections. You can easily create the Checkbox widget using simple HTML helper "@Html.EJ().CheckBox()" as follows.

1. You can create an MVC Project and add necessary assemblies, styles and scripts with the help of the given MVC-Getting Started Documentation.
2. Add the following code to the corresponding view page to render Checkbox.

HTML

```
<div class="frame">
<div class="control">
<div class="chkalign">
<h4>Hobbies</h4>
<table>
<tr>
<td class="chkrad">
@Html.EJ().CheckBox("check1").Value("Music")
<label for="check1" class="clslab">
Music
</label>
</td>
<td class="chkrad">
@Html.EJ().CheckBox("Checkbox3").Value("Sports")
<label for="Checkbox3" class="clslab">
Sports
</label>
</td>
<td class="chkrad">
@Html.EJ().CheckBox("Checkbox4").Value("Bike Riding")
<label for="Checkbox4" class="clslab">
Bike Riding
</label>
</td>
</tr>
</table>
```

```
<h4>Interest List</h4>
<table>
<tr>
<td class="chkrad">
@Html.EJ().CheckBox("Checkbox1").Value("Playing Games").Size(Size.Medium)
<label for="Checkbox1" class="clslab">Playing Games</label>
</td>
<td class="chkrad">
@Html.EJ().CheckBox("Checkbox5").Value("Hearing Songs").Size(Size.Medium)
<label for="Checkbox5" class="clslab">Hearing Songs</label>
</td>
<td class="chkrad">
@Html.EJ().CheckBox("Checkbox6").Value("Reading Books").Size(Size.Medium)
<label for="Checkbox6" class="clslab">Reading Books</label>
</td>
</tr>
</table>
</div>
</div>
</div>
```

3. Add the following styles to the corresponding view page to show the Checkbox in horizontal order.

CSS

```
<style>
td {
float: left;
}
label
{
float: right; margin:5px 10px;
}
</style>
```

4. Run the above code to render the following output.

Checkbox Creation

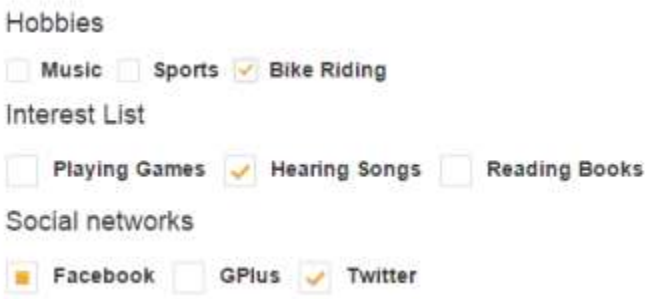
Create a Tri-State Checkbox

ASP.NET MVC Tri-State Checkbox widget renders by setting EnableTriState property to true. You can add the following code to create Tri-state Checkbox in the element of the corresponding view page.

JS

```
<h4>Social networks</h4>
<table>
<tr>
<td class="chkrad">
@Html.EJ().CheckBox("Checkbox2").Value("Facebook").Size(Size.Medium).EnableT
riState(true).CheckState(CheckState.Indeterminate) <label for="Checkbox2"
class="clslab">Facebook</label>
</td>
<td class="chkrad">
@Html.EJ().CheckBox("Checkbox7").Value("GPlus").Size(Size.Medium).EnableTriS
tate(true).CheckState(CheckState.Uncheck) <label for="Checkbox7"
class="clslab">GPlus</label>
</td>
<td class="chkrad">
@Html.EJ().CheckBox("Checkbox8").Value("Twitter").Size(Size.Medium).EnableTr
iState(true).CheckState(CheckState.Check) <label for="Checkbox8"
class="clslab">Twitter</label>
</td>
</tr>
</table>
```

Run the above code to render the following output.



Tri-state Checkbox Creation

Receive Hobbies and Interest

You can receive the Hobbies and Interest values using Checkbox. You can create a button in your corresponding view page element using @Html.EJ().Button() and add the script section to the view page. The following steps illustrate how to create and set action to the button.

Add the following code for Button creation.

ASPX-CS

```
@Html.EJ().Button("buttonNormal").Text("Submit").Size(ButtonSize.Normal)
```

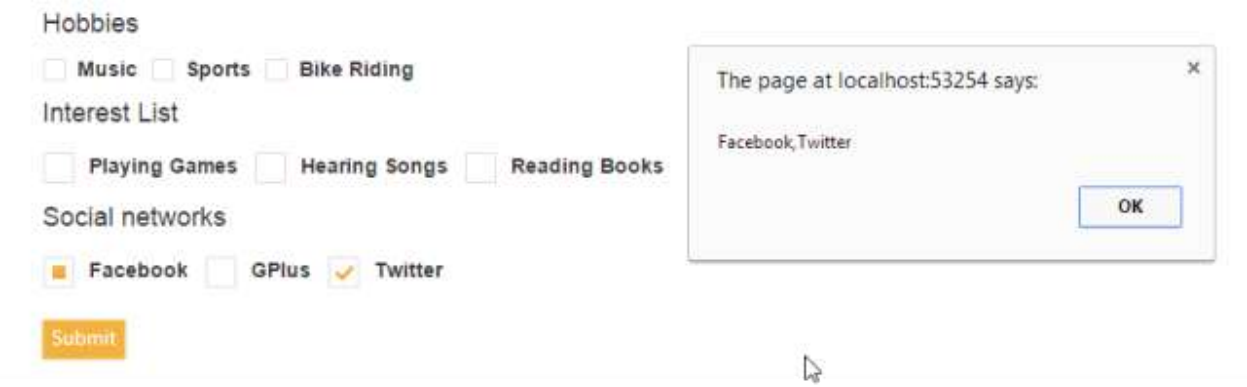
Add the script into your view page.

JS

```
<script>
$(document).ready(function () {
$("button").click(function () {
var checkedItem = [];
$(".e-checkbox").each(function () {
```

```
if ($("#" + $(this)[0].id).ejCheckBox("option", "checked"))
checkedItem.push($("#" + $(this)[0].id).ejCheckBox("option","value"));
});
alert(checkedItem);         });
});
</script>
```

Execute the above code example to render the following output.



Receive hobbies and interest

Receive Media Player

You can get the Media Player file type application like video, audio and picture using Checkbox. You can refer the following steps to render Media Player file types.

1. Add the following code in

   element of the corresponding view page.

HTML

```
<table>
<label for="check2" class="clslab">
Audio
</label>
<tr>
<td class="chkrad">
@Html.EJ().CheckBox("Checkboxs3").Value(".mp3").Size(Size.Medium)
<label for="Checkboxs3" class="clslab">
.mp3
</label>
</td>
</tr>
<tr>
<td class="chkrad">
@Html.EJ().CheckBox("Checkboxs4").Value(".AVI").Size(Size.Medium)
<label for="Checkboxs4" class="clslab">
.AVI
</label>
</td>
</tr>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</table>
<table>
<label for="Checkboxs1" class="clslab">Video</label>
<tr>
<td class="chkrad">
@Html.EJ().CheckBox("Checkboxs5").Value(".mp4").Size(Size.Medium)
<label for="Checkboxs5" class="clslab">.mp4</label>
</td>
</tr>
<tr>
<td class="chkrad">
@Html.EJ().CheckBox("Checkboxs6").Value(".wave").Size(Size.Medium)
<label for="Checkboxs6" class="clslab">.wave</label>
</td>
</tr>
</table>
```

Execute the above code to render the following output.

Receive Media player

Easy customization

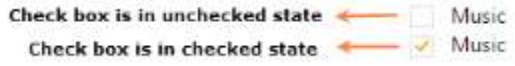
Checked state

Using Checked property, you can set the state of Checkbox. When checked property is true then tick mark is displayed and Checkbox is in checked state. When it is false, the tick mark is not displayed is in non tri-state and Checkbox is in unchecked state. When you want to use this Checked property, then checkbox should be in non Tri-state and EnableTriState property should be false.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* set the state for non Tri-state checkbox using Checked property*@
@Html.EJ().CheckBox("checkbox_unchecked").Checked(false)
<label for="checkbox_unchecked" class="clslab">Music</label>
<br />
@Html.EJ().CheckBox("checkbox_checked").Checked(true)
<label for="checkbox_checked" class="clslab">Music</label>
```

Execute the above code to render the following output.



Checkbox in binary states

Enable Tri-State

Sometimes, it is essential for you to represent the answer in partially true state. To represent the partially true types, an indeterminate state option is present. The state between checked and unchecked state is called indeterminate state. For example, a Checkbox presented to select files to send via FTP can use a tree view so that files can be selected one at a time, or by folder. When only some of the files in a folder are selected, then the checkbox for that folder could be in indeterminate state.

When you enable Tri-state, then the Checkbox includes the indeterminate state. The Checkbox has three states. EnableTriState property specifies to enable or disable the Tri-State option for Checkbox.

The following steps explains you the details about rendering the Checkbox with Tri-state options.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* Enable or disable the Tri-state using EnableTriState property *@
@Html.EJ().CheckBox("checkbox_nonTriState").EnableTriState(false)
<label for="checkbox_nonTriState" class="clslab">Music</label>
<br />
@Html.EJ().CheckBox("checkbox_triState").EnableTriState(true)
<label for="checkbox_triState" class="clslab">Music</label>
```

Execute the above code to render the following output.

Checkbox with Non-Tri state and Tri-state

Check State

You require an option to set indeterminate state for Checkbox. By using CheckState property, you can set any state that is illustrated in following table. Before using this property, enable the Tri-state for Checkbox. EnableTriState property is set true.

List of check states

Check	Check box will be in checked state
Uncheck	Check box will be in un-checked state
Indeterminate	Check box will be in indeterminate state

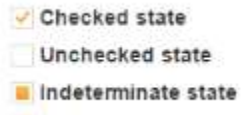
The following steps explains you the details about rendering the Checkbox with specified checked state, when the checkbox is in tri-state.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@*Add the code in CSHTML page to configure and initialize the control*@
@*set the state of Tri-state checkbox using CheckState property*@
@Html.EJ().CheckBox("checkbox_check").EnableTriState(true).CheckState(CheckS
tate.Check)
<label for="checkbox_check" class="clslab">Checked state</label>
<br />
@Html.EJ().CheckBox("checkbox_uncheck").EnableTriState(true).CheckState(Chec
kState.Uncheck)
<label for="checkbox_uncheck" class="clslab">Unchecked state</label>
<br />
@Html.EJ().CheckBox("checkbox_indeterminate").EnableTriState(true).CheckStat
e(CheckState.Indeterminate)
<label for="checkbox_indeterminate" class="clslab">Indeterminate
state</label>
```

Execute the above code to render the following output.



Checkbox in three different states

Checkbox Size

You can render Checkbox in different sizes. The following table contains some predefined size option for rendering a Checkbox in easiest way. Each size option has different height and width. Mainly it avoids the complexity in rendering Checkbox with complex CSS class.

List of checkbox size

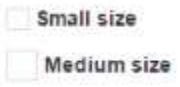
Small	Creates checkbox with Built-in small size height, width specified.
Medium	Creates checkbox with Built-in medium size height, width specified.

The following steps explains you the details about rendering the Checkbox with different size.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@* set the size of checkbox using Size property *@
@Html.EJ().CheckBox("checkbox_small").Size(Size.Small)
<label for="checkbox_small" class="clslab">Small size</label>
<br />
@Html.EJ().CheckBox("checkbox_medium").Size(Size.Medium)
<label for="checkbox_medium" class="clslab">Medium size</label>
```

Execute the above code to render the following output.



Checkbox in different sizes

Text

It specifies the text content for Checkbox. In previous programs, separate label for each Checkbox is created. You can also set the text for checkbox using Text property. Therefore, it is not essential to add label tag for each checkbox in HTML code.

The following steps explains you the details about rendering the Checkbox with text content and without writing label tag

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@*set text for checkbox using Text property *@
@Html.EJ().CheckBox("checkbox_text").Text("Music")
```

Execute the above code to render the following output.

Checkbox with text content

Rounded corner for checkbox

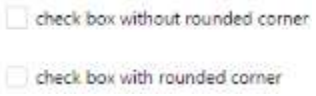
Specifies the corner of Checkbox in rounded shape. Checkbox doesn't have rounded corner by default. To set rounded corner, you can enable ShowRoundedCorner property.

The following steps explains you the details about rendering the Checkbox with rounded corner.

ASPX-CS

```
@*Add the code in CSHTML page to configure and initialize the control*@
@*set the rounded corner for checkbox *@
@Html.EJ().CheckBox("checkbox_normalCorner").ShowRoundedCorner(false).Text("
checkbox without rounded corner")
<br />
@Html.EJ().CheckBox("checkbox_roundedCorner").ShowRoundedCorner(true).Text("
checkbox with rounded corner")
```

Execute the above code to render the following output.



Checkbox with non-rounded & rounded corner

Styles Customization

CheckBox allows you to customize its appearance by using user-defined CSS and custom skin options such as colors and backgrounds. To apply custom themes, use **CssClass** property. CssClass property sets the root class for CheckBox theme.

By using this CssClass, you can override the existing styles under the theme style sheet. The theme style sheet applies theme-specific styles like colors and backgrounds. From the root class, you can customize the CheckBox control theme.

In the following example, the border color and border width of the active CheckBox is customized through the custom classes to create the success, and danger indication with CheckBox.

Copyright © 2001 - 2020 Syncfusion Inc.

HTML

```
<span style="margin-left: 15px">
@Html.EJ().CheckBox("check1").Text("Primary").Size(Syncfusion.JavaScript.Size.Medium).Checked(true).CssClass("success")
@Html.EJ().CheckBox("check2").Text("Danger").Size(Syncfusion.JavaScript.Size.Medium).Checked(true).CssClass("danger")
</span>
```

CSS

```
<style>
.success .e-chkbox-medium .e-chk-inact .e-chk-image,
.success .e-chkbox-medium .e-chk-act .e-chk-image {
background: #17ad37;
color: white;
}
.success .e-chkbox-medium .e-chk-inact,
.success .e-chkbox-medium .e-chk-act {
border-color: transparent;
}
.danger .e-chkbox-medium .e-chk-inact .e-chk-image,
.danger .e-chkbox-medium .e-chk-act .e-chk-image {
background: #d84315;
color: white;
}
.danger .e-chkbox-medium .e-chk-inact,
.danger .e-chkbox-medium .e-chk-act {
border-color: transparent;
}
</style>
```

Miscellaneous

Checkbox Id

Checkbox id is not displayed in user interface. Here, Id mentions the id attribute of the root element of Checkbox control. When you assign a value for Id property, then this older id is replaced by new id. This id value should be unique.

Set id for Checkbox control as follows.

ASPX-CS

```
@*set id for checkbox *@
@Html.EJ().CheckBox("checkbox_id").Id("sync")
```

Checkbox Id Prefix

Id prefix value is the one that is appended to id value. It is used to mention the prefix for the wrapper's id attribute. When you assign a value for IdPrefix property, the older prefix id is replaced by new prefix id.

Copyright © 2001 - 2020 Syncfusion Inc.

Set prefix id for Checkbox control as follows.

ASPX-CS

```
@*set prefix id for checkbox *@
@Html.EJ().CheckBox("checkbox_idPrefix").IdPrefix("JS")
```

Checkbox Name

The name attribute is used to identify from data after it is submitted to the server. Checkbox also contains name attribute. This name should be a unique one. It is used to receive the Checkbox value. Without using name, you can't get the particular checkbox values at the time of submitting form.

Checkbox Value

For Checkbox, the contents of the value property do not appear in the user interface. The value property contains only a meaning when submitting a form. When a Checkbox is in checked state and when the form is submitted, the name of the Checkbox is sent along with the value of the value property (When the checkbox is not checked, no information is sent).

You can set name and value for Checkbox control as follows.

ASPX-CS

```
@*set name and value for checkbox *@
@Html.EJ().CheckBox("checkbox").Name("Conformation").Value("received")
```

How to?

Render Checkbox from Code behind

Checkbox can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of Checkbox properties in the controller.

C#

```
//Namespace to get the JavaScript (Checkbox) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class CheckboxController : Controller
{
// GET: Checkbox
public ActionResult CheckboxFeatures()
{
//Initializing the Checkbox model
CheckBoxProperties BtnObj = new CheckBoxProperties();
//Initializing the datasource and other properties
BtnObj.Checked = true;
BtnObj.Text = "Checkbox";
BtnObj.ShowRoundedCorner = true;
//Passing Checkbox properties using the ViewData
ViewData["BtnModel"] = BtnObj;
return View();
}
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Binding the Checkbox properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

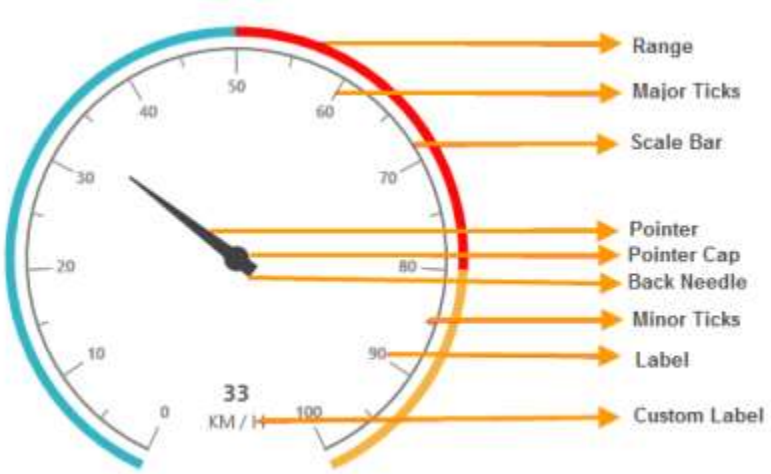
```
@{
Html.EJ().CheckBox("searchCustomer",(Syncfusion.JavaScript.Models.CheckBoxProperties)ViewData["BtnModel"]).Render();
}
```

CircularGauge

CircularGauge

The **CircularGauge** control visualizes the numerical values of scales in a circular manner. It is also a feature-rich control that provides extensive appearance customization options with support for the animation of a pointer element. The **CircularGauge** control comprises the following basic elements:

- Scales
- Pointers
- Ticks
- Labels
- Ranges
- Indicators



Circular Gauge Control Structure

The gauge display can also be customized either as a full circle or a half circle based on individual requirements. Among other helpful features, the **CircularGauge** control also includes advanced user interactivity.

Key Features

- **Sub-Gauge**: Supports for rendering of multiple sub-gauges within the main Circular Gauge.
- **User Interaction**: Allows you to directly interact with the pointers of the gauge.

Copyright © 2001 - 2020 Syncfusion Inc.

- **Indicators**: Supports for the indicator feature that shows the active or inactive state of the gauge.
- **Ranges**: Supports for highlighting the range of values in the gauge scale.
- **Pointers**: Supports for adding multiple pointers to the gauge.
- **Frame types**: Supports two types of gauge displays, full circle and half circle.
- **Animation**: Supports the animation of a pointer.
- **CustomLabel**: Supports the addition of custom label text in the required location of the gauge.

Getting Started

- The ASP.NET MVC Circular Gauge provides support to display the **Circular Gauge** within your web page and allows you to customize it. This section encompasses the details on how to configure Circular Gauge.
- You will learn how to provide data for a Circular Gauge and display that data in a suitable way. In addition, you will learn how to customize the default Circular Gauge appearance, according to your requirements.
- As a result, you will get a Circular Gauge that shows you how the Automobile speedometer works with rpm (Rotation per Minute), kph (Kilometer per hour) and speed level indication (Safe, Caution and Danger).

Analog Speedometer

Create a Circular Gauge

ASP.NET MVC Circular Gauge widget basically renders with animation and flexible APIs. You can easily create the Circular Gauge widget by using the following steps.

1. First create an MVC Project and add necessary Dll's and script with the help of the given MVC-Getting Started Documentation.
2. Add the following code example to the corresponding view page to render CircularGauge.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().CircularGauge("circulargauge"))
```

3. Add the following code example in the controller page.

C#

```
public ActionResult Default()
{
return View();
}
```

Run the above code example to get a default CircularGauge with default values.

Circular Gauge

Set Height and Width

Pointers have different height and width so you can set the Height and Width of the gauge according to your requirements.Set the basic values of the gauge such as height and width of the canvas element values that are to be rendered.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
)
```

Run the above code example and you will see the following output.

Circular Gauge with Height and Width

Set Background Color

The speedometer must have some dark BackgroundColor so that its value is clearly visible and you can vary the speed of the pointer by setting ReadOnly as false for user interaction.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
.BackgroundColor("#3D3F3D")
.ReadOnly(false)
)
```

Run the above code example and you will see the following output.

Circular Gauge with Dark Background

Copyright © 2001 - 2020 Syncfusion Inc.

Provide Scale Values

- The Scales values specifies the pointers, ticks, labels, indicators and ranges of **Circular Gauge**.
- The PointerCap can be customized with the following options. Cap Radius, cap BorderColor, cap BackgroundColor, pointer cap BorderWidth are some of the properties that are customizable.
- The speed limit in the gauge has maximum value of 200 kph. So you can set Maximum value for the gauge as 200.
- Major Ticks have the MajorIntervalValue of 20 and minor ticks have the MinorIntervalValue of 5. ShowRanges and ShowIndicators are used to display the ranges and indicators in their respective positions.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
.BackgroundColor("#3D3F3D")
.ReadOnly(false)
.Scales(scale => {
scale.ShowRanges(true)
.ShowIndicators(true)
.PointerCap(cap=>
cap.Radius(15)
.BorderWidth(0)
.BackgroundColor("#797C79")
.BorderColor("#797C79"))        .Maximum(200)
.MajorIntervalValue(20)
.MinorIntervalValue(5).Add();
//Add the labels customization code here
//Add the pointers customization code here
//Add the ticks customization code here
//Add the ranges customization code here
//Add the indicators customization code here
//Add the Custom labels customization code here
}))
```

Run the above code example and you will see the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with Scale Values

Add Label Customization

To display the value around the scales, Labels are used. By customizing the label Color it displays as specified.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
.BackgroundColor("#3D3F3D")
.ReadOnly(false)
.Scales(scale => {scale
//Add the labels customization code here
.Labels(label => label.Color("#ffffff").Add())
.Add();
//Add the pointers customization code here
//Add the ticks customization code here
//Add the ranges customization code here
//Add the indicators customization code here
//Add the Custom labels customization code here
}))
```

Run the above code example and you will see the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with Label

Add Pointers

Here, you have three Pointers that denote the kilometer value, rotation per minute value and torque value.The torque value pointer needs not be similar to the other two pointers. You can set torque pointer as marker pointer. And you can set other attributes for pointer such as Value, ShowBackNeedle, Type, MarkerType, NeedleType, BackgroundColor, Border Color, Length, Width, Radius and DistanceFromScale.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
.BackgroundColor("#3D3F3D")
.ReadOnly(false)
.Scales(scale => {scale
//Add the labels customization code here
//Add the pointers customization code here
.Pointers(pointer=>{
pointer.Value(140)
.DistanceFromScale(60)
.ShowBackNeedle(false)
.Length(20)
.Type(PointerType.Marker)
.MarkerType(MarkerType.Triangle)
.Width(10)
.BackgroundColor("#FF940A")
.Border(border => border.Color("#FF940A")).Add();
pointer.Value(110)
.ShowBackNeedle(false)
.Length(150)
.NeedleType(NeedleType.Rectangle)
.Width(2)
.BackgroundColor("#05AFFF")
.Border(border =>border.Color("#05AFFF")).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
pointer.Value(67)
.ShowBackNeedle(false)
.Length(100)
.Width(15)
.BackgroundColor("#FC5D07")
.Border(border => border.Color("#FC5D07")).Add();
})
.Add();
//Add the ticks customization code here
//Add the ranges customization code here
//Add the indicators customization code here
//Add the Custom labels customization code here
}))
```

Run the above code example and you will see the following output.

Circular Gauge with Pointers

Add Tick Details

- You can set Major Ticks with their Width and Height equal to Minor Ticks.
- You can set Color according to your preference for better visibility in dark backgrounds.
- You can specify the tick Type either major or minor type tick and DistanceFromScale values.
- To display and customize the tick value add the following code example.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
.BackgroundColor("#3D3F3D")
.ReadOnly(false)
.Scales(scale => {
scale
//Add the labels customization code here
```

```
//Add the pointers customization code here
//Add the ticks customization code here
.Ticks(tic => {
tic.Type(CircularTickTypes.Major)
.DistanceFromScale(70)
.Height(20)
.Width(3)
.Color("#ffffff").Add();
tic.Type (CircularTickTypes.Minor)
.DistanceFromScale(70)
.Height(12)
.Width(1)
.Color("#ffffff").Add();
})
.Add();
//Add the ranges customization code here
//Add the indicators customization code here
//Add the Custom labels customization code here
}))
```

Run the above code example and you will see the following output.

Circular Gauge with Ticks

Add Range Values

- Ranges denote the property of the scale value in the speedometer. The color values of the Ranges denote speed variation. Set ShowRanges as **true** for showing the ranges in the **Circular Gauge**.
- For Low speed, you can mention it as safe zone; for moderate speed, you can call it as caution zone and for high speed, you can mark it as high speed.
- You can customize the range with properties such as StartValue, EndValue, StartWidth, EndWidth, BackgroundColor , Border Color, DistanceFromScale,etc.,

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
.BackgroundColor("#3D3F3D")
.ReadOnly(false)
.Scales(scale => {
scale
//Add the labels customization code here
//Add the pointers customization code here
//Add the ticks customization code here
//Add the ranges customization code here
.Ranges(range => {
range.DistanceFromScale(30)
.StartValue(0)
.EndValue(70)
.BackgroundColor("#5DF243")
.Border(border => border.Color("#ffffff")).Add();
range.DistanceFromScale(30)
.StartValue(70)
.EndValue(140)
.BackgroundColor("#F6FF0A")
.Border(border => border.Color("#ffffff")).Add();
range.DistanceFromScale(30)
.StartValue(140)
.EndValue(200)
.BackgroundColor("#FF1807")
.Border(border => border.Color("#ffffff")).Add();
})
.Add();
//Add the indicators customization code here
//Add the Custom labels customization code here
}))
```

Run the above code example and you will see the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with Ranges

Add Indicator Details

- Indicators denote whether the pointers values are in their respective zones or not. Positioning the Indicators on the respective range value gives you the required changes.
- By using Position property, you can set the location of the indicator. You can also specify Height, Width and Type for indicators. StateRanges defines how the indicator should behave when the pointer is in certain values.
- You can customize state ranges with properties like EndValue, StartValue, BackgroundColor, BorderColor, Text, TextColor, etc.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
.BackgroundColor("#3D3F3D")
.ReadOnly(false)
.Scales(scale => {
//Add the labels customization code here
//Add the pointers customization code here
//Add the ticks customization code here
//Add the ranges customization code here
//Add the indicators customization code here
.Indicators(ind =>
{
ind.Height(10)
.Width(10)
. Type(IndicatorType.Circle)
.Position(loc => loc.X(210).Y(300))
.StateRanges(state =>
{
state.EndValue(70)
.StartValue(0)
.BackgroundColor("#5DF243")
.BorderColor("#5DF243").Text("").TextColor("#ffffff")
.Add();
state.EndValue(200)
.StartValue(70)
.BackgroundColor("#145608")
.BorderColor("#145608").Text("").TextColor("#ffffff")
.Add();
}).Add();
ind.Height(10)
.Width(10)
. Type(IndicatorType.Circle)
.Position(loc => loc.X(255).Y(200))
.StateRanges(state =>
{
state.EndValue(140)
.StartValue(70)
.BackgroundColor("#F6FF0A")
.BorderColor("#F6FF0A").Text("").TextColor("#ffffff")
.Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
state.EndValue(70)
.StartValue(0)
.BackgroundColor("#969B0C")
.BorderColor("#969B0C").Text("").TextColor("#ffffff")
.Add();
state.EndValue(200)
.StartValue(140)
.BackgroundColor("#969B0C")
.BorderColor("#969B0C").Text("").TextColor("#ffffff")
.Add();
}).Add();
ind.Height(10)
.Width(10)
. Type(IndicatorType.Circle)
.Position(loc => loc.X(300).Y(300))
.StateRanges(state =>
{
state.EndValue(140)
.StartValue(200)
.BackgroundColor("#890F06")
.BorderColor("#890F06").Text("").TextColor("#ffffff")
.Add();
state.EndValue(140)
.StartValue(0)
.BackgroundColor("#FF1807")
.BorderColor("#FF1807").Text("").TextColor("#ffffff")
.Add();
}).Add();
}).Add();
//Add the Custom labels customization code here }))
```

Run the above code example and you will see the following output.

Circular Gauge with Indicators

Copyright © 2001 - 2020 Syncfusion Inc.

Add Custom Label Details

CustomLabels are used to specify the texts that need to be displayed in the gauge. You can customize it through various properties such as Value, Position, Color, Font Size, FontFamily and FontStyle. To display the three range description, custom texts are used here.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
.BackgroundColor("#3D3F3D")
.ReadOnly(false)
.Scales(scale => {
//Add the labels customization code here
//Add the pointers customization code here
//Add the ticks customization code here
//Add the ranges customization code here
//Add the indicators customization code here
//Add the Custom labels customization code here
.CustomLabels(label=>{
label.Value("Safe")
.Color("#5DF243")
.Position(loc=>loc.X(200).Y(280))
.Font(font => { font.FontFamily("Arial").Size("12px").FontStyle("Bold"); })
.Add();
label.Value("Caution")
.Color("#F6FF0A")
.Position(loc => loc.X(253).Y(212))
.Font(font => { font.FontFamily("Arial").Size("12px").FontStyle("Bold"); })
.Add();
label.Value("Danger")
.Color("#FF1807")
.Position(loc => loc.X(290).Y(280))
.Font(font => { font.FontFamily("Arial").Size("12px").FontStyle("Bold"); })
.Add();
}).Add();
}))
```

Run the above code example and you will see the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with Custom label

Interaction and Animation

Interaction

- **Circular Gauge** control contains **Interaction** feature. You can use this interaction feature to change the pointer values manually. You can achieve this by clicking and dragging the pointer over the Gauge and you can see the value of pointer changes dynamically while dragging.
- To Enable/Disable the user interaction you can use the Boolean property called ReadOnly. The user interaction option is enabled when you set the value as false for the property readOnly.By default it holds the true value.That is by default it does not support interaction.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
// For User interaction
.ReadOnly(false))
)
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with basic interaction property

Animations

- **Circular Gauge** contains an attractive concept called **Animation**. The animation option enables the pointer to rotate from the minimum value to the current value with animation effects. By using this animation you can change the pointer value dynamically.You can apply the animation on pointer either by clockwise or counterclockwise based on the scale direction.
- You can enable / disable it using the property EnableAnimation. Animation is enabled when you set enableAnimation as 'true'. By default it holds the true value. You can control the speed of the pointer during animating by using the property AnimationSpeed. It is a numerical value that holds the time in milliseconds. That is when the value is given as 1000, it is considered as 1 second.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
// For enabling animation
.EnableAnimation(true)
// For setting animation speed
.AnimationSpeed(1000)
)
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with basic Animation property

Gradient

You can change the interior gradient of **Circular Gauge** by using InteriorGradient property. The IsRadialGradient property is used to check whether the gradient is circular or not.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.InteriorGradient(gradient=>gradient
.ColorInfo(
//..
).Add();
)
.IsRadialGradient(true)
)
```

Distance From Corner

You can display the circular gauge from distance apart from the corner by specifying value for DistanceFromCorner property.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.DistanceFromCorner(25)
)
```

Resize

Circular gauge can be responsive while resizing by specifying EnableResize property as true.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.EnableResize(true)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Localization

The circular gauge can be localized based on name of culture specified in Locale property.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Locale("en-US")
)
```

Themes

CircularGauge Theme is a set of pre-defined options that are applied to the control before **CircularGauge** is instantiated. Following predefined themes are available in JavaScript **CircularGauge**.

1. flatlight
2. flatdark
3. gradientlight
4. gradientdark
5. azure
6. azuredark
7. lime
8. limedark
9. saffron
10. saffrondark
11. gradientazure
12. gradientazuredark
13. gradientlime
14. gradientlimedark
15. gradientsaffron
16. gradientsaffrondark

The theme for circular gauge can be specified using Theme property.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Theme("flatlight")
)
```

Circular Gauge Values

The Minimum, Maximum, Radius and Value attributes of circular gauge are used to render the circular gauge with specified location.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Maximum(120)
.Minimum(10)
.Value(30)
.Radius(100)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Scales

Scales are the basic functional block of the **Circular Gauge**. By customizing the Scales, the appearance of the **Gauge** can be improved. The functional blocks of Circular Gauge are

- Pointers
- Labels
- CustomLabels
- Indicators
- Ticks
- Ranges
- Sub gauges.

Adding Scale Collection

Scale collection is directly added to the Gauge object. Refer the following code example to add scale collection in **Gauge** control.

ASPX-CS

```
//For circular gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(SC =>
{
SC.Radius(130).Add();
}))
```

Execute the above code to render the following output.

Circular Gauge with scale radius.

Scale Customization

Colors and Border

- The Scale border is modified with the object called Border. It has two border property namely Color and Width which are used to customize the border color of the scale and border width of the scale.

Copyright © 2001 - 2020 Syncfusion Inc.

- Setting the background color improves the look and feel of the **Circular Gauge**. You can customize the background color of the scale using BackgroundColor.
- The scale bar of circular gauge can be enabled by setting ShowScaleBar property as true.

ASPX-CS

```
//For circular gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(SC =>
{
SC.Radius(130)
.BackgroundColor("Red")
.ShowScaleBar(true)
.Border(b =>{
//For scale border width
b.Width(3)
//For scale border color
.Color("Blue");
})
.Pointers(pointer =>
{
pointer.Length(80).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with customized scale border

Pointer Cap

- **Pointer cap** is a circular shape element that is located at the center of the **Circular Gauge**. The pointer cap is one of the cynosure of the Circular Gauge. By customizing the pointer cap, Gauge style is improved. The pointer cap is modified with the object PointerCap.
- It contains Radius, BorderColor, BorderWidth, InteriorGradient and BackgroundColor properties. The property radius is used to set the radius for the pointer cap. InteriorGradient is used to provide the gradient effects to the pointer cap.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
//For circular gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(SC =>
{
SC.PointerCap(cap =>
{
//For setting pointer cap radius
cap.Radius(10)
// For setting pointer cap border width
.BorderWidth(4)
// For setting pointer cap border color
.BorderColor("Blue")
// For setting pointer cap background
.BackgroundColor("Red");
}).Add();
}))
```

Execute the above code to render the following output.

Circular Gauge with customized pointer cap

Appearance

- Circular Gauge contains two types of scale direction such as clockwise and counter clockwise. You can set them by enumerable property called Direction. And you can set the minimum and maximum values for the scale with the properties Minimum and Maximum. The two properties MinorIntervalValue and MajorIntervalValue are the values used to set interval value for the ticks and labels.
- The Radius property is used to set the radius value for the circular scale and the Size property is used to set the scale bar width. You can also adjust the Opacity of the scale with the property Opacity. The value for opacity lies between 0 and 1. You can also give some shadow effects for the scale by using the property ShadowOffset. The property StartAngle is used to set starting

Copyright © 2001 - 2020 Syncfusion Inc.

position of the scale at certain angle and SweepAngle is used to shrink or expand the scale to certain angle.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(scale =>
{
// For setting scale bar size
scale.Size(30)
// For setting scale minimum value
.Minimum(20)
// For setting scale maximum value
.Maximum(120)
// For setting scale major interval value
.MajorIntervalValue(20)
// For setting scale minor interval
.MinorIntervalValue(5)
// For setting scale background color
.BackgroundColor("Red")
// For setting scale bar opacity
.Opacity(0.5)
// For setting scale bar shadow offset
.ShadowOffset(20)
// For setting scale direction
.Direction(Directions.CounterClockwise).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with customized scale values

Enable/Disable properties

You can enable / disable properties in Circular Gauge using some properties in scale collection. The ShowIndicators property is used to enable/disable the indicators. ShowLabels, ShowTicks,

ShowRanges, ShowPointers ans ShowScaleBar are used to enable/ disable labels, ticks, ranges, pointers and scale bar respectively.

Multiple Scales

You can set **Multiple scales** for a single **Circular Gauge** control by using an array of scale objects. Each scale object is independent of each other. The following code example refers to two scale objects in a Gauge.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(scale =>
{
// For setting  first scale
scale.ShowScaleBar(true)
.Size(10)
.Radius(150)
.Minimum(20)
.Maximum(120)
.MajorIntervalValue(20)
.MinorIntervalValue(5)
.Pointers(p => { p.Length(120).Value(50).Add(); })
.Direction(Directions.Clockwise)
.ShadowOffset(20).Add();
// For setting second scale
scale.Size(10)
.ShowScaleBar(false)
.Radius(80)
.MajorIntervalValue(10)
.Labels(lb =>lb.DistanceFromScale(-40).Color("Red").Add())
.Ticks(t =>t.Color("Red").Add())
.Pointers(p => { p.Length(50).Value(40).DistanceFromScale(-30).Add();  })
.Direction(Directions.CounterClockwise)
.Opacity(0.5)
.ShadowOffset(5).Add();
})
)
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with multiples scales

Pointers

Pointer value points out the actual value set in the Circular Gauge. You can customize the Pointers to improve the appearance of Gauge.

Adding Pointer Collection

Pointer collection is directly added to the scale object. To add pointer collection in a Gauge control refer the following code example.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(scale =>
{
scale.Pointers(PO =>
{
// For setting pointer value
PO.Value(30).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with pointer collection

Adding Pointer Value

Pointer value is the important element in the **Circular Gauge** that indicates the Gauge value. Real purpose of the Circular Gauge is based on the pointer value. You can set the pointer Value either directly during rendering the control or it can be achieved by public method too.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(scale =>
{
scale.ShowScaleBar(true)
.MajorIntervalValue(10)
.MinorIntervalValue(2)
.Radius(150)
.Size(2)
.ShowRanges(true)
.Ranges(ran =>
{
ran.StartValue(20)
.EndValue(80)
.BackgroundColor(ConsoleColor.Green.ToString())
.Add();
})
.Pointers(PO =>
{
// For setting pointer value
PO.Value(30).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with customized pointer value

Pointer Styles

Colors and Border

- The Pointers border is modified with the object called Border as in scales. It has two border property called Color and Width which are used to customize the border color of the pointer and border width of the pointer.
- You can set the background color to improve the look of the **Circular Gauge** and you can customize the background color of the scale using BackgroundColor.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowScaleBar(true)
.Radius(110)
.Pointers(PO =>
{
// For setting pointer Value
PO.Value(45)
// For setting pointer length
.Length(80)
// For setting pointer width
.Width(16)
// For setting pointer background
.BackgroundColor(ConsoleColor.Yellow.ToString())
// For setting pointer border
.Border(border =>border.Color(ConsoleColor.Green.ToString()).Width(2))
// For setting pointer opacity
.Opacity(0.6).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with pointer collection

Appearance

- Based on the value, the **pointer** point out the label value. You can set the pointer length and width using Length and Width property respectively.
- And you can also adjust the opacity of the pointer using the property Opacity which holds the value between 0 and 1. You can add the gradient effects to the pointer using Gradients object.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowScaleBar(true)
.Radius(110)
.BackgroundColor(ConsoleColor.Yellow.ToString())
.Border(border =>border.Color(ConsoleColor.Red.ToString()).Width(2))
.Pointers(PO =>
{
PO.Value(45)
// For setting pointer background
.BackgroundColor(ConsoleColor.Yellow.ToString())
// For setting pointer border
.Border(border =>border.Color(ConsoleColor.Red.ToString()).Width(2))
// For setting pointer length
.Length(80)
// For setting pointer width
.Width(16)
// For setting pointer opacity
.Opacity(0.6).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with customized pointer styles

Position the pointer

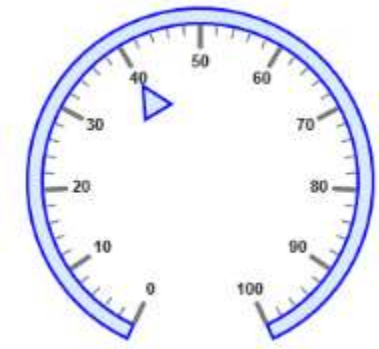
- Pointer can be positioned with the help of two properties such as **DistanceFromScale** and **Placement**. DistanceFromScale property defines the distance between the scale and pointer. Placement property is used to locate the pointer with respect to scale either inside the scale or outside the scale or along the scale.
- It is an enumerable data type. Both the property is applied only if pointer Type is marker. For NeedleType marker, it renders with default position that is unchangeable.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowScaleBar(true)
.Size(10)
.Radius(110)
.BackgroundColor("#DCEBF9")
.Border(border=>border.Color(ConsoleColor.Blue.ToString()).Width(2))
.Pointers(PO =>
{
PO.Value(40)
.Length(20)
.Width(20)
.BackgroundColor("#DCEBF9")
.Border(border=>border.Color(ConsoleColor.Blue.ToString()).Width(2))
// For setting distance between scale and pointer
.DistanceFromScale(10)
// For setting pointer placement
.Placement(PointerPlacement.Near)
// For setting pointer type
.Type(PointerType.Marker)
// For setting marker type
.MarkerType(MarkerType.Triangle)
.Add();
}).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Execute the above code to render the following output.



Circular Gauge with customized pointer type as marker

Types

- Circular gauge pointer has two types such as,
    1. Needle
    2. Marker
- Needle type pointers are the default pointers that cannot be positioned and that is located at the center of the gauge. There are four different shapes of needle pointers such as
    1. Rectangle
    2. Triangle
    3. Trapezoid
    4. Arrow
- For marker pointer, the available dimensions are
    1. Rectangle
    2. Triangle
    3. Ellipse
    4. Diamond
    5. Pentagon
    6. Circle
    7. Slider
    8. Pointer
    9. Wedge
    10. Trapezoid
    11. Rounded Rectangle

Pointer Image

In ASP.NET MVC Circular Gauge, it is possible to replace the pointer with some images. You can fix an image instead of rendering the pointer.

ImageUrl

To implement the pointer image we need to give the API called `ImageUrl`. It is a string data type. Image type pointer is applicable for both marker and needle type pointers and it is possible to combine the normal marker pointer type with an image type. The three possibilities are

Copyright © 2001 - 2020 Syncfusion Inc.

1. Needle Image
2. Marker Image
3. Marker pointer with Image

Needle Image

In NeedleType, needle pointer is completely replaced by image. You can implement it with the help of the following example.

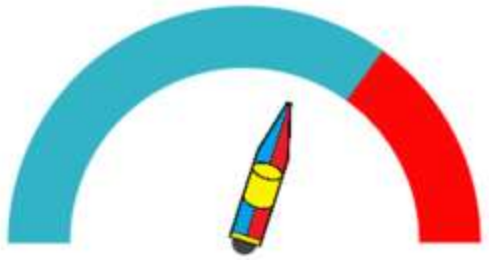
ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// To set frame type as half circle .Frame(fr =>
fr.FrameType(Frame.HalfCircle))
// To set scale options.Scales(scale =>      {
// set basic appearance
scale.ShowRanges(true).ShowLabels(false).StartAngle(180)
.SweepAngle(180).Radius(130).ShowScaleBar(false)
// To set pointer option
.Pointers(pointer => {
// To set pointer type as needle
pointer.Type(PointerType.Needle)
// To set needle type as image
.NeedleType(NeedleType.Image)
// To set image url for pointer image
.ImageUrl("nib.png")
// To set pointer value
.Value(60)
// To set pointer dimension
.Length(30).Width(100).Add(); })
// To set tick options
.Ticks(tic => { tic.Height(0).Width(0).Add(); })
// To set range options
.Ranges(range => {
range.DistanceFromScale(-30).StartValue(0)
.EndValue(70).Size(40).Add();
range.DistanceFromScale(30).StartValue(70)
.EndValue(100).BackgroundColor("#fc0606")
.Border(border => border.Color("#fc0606")).Size(40).Add();
}).Add();
})
)
```

C#

```
public partial class CircularGaugeController : Controller
{
//        // GET: /ToolTip/
public ActionResult Semicircular()
{
return View();
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Semi-circular Gauge with needle pointer as image

Marker Image

In MarkerType, the marker pointer is completely replaced by the image. You can implement it with the help of the following example.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// To set frame type as half circle .Frame(fr =>
fr.FrameType(Frame.HalfCircle))
// To set scale options.Scales(scale =>
{
// set basic appearance
scale.ShowRanges(true).ShowLabels(false).StartAngle(180)
.SweepAngle(180).Radius(130).ShowScaleBar(false)
// To set pointer option
.Pointers(pointer => {
// To set pointer type as marker
pointer.Type(PointerType.Marker)
// To set needle type as image
.MarkerType(MarkerType.Image)
// To set image url for pointer image
.ImageUrl("ball.png")
// To set pointer value
.Value(60)
// To set pointer dimension
.Length(30).Width(100).Add(); })
// To set tick options
.Ticks(tic => { tic.Height(0).Width(0).Add(); })
// To set range options
.Ranges(range => {
range.DistanceFromScale(-30).StartValue(0)
.EndValue(70).Size(40).Add();
range.DistanceFromScale(30).StartValue(70)
.EndValue(100).BackgroundColor("#fc0606")
.Border(border => border.Color("#fc0606")).Size(40).Add();
}).Add();
})
)
```

C#

```
public partial class CircularGaugeController : Controller
{
//        // GET: /ToolTip/
```

```
public ActionResult Semicircular()
{
return View();
}
}
```

Semi-circular Gauge with marker pointer as image

Marker pointer with Image

In this type, marker pointer is drawn first and then the image is loaded. You can implement it with the help of following example.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// To set frame type as half circle
.Frame(fr => fr.FrameType(Frame.HalfCircle))
// To set scale options
.Scales(scale =>      {
// set basic appearance
scale.ShowRanges(true).ShowLabels(false).StartAngle(180)
.SweepAngle(180).Radius(130).ShowScaleBar(false)
// To set pointer option
.Pointers(pointer => {
// To set pointer type as marker
pointer.Type(PointerType.Marker)
// To set needle type as rectangle
.MarkerType(MarkerType.Rectangle)
// To set image url for pointer image
.ImageUrl("ball.png")
// To set pointer value
.Value(50)
// To set pointer dimension
.Length(30).Width(100)
.Border(border => border.Color("Black").Width(3))
.Add(); })
// To set tick options
.Ticks(tic => { tic.Height(0).Width(0).Add(); })
// To set range options
.Ranges(range => {
range.DistanceFromScale(-30).StartValue(0)
.EndValue(70).Size(40).Add();
range.DistanceFromScale(30).StartValue(70)
.EndValue(100).BackgroundColor("#fc0606")
.Border(border => border.Color("#fc0606")).Size(40).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}).Add();
})
)
```

C#

```
public partial class CircularGaugeController : Controller
{
//         // GET: /ToolTip/
public ActionResult Semicircular()
{
return View();
}
}
```

Semi-circular Gauge with marker pointer with image

Multiple Pointers

Circular Gauge can have multiple pointers on it. You can use any combination and any number of pointers in a Gauge. That is, a Gauge can contain any number of marker pointer and any number of needle pointers. Refer the following code example containing two pointers.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowScaleBar(true)
.Size(10)
.Radius(110)
.BackgroundColor("#DCEBF9")
.Border(border =>border.Color(ConsoleColor.Green.ToString()).Width(2))
.Pointers(PO =>
{
// For setting pointer1
PO.Value(40)
.Length(80)
.Width(16)
.Opacity(0.6)
.BackgroundColor("#DCEBF9")
.Border(border
=>border.Color(ConsoleColor.Green.ToString()).Width(2)).Add();
// For setting pointer2
PO.Placement(PointerPlacement.Near)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Type(PointerType.Marker)
.MarkerType(MarkerType.Triangle)
.Length(20)
.Width(20)
.Value(60)
.BackgroundColor("#DCEBF9")
.Border(border
=>border.Color(ConsoleColor.Green.ToString()).Width(2)).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with multiple pointers

Pointer Value

- Gauge PointerValueText is used to display the current value of the pointer in the **Circular Gauge** control.
- You can position the Circular Gauge pointer value with the gauge as center by using the API called Distance. You can Disable/ Enable these pointers value by using the API ShowValue.

ASPX-CS

```
@(Html.EJ().CircularGauge("CoreCircularGauge")
// Setting basic properties
.Radius(100).Value(55).BackgroundColor("transparent")
// Setting scale properties
.Scales(SC =>{
// enable rangesSC
.ShowRanges(true)
// Setting ticks option
.Ticks(tic => { tic.Height(0).Width(0).Add(); })
// Setting range properties
.Ranges(range =>
{
range.Size(40).StartValue(0).EndValue(50).BackgroundColor("#1B4279").Border(
border =>
border.Color("#1B4279")).Add();
range.Size(40).StartValue(50).EndValue(100).BackgroundColor("#91B8F3").Borde
r(border =>
```

```
border.Color("#91B8F3")).Add();
})
// Setting pointer option
.Pointers(pointer =>{pointer.PointerValueText(value=>
// enable showValue property
value.ShowValue(true)
// setting distance property
.Distance(10)
.Color("#8c8c8c"))
.Add();})
.Add();}))
```

C#

```
public partial class CircularGaugeController : Controller
{
//// GET: /ToolTip/
public ActionResult Semicircular()
{
return View();
}
}
```

Run the above code to render the output as follows.

Circular Gauge with pointer value text.

Appearance

Appearance of the Circular Gauge PointerValueText is adjusted by using four properties. Such as **color**, **angle**, **autoAngle** and **opacity**.

- Color property is used to set the color of the pointer value text.
- Angle property is used to set the angle in which the text is displayed.
- AutoAngle is used to display the text in certain angle based on pointer position angle.
- Opacity is used to customize the brightness of the text.

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge")
// Setting basic properties
.Radius(100).Value(55).BackgroundColor("transparent")
// Setting scale properties.
Scales(SC =>{
// enable ranges
SC.ShowRanges(true)
// Setting ticks option
.Ticks(tic => { tic.Height(0).Width(0).Add(); })
// Setting range properties
.Ranges(range =>
{
range.Size(40).StartValue(0).EndValue(50).BackgroundColor("#1B4279").Border(
border =>
border.Color("#1B4279")).Add();
range.Size(40).StartValue(50).EndValue(100).BackgroundColor("#91B8F3").Borde
r(border =>
border.Color("#91B8F3")).Add();
})
// Setting pointer option
.Pointers(pointer
=>{pointer.PointerValueText(value=>value.ShowValue(true).Distance(10)
// Setting opacity property
.Opacity(1)
// Setting color property
.Color("Red")
// Setting auto angle property
.autoAngle(false)
// Setting angle property.Angle(0))
.Add();
}).Add();
})
)
```

C#

```
public partial class CircularGaugeController : Controller
{
//        // GET: /ToolTip/
public ActionResult Semicircular()
{
return View();
}
}
```

Run the above code to render the output as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with customized pointer value text.

Font Options

Similar to other collection, Font option is also available in this pointer value text such as Size, FontFamily and FontStyle.

ASPX-CS

```
@(Html.EJ().CircularGauge("CoreCircularGauge")
// Setting basic properties
.Radius(100).Value(55).BackgroundColor("transparent")
// Setting scale properties
.Scales(SC =>{
// enable rangesSC
.ShowRanges(true)
// Setting ticks option
.Ticks(tic => {
tic.Height(0).Width(0)
.Add(); })
// Setting range properties
.Ranges(range =>{
range.Size(40).StartValue(0).EndValue(50).BackgroundColor("#1B4279").Border(
border =>
border.Color("#1B4279")).Add();
range.Size(40).StartValue(50).EndValue(100).BackgroundColor("#91B8F3").Borde
r(border =>
border.Color("#91B8F3")).Add();})
// Setting pointer option
.Pointers(pointer
=>{pointer.PointerValueText(value=>value.ShowValue(true).Distance(10).Opacit
y(1).Color("Red").autoAngle(false).Angle(0)
// Setting font
option.Font(fo=>fo.Size("15px").FontFamily("Arial").FontStyle("Normal"))).Ad
d();}).Add();
})
)
```

C#

```
public partial class CircularGaugeController : Controller
{
//// GET: /ToolTip/
public ActionResult Semicircular()
{
return View();
}
}
```

Run the above code to render the output as follows.

Circular Gauge with customized font option in pointer value text.

Labels

Labels are units that are used to display the values in the scales. You can customize Labels with the properties like Angle, Color, Font, Opacity, etc.

Adding Label Collection

Label collection is directly added to the scale object. Refer the following code example to add label collection in a **Gauge**.

ASPX-CS

```
//For circular gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.Labels(lb =>
{
// For setting label angle
lb.Angle(30).Add();
}).Add();
}))
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with label collection

Label Customization

Appearance

- The attribute Angle is used to display the labels in the specified angles and Color attribute is used to display the labels in specified color. You can adjust the opacity of the label with the property Opacity and the values of it lies between 0 and 1.
- You can adjust the labels based on the tick's direction by setting AutoAngle as true. IncludeFirstValue is an special property especially used in some special scenarios such as in clock, where the value 0 needs to be replaced with that of 12. By enabling this property the first value of the label is not rendered.
- Font option is also available on the labels. The basic three properties of fonts such as Size, Family and Style can be achieved by size, fontStyle and fontFamily. Labels are two types such as major and minor.Major types labels are for major interval values and minor types labels are for minor interval values.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowScaleBar(true)
.BackgroundColor("#FAF4B5")
.Border(bo =>bo.Color("Yellow").Width(2))
.Radius(110)
.Size(10)
.Pointers(pointer =>
{
pointer.Border(bo =>bo.Width(2).Color("Yellow"))
.BackgroundColor("#FAF4B5")
.Value(40).Length(80)
.Width(16).Opacity(0.6).Add();
})
.Labels(lb =>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
// For setting label angle
lb.Angle(30)
// For setting label opacity
.Opacity(0.8)
// For disable the include first value property
.IncludeFirstValue(false)
// For setting label color
.Color("Yellow")
// For setting label font
.Font(f =>f.Size("15px").FontFamily("Arial").FontStyle("bold")).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with customized label

Unit text and Position

- UnitText is used to add some text along with the labels. For example, in speedometer, you need to mention the units in kph. You can also add the unit text in front of the labels. You can achieve this by using an enumerable property UnitTextPosition. With this you can position the unit text in front or back.
- Labels can be positioned with the help of two properties such as DistanceFromScale and Placement. **DistanceFromScale** property defines the distance between the scale and labels. **Placement** property is used to locate the labels with respect to scale either inside the scale or outside the scale or along the scale. It is an enumerable data type.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowRanges(true)
.ShowScaleBar(true)
.Radius(150).Size(2)
.Pointers(pointer =>
{
pointer.Value(40).Length(100)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.ShowBackNeedle(true).Add();
})
.Labels(lb =>{
// For setting unit text
lb.UnitText("kmph")
// For setting unit text position
.UnitTextPosition(UnitTextPlacement.Back).Add();
})
.Ranges(ran =>
{
ran.DistanceFromScale(-
30).StartValue(0).EndValue(50).BackgroundColor("Green").Placement(RangePlace
ment.Far).Add();
ran.DistanceFromScale(-
30).StartValue(50).EndValue(80).BackgroundColor("Yellow").Placement(RangePla
cement.Far).Add();
ran.DistanceFromScale(-
30).StartValue(80).EndValue(100).BackgroundColor("Red").Placement(RangePlace
ment.Far).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with unit text

Multiple Labels

You can achieve multiple labels such as minor and major Type in a **Gauge** sample scale. Refer the following code example for multiple labels variation.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowRanges(true)
.ShowScaleBar(true)
```

```
.Radius(150)
.Size(5)
.MinorIntervalValue(5)
.BackgroundColor("Yellow")
.Border(border =>border.Width(1.5).Color("Red"))
.PointerCap(cap =>
cap.BackgroundColor("Yellow").BorderColor("Red").BorderWidth(0.5).Radius(10)
)
.Labels(lb =>
{
// For setting label1
lb.Type(GaugeTypes.Minor).Color("Yellow").Add();
// For setting label2
lb.Type(GaugeTypes.Major).Color("Red").Add();
})
.Pointers(pointer =>
{
pointer.Length(110)
.BackgroundColor("Yellow")
.Border(bo =>bo.Width(1.5).Color("Red")).Add();
})
.Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with multiple labels

Ticks

Ticks are used to mark some values on the scale. Based on the tick's Value you can set the labels on the required position.

Adding Tick Collection

Tick collection is directly added to the scale object. Refer the following code example to add tick collection in a **Gauge** control.

ASPX-CS

```
//For circular gauge rendering
```

```
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.Ticks(tick =>
{
// For setting tick
tick.Type(CircularTickTypes.Major).Color("Red").Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with tick collection

Tick Customization

- Height and width of the ticks can be applied by using the properties Height and Width. You can customize ticks with the properties such as angle, color, etc. Angle attribute is used to display the labels in the specified angles and Color attribute is used to display the labels in specified color. Ticks are two types such as major and minor.
- Major Type ticks are for major interval values and minor type ticks are for minor interval values.You can position ticks with the help of two properties such as DistanceFromScale and Placement. **DistanceFromScale** property defines the distance between the scale and ticks. **Placement** property is used to locate the ticks with respect to scale either inside the scale or outside the scale or along the scale. It is an enumerable data type.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.Ticks(tick =>
{
```

```
// For setting tick1
tick.Type(CircularTickTypes.Major).Color("Red").Add();
// For setting tick2
tick.Type(CircularTickTypes.Minor)
// For setting tick color
.Color("Yellow")
// For setting tick height
.Height(8)
// For setting tick placement
.Placement(TickPlacement.Near)
// For setting tick distance from scale
.DistanceFromScale(5).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with tick customization

Indicators

Indicators simply indicates the current status of the pointer. Indicators are in several formats such as in shape format, textual format and image format.

Adding Indicator Collection

Indicators collection is directly added to the scale object. Refer the following code to add indicator collection in a **Gauge** control.

ASPX-CS

```
//For circular gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowIndicators(true)
.Indicators(ind =>
{
```

```
ind.Height(10)
.Width(10)
.Type(IndicatorType.Circle)
.Position(position =>position.X(185).Y(300)).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with indicator collection.

Basic Customization

- You can enable indicators by setting ShowIndicators to 'true'. The Height and Width property for the indicators are used to specify the area allocated to the indicator for the width and height respectively. You can use the Position collection to position the indicators along X and Y axis.
- Indicators are of several types such as, circle, rectangle, rounded rectangle, text and image. By using the Type property you can avail those shapes. For image type ImageUrl property is used.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowIndicators(true)
.MinorIntervalValue(5)
.BackgroundColor("#5DF243")
.Border(bo =>bo.Width(1.5).Color("Black"))
.ShowScaleBar(true).Radius(120).Size(5)
.Pointers(pointer =>
{
pointer.BackgroundColor("#5DF243")
.Border(bo =>bo.Width(1.5).Color("Black"))
.Length(110).Add();
})
```

```
.Indicators(ind =>
{
// For setting indicator height
ind.Height(10)
// For setting indicator width
.Width(10)
// For setting indicator type
.Type(IndicatorType.Circle)
// For setting indicator position
.Position(position =>position.X(185).Y(300)).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with customized indicator with basic properties

State Ranges

- State ranges are used to specify the indicator behavior in the specified region. Use StartValue and EndValue to set the range bound for the pointer. Whenever the pointer cross the specified region, the indicator attributes are applied for ranges.
- The BackgroundColor and BorderColor sets the appearance behavior for the indicators. For text type indicators you can give value for text. And Text can be changed whenever the pointer crosses its state range area. There are many basic Font options available for the text in the state range such as Size, FontStyle and FontFamily.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowIndicators(true)
.MinorIntervalValue(5)
.BackgroundColor("#5DF243")
.Border(bo =>bo.Width(1.5).Color("Black"))
.ShowScaleBar(true).Radius(150).Size(5)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Pointers(pointer =>
{
pointer.BackgroundColor("#5DF243")
.Border(bo =>bo.Width(1.5).Color("Black"))
.Length(110).Add();
})
.Indicators(ind =>
{
// For setting indicator height
ind.Height(10)
// For setting indicator width
.Width(10)
// For setting indicator type
.Type(IndicatorType.Circle)
// For setting indicator position
.Position(position =>position.X(185).Y(300))
// For setting indicator state range collection
.StateRanges(st =>
{
// For setting state range End Value
st.EndValue(100)
// For setting state range start value
.StartValue(0)
// For setting indicator background color
.BackgroundColor("#5DF243")
// For setting indicator border color
.BorderColor("Black")
// For setting indicator text
.Text("")
// For setting indicator text color
.TextColor("#870505").Add();
}).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with customized indicator

Copyright © 2001 - 2020 Syncfusion Inc.

Multiple Indicators

You can use multiple indicators for a single Gauge. Each indicator have a list of StateRanges. Refer the following code example for multiple Indicators.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowIndicators(true)
.ShowRanges(true)
.MinorIntervalValue(5)
.ShowScaleBar(true).Radius(150).Size(5)
.Pointers(pointer =>
{
pointer.Length(110).Value(70).Add();
})
.Ranges(ran =>
{
ran.DistanceFromScale(-
30).StartValue(0).EndValue(50).BackgroundColor("Green").Placement(RangePlace
ment.Far).Add();
ran.DistanceFromScale(-
30).StartValue(50).EndValue(100).BackgroundColor("Red").Placement(RangePlace
ment.Far).Add();
})
.Indicators(ind =>
{
//Indicator1
ind.Height(10).Width(10)
.Type(IndicatorType.Circle)
.Position(position =>position.X(165).Y(300))
.StateRanges(st =>
{
st.EndValue(50)
.StartValue(0)
.BackgroundColor("#24F92F")
.BorderColor("Black").Add();
st.EndValue(50)
.StartValue(100)
.BackgroundColor("#322C04")
.BorderColor("Black").Add();
}).Add();
//Indicator2
ind.Height(10).Width(10)
.Type(IndicatorType.Circle)
.Position(position =>position.X(215).Y(300))
.StateRanges(st =>
{
st.EndValue(50)
.StartValue(0)
.BackgroundColor("#600000")
.BorderColor("Black").Add();
st.EndValue(100)
.StartValue(50)
.BackgroundColor("#FF4F2A")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.BorderColor("Black").Add();
}).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with multiple indicators

Ranges and Frames

Ranges are used to specify or group the scale values. By using ranges, you can describe the values in the pointers.

Add Range Collection

Range collection is directly added to the scale object. Refer the following code example to add range collection in a **Gauge** control.

ASPX-CS

```
//For circular gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowRanges(true)
.Ranges(ran =>
{
ran.StartValue(20)
.EndValue(80)
.BackgroundColor("Green")
.Placement(RangePlacement.Far).Add();
}).Add();
})
)
```

Range Customization

Appearance

- The API Size is used to specify the width of the ranges. The major attributes for ranges are StartValue and EndValue. **StartValue** defines the start position of the ranges and **EndValue** defines the end position of the ranges.
- StartWidth and EndWidth are used to specify the range width at the starting and ending position of the ranges. You can add the gradient effects and opacity to the ranges by using Gradient object and Opacity property.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowRanges(true)
.ShowScaleBar(true)
.Radius(150).Size(5)
.Ranges(ran =>
{
//For setting range start value
ran.StartValue(20)
//For setting range end value
.EndValue(80)
//For setting range background color
.BackgroundColor("Green")
//For setting range placement
.Placement(RangePlacement.Far).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with customized ranges with startValues and endValues

Colors and Border

- By customizing the ranges, the appearance of the Gauge can be improved. The range border is modified with the object called Border. It has two border property such as Color and Width. These are used to customize the border color of the ranges and border width of the ranges.
- You can set the background color to improve the look and feel of the Circular Gauge. For customizing the background color of the ranges, BackgroundColor is used.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowRanges(true)
.ShowScaleBar(true)
.Radius(150).Size(5)
.Ranges(ran =>
{
//For setting range start value
ran.StartValue(20)
//For setting range end value
.EndValue(80)
//For setting range background color
.BackgroundColor("Yellow")
//For setting range placement
.Placement(RangePlacement.Far)
//For setting range border
.Border(bo =>bo.Width(2).Color("Green")).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with customized range colors and borders

Copyright © 2001 - 2020 Syncfusion Inc.

Position the ranges

- You can position ranges using two properties such as DistanceFromScale and Placement.
- **DistanceFromScale** property defines the distance between the scale and range.
- **Placement property** is used to locate the pointer with respect to scale either inside the scale or outside the scale or along the scale. It is an enumerable data type.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowRanges(true)
.ShowScaleBar(true)
.Radius(150).Size(2)
.Ranges(ran =>
{
//For setting range start value
ran.StartValue(0)
//For setting range end value
.EndValue(100)
//For setting range background color
.BackgroundColor("Green")
//For setting range placement
.Placement(RangePlacement.Far)
//For setting distance between scale and ranges
.DistanceFromScale(-30)
//For setting range border
.Border(bo =>bo.Width(2).Color("Black")).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with customized ranges

Copyright © 2001 - 2020 Syncfusion Inc.

Multiple Ranges

You can set multiple ranges by adding an array of ranges objects. Refer the following code example for multiple ranges functionality.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(sc1 =>
{
sc1.ShowRanges(true)
.ShowScaleBar(true)
.Radius(150).Size(2)
.Pointers(p =>
{
p.Value(40)
.ShowBackNeedle(true)
.Length(100).Add();
})
.Ranges(ran =>
{
//For setting range1
ran.StartValue(0)
.EndValue(50)
.BackgroundColor("Green")
.Placement(RangePlacement.Far)
.DistanceFromScale(-30).Add();
//For setting range2
ran.StartValue(50)
.EndValue(80)
.BackgroundColor("Yellow")
.Placement(RangePlacement.Far)
.DistanceFromScale(-30).Add();
//For setting range3
ran.StartValue(80)
.EndValue(100)
.BackgroundColor("Red")
.Placement(RangePlacement.Far)
.DistanceFromScale(-30).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with multiple ranges

Frames

- Frame is the element that decides the appearance of the Circular Gauge. You can customize it using the object called Frame. It has the properties such as frameType, backGroundUrl, halfCircleFrameStartAngle and halfCircleFrameEndAngle.
- FrameType is used to specify whether frame is a half circle frame or full circle frame. HalfCircleFrameStartAngle and HalfCircleFrameEndAngle are used to specify the angle for Gauge with frame type as half circle. BackgroundUrl is used to set the background image for the frame.

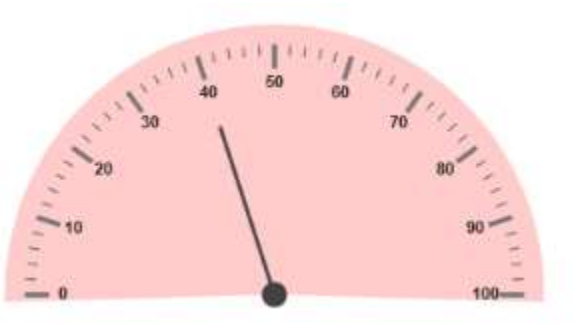
ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Frame(f =>
{
//For setting type
f.FrameType(Frame.HalfCircle)
//For setting half circle frame start angle
.HalfCircleFrameStartAngle(205)
//For setting half circle frame end angle
.HalfCircleFrameEndAngle(335).ToString();
})
.BackgroundColor("#FFCCCC")
.Scales(scale =>
{
scale.StartAngle(180)
.SweepAngle(180)
.PointerCap(cap =>cap.Radius(8))
.Pointers(pointer =>
{
pointer.NeedleType(NeedleType.Rectangle)
.Width(1).Length(120)
.Value(40).Add();
}).Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

Execute the above code to render the following output.



Circular Gauge with multiple ranges

Legend

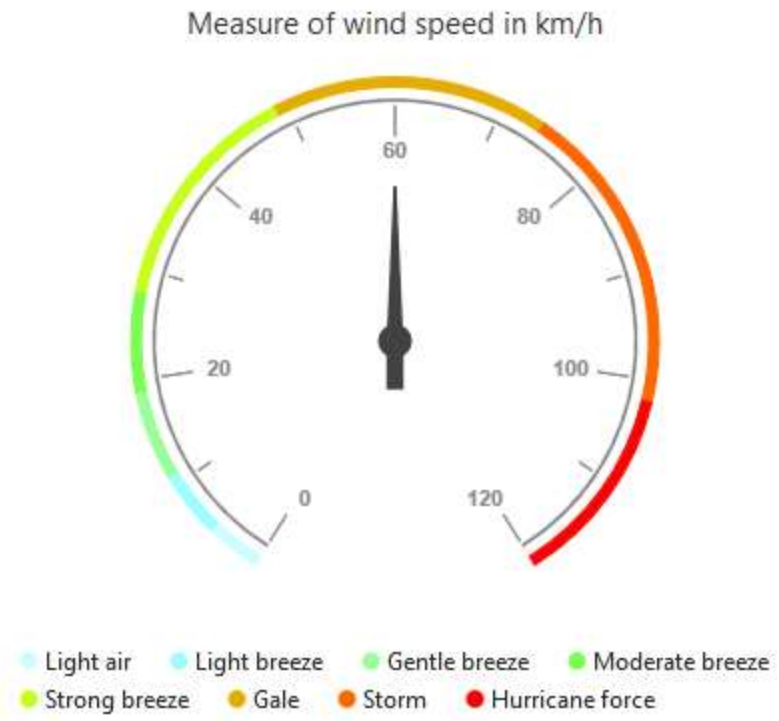
The Legend contains the list of the ranges that appear in the circular gauge

Legend Visibility

By default, the legend will not be displayed in the circular gauge. You can enable or disable it by using the Visible property of the legend.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
//Visible CircularGauge legend
.Legend(lg=>lg.Visible(true))
//...
)
```



Click here to view the online demo sample for legend in the circular Gauge.

Legend Text

The text displayed in the legend can be customized by using the LegendText property present in the ranges of the circular gauge. When the legendText is not specified in the ranges, then the legend item for that particular range will not displayed. By default the legendText value is **null** .

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
.Scales(scale =>
{
scale.Ranges(range =>
{
range.LegendText("Light air").Add();
})
})
)
```

Position and Align the Legend

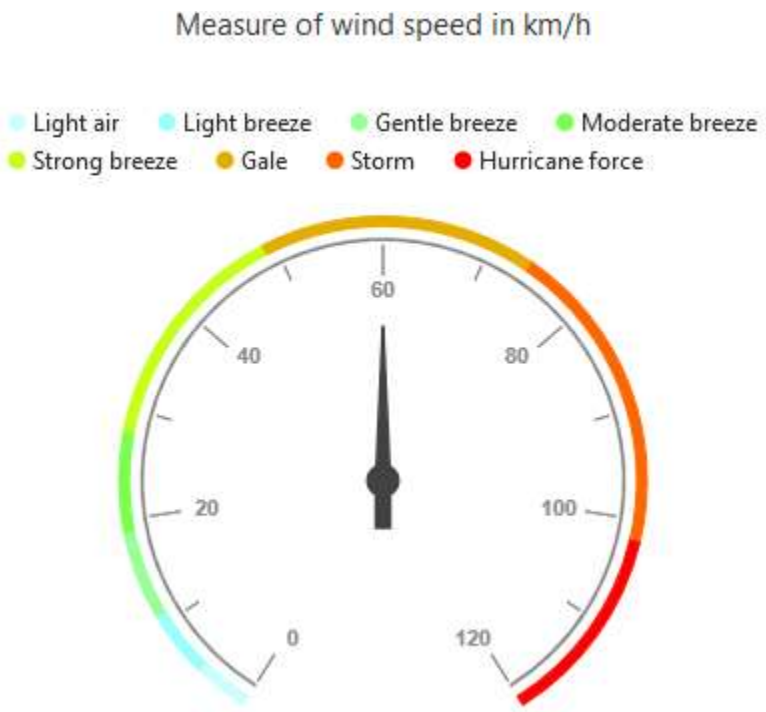
By using the Position property, you can position the legend at *left*, *right*, *top* or *bottom* of the CircularGauge. The legend is positioned at the **bottom** of the circular gauge, by default.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg.
//...
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Place the legend at top of the CircularGauge
Position(CircularLegendPosition.Top)
)
//...
)
```



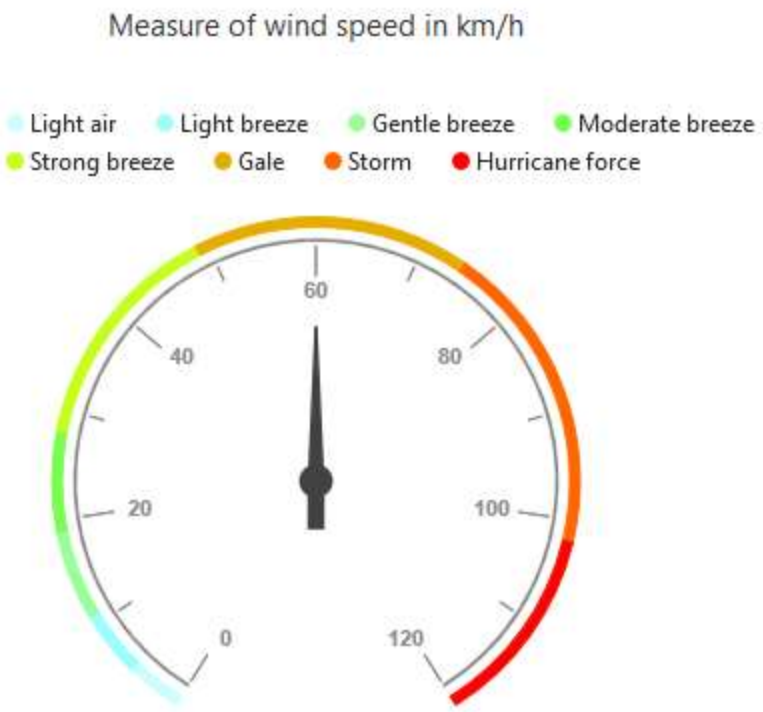
Legend Alignment

You can align the legend to the *center*, *far* or *near* based on its position by using the Alignment property.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg.
//...
//The below two settings will place the legend at the top-right corner of
the gauge.
Position(CircularLegendPosition.Top)
.Alignment(CircularLegendAlignment.Far)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Customization

Legend Fill and Opacity

You can change the opacity and fill color of legend text using Opacity and Fill property of legend.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg
//...
//fill color of legend
.Fill('red')
//opacity of legend
.Opacity(0.8)
)
//...
)
```

Legend shape

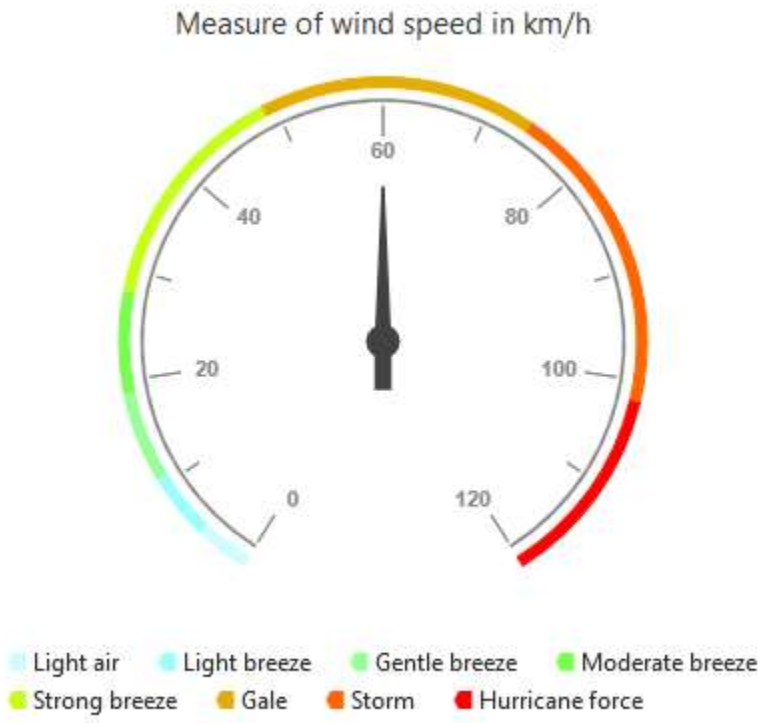
To change the legend item shape, you have to specify the desired shape in the Shape property of the legend. By default, the shape of the legend is **circle**.It also supports rectangle,diamond,triangle,slider,line,pentagon,trapezoid and wedge shapes.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg
//...
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Change legend shape
.Shape(CircularLegendShape.Slider)
)
//...
)
```

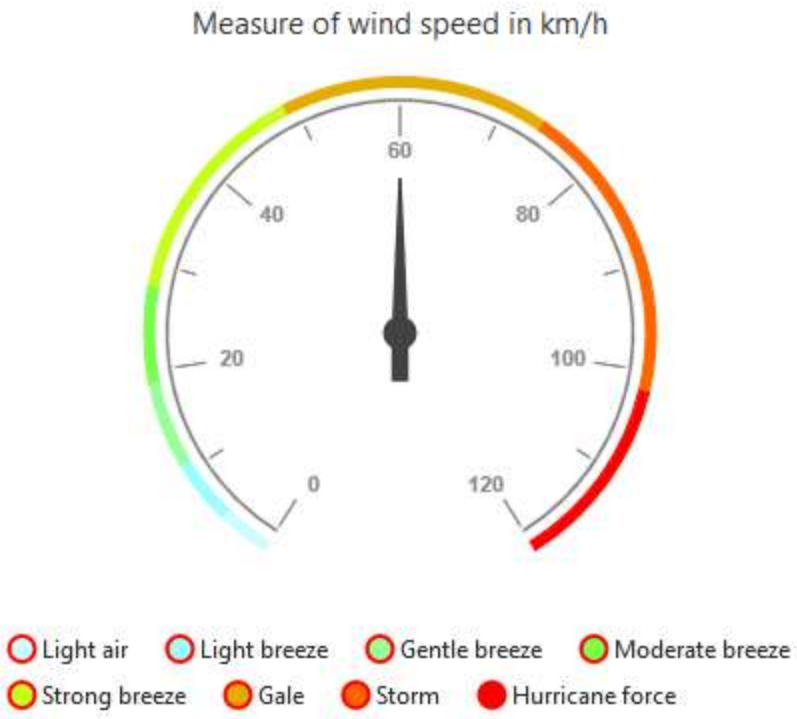


Legend Item Size and Border

You can change the size of the legend items by using the Width and Height properties in the ItemStyle. To change the legend item border, use Border property of the legend itemStyle. The color and width of legend item border can be customized using border Color and Width property.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg
//...
//Change legend items border, height and width
.ItemStyle(item=>item.Width(13).Height(13).Border(br=>br.Width(2).Color("#FF
0000")))
)
//...
)
```

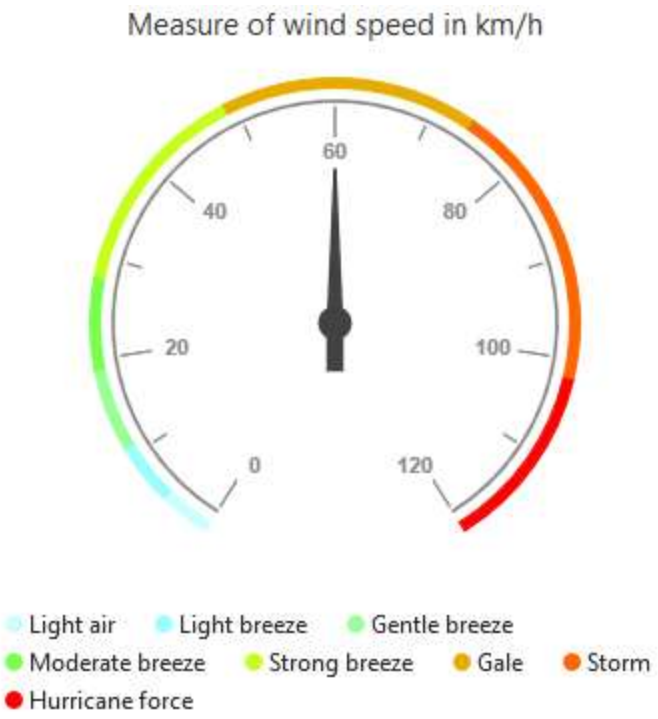


Legend size

You can change the default legend size by using the Size property of the legend. The height and width of legend size can customized using Height and Width property.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg
//...
//Change legend size
.Size(size=>size.Height("100").Width("350"))
)
//...
)
```



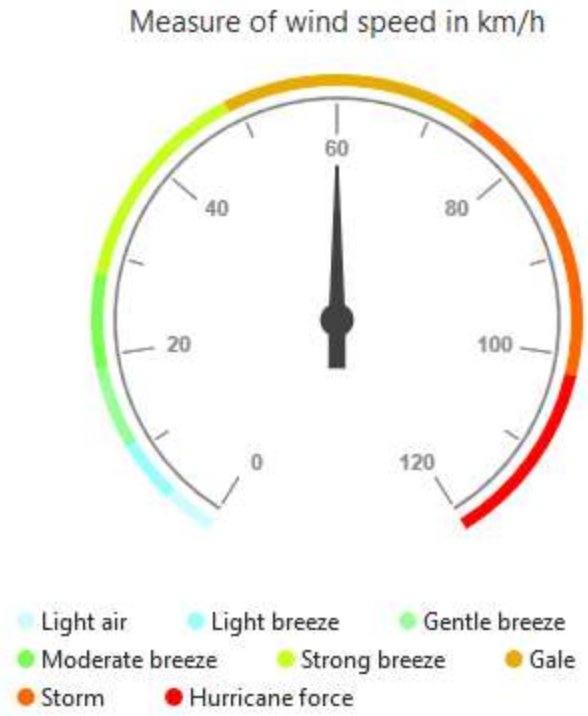
Legend Item Padding

You can control the spacing between the legend items by using the ItemPadding option of the legend. The default value is 20.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg
//...
//Add space between each legend item
.ItemPadding(30)
)
//...
)
>
```

Copyright © 2001 - 2020 Syncfusion Inc.

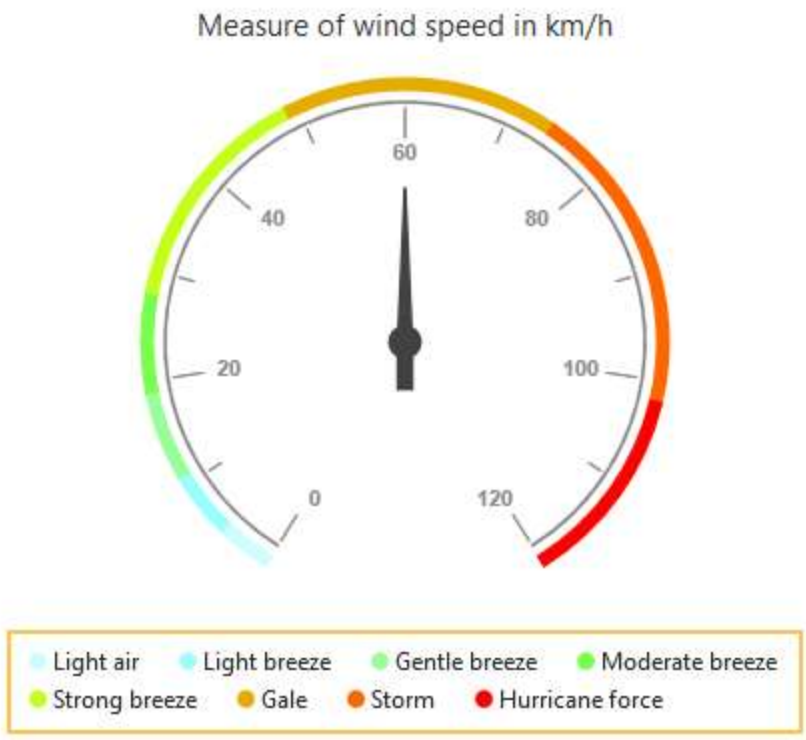


Legend border

You can customize the legend border by using the Border option in the legend. The legend border can be customized using border Color and Width property.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg
//...
//Set border color and width to legend
.Border(br=>br.Color("#FFC342").Width(2))
)
//...
)
```



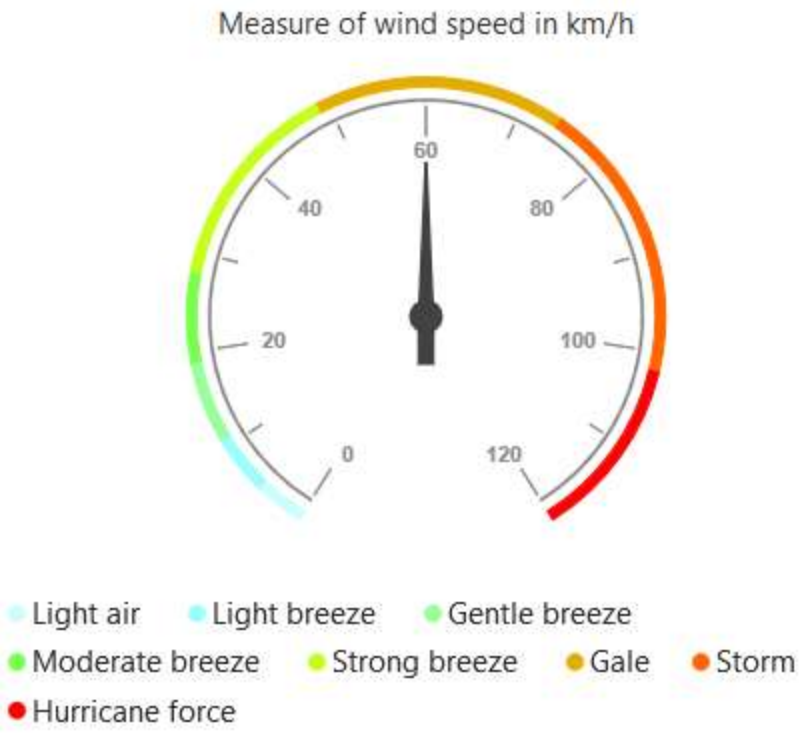
Font of the legend text

The Font of the legend item text can be customized by using properties such as FontFamily, FontStyle, FontWeight and Size of legend font.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg
//...
//Customize the legend item text
.Font(font=>font.FontFamily("Segoe
UI").FontStyle(CircularGaugeFontStyle.Normal)
.FontWeight(CircularGaugeFontWeight.Bold).Size("15px"))
)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Events

Legend Item Render

LegendItemRender event triggers before rendering the legend items. This event is triggered for each legend item in Circular gauge. You can use this event to customize legend item shape or add custom text to legend item dynamically

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg
.Visible(true)
//...
)
//Subscribe the legend item render event
.LegendItemRender("onLegendRender")
)
function onLegendRender(sender) {
//Get legend item details before rendering
var legendItem = sender.data;
}
```

Legend Item Click

You can get the legend item details such as *RangeIndex, bounds and shape* by subscribing the LegendItemClick event of the circular gauge. When the legend item is clicked, it triggers the event and returns the legend information

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().CircularGauge("circulargauge1")
// ...
.Legend(lg=>lg
.Visible(true)
//...
)
//Subscribe the legend item click event
.LegendItemClick("onLegendClicked")
)
function onLegendClicked(sender) {
//Get legend item details on legend item click.
var legendItem = sender.data;
}
```

Custom labels

Custom labels are the texts that you can use them in any location of the **Gauge**.

Adding Custom Label Collection

Custom labels collection is directly added to the scale object. Refer the following code to add CustomLabels collection in a Gauge control.

ASPX-CS

```
//For circular gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(scale =>
{
scale.CustomLabels(label =>
{
//custom label
label.TextAngle(10)
.Color("Red")
.Value("CustomLabel1")
.Font(f =>f.Size("20px").FontFamily("Arial").FontStyle("bold"))
.Position(p =>p.X(180).Y(100)).Add();
}).Add();
})
)
```

Basic Customization

- You can customize custom labels using the properties such as TextAngle, Color and Font. **TextAngle** attribute is used to display the custom labels in the specified angles and **Color** attribute is used to display the custom labels in specified color.
- You can use Value attribute to set the text value in the custom labels. To display the custom labels, set ShowCustomLabels as ‘true’. To set the location of the custom label in Circular Gauge, Position property is used. By using X and Y axis you can adjust the position of the custom labels.
- Font option is also available on custom labels. The basic three properties of fonts such as size, family and style can be achieved by Size, FontStyle and FontFamily attributes.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(scale =>
{
scale.Size(2)
.ShadowOffset(10)
.ShowRanges(true)
.ShowScaleBar(true)
.Radius(150)
.ShowLabels(true)
.CustomLabels(cl =>
{
//For setting custom label text angle
cl.TextAngle(10)
//For setting custom label color
.Color("Red")
//For setting custom label color
.Value("CustomLabel1")
//For setting custom label font option
.Font(f =>f.Size("20px").FontFamily("Arial").FontStyle("bold"))
//For setting custom label position
.Position(p =>p.X(180).Y(100)).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with customized custom label

Multiple Custom Labels

You can set multiple custom labels in a single **Circular Gauge** by adding an array of custom label objects. Refer the following code example for multiple custom label functionality.

ASPX-CS

```
// For Circular Gauge rendering
@(Html.EJ().CircularGauge("circulargauge")
.Scales(scale =>
{
```

```
scale.Size(2)
.ShadowOffset(10)
.ShowRanges(true)
.ShowScaleBar(true)
.Radius(150)
.ShowLabels(true)
.CustomLabels(cl =>
{
//custom label1
cl.TextAngle(10)
.Color("Red")
.Value("CustomLabel1")
.Font(f =>f.Size("20px").FontFamily("Arial").FontStyle("bold"))
.Position(p =>p.X(180).Y(100)).Add();
//custom label2
cl.TextAngle(10)
.Color("Green")
.Value("CustomLabel2")
.Font(f =>f.Size("20px").FontFamily("Arial").FontStyle("bold"))
.Position(p =>p.X(180).Y(250)).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Circular Gauge with multiple custom labels

Outer Custom Label

- **Outer Custom Label** is used to show custom labels outside the gauge control. The Outer Custom Label can be positioned with API called `OuterCustomLabelPosition`. The value for this API is enumerable type and its possible values are,
    1. Right
    2. Left
    3. Top
    4. Bottom

Copyright © 2001 - 2020 Syncfusion Inc.

- When a custom label is to be displayed as an Outer Custom Label, set the API PositionType as Outer. Refer to the following code example to get the Outer Custom Label.

ASPX-CS

```
@(Html.EJ().CircularGauge("circularGaugeTooltip")
//Defines the outer label position.
.OuterCustomLabelPosition(OuterCustomLabelPosition.Right)
//Defines the tooltip object.
.Tooltip(tooltip=>tooltip
// Enables the label tooltip.
.ShowLabelTooltip(true)
// Enables the custom label tooltip.
.ShowCustomLabelTooltip(true))
// Customizes the scale options.
.Scales(SC =>{SC.Radius(130).ShowLabels(true)
// Customizes the custom label options.
.CustomLabels(cl => {cl.Value("AverageSpeed").Font(f
=>f.Size("20px").FontFamily("Arial").FontStyle("bold")).Position(p
=>p.X(360).Y(30)).Add();})
// Customizes the pointers options.
.Pointers(PO =>{PO.Value(60).Length(90).Add();}).Add();}))
```

C#

```
public ActionResult Print()
{
var DataSource = new ScheduleDataDataContext().DefaultSchedules.ToList();
ViewBag.dataSource = DataSource;return View();
}
```

Execute the above code to render the following output.

Circular gauge with outer custom label.

Tooltip

- **Tooltip** feature has been added to the Circular Gauge. **Circular Gauge** has several elements such as pointers, label, customLabel, scales, etc.

Copyright © 2001 - 2020 Syncfusion Inc.

- There is a need for Tooltip feature in the Circular Gauge control because whenever the text hides or overrides with other gauge elements, it may not be fully visible. For resolving those problems Tooltip feature has been implemented in the Circular Gauge control.

Default Tooltip

- Tooltip has three attributes in it. The first two attributes such as ShowLabelTooltip and ShowCustomLabelTooltip are for enabling the Tooltip for label as well as custom label in default appearance.
- ShowLabelTooltip is to enable the Tooltip for labels and ShowCustomLabelTooltip is for enabling the Tooltip option for customLabels.

ASPX-CS

```
@(Html.EJ().CircularGauge("circularGaugeTooltip")
//Defines the tooltip object.
.Tooltip(tooltip=>tooltip
// Enables the label tooltip.
.ShowLabelTooltip(true)
// Enables the custom label tooltip.
.ShowCustomLabelTooltip(true))
//Customizes the scale options.
.Scales(SC =>{SC.Radius(130).ShowLabels(true)
//Customizes the custom label options.
.CustomLabels(cl => {cl.Value("0 9 5 3 4 5").Font(f
=>f.Size("20px").FontFamily("Arial").FontStyle("bold")).Position(position =>
position.X(180).Y(200))
.Add();})
//Customizes the pointers options.
.Pointers(PO =>{PO.Value(60).Length(90)
.Add();})
.Add();
})
)
```

C#

```
public partial class CircularGaugeController : Controller
{
//// GET: /ToolTip/
public ActionResult Tooltip()
{
return View();
}
}
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Gauge with Default ToolTip

Tooltip Template

In **Tooltip** option, you can customize the Tooltip window by adding the tooltip template on that page with the help of API TemplateID. Refer to the following code example to know more about Tooltip template.

ASPX-CS

```
@(Html.EJ().CircularGauge("circularGaugeTooltip")
//Defines the tooltip object.
.Tooltip(tooltip=>tooltip
// Enables the label tooltip.
.ShowLabelTooltip(true)
// Enables the custom label tooltip.
.ShowCustomLabelTooltip(true)
// Enables the tooltip template ID.
.TemplateID("Tooltip"))
// Customizes the scale options.
.Scales(SC =>{SC.Radius(130).ShowLabels(true)
// Customizes the custom label options.
.CustomLabels(cl => {cl.Value("0 9 5 3 4 5").Font(f
=>f.Size("20px").FontFamily("Arial").FontStyle("bold")).Position(position =>
position.X(180).Y(200)).Add();})
// Customizes the pointers options..pointers(PO
=>{PO.Value(60).Length(90).Add();})
.Add();
})
)
```

C#

```
public partial class CircularGaugeController : Controller
{
// GET: /ToolTip/
public ActionResult Tooltip()
{
return View();
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Execute the above code to render the following output.

Circular gauge with tooltip template

Sub Gauges

A **Circular Gauge** containing another circular gauge is said to be SubGauges. In order to make a sample like watch that has second gauge, minute gauge and hour gauge, sub gauges are used.

Adding SubGauges

Sub gauge collection is directly added to the scale object. Refer the following code example to add custom sub gauge collection in a **Gauge** control

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge")
.Value(50)
.Scales(scale =>
{
scale.Radius(190)
//For setting sub gauge
.SubGauges(gauge =>
{
gauge.ControlID("Subgauge1")
.Height(200)
.Width(200)
.Position(p =>p.X(100).Y(120)).Add();
}).Add();
})
)
@(Html.EJ().CircularGauge("Subgauge1")
.BackgroundColor("Blue")
.Value(50)
.Scales(scale=>{scale.Radius(150).Add();})
)
```

Basic Customization

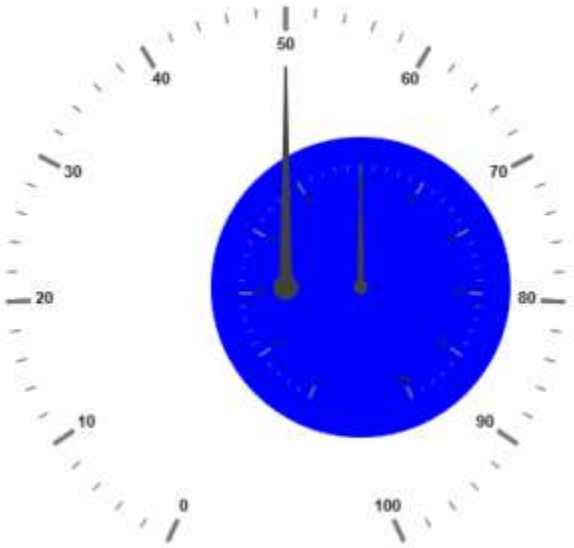
Basic attributes such as Height and Width property are used to set height and width of the sub gauge. You can easily position the gauge in another gauge using the Position object and by giving the X and Y Coordinates value. **ControlID** attribute is used to specify the sub gauge ID.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().CircularGauge("Subgauge1")
.BackgroundColor("Blue")
.Value(50)
.Radius(110)
.Scales(scale=>{scale.Radius(110).Add();})
)
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
.Value(50)
.Scales(scale =>
{
scale.Radius(190)
.SubGauges(gauge =>
{
//For setting sub gauge control ID
gauge.ControlID("Subgauge1")
//For setting sub gauge Height
.Height(250)
//For setting sub gauge width
.Width(250)
//For setting sub gauge position
.Position(p =>p.X(150).Y(100)).Add();
}).Add();
})
)
```

Execute the above code to render the following output.



Circular Gauge with sub gauge

Multiple SubGauges

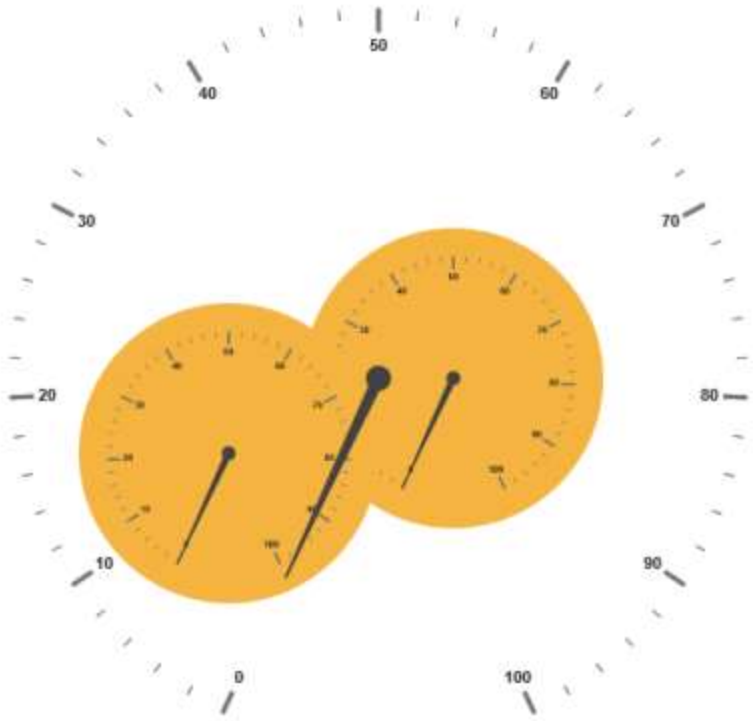
You can set multiple sub gauges in a single **Circular Gauge** by adding an array of sub gauge objects. Refer the following code example for multiple sub gauges functionality.

ASPX-CS

```
@(Html.EJ().CircularGauge("Subgauge1")
.BackgroundColor("#f5b43f")
.Scales(scale => { scale.Radius(150).Add(); })
)
@(Html.EJ().CircularGauge("Subgauge2")
.BackgroundColor("#f5b43f")
.Scales(scale => { scale.Radius(150).Add(); })
)
@(Html.EJ().CircularGauge("circulargauge")
.Height(500)
.Width(500)
.Scales(scale =>
{
scale.Radius(250)
.SubGauges(gauge =>
{
//Sub gauge1
gauge.ControlID("Subgauge1")
.Height(200)
.Width(200)
.Position(p =>p.X(200).Y(150)).Add();
//Sub gauge2
gauge.ControlID("Subgauge2")
.Height(200)
.Width(200)
.Position(p =>p.X(50).Y(200)).Add();
}).Add();
})
)
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.



Circular Gauge with multiple sub gauges

Gauge Position

Semi-circular Gauge can be positioned within the canvas element which provides better appearance for the gauge in the canvas.

Positioning

- Semi-circular Gauge can be positioned with the help of the attribute called GaugePosition. It is an enumerable value. You can position the gauge away from the corner with the help of the DistanceFromCorner attribute.
- The possible enum values for the gaugePosition are as follows:
    1. TopLeft
    2. TopCenter
    3. TopRight
    4. MiddleLeft
    5. Center
    6. MiddleRight
    7. BottomLeft
    8. BottomCenter
    9. BottomRight

ASPX-CS

```
@(Html.EJ().CircularGauge("SemiCircularGauge").BackgroundColor("transparent"
)
```

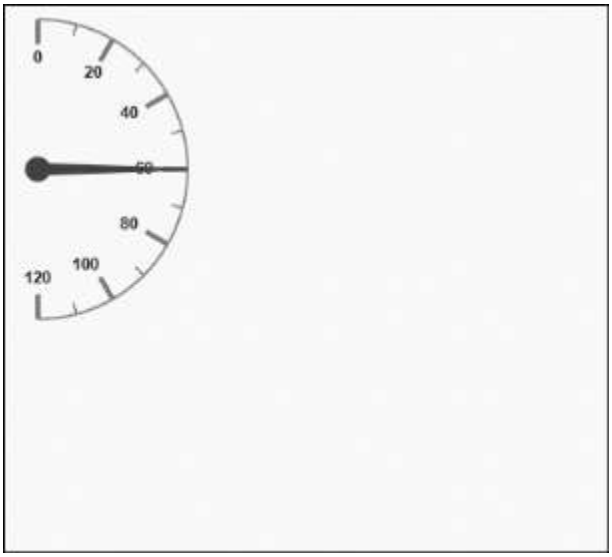
Copyright © 2001 - 2020 Syncfusion Inc.

```
// To set dimension of the canvas.
.Width(500).Height(500).Radius(100).Value(60)
// To set gauge position.
.GaugePosition(GaugePosition.TopLeft)
// To set gauge distance from corner.
.DistanceFromCorner(25)
// To set frame settings.
.Frame(fr=>fr.FrameType(Frame.HalfCircle)
// To set frame start angle.
.HalfCircleFrameStartAngle(270)
// To set frame end angle.
.HalfCircleFrameEndAngle(90))
// To set basic scale settings.
.Scales(SC =>{SC.Radius(100)
.Maximum(120)
.MajorIntervalValue(20)
.MinorIntervalValue(10)
.ShowScaleBar(true)
.Size(1)
.Border(border => border.Width(0.5))
.StartAngle(270)
.SweepAngle(180).Add();}))
```

C#

```
public partial class CircularGaugeController : Controller
{
//        // GET: /ToolTip/
public ActionResult Semicircular()
{
return View();
}
}
```

Execute the above code to render the following output.



Semi-circular Gauge with default top left position

Exporting

- Circular Gauge has an exporting feature that converts Gauge control into image format and then export in client side. The method API `exportImage` is used to export the Circular Gauge.
- It has two arguments such as **file name** and **file format** to specify the file name and file formats. For exporting refer the following code example.

JS

```
@(Html.EJ().CircularGauge("circulargauge"))
<input type="submit" value="Export Image" id="btnExportImage" />
<script type="text/javascript">
$(function () {
$("#btnExportImage").ejButton({ width: "100px", click: "buttonClickEvent",
});
});
function buttonClickEvent() {
var FileName = $("#txtFileName").val();
var FileFormat = $("#ddlFileType").val();
$("#circulargauge").ejCircularGauge("exportImage", FileName, FileFormat);
}
</script>
```

Execute the above code to render the following output.

Circular Gauge control Export Functionality

Methods and Events

Public Methods

Destroying the Circular Gauge

The `destroy` method is used to destroy the **CircularGauge** widget. All events bound using this._on will be unbind automatically and bring the control to pre-init state.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script type="text/javascript">
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.destroy();
</script>
```

Getting Back Needle Length

The getBackNeedleLength method is used to get the needle length of **CircularGauge**.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({ scales: [{ pointers: [{
showBackNeedle: true }] }] });
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getBackNeedleLength(0, 0);
</script>
```

Getting Custom Label Angle

The getCustomLabelAngle method is used to get the angle of custom label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales:
[{customLabels:[{textAngle:30,value:"MyLabel",position:{x:250,y:300},color:"
#fc0606",font:{size: "20px", fontFamily: "Arial", fontStyle: "Bold" }}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getCustomLabelAngle(0, 0);
</script>
```

Getting Custom Label value

The getCustomLabelValue method is used to get the value of custom label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales:
[{customLabels:[{textAngle:30,value:"MyLabel",position:{x:250,y:300},color:"
#fc0606",font:{size: "20px", fontFamily: "Arial", fontStyle: "Bold" }}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getCustomLabelValue(0, 0);
</script>
```

Getting Label Angle

The getLabelAngle method is used to get angle of label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getLabelAngle(0, 0);
</script>
```

Getting Label Distance From Scale

The getLabelDistanceFromScale method is used to get the distance value from scale for label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getLabelDistanceFromScale(0, 0);
</script>
```

Getting Label Placement

The getLabelPlacement method is used to get placement of label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getLabelPlacement(0, 0);
</script>
```

Getting Label Style

The getLabelStyle method is used to get style of label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getLabelStyle(0, 0);
</script>
```

Getting Major Interval Value

The getMajorIntervalValue method is used to get major interval value of CircularGauge.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getMajorIntervalValue(0);
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Getting Maker Distance From Scale

The getMarkerDistanceFromScale method is used to get distance from scale value of marker.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getMarkerDistanceFromScale(0);
</script>
```

Getting Maker Style

The getMarkerStyle method is used to get distance from scale value of marker.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getMarkerStyle(0, 0);
</script>
```

Getting Maximum Value

The getMaximumValue method is used to get maximum value of CircularGauge.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getMaximumValue(0);
</script>
```

Getting Minimum Value

The getMinimumValue method is used to get minimum value of CircularGauge.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getMinimumValue(0);
</script>
```

Getting Minor Interval Value

The getMinorIntervalValue method is used to get minor interval value of CircularGauge.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getMinorIntervalValue(0);
</script>
```

Getting Needle Style

The getNeedleStyle method is used to get style of needle.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getNeedleStyle(0, 0);
</script>
```

Getting Pointer Cap Border Width

The getPointerCapBorderWidth method is used to get border width of pointer cap.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getPointerCapBorderWidth(0);
</script>
```

Getting Pointer Cap Radius

The getPointerCapRadius method is used to get radius of pointer cap.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getPointerCapRadius(0);
</script>
```

Getting Pointer Length

The getPointerLength method is used to get pointer length.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getPointerLength(0, 0);
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Getting Pointer Needle Type

The getPointerNeedleType method is used to get needle type of pointer.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getPointerNeedleType(0, 0);
</script>
```

Getting Pointer Placement

The getPointerPlacement method is used to get placement of pointer.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getPointerPlacement(0, 0);
</script>
```

Getting Pointer Value

The getPointerValue method is used to get pointer value.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getPointerValue(0, 0);
</script>
```

Getting Pointer Value

The getPointerWidth method is used to get pointer width.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getPointerWidth(0, 0);
</script>
```

Getting Range Border Width

The getRangeBorderWidth method is used to get border width of range.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getRangeBorderWidth(0, 0);
</script>
```

Getting Range Distance From Scale

The getRangeDistanceFromScale method is used to get range distance from scale.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getRangeDistanceFromScale(0, 0);
</script>
```

Getting Range End Value

The getRangeEndValue method is used to get end value of range.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getRangeEndValue(0, 0);
</script>
```

Getting Range Position

The getRangePosition method is used to get range position.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getRangePosition(0, 0);
</script>
```

Getting Range Size

The getRangeSize method is used to get range size.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
circulargaugeObj.getRangeSize(0, 0);
</script>
```

Getting Range Start Value

The getRangeStartValue method is used to get range start value.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getRangeStartValue(0, 0);
</script>
```

Getting Scale Bar Size

The getScaleBarSize method is used to get scale bar size.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getScaleBarSize(0);
</script>
```

Getting Scale Border Width

The getScaleBorderWidth method is used to get border width of scale.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({ scales: [{showScaleBar: true,
size: 6, border:{Width: 1.5} }] });
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getScaleBorderWidth(0);
</script>
```

Getting Scale Direction

The getScaleDirection method is used to get scale direction.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getScaleDirection(0);
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Getting Scale Radius

The getScaleRadius method is used to get scale radius.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getScaleRadius(0);
</script>
```

Getting Start Angle

The getStartAngle method is used to get start angle.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getStartAngle(0);
</script>
```

Getting Sub Gauge Location

The getSubGaugeLocation method is used to get location of subGauge.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<div id="subGauge1"></div>
<script>
$("#subGauge1").ejCircularGauge({backgroundColor: "#f5b43f",scales:
[{radius: 150}]});
$("#CoreCircularGauge").ejCircularGauge({height: 500,width: 500,scales:
[{radius: 250,subGauges: [{controlID: "subGauge1",height: 400,width:
200,position: { x: 200, y: 150 }}]}]});
circulargaugeObj.getSubGaugeLocation(0, 0);
</script>
```

Getting Sweep Angle

The getSweepAngle method is used to get sweep angle.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getSweepAngle(0);
</script>
```

Getting Tick Angle

The getTickAngle method is used to get tick angle.

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getTickAngle(0, 0);
</script>
```

Getting Tick Distance From Scale

The getTickDistanceFromScale method is used to get tick distance from scale value.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getTickDistanceFromScale(0, 0);
</script>
```

Getting Tick Height

The getTickHeight method is used to get tick height.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getTickHeight(0, 0);
</script>
```

Getting Tick Placement

The getTickPlacement method is used to get tick placement.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getTickPlacement(0, 0);
</script>
```

Getting Tick Style

The getTickStyle method is used to get tick style.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getTickStyle(0, 0);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</script>
```

Getting Tick Width

The getTickWidth method is used to get tick width.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.getTickWidth(0, 0);
</script>
```

Setting IncludeFirstValue

The includeFirstValue method is used to set includeFirstValue.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.includeFirstValue(0, 0, false);
</script>
```

Redrawing Circular Gauge

The redraw method is used to redraw the Circular Gauge widget.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.redraw("scale");
</script>
```

Setting Back Needle Length

The setBackNeedleLength method is used to set the needle length of **CircularGauge**.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({ scales: [{ pointers: [{
showBackNeedle: true }] }] });
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setBackNeedleLength(0, 0, 10);
</script>
```

Setting Custom Label Angle

The setCustomLabelAngle method is used to set the angle of custom label.

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales:
[{customLabels:[{value:"MyLabel",position:{x:250,y:300},color:"#fc0606",font
: { size: "20px", fontFamily: "Arial", fontStyle: "Bold" }}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setCustomLabelAngle(0, 0, 10);
</script>
```

Setting Custom Label value

The setCustomLabelValue method is used to set the value of custom label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales:
[{customLabels:[{value:"MyLabel",position:{x:180,y:300},color:"#fc0606",font
:{size: "20px", fontFamily: "Arial", fontStyle: "Bold" }}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setCustomLabelValue(0, 0, "CircularGauge");
</script>
```

Setting Label Angle

The setLabelAngle method is used to set angle of label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setLabelAngle(0, 0, 10);
</script>
```

Setting Label Distance From Scale

The setLabelDistanceFromScale method is used to set the distance value from scale for label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setLabelDistanceFromScale(0, 0, 10);
</script>
```

Setting Label Placement

The setLabelPlacement method is used to set placement of label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setLabelPlacement(0, 0, 'far');
</script>
```

Setting Label Style

The setLabelStyle method is used to set style of label.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setLabelStyle(0, 0, 'major');
</script>
```

Setting Major Interval Value

The setMajorIntervalValue method is used to set major interval value of CircularGauge.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setMajorIntervalValue(0, 10);
</script>
```

Setting Maker Distance From Scale

The setMarkerDistanceFromScale method is used to set distance from scale value of marker.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setMarkerDistanceFromScale(0, 10);
</script>
```

Setting Maker Style

The setMarkerStyle method is used to set distance from scale value of marker.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setMarkerStyle(0, 0, 'rectangle');
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Setting Maximum Value

The setMaximumValue method is used to set maximum value of CircularGauge.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setMaximumValue(0, 130);
</script>
```

Setting Minimum Value

The setMinimumValue method is used to set minimum value of CircularGauge.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setMinimumValue(0, 10);
</script>
```

Setting Minor Interval Value

The setMinorIntervalValue method is used to set minor interval value of CircularGauge.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setMinorIntervalValue(0, 2);
</script>
```

Setting Needle Style

The setNeedleStyle method is used to set style of needle.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setNeedleStyle(0, 0, 'arrow');
</script>
```

Setting Pointer Cap Border Width

The setPointerCapBorderWidth method is used to set border width of pointer cap.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setPointerCapBorderWidth(0, 5);
</script>
```

Setting Pointer Cap Radius

The setPointerCapRadius method is used to set radius of pointer cap.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setPointerCapRadius(0, 10);
</script>
```

Setting Pointer Length

The setPointerLength method is used to set pointer length.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setPointerLength(0, 0, 90);
</script>
```

Setting Pointer Needle Type

The setPointerNeedleType method is used to set needle type of pointer.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setPointerNeedleType(0, 0, 'triangle');
</script>
```

Setting Pointer Placement

The setPointerPlacement method is used to set placement of pointer.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setPointerPlacement(0, 0,'near');
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Setting Pointer Value

The setPointerValue method is used to set pointer value.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setPointerValue(0, 0, 10);
</script>
```

Setting Pointer Value

The setPointerWidth method is used to set pointer width.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setPointerWidth(0, 0, 10);
</script>
```

Setting Range Border Width

The setRangeBorderWidth method is used to set border width of range.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setRangeBorderWidth(0, 0, 5);
</script>
```

Setting Range Distance From Scale

The setRangeDistanceFromScale method is used to set range distance from scale.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setRangeDistanceFromScale(0, 0, 10);
</script>
```

Setting Range End Value

The setRangeEndValue method is used to set end value of range.

JS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setRangeEndValue(0, 0, 70);
</script>
```

Setting Range Position

The setRangePosition method is used to set range position.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setRangePosition(0, 0, 'far');
</script>
```

Setting Range Size

The setRangeSize method is used to set range size.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setRangeSize(0, 0, 10);
</script>
```

Setting Range Start Value

The setRangeStartValue method is used to set range start value.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({scales: [{showRanges: true,ranges:
[{distanceFromScale: -30,startValue: 0,endValue: 70}]}]});
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setRangeStartValue(0, 0, 10);
</script>
```

Setting Scale Bar Size

The setScaleBarSize method is used to set scale bar size.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setScaleBarSize(0, 160);
</script>
```

Setting Scale Border Width

The setScaleBorderWidth method is used to set border width of scale.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge({ scales: [{showScaleBar: true,
size: 6, border:{Width: 1.5} }] });
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setScaleBorderWidth(0, 3);
</script>
```

Setting Scale Direction

The setScaleDirection method is used to set scale direction.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setScaleDirection(0, 'clockwise');
</script>
```

Setting Scale Radius

The setScaleRadius method is used to set scale radius.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setScaleRadius(0, 140);
</script>
```

Setting Start Angle

The setStartAngle method is used to set start angle.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setStartAngle(0, 10);
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Setting Sub Gauge Location

The setSubGaugeLocation method is used to set location of subGauge.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<div id="subGauge1"></div>
<script>
$("#subGauge1").ejCircularGauge({backgroundColor: "#f5b43f",scales:
[{radius: 150}]});
$("#CoreCircularGauge").ejCircularGauge({height: 500,width: 500,scales:
[{radius: 250,subGauges: [{controlID: "subGauge1",height: 400,width:
200,position: { x: 200, y: 150 }}]}]});
circulargaugeObj.setSubGaugeLocation(0, 0, {x:50,y:100});
</script>
```

Setting Sweep Angle

The setSweepAngle method is used to set sweep angle.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setSweepAngle(0, 220);
</script>
```

Setting Tick Angle

The setTickAngle method is used to set tick angle.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setTickAngle(0, 0, 10);
</script>
```

Setting Tick Distance From Scale

The setTickDistanceFromScale method is used to set tick distance from scale value.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setTickDistanceFromScale(0, 0, 15);
</script>
```

Setting Tick Height

The setTickHeight method is used to set tick height.

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setTickHeight(0, 0, 10);
</script>
```

Setting Tick Placement

The setTickPlacement method is used to set tick placement.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setTickPlacement(0, 0, 'near');
</script>
```

Setting Tick Style

The setTickStyle method is used to set tick style.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setTickStyle(0, 0, 'minor');
</script>
```

Setting Tick Width

The setTickWidth method is used to set tick width.

JS

```
@(Html.EJ().CircularGauge("CoreCircularGauge"))
<script>
$("#CoreCircularGauge").ejCircularGauge();
var circulargaugeObj = $("#CoreCircularGauge").data("ejCircularGauge");
circulargaugeObj.setTickWidth(0, 0, 5);
</script>
```

Events

Draw Custom Label

The DrawCustomLabel event is triggered while custom labels are drawn on the gauge.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//draw custom label event
.DrawCustomLabel("onDrawCustomLabel")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//...
)
function onDrawCustomLabel(sender) {
// do something
}
```

Draw Indicators

The DrawIndicators event is triggered while indicators are being drawn on the gauge.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//draw indicators event
.DrawIndicators("onDrawIndicators")
//...
)
function onDrawIndicators(sender) {
// do something
}
```

Draw Labels

The DrawLabels event is triggered while labels are being drawn on the gauge.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//draw labels event
.DrawLabels("onDrawLabels")
//...
)
function onDrawLabels(sender) {
// do something
}
```

Draw Pointer Cap

The DrawPointerCap event is triggered while pointer cap is being drawn on the gauge.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//draw pointer cap event
.DrawPointerCap("onDrawPointerCap")
//...
)
function onDrawPointerCap(sender) {
// do something
}
```

Draw Pointers

The DrawPointers event is triggered while pointer cap is being drawn on the gauge.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//draw pointers event
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.DrawPointers("onDrawPointers")
//...
)
function onDrawPointers(sender) {
// do something
}
```

Draw Range

The DrawRange event is triggered when ranges starts to be drawn on the gauge.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//draw range event
.DrawRange("onDrawRange")
//...
)
function onDrawRange(sender) {
// do something
}
```

Draw Ticks

The DrawTicks event is triggered when ticks are being drawn on the gauge.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//draw ticks event
.DrawTicks("onDrawTicks")
//...
)
function onDrawTicks(sender) {
// do something
}
```

Load

The Load event is triggered when gauge starts to load.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//load event
.Load("onLoad")
//...
)
function onLoad(sender) {
// do something
}
```

Mouse Click

The MouseClick event is triggered when left mouse button is clicked.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//mouse click event
.MouseClick("onMouseClick")
//...
)
function onMouseClick(sender) {
// do something
}
```

Mouse Click Move

The MouseClickMove event is triggered when clicking and dragging the mouse pointer over the gauge pointer.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//mouse click move event
.MouseClickMove("onMouseClickMove")
//...
)
function onMouseClickMove(sender) {
// do something
}
```

Mouse Click Up

The MouseClickUp event is triggered when clicking and dragging the mouse pointer over the gauge pointer.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//mouse click up event
.MouseClickUp("onMouseClickUp")
//...
)
function onMouseClickUp(sender) {
// do something
}
```

Render Complete

The RenderComplete event is triggered when rendering of the gauge is completed.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//render complete event
.RenderComplete("onRenderComplete")
//...
)
function onRenderComplete(sender) {
// do something
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Range Mouse Move

The RangeMouseMove event is triggered when moving mouse on ranges.

ASPX-CS

```
@(Html.EJ().CircularGauge("circulargauge1")
//range mouse move event
.RangeMouseMove("onRangeMouseMove")
//...
)
function onRangeMouseMove(sender) {
// do something
}
```

DoubleClick

The DoubleClick event is triggered when double clicking the gauges.

ASPX-CS

```
@(Html.EJ().CircularGauge("gauge")
//double click event
.DoubleClick("onDoubleClick")
//...
)
function onDoubleClick(sender) {
// do something
}
```

RightClick

The RightClick event is triggered when right clicking the gauges.

ASPX-CS

```
@(Html.EJ().CircularGauge("gauge")
//right click event
.RightClick("onRightClick")
//...
)
function onRightClick(sender) {
// do something
}
```

MVVM

AngularJS

Circular Gauge contains AngularJS support. You can add object as well as array object in the Circular Gauge. The two way binding support is given to the pointer value, minimum scale value and maximum scale value.

Rendering the Circular Gauge

ej-CircularGauge is the control tag in which ej is tag prefix and CircularGauge is the control name.The following code example helps you to render Circular Gauge.

HTML

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div ng-app="syncApp">
<div ng-controller="CircularGauge">
<ej-CircularGauge id="CircularGauge1" e-backgroundColor="transparent" e-
value="50"
e-width="500" e-readOnly="false" e-load= "loadGaugeTheme"
e-enableAnimation="false">
</ej-CircularGauge>
</div>
</div>
```

JS

```
<script type="text/javascript">
<!—binding the value to the scope variables in application controller-->
angular.module('syncApp', ['ejangular'])
.controller('CircularGauge', function ($scope) {
$scope.value = 50;
$scope.minimum = 0;
$scope.maximum = 120;
});
</script>
```

Execute the above code to render the output as follows.

Default Circular gauge in AngularJS

Adding Scale Collection

Scale is an array object and you can use the inner tag for it. Object in the array collection (i.e. border) is extended with hyphen in the same tag.

Example: e-border-width and e-border-color.

HTML

```
<!--To Render the Circular gauge-->
<ej-CircularGauge id="CircularGauge1">
<!--Adding Scale collection to the Circular gauge-->
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<e-scales>
<e-scale e-showRanges="true" e-startAngle="122" e-sweepAngle="296"
e-radius="130" e-showScaleBar="true" e-size="1" e-maximum="120"
e-majorIntervalValue="20" e-minorIntervalValue="10"
e-border-width="0.5">
</e-scale>
</e-scales>
</ej-CircularGauge>
```

Execute the above code to render the following output.

Circular gauge with scale customization in AngularJS

Adding Pointer Collection

Pointer is an array object and you can use the inner tag for it. Object in the array collection (i.e. pointer cap) is extended with hyphen in the same tag.

Example: e-pointerCap-radius.

HTML

```
<!--To Render the Circular gauge-->
<ej-CircularGauge id="CircularGauge1">
<!--Adding Scale collection to the Circular gauge-->
<e-scales>
<e-scale>
<!--Adding pointer collection to the scale collection-->
<e-pointers>
<e-pointer e-showBackNeedle="true" e-backNeedleLength="20"
e-length="95" e-width="7" e-value="80"
e-pointerCap-radius="12">
</e-pointer>
</e-pointers>
</e-scale>
</e-scales>
</ej-CircularGauge>
```

Execute the above code to render the output as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

50

Circular gauge with pointer customization in AngularJS

Adding Label Collection

Label is also an array object. You can use the inner tag for it.

HTML

```
<!--To Render the Circular gauge-->
<ej-CircularGauge id="CircularGauge1">
<!--Adding Scale collection to the Circular gauge-->
<e-scales>
<e-scale>
<!--Adding pointer collection to the scale collection-->
<e-pointers>…</e-pointers>
<!--Adding labels collection to the scale collection-->
<e-labels>
<e-label e-color="#8c8c8c">
</e-label>
</e-labels>
</e-scale>
</e-scales>
</ej-CircularGauge>
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

50

Circular gauge with label customization in AngularJS

Adding Tick Collection

Tick is an array object. You can use the inner tag for it.

HTML

```
<!--To Render the Circular gauge-->
<ej-CircularGauge id="CircularGauge1">
<!--Adding Scale collection to the Circular gauge-->
<e-scales>
<e-scale>
<!--Adding pointer collection to the scale collection-->
<e-pointers>…</e-pointers>
<!--Adding labels collection to the scale collection-->
<e-labels>…</e-labels>
<!--Adding ticks collection to the scale collection-->
<e-ticks>
<e-tick e-type="major" e-distanceFromScale="2" e-height="16"
e-width="1" e-color="#8c8c8c">
</e-tick>
<e-tick e-type="minor" e-distanceFromScale="2" e-height="8"
e-width="1" e-color="#8c8c8c">
</e-tick>
</e-ticks>
</e-scale>
</e-scales>
</ej-CircularGauge>
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

50

Circular gauge with ticks customization in AngularJS

Adding Range Collection

Range is an array object. You can use the inner tag for it. Object in the array collection (i.e. border) is extended with hyphen in the same tag.

Example: e-border-color.

HTML

```
<!--To Render the Circular gauge-->
<ej-CircularGauge id="CircularGauge1">
<!--Adding Scale collection to the Circular gauge-->
<e-scales>
<e-scale>
<!--Adding pointer collection to the scale collection-->
<e-pointers>…</e-pointers>
<!--Adding labels collection to the scale collection-->
<e-labels>…</e-labels>
<!--Adding ticks collection to the scale collection-->
<e-ticks>…</e-ticks>
<!--Adding ranges collection to the scale collection-->
<e-ranges>
<e-range e-distanceFromScale="-30" e-startValue="0" e-endValue="70">
</e-range>
<e-range e-distanceFromScale="-30" e-startValue="70"
e-endValue="110" e-backgroundColor="#fc0606"
e-border-color="#fc0606">
</e-range>
<e-range e-distanceFromScale="-30" e-startValue="110"
e-endValue="120" e-backgroundColor="#f5b43f"
e-border-color="#f5b43f">
</e-range>
</e-ranges>
</e-scale>
</e-scales>
</ej-CircularGauge>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Execute the above code to render the following output.

Circular gauge Rendered in AngularJS

Two Way Binding

Circular Gauge support the two way binding for the property value, minimum and maximum as mentioned earlier. The following code example explains how to achieve the two way binding in Circular Gauge.

HTML

```
<div ng-app="syncApp">
<div ng-controller="CircularGauge">
<div>
<ej-CircularGauge id="CircularGauge1" e-backgroundColor="transparent" e-
value="nvalue" e-width="500" e-readOnly="false" e-load= "loadGaugeTheme" e-
enableAnimation="false">
<e-scales>
<e-scale e-showRanges="true" e-startAngle="122" e-sweepAngle="296"
e-radius="130" e-showScaleBar="true" e-size="1"
<!—binding maximum value using angular JS -->
e-maximum="maximum"
<!—binding minimum value using angular JS -->
e-minimum="minimum"
e-majorIntervalValue="20"
e-minorIntervalValue="10" e-border-width="0.5">
<e-pointers>
<e-pointer e-showBackNeedle="true" e-backNeedleLength="20"
e-length="95" e-width="7"
<!—binding pointer value using angular JS -->
e-value="value"
e-pointerCap-radius="12">
</e-pointer>
</e-pointers>
<e-labels>
<e-label e-color="#8c8c8c"></e-label>
</e-labels>
<e-ticks>
<e-tick e-type="major" e-distanceFromScale="2" e-height="16"
e-width="1" e-color="#8c8c8c">
</e-tick>
```

```
<e-tick e-type="minor" e-distanceFromScale="2" e-height="8"
e-width="1" e-color="#8c8c8c">
</e-tick>
</e-ticks>
<e-ranges>
<e-range e-distanceFromScale="-30" e-startValue="0" e-endValue="70">
</e-range>
<e-range e-distanceFromScale="-30" e-startValue="70"
e-endValue="110" e-backgroundColor="#fc0606"
e-border-color="#fc0606">
</e-range>
<e-range e-distanceFromScale="-30" e-startValue="110"
e-endValue="120" e-backgroundColor="#f5b43f"
e-border-color="#f5b43f">
</e-range>
</e-ranges>
</e-scale>
</e-scales>
</ej-CircularGauge>
</div>
<input type="text" id="txtMax" e-value="nvalue" ej-numerictextbox ng-
model="nvalue"  e-decimalplaces="2" e-showspinbutton="false"
Style="width:110px"/>
</div>
</div>
<script type="text/javascript">
<!—binding the value to the scope variables in application controller-->
angular.module('syncApp', ['ejangular'])
.controller('CircularGauge', function ($scope) {
$scope.value = 50;
$scope.minimum = 0;
$scope.maximum = 120;
});
</script>
```

Execute the above code to render the following output.

50

Circular gauge with two way binding in AngularJS

KnockoutJS

- KnockoutJS support allows you to bind the HTML elements against any of the available data models.Two types of KnockoutJS binding is supported as of AngularJS,
    1. one-way binding
    2. two-way binding
- One way binding refers to the process of applying observable values to all the available properties of the Circular Gauge control, but the changes made in gauge control does not reflect and trigger in turn to the observable collection. This kind of binding applies to all the properties of the circular gauge control.
- Two-way binding supports both the processes – it applies the observable values to the Circular Gauge properties as well as the changes made in the Circular Gauge control also reflects back and triggers within the observable collections. Only few of the schedule properties support two-way binding and they are as follows
    1. value
    2. maximum
    3. minimum

ASPX-CS

```
<div id="CircularGauge1"
data-bind="ejCircularGauge: {
value:sampleValue,
minimum:minimumValue,
maximum:maximumValue
}">
</div>
```

JS

```
<script type="text/javascript">
$(function () {
window.viewModel = {
sampleValue: ko.observable(50),
minimumValue: ko.observable(10),
maximumValue: ko.observable(150)
};
$(function () {
ko.applyBindings(viewModel);
});
});
</script>
```

Execute the above code to render the following output. The following screenshot is the output of ASP.

Copyright © 2001 - 2020 Syncfusion Inc.

Circular Gauge with KnockoutJS binding

ColorPicker

Overview

The ASP.NET MVCColorPicker control provides you a rich visual interface for color selection. You can select the color from the professionally designed palettes or custom color. By clicking a point on the color, you can change the active color to the color that is located under the pointer.

You can also choose colors in different specifications; red-green-blue-alpha (opacity) (RGBA), hue-saturation-value (HSV) and hexadecimal (HEX). The ColorPicker provides a selection of basic colors, standard presets, custom colors and color swatches.

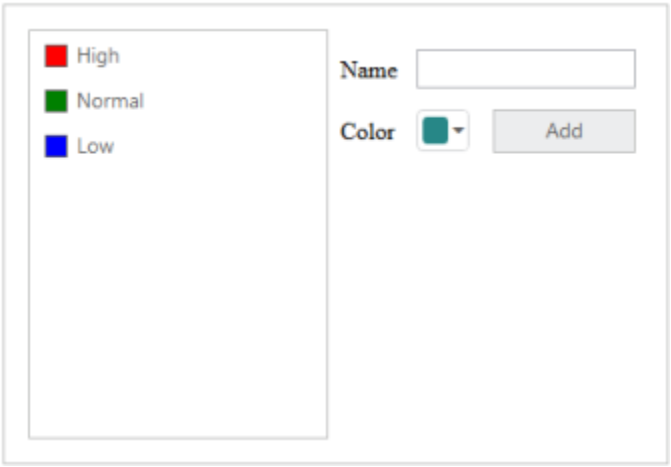
Getting Started

This section explains briefly about how to create a ColorPicker in your application with, ASP.NET MVC.

Create your first ColorPicker in ASP.NET MVC

The Essential ASP.NET MVCColorPicker control provides support for selecting the colors in different sources such as palettes, picker or custom palettes. You can also render the color value from control in three formats such as RGB, HSV and HEXCODE.

In this example, you can learn how to customize ColorPicker control in a category Application.



Copyright © 2001 - 2020 Syncfusion Inc.

ColorPicker Control

In the following sections you can learn, How to:

- Create ColorPicker control
- Initialize the other widgets
- Add Value to ListBox Control

Create ColorPicker Control

Use the following steps to create the ColorPicker control.

1. You can create a MVC Project and add necessary Dll's and Scripts with the help of the given MVC-Getting Started Documentation.
2. Add the following code example to the corresponding view page for rendering the ColorPicker window.

ASPX-CS

```
@Html.EJ().ColorPicker("CategoryColor").Value("#278787")
```

3. Run this code to render the resultant output of the above steps.

Initialize the other widgets

To add the priority value to the ListBox, the text value is obtained from the input element and color for each priority is received by ColorPicker control. To add each new priority value to ListBox control, click the Add button.

You can refer to the following link for more information on creation on ListBox

http://help.syncfusion.com

1. The following code example is used to create the Priority form using ListBox control and ColorPicker control.

Copyright © 2001 - 2020 Syncfusion Inc.

HTML

```
<div class="content-container-fluid">
<div class="row">
<div class="sample-area">
<div class="frame">
<div id="control">
<ul id="ColorValues">
<li><span class="color high"></span>High</li>
<li><span class="color normal"></span>Normal</li>
<li><span class="color low"></span>Low</li>
</ul>
@Html.EJ().ListBox("selectPriority").TargetID("ColorValues")
</div>
</div>
</div>
<div id="Properties">
<table class="prop-grid">
<tr class="row">
<td class="column">Name
</td>
<td class="column">
<input type="text" id="categoryName" />
</td>
</tr>
<tr class="row">
<td class="column">Color
</td>
<td class="column">
<!--Colorpicker element-->
@Html.EJ().ColorPicker("CategoryColor").Value("#278787")
</td>
<td class="column">
<!--Add button for add the new category-->
@Html.EJ().Button("AddCategory").Text("Add").Width("82px").Height("28px").Ty
pe(ButtonType.Button).ClientSideEvents(events =>
events.Click("addCategoryValue"))
</td>
</tr>
<tr class="row">
</tr>
</table>
</div>
</div>
</div>
```

2. Add the following style section to align form fields.

CSS

```
<style>
.content-container-fluid > .row {
width: 410px;
border: 1px solid #bbbcbb;
padding: 16px;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
.color.high {
background-color: red;
}
.color.normal {
background-color: green;
}
.color.low {
background-color: blue;
}
.sample-area {
width: 205px;
}
.sample-area, #Properties {
display: inline-block;
float: left;
}
#Properties #categoryName {
width: 140px;
height: 20px;
}
#Properties .column {
display: inline-block;
width: 45px;
margin: 10px 0 0;
}
#Properties .row {
padding: 10px 0px 5px 0px;
}
.color {
width: 13px;
height: 13px;
border: 1px solid;
display: inline-block;
margin-right: 6px;
margin-bottom: -3px;
}
</style>
```

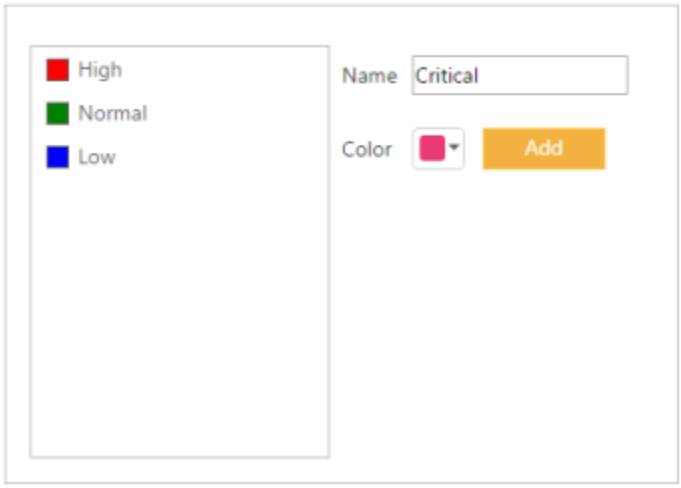
3. Initialize the element in

JS

```
<script>
var listBoxObj, colorObj;
jQuery(function ($) {
//initialize the listbox with object creation
listBoxObj = $("#selectPriority").data('ejListBox');
//initialize the colorpicker with object creation
colorObj = $("#CategoryColor").data('ejColorPicker');
});
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

4. Run the above code to render the following output.



Color Picker control

Add value to ListBox Control

You can add the value to ListBox with selected color by performing the button click event. The following script section define the click event for the button element.

1. Initialize the click event to button element in

JS

```
<script>
jQuery(function ($) {
//reuse the previous section script block
//The following function used to add the new value to the listbox control
function addCategoryValue() {
if ($("#categoryName").val() !== "") {
//To get the selected color from the colorpicker by using getValue()
listBoxObj.addItem("<span class='color' style='background-color: " +
colorObj.getValue() + "' ></span>" + $("#categoryName").val());
$("#categoryName").val("");
}
}
</script>
```

2. The following screenshot illustrates the resultant output after you click Add button.

Value from Color Picker control

Behavior Settings

ShowPreview

The ColorPicker control provides live preview support for current cursor selection color and selected color. ShowPreview property allows you to preview the selected color in the picker or from the palette.

The ShowPreview property is Boolean type and its default value is true.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787").ShowPreview(true)
```

The following screenshot displays the output of the above code example.

ColorPicker with Show Preview option

Copyright © 2001 - 2020 Syncfusion Inc.

showRecentColors

The ColorPicker control allows you to store the color values in custom list by using ShowRecentColors property. The ColorPicker keeps up to 11 colors in a custom list. By clicking the add button, the selected color from picker or palette gets added in the recent color list.

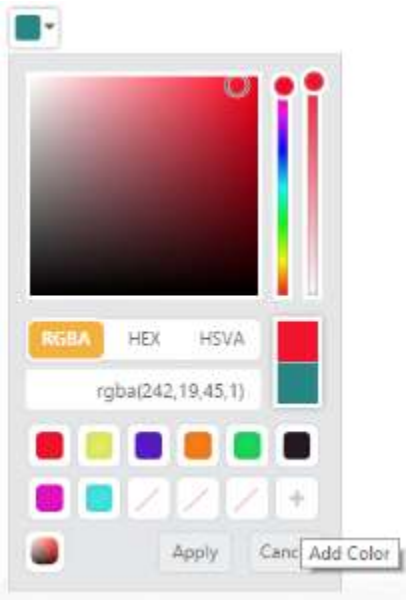
The ShowRecentColors property is Boolean type and its default value is false.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787").ShowRecentColors(true
)
```

The following screenshot displays the output of the above code example.



ColorPicker with Recent Color Swatches

EnableOpacity

The ColorPicker control allows you to enable or disable the opacity slider. You can achieve this by using the EnableOpacity property.

The EnableOpacity property is Boolean type and its default value is true.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787").EnableOpacity(false)
```

The following screenshot displays the output of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.

ColorPicker with Opacity Slider as disabled state

Columns

The palette model consists of color values in the rows and columns order. Palette only consists of predefined colors and allows you to select anyone color from it. The Columns property allows you to modify the number of columns in palette model.

The Columns property is Number type and its default value is 10.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787").Columns(9)
```

The following screenshot displays the output of the above code example.

ColorPicker with Columns

Copyright © 2001 - 2020 Syncfusion Inc.

Configure Values

OpacityValue

The ColorPicker control allows you to change the opacity value by using the OpacityValue property. The selected color opacity is adjusted by using the OpacityValue.

The OpacityValue property is Number type and its default value is 100.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787").OpacityValue(40)
```

The following screenshot displays the output of the above code example.

ColorPicker with Opacity Value

Button and TooltipText

ButtonText

The ColorPicker control allows you to define the text to be displayed in button elements. You can specify the text by using ButtonText property. In ColorPicker control, popup contains two button elements “Apply” and “Cancel”.

To configure the ButtonText property for the button elements, use the corresponding default values listed in the following table.

List of Button elements

Element	Default value
Apply	Apply
Cancel	Cancel

Copyright © 2001 - 2020 Syncfusion Inc.

TooltipText

The ColorPicker control consists of more number of sub controls and elements. To provide some information about each element and sub control, you can use the tooltip concept and you can achieve this by using TooltipText property.

To configure the TooltipText, use the following listed elements and its corresponding default value.

List of Tooltip elements

Element	Default value
Switcher	Switcher
AddButton	Add Color
Basic	Basic
MonoChrome	Mono Chrome
FlatColors	Flat Colors
SeaWolf	Sea Wolf
WebColors	Web Colors
Sandy	Sandy
PinkShades	Pink Shades
Misty	Misty
Vintage	Vintage
MoonLight	Moon Light
CandyCrush	Candy Crush
CurrentColor	Current Color
SelectedColor	Selected Color
Citrus	Citrus

When it is necessary to set the button text and TooltipText values in Spanish culture, the ColorPicker allow you to define the culture values to ButtonText and TooltipText property. The following section explains on how to define the Spanish culture values to ColorPicker control.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787").ColorPickerButtonText
(color=>
color.Apply("aplicar").Cancel("cancelar")).ColorPickerTooltipText(tooltip=>
tooltip.Sandy("arenoso"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot displays the output of the above code example.

ColorPicker with Culture Support

Appearance and Styling

modelType

The ColorPicker allows you to define the model type to be displayed in control at initial time by using the property *ModelType*.

The ModelType property is Enum type and its default value is default.

List of modelType

ModelType	Syntax	Description
Default	ModelType(ModelType.Default)	Control rendered with both model. You can switch to palette or picker model.
Picker	ModelType(ModelType.Picker)	Control rendered with picker model only.
Palette	ModelType(ModelType.Palette)	Control rendered with palette model only.

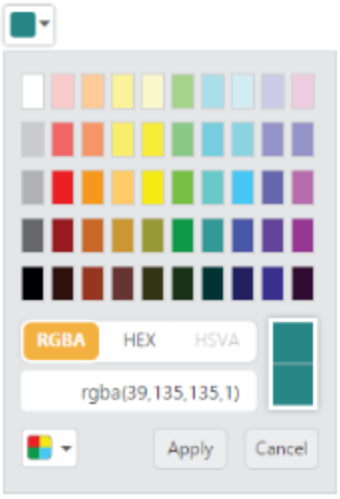
In the following code example, the ColorPicker popup model type is set as Palette when you drop down the ColorPicker popup.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787").ModelType(ModelType.Palette)
```

The following screenshot displays the output of the above code example.



ColorPicker rendered with Palette Model

Palette

The ColorPicker allow you to define the palette type to be displayed in control at initial time by using the Palette property. The Palette property is Enum type and its default value is BasicPalette.

List of palette

Palette	Syntax	Description	Dependent Property
BasicPalette	Palette(PaletteType.BasicPalette)	The palette model rendered with predefined color values.	ModelType(ModelType.Palette)
CustomPalette	Palette(PaletteType.CustomPalette)	The palette model renders with the specified custom color values.	

BasicPalette

The BasicPalette type renders with predefined color values. The BasicPalette model has 12 different preset patterns. Each pattern consists of 50 colors and over 600 colors are available by default.

PresetType

The ColorPicker control allows you to define the preset model to be rendered initially in palette type. This can be achieved by using the “PresetType” property. Totally 12 types of presets are available.

The PresetType property is Enum type and its default value is “Basic”.

Property Table

PresetType	Syntax	Dependent Property
Basic	PresetType(PresetsType.Basic)	Palette(PaletteType.BasicPalette)
MonoChrome	PresetType(PresetsType.MonoChrome)	

Copyright © 2001 - 2020 Syncfusion Inc.

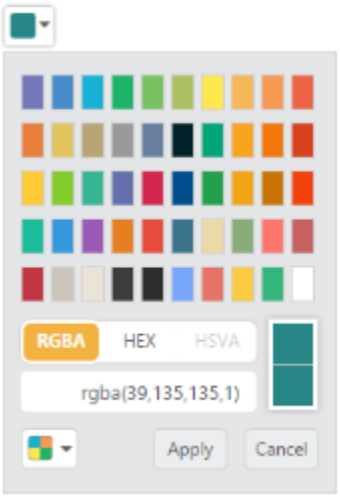
FlatColors	PresetType(PresetsType.FlatColors)	
SeaWolf	PresetType(PresetsType.SeaWolf)	
WebColors	PresetType(PresetsType.WebColors)	
Sandy	PresetType(PresetsType.Sandy)	
PinkShades	PresetType(PresetsType.PinkShades)	
Misty	PresetType(PresetsType.Misty)	
Citrus	PresetType(PresetsType.Citrus)	
Vintage	PresetType(PresetsType.Vintage)	
MoonLight	PresetType(PresetsType.MoonLight)	
CandyCrush	PresetType(PresetsType.CandyCrush)	

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787").ModelType(ModelType.Palette).PresetType(PresetsType.FlatColors)
```

The following screenshot displays the output of the above code example.



ColorPicker with Presets

CustomPalette

The ColorPicker control allows you to define the custom colors in the palette model by using Palette property. Custom palettes are created by passing a comma delimited string of HEX values or an array of colors in Custom property. The CustomPalette model is only applicable when you set ModelType as Palette.

Copyright © 2001 - 2020 Syncfusion Inc.

The CustomPalette property is a dependent property of Palette and ModelType property.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@{List<String> colors = new List<string>() { "ffffff", "ffccff", "ff99ff",
"ff66ff", "ff33ff", "ff00ff", "ccffff", "ccccff","cc99ff", "cc66ff",
"cc33ff", "cc00ff", "99ffff", "99ccff", "9999ff", "9966ff","9933ff",
"9900ff", "ffffcc", "ffcccc" };}
@Html.EJ().ColorPicker("colorPicker").Value("#278787").ModelType(ModelType.P
alette).Palette(PaletteType.CustomPalette).Custom(colors)
```

The following screenshot displays the output of the above code example.

ColorPicker with Customized Colors

DisplayInline

The ColorPicker control allows you to embed the popup in the order of DOM element flow by using the DisplayInline property. Using DisplayInline property to make ColorPicker popup always in visible state. Also associate ColorPicker with element instead of input.

The DisplayInline property is Boolean type and its default value is false.

The following steps explain you how to get the ColorPicker popup in DisplayInline state.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787").DisplayInline(true).T
agName("div")
```

The following screenshot displays the output of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.

ColorPicker in Display Inline

Theme Support

The ColorPicker control supports rich appearance. It supports 12 different themes of Essential ASP.NET MVC and bootstrap themes. To use these twelve themes, refer the themes files in HTML page.

You require two style sheets to apply styles to ColorPicker control; one ej.widgets.core.min.css and one ej.theme.min.css. When you use ej.widgets.all.min.css then, it is not necessary to use ej.widgets.core.min.css and ej.theme.min.css because ej.widgets.all.min.css is a combination of these two.

The core style sheet applies styles related to positioning and size, but are not related to the color scheme and always require the control to look correct and function properly. The theme style sheet applies theme-specific styles like colors and backgrounds.

The following list is the twelve themes supported by ColorPicker:

- default-theme
- flat-azure-dark
- flat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

1. In the CSHTML page, configure the ColorPicker widget with built in theme support.

HTML

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
<!doctype html>
<html>
<head>
<title>Essential Studio for JavaScript : ColorPicker - Built-in
ThemeSupport</title>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<meta name="viewport" content="width=device-width, initial-scale=1.0"
charset="utf-8"  />
<link href="http://cdn.syncfusion.com/js/web/flat-saffron-dark/ej.web.all-
latest.min.css" rel="stylesheet" />
<script src="http://code.jquery.com/jquery-1.10.2.min.js"></script>
<script src="http://cdn.syncfusion.com/js/web/ej.web.all-
latest.min.js"></script>
</head>
<body>
<div id="control">
@Html.EJ().ColorPicker("colorPicker").Value("#278787")
</div>
</body>
</html>
```

Note: jQuery.easing external dependency has been removed from version 14.3.0.49 onwards. Kindly include this jQuery.easing dependency for versions lesser than 14.3.0.49 in order to support animation effects.

The following screenshot displays the output of the above code example.

ColorPicker with Theme Support

CustomCss

The ColorPicker control also allows you to customize its appearance using user-defined CSS and custom skin options such as colors and backgrounds. To apply custom themes use the CssClass property. CssClass property sets the root class for ColorPicker theme.

Using this property you can override the existing styles under the theme style sheet. The theme style sheet applies theme-specific styles like colors and backgrounds. In the following example, the value of CssClass property is set as Light-Blue. Light-Blue is added as root class to ColorPicker control at the runtime. From this root class you can customize the ColorPicker control theme.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().ColorPicker("colorPicker").Value("#278787").CssClass("Light-
Blue")
```

2. Custom CSS Styles.

CSS

```
<style>
.Light-Blue.e-colorwidget.e-widget, .Light-Blue.e-colorpicker.e-
popup,.Light-Blue.e-colorwidget .e-in-wrap.e-box .e-select, .Light-Blue.e-
colorwidget .e-in-wrap.e-box, .Light-Blue.e-colorwidget .e-down-arrow
{
background: none repeat scroll 0 0 lightblue;
}
.Light-Blue.e-colorpicker .e-footer .e-cancelButton.e-btn, .Light-Blue.e-
colorpicker .e-footer .e-applyButton.e-btn
{
background: none repeat scroll 0 0 white;
}
</style>
```

The following screenshot displays the output of above steps.

ColorPicker with Custom Theme

KnockoutJS Binding

KnockoutJS support allows you to bind the HTML elements against any of the available data models.

Two types of KnockoutJS binding is supported,

- One-way binding
- Two-way binding

One-way binding refers to the process of applying observable values to all the available properties of the ColorPicker widget. The changes made in ColorPicker widget are not reflected and triggered in turn to the observable collection. This kind of binding is applied to all the properties of the ColorPicker widget.

Copyright © 2001 - 2020 Syncfusion Inc.

Two-way binding supports both the processes. It applies the observable values to the ColorPicker widget properties and also the changes made in the ColorPicker widget are reflected back and triggered within the observable collections.

For more information about KnockoutJS binding, you can refer to the online documentation in the following link location,

http://help.syncfusion.com/aspnetmvc/colorpicker/knockout-binding

1. The following example depicts how you can bind data to the ColorPicker widget through KnockoutJS support that enables and populates data to a ColorPicker widget based on the value set to the other ColorPicker widget.

ASPX-CS

```
@*Add the following script in view page for KnockoutJS support*@
<script src="http://cdn.syncfusion.com/js/assets/external/knockout.min.js">
</script>
<script
src="http://cdn.syncfusion.com/13.1.0.21/js/web/ej.unobtrusive.min.js">
</script>
<script src="http://cdn.syncfusion.com/13.1.0.21/js/ej.widget.ko.min.js">
</script>
<div class="content-container-fluid">
<div class="row" style="width: 100%">
<div class="cols-sample-area" style="width: 100%">
<div class="frame" style="width: 420px">
<div id="control" style="float: left; width: 70%; margin-left: 10px">
<input id="colorpick" data-bind="ejColorPicker: { value: value, modelType:
palette }" />
<h6><span style="font-style: italic; font-weight: normal; position:
absolute; margin-top: 5px;">Note:Two Way Knockout Support</span></h6>
</div>
<div id="binding" style="float: left; width: 23%">
<input id="colorpick1" data-bind="ejColorPicker: { value: value, modelType:
picker }" />
</div>
</div>
</div>
</div>
</div>
```

ASPX-CS

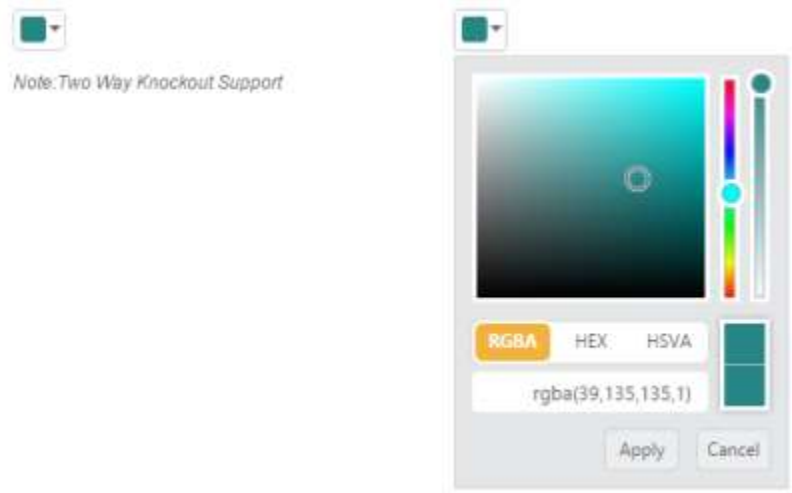
```
<script>
window.viewModel = {
value: ko.observable("#278787"),
palette: ko.observable("palette"),
picker: ko.observable("picker")
};
$(function () {
ko.applyBindings(viewModel);
});
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

CSS

```
<style>
.element {
display: inline-block;
}
.frame {
width: 600px;
border: 0px;
}
#control {
width: 600px;
}
</style>
```

The following screenshot displays the output of the above code example.



ColorPicker with KnockoutJS Support

AngularJS Binding

The ColorPicker widget is availed with two types of AngularJS support namely,

- One-way binding
- Two-way binding

One-way binding refers to the process of applying scope values to all the available properties of the ColorPicker widget. The changes made in ColorPicker widget are not reflected or triggered in turn to the scope collection. This kind of binding is applied to all the properties of the ColorPicker widget.

Two-way binding supports both the processes. It applies the scope values to the ColorPicker properties, as well as the changes made in the ColorPicker widget are reflected back and triggered within the AngularJS scope change function.

Apply the plugin and property assigning to the ColorPicker widget element through the directive that starts with “e-“.

To know more about the AngularJS binding, you can refer to the online documentation in the following link location,

Copyright © 2001 - 2020 Syncfusion Inc.

http://help.syncfusion.com/js/angularjs

1. The following code example depicts the way to bind data to the ColorPicker widget through AngularJS support.

ASPX-CS

```
@*Add the following scripts in your view page for AngularJS support*@
<script
src="http://cdn.syncfusion.com/js/assets/external/angular.min.js"></script>
<script
src="http://cdn.syncfusion.com/13.1.0.21/js/web/ej.unobtrusive.min.js">
</script>
<script
src="http://cdn.syncfusion.com/13.1.0.21/js/ej.widget.angular.min.js">
</script>
<div class="content-container-fluid" ng-app="PickerCtrl">
<div class="row" style="width: 100%" ng-controller="ColorPickerCtrl">
<div class="cols-sample-area" style="width: 100%">
<div class="frame">
<div id="control">
<div class="element" style="margin-left: 45px;">
<input id="picker" ej-colorpicker e-value="colorValue" e-modeltype="palette"
/>
</div>
<div class="element" style="margin-left: 234px">
<input id="custom" ej-colorpicker e-value="colorValue" e-modeltype="picker"
/>
</div>
<h6><span style="font-style: italic; font-weight: normal; position:
absolute; margin-top: 5px; margin-left: 45px;">Note:Two Way AngularJS
Support</span></h6>
</div>
</div>
</div>
<script>
angular.module('PickerCtrl', ['ejangular'])
.controller('ColorPickerCtrl', function ($scope) {
$scope.colorValue = "#278787";
});
</script>
</div>
</div>
```

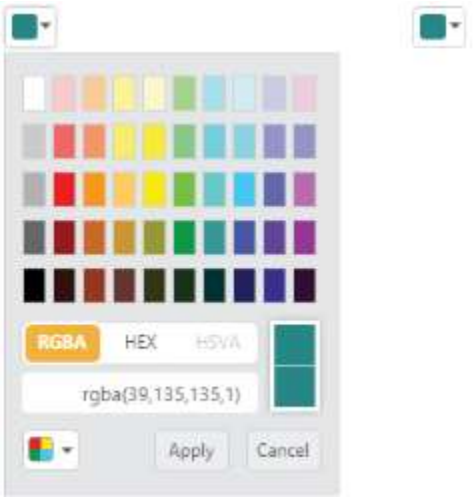
CSS

```
<style>
.element {
display: inline-block;
}
.frame {
width: 457px;
border: 0px;
}
#control {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
width: 600px;
}
</style>
```

The following screenshot displays the output of the above code example.



ColorPicker with AngularJS Support

Keyboard Interaction

You can use keyboard shortcut keys as an alternative to the mouse while using the ColorPicker widget. The ColorPicker widget allows you to perform all kinds of actions using keyboard shortcuts.

Keyboard shortcut keys

Shortcut Key	Description
Alt + j	Focuses into the ColorPicker control
Alt + Down	Open / Close the Popup
Up	Increase the brightness value
Down	Decrease the brightness value
Right	Increase the saturation value
Left	Decrease the saturation value
Enter	Choose the current color
Esc	Closes the popup
Tab	Choose the next element
Home	Downwards to value 0
End	Upwards to value 100

Copyright © 2001 - 2020 Syncfusion Inc.

Configure Keyboard Interaction

The following steps explain how you can enable keyboard interaction for ColorPicker textbox.

1. In the CSHTML page, configure the ColorPicker widget and enable keyboard interaction by the access key property.

ASPX-CS

```
@*In the CSHTML page, add the HTMl helpers to render ColorPicker widget and
enable keyboard interaction by the access key property*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787")
```

JS

```
<script>
jQuery(function ($) {
$(document).on("keydown", function (e) {
if (e.altKey && e.keyCode === 74) { // j- key code.
$("#colorPickerWrapper").focus();
}
});
});
</script>
```

The following screenshot displays the output of the above code example.

ColorPicker with Keyboard Navigation

Miscellaneous

getValue

The getValue() method in ColorPicker returns the hexadecimal value.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787")
```

JS

```
<script>
var ColorObj;
jQuery(function ($) {
ColorObj = $("#colorPicker").ejColorPicker({ value: "#278787"
}).data('ejColorPicker');
ColorObj.getValue();
});
</script>
```

setValue

The setValue() method in ColorPicker is used to set the color value. The given value is in hexadecimal form.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker")
```

JS

```
<script>
var ColorObj;
jQuery(function ($) {
ColorObj = $("#colorPicker").ejColorPicker().data('ejColorPicker');
ColorObj.setValue("#278787");
});
</script>
```

getColor

The getColor() method in ColorPicker control returns the color value in r,g,b,a form.

1. In the CSHTML page, configure the ColorPicker widget as follows.

ASPX-CS

```
@*In the CSHTML page, add the HTML helpers to render ColorPicker widget*@
@Html.EJ().ColorPicker("colorPicker").Value("#278787")
```

JS

```
<script>
var ColorObj;
jQuery(function ($) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
ColorObj = $("#colorPicker").ejColorPicker({value: "#278787"
}).data('ejColorPicker');
ColorObj.getColor();
});
</script>
```

How to?

Render ColorPicker from Code behind

ColorPicker can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of ColorPicker properties in the controller.

C#

```
//Namespace to get the JavaScript (ColorPicker) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class ColorPickerController : Controller
{
// GET: ColorPicker
public ActionResult ColorPickerFeatures()
{
//Initializing the ColorPicker model
ColorPickerProperties ColorObj = new ColorPickerProperties();
//Initializing the datasource and other properties
ColorObj.ShowPreview= true;
ColorObj.Value = "#278787";
//Passing ColorPicker properties using the ViewData
ViewData["ColorModel"] = ColorObj;
return View();
}
}
}
```

Binding the ColorPicker properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().ColorPicker("searchCustomer",(Syncfusion.JavaScript.Models.ColorPi
ckerProperties)ViewData["ColorModel"]).Render();
}
```

ComboBox

Overview

The ComboBox component allows the user to type a value or choose an option from the list of predefined options.

When an arrow icon accompanied with this component is pressed, the dropdown displays a list of values, from which the user can select one.

Copyright © 2001 - 2020 Syncfusion Inc.

Key features

- **Data binding - Allows binding and accessing the list of items from local or server-side data source.**
- **[Custom values](https://help.syncfusion.com/aspnetmvc/combobox/getting-started#custom values)** - Allows setting user-defined values that is not in the popup list.
- **Grouping - Supports grouping of logically related items under a single or specific category.**
- **Sorting - Supports sorting of list items in an alphabetical order (either ascending or descending).**
- **Filtering - Allows filtering of list items based on a character typed in the component.**
- **Templates - Allows customizing the list items, selected value, header, footer, category group header, and no records content.**
- **Accessibility - Provided with built-in accessibility support that helps to access all the ComboBox component features through the keyboard, screen readers, or other assistive technology devices.**

Getting Started

This section explains how to create a simple **ComboBox** component and configure its available functionalities.

1.Create an MVC Project and add necessary assemblies, scripts, and CSS files given in MVC-Getting Started Documentation. 2.Add ComboBox control using the helper from EJ namespace.

Initialize the ComboBox

The ComboBox can be initialized as:

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("select")
.Width("100%")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.ComboBoxFields(f=>f.Text("text"))
.Placeholder("Select")
.Render();
}
</div>
</div>
```

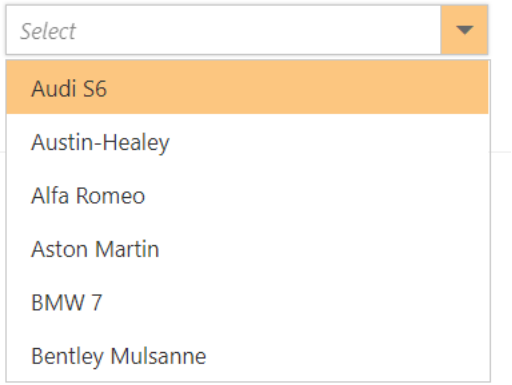
C#

```
public class CarsList
{
public string text { get; set; }
public static List<CarsList> GetCarsList()
{
List<CarsList> car = new List<CarsList>();
car.Add(new CarsList { text = "Audi S6" });
car.Add(new CarsList { text = "Austin-Healey" });
car.Add(new CarsList { text = "Alfa Romeo" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
car.Add(new CarsList { text = "Aston Martin" });
car.Add(new CarsList { text = "BMW 7" });
car.Add(new CarsList { text = "Bentley Mulsanne" });
return car;
}
public ActionResult Default()
{
ViewBag.datasource = GetCarsList();
return View();
}
}
```

Output for ComboBox control is as follows.



Binding data source

After initializing, populate the ComboBox with data using the **DataSource** property. Here, an array of string values is passed to the ComboBox component.

HTML

```
<div class="frame">
<div class="control">
@{
string[] datasource = new string[] { "Badminton", "Cricket", "Football",
"Golf", "Tennis" };
Html.EJ()
.ComboBox("select")
.Width("100%")
.Datasource(datasource)
.Placeholder("Select a game")
.Render();
}
</div>
</div>
```

Output for ComboBox control is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Custom values

The ComboBox allows the user to give input as custom value which is not required to be present in the predefined set of values. By default, this support is enabled by the **AllowCustom** property. In this case, both text field and value field are considered as same. The custom value will be sent to post back handler when a form is about to be submitted.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("select")
.Width("100%")
.Datasource((IEnumerable<Flowers>)ViewBag.datasource)
.AllowCustom(true)
.ComboBoxFields(f=>f.Text("text").Value("text"))
.Placeholder("Select")
.Render();
}
</div>
</div>
```

C#

```
public class CarsList
{
public string text { get; set; }
public static List<CarsList> GetCarsList()
{
List<CarsList> car = new List<CarsList>();
car.Add(new CarsList { text = "Audi S6" });
car.Add(new CarsList { text = "Austin-Healey" });
car.Add(new CarsList { text = "Alfa Romeo" });
car.Add(new CarsList { text = "Aston Martin" });
car.Add(new CarsList { text = "BMW 7" });
car.Add(new CarsList { text = "Bentley Mulsanne" });
return car;
}
public ActionResult Default()
{
ViewBag.datasource = GetCarsList();
return View();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
}
```

Output for allowCustom ComboBox control is as follows.

Configure the popup list

By default, the width of the popup list automatically adjusts according to the ComboBox input element's width, and the height of the popup list is '300px'.

The height and width of the popup list can also be customized by using the **popupHeight** and **popupWidth** properties respectively.

In the following sample, popup list's width and height are configured.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("select")
.Width("100%")
.Datasource((IEnumerable<CarsList>)ViewBag.datasource)
.PopupHeight("200px")
.PopupWidth("200px")
.Placeholder("Select")
.Render();
}
</div>
</div>
```

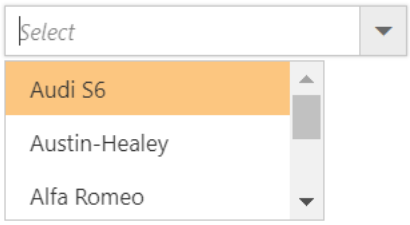
C#

```
public class CarsList
{
public string text { get; set; }
public static List<CarsList> GetCarsList()
{
List<CarsList> car = new List<CarsList>();
car.Add(new CarsList { text = "Audi S6" });
car.Add(new CarsList { text = "Austin-Healey" });
car.Add(new CarsList { text = "Alfa Romeo" });
car.Add(new CarsList { text = "Aston Martin" });
car.Add(new CarsList { text = "BMW 7" });
car.Add(new CarsList { text = "Bentley Mulsanne" });
return car;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
public ActionResult Default()
{
ViewBag.datasource = GetCarsList();
return View();
}
}
```

Output for ComboBox control is as follows.



ComboBox Dependencies

The external script dependencies of the ComboBox control are as follows:

- jQuery 1.7.1 and later versions.

The internal script dependency ej.web.all.js is a bundle of all Syncfusion ASP.NET MVC controls. If you use ej.web.all.js in your application, you can leave this section, or else try to render ComboBox in your application using the ej.combobox.min.js file. Refer to the following frameworks and controls in your project.

FileÂ	Description / Usage
ej.core.min.js	Must be referred always before using all the JS controls.
ej.data.min.js	Used to handle data operation and should be used while binding data to JS controls.
ej.ComboBox.min.js	The ComboBoxâ€™s main file
ej.globalize.min.js	Should be referred when localization used in ComboBox.

Data Binding

The ComboBox loads the data either from local data sources or remote data services using the `DataSource` property. It supports the data type of `array` or **DataManager**.

The ComboBox also supports different kinds of data services such as OData, OData V4, and Web API, and data formats such as XML, JSON, and JSONP with the help of `DataManager` adaptors.

| Fields | Type | Description |

|------|------|-------------|

| text | `string` | Specifies the display text of each list item. |

| value | string | Specifies the hidden data value mapped to each list item that should contain a unique value. |

| groupBy | string | Specifies the category under which the list item has to be grouped. |

| iconCss | string | Specifies the icon class of each list item. |

When binding complex data to the ComboBox, the fields should be mapped correctly. Otherwise, the selected item remains undefined.

Binding local data

Local data can be represented in two ways as described below.

1. Array of simple data

The ComboBox has support to load array of primitive data such as strings and numbers. Here, both value and text field act the same.

HTML

```
<div class="frame">
<div class="control">
@{
string[] datasource = new string[] { "Badminton", "Cricket", "Football",
"Golf", "Tennis" };
Html.EJ()
.ComboBox("ComboBox")
.Width("100%")
.Datasource(datasource)
.Placeholder("Select a game")
.Render();
}
</div>
</div>
```

Output for array-data ComboBox control is as follows.

2. Array of JSON data

The ComboBox can generate its list items through an array of complex data. For this, the appropriate columns should be mapped to the **ComboBoxFields** property.

In the following example, id column and text column from complex data have been mapped to the value field and text field, respectively.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("ComboBoxId")
.Width("100%")
.Datasource((IEnumerable<Flowers>)ViewBag.datasource)
.AllowCustom(true)
.ComboBoxFields(f=>f.Text("text").Value("id"))
.Placeholder("Select a flower")
.Render();
}
</div>
</div>
```

C#

```
public class Flowers
{
public string text { get; set; }
public int id { get; set; }
public static List<Flowers> GetFlowers()
{
List<Flowers> flower = new List<Flowers>();
flower.Add(new Flowers { text = "Anemone Galilee", id=0 });
flower.Add(new Flowers { text = "Allium drumstick", id=1 });
flower.Add(new Flowers { text = "Artichoke thistle" id=2 });
flower.Add(new Flowers { text = "Boronia" id=3 });
flower.Add(new Flowers { text = "Bouvardia" id=4 });
flower.Add(new Flowers { text = "Blue lace flower" id=5 });
flower.Add(new Flowers { text = "Bird of paradise" id=6 });
flower.Add(new Flowers { text = "Cone flower" id=7 });
flower.Add(new Flowers { text = "Cosmos" id=8 });
flower.Add(new Flowers { text = "Calla lily white" id=9 });
flower.Add(new Flowers { text = "Common Yarrow" id=10 });
return flower;
}
public ActionResult Default()
{
ViewBag.datasource = GetFlowers();
return View();
}
}
```

Output for remote-data ComboBox control is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Binding remote data

The ComboBox supports retrieval of data from remote data services with the help of **DataManager** component. The **Query** property is used to fetch data from the database and bind it to the ComboBox.

In the following sample, displayed first 6 contacts from the customer table of Northwind Data Service.

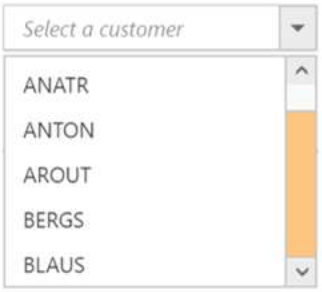
HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("searchCustomer")
.Datasource(d =>
d.URL("//js.syncfusion.com/ejServices/wcf/NorthWind.svc/").Offline(false).Cr
ossDomain(true))
.Query("ej.Query().from('Suppliers').select('SupplierID', 'ContactName')")
.ComboBoxFields(f => f.Text("ContactName").Value("SupplierID"))
.Width("100%")
.Placeholder("Search a customer")
.Render();
}
</div>
</div>
```

C#

```
public ActionResult Databindingremote()
{
return View();
}
```

Output for remote-data ComboBox control is as follows.



SQL Data Binding

Fetch the Data from SQL data source and initialize the control with DataSource property. Specify the column names in the Fields property.

HTML

```
@Html.EJ()ComboBox("selectEmployee").Datasource((IEnumerable<Object>)ViewBag
.Data)ComboBoxFields(df =>
df.ID("Id").Text("Name").Value("Designation")).Width("150px")
```

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
public ActionResult DropdownlistFeatures()
{
List<Employee> data = new List<Employee>();
SqlConnection con = new SqlConnection(@"Data
Source=(LocalDB)\MSSQLLocalDB;AttachDbFilename=|DataDirectory|\SampleDB.mdf;
Integrated Security=True");
using (con)
{
con.Open();
SqlDataReader myReader = null;
SqlCommand myCommand = new SqlCommand("select * From [Table]",
con);
myReader = myCommand.ExecuteReader();
if (myReader.Read())
{
data.Add(new Employee(myReader["Name"].ToString(),
myReader["Designation"].ToString()));
}
con.Close();
ViewBag.Data = data;
}
return View();
}
public class Employee
{
public string Name { get; set; }
public string Designation { get; set; }
public Employee(string name, string deg)
{
this.Name = name;
this.Designation = deg;
}
}
```

LINQ Data Binding

Language-Integrated Query (LINQ) is not only about retrieving data. It is also a powerful tool for transforming data. By using a LINQ query, you can use a source sequence as input, and modify it in many ways to create a new output sequence.

Defines model class

C#

```
public class Employee
{
public string name { set; get; }
public string employeeID { set; get; }
public string designation { set; get; }
public Employee() { }
public Employee(string name, string id, string designation)
{
name = name;
employeeID = id;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
designation = designation;
}
}
```

In code behind, fetch the data from Employee class and assigned to the ComboBox are as follows:

C#

```
public ActionResult ComboBoxFeatures()
{
List<Employee> data = new List<Employee>() { };
data.Add(new Employee("Nancy", "E11011", "Technical Writer"));
data.Add(new Employee("Angel", "E11012", "Professor"));
data.Add(new Employee("Daniah", "E11013", "Dancer"));
data.Add(new Employee("Jenifer", "E11014", "Beautician"));
data.Add(new Employee("Prince", "E11015", "Developer"));
var db = from result in data
select result;
ViewBag.dataSource = db.ToList();
return View();
}
```

HTML

```
@Html.EJ().ComboBox("select").Datasource((IEnumerable<Employee>)ViewBag.data
source)ComboBoxFields(df =>
df.ID("employeeID").Text("name").Value("designation")).Placeholder("Select a
Student").Width("100%")
```

XmlDataSource

The XmlDataSource is used to work with XML documents. The following steps explain the details about the data binding from XmlDataSource.

Step 1: Create an XML Data source as follows:

XML

```
<?xml version="1.0" encoding="utf-8" ?>
<Students>
<Student>
<Name>Abhishek</Name>
<Location>Dhanbad</Location>
</Student>
<Student>
<Name>Aman</Name>
<Location>Samastipur</Location>
</Student>
<Student>
<Name>Vicky</Name>
<Location>Munger</Location>
</Student>
<Student>
<Name>Chandan</Name>
<Location>Bhagalpur</Location>
</Student>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<Student>
<Name>Ravi</Name>
<Location>Dhanbad</Location>
</Student>
</Students>
```

Step 2: Read data from the XML file.

C#

```
using System.Xml;
using DataBinding.Models;
public ActionResult ComboBoxFeatures()
{
List<Product> data = new List<Product>();
using (XmlReader reader =
XmlReader.Create("D:/Sample/MVC/DataBinding/DataBinding/App_Data/XMLData.xml
"))
{
while (reader.Read())
{
if (reader.IsStartElement())
{
switch (reader.Name.ToString())
{
case "Name":
data.Add(new Product { name = reader.ReadString() });
break;
}
}
}
}
ViewBag.data = data;
return View();
}
```

Step 3: Assign the data to the ComboBox's DataSource property. Specify the column names in the ComboBoxFields property.

RAZOR

```
@using DataBinding.Models
@Html.EJ().ComboBox("selectCar").Datasource((IEnumerable<Product>)ViewBag.da
ta).ComboBoxFields(df => df.Text("name").Value("name")).Placeholder("Select
a Student").Width("100%")
```

EntityDataSource

Bind data to the ComboBox through Entity Framework. Please follow the below steps.

1. Create an entity data model

Please refer to the link for more information.

2. Refer the entity data model to your project and bind the data to the ComboBox.

Copyright © 2001 - 2020 Syncfusion Inc.

In code behind, create an object for the Entity mode (NORTHWNDEntities), and fetch the data from the Employees class and store it in the List.

Assign the data to the ComboBox's DataSource property. Specify the column names in the fields property.

C#

```
public ActionResult ComboBoxFeatures()
{
NORTHWNDEntities sample = new NORTHWNDEntities();
var dataset = sample.Employees
.Select(x => new Employee
{
EmployeeID = x.EmployeeID,
FirstName = x.FirstName
}).ToList();
ViewBag.DataSource = dataset;
}
public class Employee
{
public int EmployeeID { get; set; }
public string FirstName { get; set; }
}
```

RAZOR

```
@Html.EJ().ComboBox("selectEmployee").Datasource((IEnumerable<Object>)ViewBa
g. DataSource).ComboBoxFields(df => df.Text("FirstName ").Value("EmployeeID
")).Width("150px")
```

AccessDataSource

The data can also be bound to the ComboBox using OLEDB database as depicted below.

RAZOR

```
Html.EJ().ComboBox("selectEmployee").Datasource((IEnumerable<Object>)ViewBag
. DataSource).ComboBoxFields(df =>
df.ID("Id").Text("Name").Value("Designation")).Width("150px")
```

The server-side code to retrieve and bind the data to ComboBox are as follows. Also, define a class with all the required fields as depicted in the below code example.

C#

```
public ActionResult ComboBoxFeatures()
{
OleDbConnection conn = new
OleDbConnection(@"Provider=Microsoft.Jet.OLEDB.4.0;Data
Source=|DataDirectory|\Database.mdb");
conn.Open();
OleDbCommand cmd = new OleDbCommand(" SELECT * from [Employees]", conn);
OleDbDataReader reader = null;
List<EmployeeDetails> data = new List<EmployeeDetails>();
reader = cmd.ExecuteReader();
while (reader.Read())
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
data.Add(new EmployeeDetails(reader["Name"].ToString(),
reader["Designation"].ToString()));
}
conn.Close();
ViewBag. DataSource = data;
}
public class EmployeeDetails
{
public string Name { get; set; }
public string Designation { get; set; }
public EmployeeDetails(string name, string deg)
{
this.Name = name;
this.Designation = deg;
}
}
```

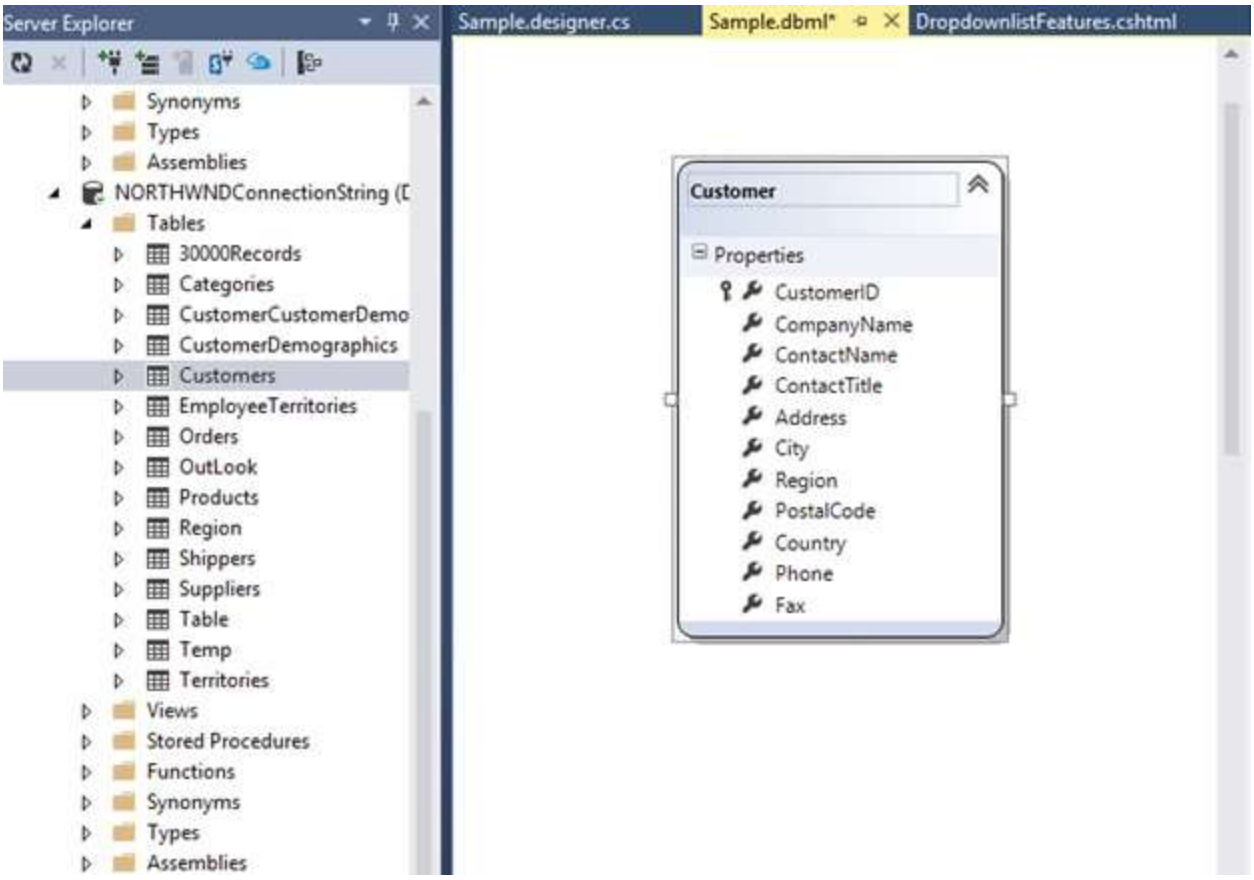
LINQ to SQL Data Binding

The LINQ to SQL can be used as the data source of the ComboBox in that the data model of a relational database is mapped to an object model and allow us to use the LINQ technology to access SQL database.

To create LINQ to SQL classes

- Right-click the App_Code folder and then click Add New Item.
- Under Installed templates, select LINQ to SQL Classes template, type a name for the .dbml file, and then click Add.
- The Object Relational Designer window is displayed.
- In Server Explorer, drag the database table into the Object Relational Designer window.
- The table and its columns are represented as an entity in the designer window.

Copyright © 2001 - 2020 Syncfusion Inc.



In code behind, fetch the data from classes and stored it to the ViewBag as follows

C#

```
ViewBag.dataSource = new SampleDataContext().Customers.ToList();
```

HTML

```
@Html.EJ().ComboBox("customers").Datasource((IEnumerable<Customer>)ViewBag.d
ataSource).ComboBoxFields(df =>
df.Text("CompanyName").Value("CustomerID")).Placeholder("Select a
Customer").Width("100%")
```

Copyright © 2001 - 2020 Syncfusion Inc.

Remote data

To bind remote data to the ComboBox, you can assign a service data as an instance of DataManager to the Datasource property.

OData

OData is a standardized protocol for creating and consuming data. You can provide the OData service URL directly to the Datasource URL property.

HTML

```
@Html.EJ().ComboBox("ComboBoxOData").Datasource(dataSource =>
dataSource.URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders")).Co
mboBoxFields(df=>df.Text("ShipCountry").Value("OrderID"))
```

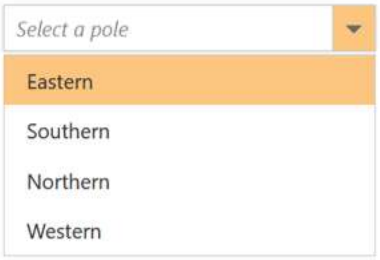
OData Version 4

For OData Version 4 support ODataV4Adaptor should be used. By using URL property of Datasource, you can bind OData Version 4 Service link and specify Adaptor value as enum AdaptorType.ODataV4Adaptor.

For further details about OData service refer to the link.

HTML

```
@Html.EJ().ComboBox("ComboBox1").Datasource(dataSource
=>dataSource.URL("http://services.odata.org/V4/Northwind/Northwind.svc/Regio
ns/").Adaptor(AdaptorType.ODataV4Adaptor)).ComboBoxFields(df =>
df.Text("RegionDescription").Value("RegionID"))
```



Note: Events associated with remote data bind is listed here.

WebAPI

Using WebApiAdaptor, you can bind WebApi service's data to ComboBox. The data from WebApi service must be returned as an object that has the property "Items" with its value as data source and another property "Count" with its value as dataSource's total records count.

HTML

```
@Html.EJ().ComboBox("ComboBox1").Datasource(dataSource =>
dataSource.URL("/api/Orders").Adaptor(AdaptorType.WebApiAdaptor)).ComboBoxFi
elds(df => df.Text("Name").Value("EmployeeID"))
```

C#

Copyright © 2001 - 2020 Syncfusion Inc.

```
public class OrdersController : ApiController
{
NorthwindDataContext db = new NorthwindDataContext();
// GET API/<controller>
public PageResult<EmployeePhoto> Get(ODataQueryOptions opts)
{
List<EmployeePhoto> photos = db.EmployeePhotos.ToList();
return new PageResult<EmployeePhoto>(photos as IEnumerable<EmployeePhoto>,
null, photos.Count);
}
}
```

Templates

The ComboBox has been provided with several options to customize each list item, group title, selected value, header, and footer elements.

Item template

The content of each list item within the ComboBox can be customized with the help of **ItemTemplate** property.

In the following sample, each list item is split into two columns to display the relevant data.

HTML

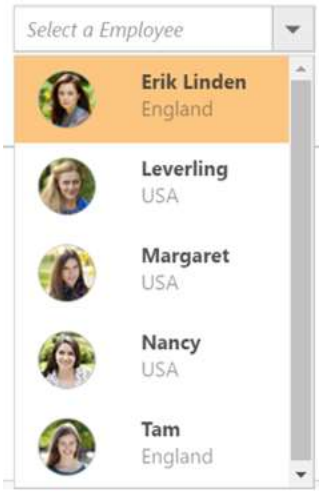
```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("selectCountry")
.Width("100%")
.Datasource((IEnumerable<empList>)ViewBag.datasource)
.ComboBoxFields(h=>h.Text("text"))
.HeaderTemplate("<div class=\"head\">  Photo  <span style=\"padding-
left:42px\"> Contact Info </span></div>")
.ItemTemplate("<div><img class=\"eimg\"
src=\"../Images/combobox/${eimg}.png\" alt=\"employee\"/><div
class=\"ename\"> ${text} </div><div class=\"temp\"> ${country}
</div></div>")
.FooterTemplate("<div class=\"Foot\"> Total Items Count: 5 </div>")
.Placeholder("Select a employee")
.Render();
}
</div>
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

CSS

```
<style>
.ename {
font-weight: bold;
display: block !important;
opacity: .87;
}
.tempName {
padding: 5px 42px;
opacity: .87;
}
.temp {
margin-top: -15px;
opacity: .54;
}
.eimg {
border-radius: 50%;
padding: 10px 16px;
width: 40px;
height: 40px;
float: left;
}
.tempImg {
padding-bottom: 3px;
border-radius: 50%;
float: left;
}
.e-dropdownbase .e-list-item * {
display: block;
}
</style>
```

Output for item template ComboBox control is as follows.



Copyright © 2001 - 2020 Syncfusion Inc.

Group template

The group header title with appropriate sub-items are categorized that is customized with the help of **GroupTemplate** property. This template is common for both inline and floating group header template.

In the following sample, employees are grouped according to their city.

{% highlight html %}

@{

Html.EJ()

.ComboBox("selectCountry")

.Width("100%")

.Datasource((IEnumerable<empList>)ViewBag.datasource)

.ComboBoxFields(h=>h.Text("text").GroupBy("country"))

.ItemTemplate(" <div class=\"ename\"> ${text} <div class=\"temp\"> ${country} ")

.GroupTemplate("${country}")

.Placeholder("Select a country")

.Render();

}

{% endhighlight %}

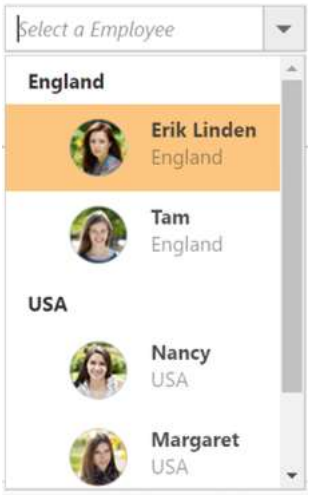
CSS

```
<style>
.ename {
font-weight: bold;
display: block !important;
opacity: .87;
}
.tempName {
padding: 5px 42px;
opacity: .87;
}
.temp {
margin-top: -15px;
opacity: .54;
}
.eimg {
border-radius: 50%;
padding: 10px 16px;
width: 40px;
height: 40px;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
float: left;
}
.tempImg {
padding-bottom: 3px;
border-radius: 50%;
float: left;
}
.e-dropdownbase .e-list-item * {
display: block;
}
</style>
```

Output for group template ComboBox control is as follows.



Header template

The header element is shown statically at the top of the popup list items within the ComboBox, and any custom element can be placed as a header element using the **HeaderTemplate** property.

In the following sample, the list items and its headers are designed and displayed as two columns similar to multiple columns of the grid.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("selectCountry")
.Width("100%")
.Datasource((IEnumerable<empList>)ViewBag.datasource)
.ComboBoxFields(h=>h.Text("text"))
.ItemTemplate("<div><img class=\"eimg\"
src=\"../Images/combobox/${eimg}.png\" alt=\"employee\"/><div
class=\"ename\"> ${text} </div><div class=\"temp\"> ${country}
</div></div>")
.HeaderTemplate("<div class=\"head\">  Photo  <span style=\"padding-
left:42px\"> Contact Info </span></div>")
.FooterTemplate("<div class=\"Foot\"> Total Items Count: 5 </div>")
.Placeholder("Select a country")
```

Copyright © 2001 - 2020 Syncfusion Inc.

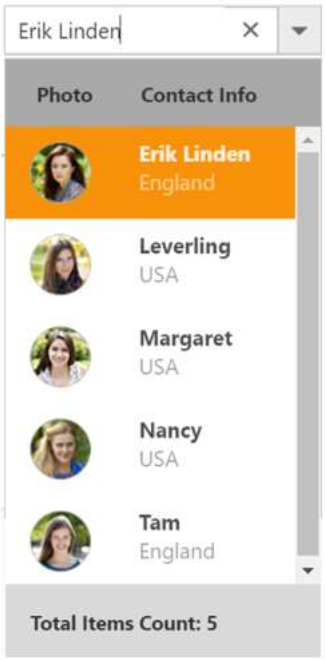
```
.Render();
}
</div>
</div>
```

CSS

```
<style>
.head {
background-color: #a9a9a9;
height: 30px;
font-weight: bold;
padding: 14px 0 0 20px;
}
.ename {
font-weight: bold;
display: block !important;
opacity: .87;
}
.tempName {
padding: 5px 42px;
opacity: .87;
}
.temp {
margin-top: -15px;
opacity: .54;
}
.eimg {
border-radius: 50%;
padding: 10px 16px;
width: 40px;
height: 40px;
float: left;
}
.tempImg {
padding-bottom: 3px;
border-radius: 50%;
float: left;
}
.e-dropdownbase .e-list-item * {
display: block;
}
</style>
```

Output for item template ComboBox control is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Footer template

The ComboBox has an option to show a footer element at the bottom of the list items in the popup list. Here, you can place any custom element as a footer element using the **FooterTemplate** property.

In the following sample, footer element displays the total number of list items present in the ComboBox.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("selectCountry")
.Width("100%")
.Datasource((IEnumerable<empList>)ViewBag.datasource)
.ComboBoxFields(h=>h.Text("text"))
.ItemTemplate("<div><img class=\"eimg\"
src=\"../Images/combobox/${eimg}.png\" alt=\"employee\"/><div
class=\"ename\"> ${text} </div><div class=\"temp\"> ${country}
</div></div>")
.FooterTemplate("<div class=\"Foot\"> Total Items Count: 5 </div>")
.Placeholder("Select a employee")
.Render();
}
</div>
</div>
```

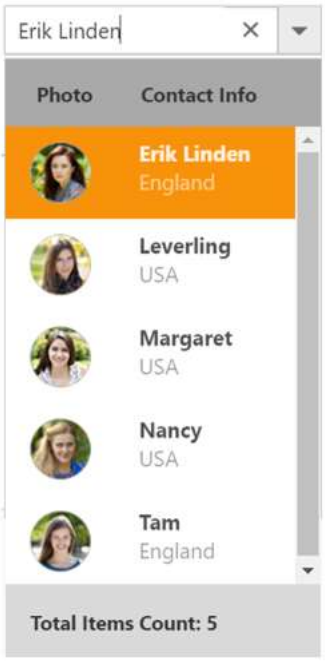
CSS

```
<style>
.Foot {
background-color: #dadada;
vertical-align: middle;
padding: 16px;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
font-weight: bold;
}
.ename {
font-weight: bold;
display: block !important;
opacity: .87;
}
.tempName {
padding: 5px 42px;
opacity: .87;
}
.temp {
margin-top: -15px;
opacity: .54;
}
.eimg {
border-radius: 50%;
padding: 10px 16px;
width: 40px;
height: 40px;
float: left;
}
.tempImg {
padding-bottom: 3px;
border-radius: 50%;
float: left;
}
.e-dropdownbase .e-list-item * {
display: block;
}
</style>
```

Output for footer template ComboBox control is as follows.



No records template

The ComboBox is provided with the support to custom design the popup list content when no data is found and no matches found on search with the help of **NoRecordsTemplate** property.

In the following sample, popup list content displays the notification of no data available.

{% highlight html %}

@{

Html.EJ()

.ComboBox("searchCustomer")

.Datasource(d => d.URL("//js.syncfusion.com/ej/ejServices/wcf/NorthWind.svc/").Offline(false).CrossDomain(true))

.Query("ej.Query().from('Suppliers').select('SupplierID', 'ContactName').take(0)")

.ComboBoxFields(f => f.Text("ContactName").Value("SupplierID"))

.Width("100%")

.NoRecordsTemplate(" NO DATA AVAILABLE")

.Placeholder("Search a customer")

.Render();

}

{% endhighlight %}

C#

```
public ActionResult Databinding()
{
return View();
}
```

Output for no records template ComboBox control is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Action failure template

There is also an option to custom design the popup list content when the data fetch request fails at the remote server. This can be achieved by using the **ActionFailureTemplate** property.

In the following sample, when the data fetch request fails, the ComboBox displays the notification.

{% highlight html %}

@{

Html.EJ()

.ComboBox("searchCustomer")

.Datasource(d => d.URL("//js.syncfusion.com/ej/ejServices/wcf/NorthWind.svc/").Offline(false).CrossDomain(true))

.Query("ej.Query().from('Suppliers').select('SupplierID', 'ContactName')")

.ComboBoxFields(f => f.Text("ContactName").Value("SupplierID"))

.Width("100%")

.ActionFailureTemplate("Data fetch get fails")

.Placeholder("Search a customer")

.Render();

}

{% endhighlight %}

C#

```
public ActionResult Databinding()
{
return View();
}
```

Grouping

The ComboBox supports the wrapping of nested elements into a group based on different categories. The category of each list item can be mapped through the **GroupBy** field in the data table. The group header is displayed both as inline and fixed headers. The fixed group header content is updated dynamically on scrolling the popup list with its category value.

In the following sample, vegetables are grouped according on its category using the GroupBy field.

HTML

```
<div class="frame">
<div class="control">
@{
```

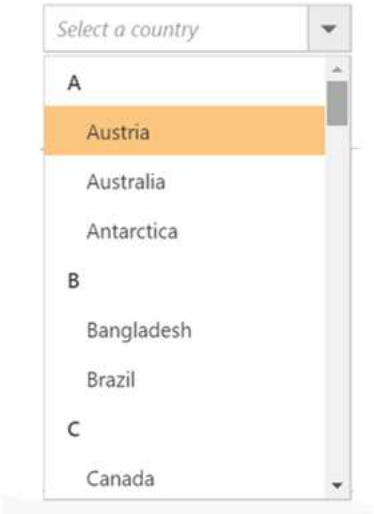
Copyright © 2001 - 2020 Syncfusion Inc.

```
Html.EJ()
.ComboBox("groupingCountry")
.Datasource((IEnumerable<Countries>)ViewBag.datasource)
.Width("100%")
.ComboBoxFields(fields => fields.GroupBy("category").Text("text"))
.Placeholder("Select a country")
.Render();
}
</div>
</div>
```

C#

```
public string text { get; set; }
public string category { get; set; }
public static List<Countries> GetCountries()
{
List<Countries> country = new List<Countries>();
country.Add(new Countries { text = "Austria", category = "A" });
country.Add(new Countries { text = "Australia", category = "A" });
country.Add(new Countries { text = "Antarctica", category = "A" });
country.Add(new Countries { text = "Bangladesh", category = "B" });
country.Add(new Countries { text = "Brazil", category = "B" });
country.Add(new Countries { text = "Canada", category = "C" });
country.Add(new Countries { text = "Cuba", category = "C" });
country.Add(new Countries { text = "Denmark", category = "D" });
country.Add(new Countries { text = "Dominica", category = "D" });
return country;
}
}
}
```

Output for grouping ComboBox control is as follows.



Copyright © 2001 - 2020 Syncfusion Inc.

Customization

The grouping header is also provided with the customization option. This allows custom designing using the groupTemplate property for both the inline and fixed headers as referred here:

Group Template support to ComboBox

Sorting

The ComboBox has built-in support to sort data items when SortOrder is specified. The available sort orders are ascending, descending and none.

To sort the data in ascending order, set the SortOrder as ascending.

The following sample illustrates how to sort the data.

HTML

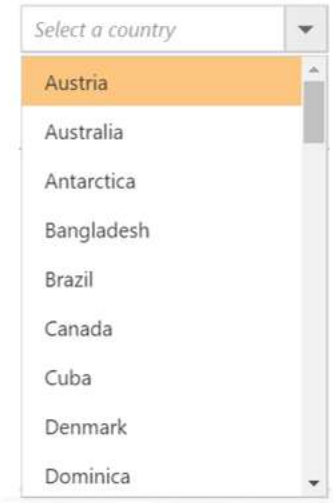
```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("Sorting")
.Datasource((IEnumerable<Countries>)ViewBag.datasource)
.Width("100%")
.ComboBoxFields(fields => fields.Text("text"))
.Placeholder("Select a country")
.SortOrder(SortOrder.Ascending)
.Render();
}
</div>
</div>
```

C#

```
public string text { get; set; }
public string category { get; set; }
public static List<Countries> GetCountries()
{
List<Countries> country = new List<Countries>();
country.Add(new Countries { text = "Austria", category = "A" });
country.Add(new Countries { text = "Australia", category = "A" });
country.Add(new Countries { text = "Antarctica", category = "A" });
country.Add(new Countries { text = "Bangladesh", category = "B" });
country.Add(new Countries { text = "Brazil", category = "B" });
country.Add(new Countries { text = "Canada", category = "C" });
country.Add(new Countries { text = "Cuba", category = "C" });
country.Add(new Countries { text = "Denmark", category = "D" });
country.Add(new Countries { text = "Dominica", category = "D" });
return country;
}
}
}
```

Output for Sorting is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Filtering

The ComboBox has built-in support to filter data items when AllowFiltering is enabled. The filter operation starts as soon as you start typing characters in the component.

To display filtered items in the popup, filter the required data and return it to the ComboBox via **updateData** method by using the **filtering** event.

The following sample illustrates how to query the data source, and pass the data to the ComboBox through the updateData method in Filtering event.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("selectCountry")
.AllowFiltering(true)
.ComboBoxFields(h => h.Text("text").Value("category"))
.Query("new ej.Query().select(['text','category']).take(25)")
.ClientSideEvents(h => h.Filtering("filtering"))
.Datasource((IEnumerable<Countries>)ViewBag.datasource)
.Placeholder("Select a country")
.Render();
}
</div>
</div>
<script type="text/javascript">
function filtering(e) {
var query = new ej.Query().select(['text','category']);
query = (e.text !== '') ? query.where('text', 'startswith', e.text, true) :
query;
e.updateData(e.model.dataSource, query);
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
public string text { get; set; }
public string category { get; set; }
public static List<Countries> GetCountries()
{
List<Countries> country = new List<Countries>();
country.Add(new Countries { text = "Austria", category = "A" });
country.Add(new Countries { text = "Australia", category = "A" });
country.Add(new Countries { text = "Antarctica", category = "A" });
country.Add(new Countries { text = "Bangladesh", category = "B" });
country.Add(new Countries { text = "Brazil", category = "B" });
country.Add(new Countries { text = "Canada", category = "C" });
country.Add(new Countries { text = "Cuba", category = "C" });
country.Add(new Countries { text = "Denmark", category = "D" });
country.Add(new Countries { text = "Dominica", category = "D" });
...
return country;
}
}
}
```

Output for filtering ComboBox control is as follows.

Limit the minimum filter character

When filtering the list items, you can set the limit for character count to raise remote request and fetch filtered data on the ComboBox. This can be done by manual validation within the filter event handler.

In the following example, the remote request does not fetch the search data until the search key contains three characters.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("selectCountry")
.AllowFiltering(true)
.ComboBoxFields(h => h.Text("text").Value("category"))
.Query("new ej.Query().select(['text','category']).take(25)")
.ClientSideEvents(h => h.Filtering("filtering"))
.Datasource((IEnumerable<Countries>)ViewBag.datasource)
.Placeholder("Select a country")
.Render();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</div>
</div>
<script type="text/javascript">
function filtering(e) {
if(e.text == '') e.updateData(e.model.dataSource);
else{
// restrict the remote request until search key contains 3 characters.
if (e.text.length < 3) { return; }
var query = new Query().select(['text', 'category']);
query = (e.text !== '') ? query.where('text', 'startswith', e.text, true) :
query;
e.updateData(e.model.dataSource, query);
}
}
</script>
```

C#

```
public string text { get; set; }
public string category { get; set; }
public static List<Countries> GetCountries()
{
List<Countries> country = new List<Countries>();
country.Add(new Countries { text = "Austria", category = "A" });
country.Add(new Countries { text = "Australia", category = "A" });
country.Add(new Countries { text = "Antarctica", category = "A" });
country.Add(new Countries { text = "Bangladesh", category = "B" });
country.Add(new Countries { text = "Brazil", category = "B" });
country.Add(new Countries { text = "Canada", category = "C" });
country.Add(new Countries { text = "Cuba", category = "C" });
country.Add(new Countries { text = "Denmark", category = "D" });
country.Add(new Countries { text = "Dominica", category = "D" });
...
return country;
}
}
}
```

Change the filter type

While filtering, you can change the filter type to `contains`, `startsWith`, or `endsWith` for string type within the filter event handler.

In the following examples, data filtering is done with the `endsWith` type.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("selectCountry")
.AllowFiltering(true)
.ComboBoxFields(h => h.Text("text").Value("category"))
.Query("new ej.Query().select(['text','category']).take(25)")
.ClientSideEvents(h => h.Filtering("filtering"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

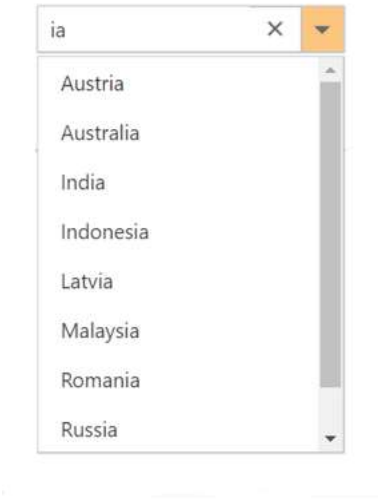
```
.Datasource((IEnumerable<Countries>)ViewBag.datasource)
.Placeholder("Select a country")
.Render();
}
</div>
</div>
<script type="text/javascript">
function filtering(e) {
var query = new ej.Query().select(['text','category']);
query = (e.text !== '') ? query.where('text', 'endswith', e.text, true) :
query;
e.updateData(e.model.dataSource, query);
}
</script>
```

C#

```
public string text { get; set; }
public string category { get; set; }
public static List<Countries> GetCountries()
{
List<Countries> country = new List<Countries>();
country.Add(new Countries { text = "Austria", category = "A" });
country.Add(new Countries { text = "Australia", category = "A" });
country.Add(new Countries { text = "Antarctica", category = "A" });
country.Add(new Countries { text = "Bangladesh", category = "B" });
country.Add(new Countries { text = "Brazil", category = "B" });
country.Add(new Countries { text = "Canada", category = "C" });
country.Add(new Countries { text = "Cuba", category = "C" });
country.Add(new Countries { text = "Denmark", category = "D" });
country.Add(new Countries { text = "Dominica", category = "D" });
...
return country;
}
}
}
```

Output for filtering ComboBox control is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Case sensitive filtering

Data items can be filtered either with or without case sensitivity using the DataManager. This can be done by passing the fourth optional parameter of the **where** clause.

The following example shows how to perform case-sensitive filter.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("selectCountry")
.AllowFiltering(true)
.ComboBoxFields(h => h.Text("text").Value("category"))
.Query("new ej.Query().select(['text','category']).take(25)")
.ClientSideEvents(h => h.Filtering("filtering"))
.Datasource((IEnumerable<Countries>)ViewBag.datasource)
.Placeholder("Select a country")
.Render();
}
</div>
</div>
<script type="text/javascript">
function filtering(e) {
var query = new ej.Query().select(['text','category']);
query = (e.text !== '') ? query.where('text', 'startswith', e.text, false) :
query;
e.updateData(e.model.dataSource, query);
}
</script>
```

C#

```
public string text { get; set; }
public string category { get; set; }
public static List<Countries> GetCountries()
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
List<Countries> country = new List<Countries>();
country.Add(new Countries { text = "Austria", category = "A" });
country.Add(new Countries { text = "Australia", category = "A" });
country.Add(new Countries { text = "Antarctica", category = "A" });
country.Add(new Countries { text = "Bangladesh", category = "B" });
country.Add(new Countries { text = "Brazil", category = "B" });
country.Add(new Countries { text = "Canada", category = "C" });
country.Add(new Countries { text = "Cuba", category = "C" });
country.Add(new Countries { text = "Denmark", category = "D" });
country.Add(new Countries { text = "Dominica", category = "D" });
...
return country;
}
}
}
```

Output for filtering ComboBox control is as follows.

Localization

The Localization library allows you to localize the static text content of the **noRecordsTemplate** and **actionFailureTemplate** properties according to the culture currently assigned to the ComboBox.

| Locale key | en-US (default) |

|------|------|-------------|

| noRecordsTemplate | No records found |

| actionFailureTemplate | The request failed |

Loading translations

To load translation object to your application, use the `load` function of **L10n** class.

In the following sample, French culture is set to the ComboBox and no data is loaded. Hence, the `noRecordsTemplate` property displays its text in French culture initially, and if the sample is run offline, the `actionFailureTemplate` property displays its text appropriately.

HTML

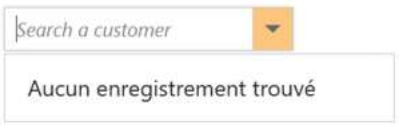
```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("searchCustomer")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Datasource(d =>
d.URL("//js.syncfusion.com/ejServices/wcf/NorthWind.svc/").Offline(false).Cr
ossDomain(true))
.Query("ej.Query().from('Suppliers').select('SupplierID',
'ContactName').take(0)")
.ComboBoxFields(f => f.Text("ContactName").Value("SupplierID"))
.Width("100%")
.Locale("fr-BE")
.Placeholder("Sélectionnez un customer")
.Render();
}
</div>
</div>
<script>
ej.ComboBox.locale["fr-BE"]={
'noRecordsTemplate': "Aucun enregistrement trouvé",
'actionFailureTemplate': "Modèle d'échec d'action"
}
</script>
```

C#

```
public ActionResult Databindingremote()
{
return View();
}
```



Accessibility

The ComboBox component has been designed, keeping in mind the WAI-ARIA specifications, and applies the WAI-ARIA roles, states, and properties along with keyboard support. This component is characterized by complete keyboard interaction support and ARIA accessibility support that makes it easy for people who uses assistive technologies (AT) or those who completely rely on keyboard navigation.

ARIA attributes

The ComboBox component uses the combobox role, and each list item has an option role. The following

ARIA attributes denote the ComboBox state.

| **Properties** | **Functionalities** |

| --- | --- |

| aria-haspopup | Indicates whether the ComboBox input element has a popup list or not. |

| aria-expanded | Indicates whether the popup list is expanded or not. |

Copyright © 2001 - 2020 Syncfusion Inc.

| aria-selected | Indicates the selected option. |

| aria-readonly | Indicates the readonly state of the ComboBox element. |

| aria-disabled | Indicates whether the ComboBox component is in a disabled state or not. |

| aria-activedescendent | This attribute holds the ID of the active list item to focus its descendant child element. |

| aria-owns | This attribute contains the ID of the popup list to indicate popup as a child element. |

| aria-autocomplete | This attribute contains the 'both' to a list of options shows and the currently selected suggestion also shows inline. |

Keyboard interaction

You can use the following key shortcuts to access the ComboBox without interruptions.

| **Keyboard shortcuts** | **Actions** |

| --- | --- |

| Arrow Down | Selects the first item in the ComboBox when no item selected. Otherwise, selects the item next to the currently selected item. |

| Arrow Up | Selects the item previous to the currently selected one. |

| Page Down | Scrolls down to the next page and selects the first item when popup list opens. |

| Page Up | Scrolls up to the previous page and selects the first item when popup list opens. |

| Enter | Selects the focused item and popup list closes when it is in open state. |

| Tab | Focuses on the next TabIndex element on the page when the popup is closed. Otherwise, closes the popup list and remains the focus of the component. |

| Shift + tab | Focuses on the previous TabIndex element on the page when the popup is closed. Otherwise, closes the popup list and remains the focus of the component. |

| Alt + Down | Opens the popup list. |

| Alt + Up | Closes the popup list.|

| Esc(Escape) | Closes the popup list when it is in an open state and the currently selected item remains the same. |

| Home | Selects the first item when popup open state. If it is in closed state, cursor moves to before of first character in input |

| End | Selects the last item when popup open state. If it is in closed state, cursor moves to next of last character in input |

In the following sample, focus the ComboBox component using the alt+t keys.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
```

Copyright © 2001 - 2020 Syncfusion Inc.

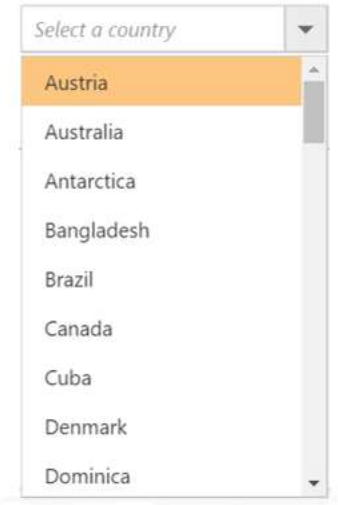
```
.ComboBox("groupingCountry")
.Datasource((IEnumerable<Countries>)ViewBag.datasource)
.Width("100%")
.ComboBoxFields(fields => fields.Text("text"))
.Placeholder("Select a country")
.Render();
}
</div>
</div>
<script type="text/javascript">
$(function () {
$(document).on("keydown", function (e) {
if (e.altKey && e.keyCode === 84 /* t */) {
// press alt+t to focus the control.
$("#groupingCountry").focus();
}
});
});
</script>
```

C#

```
public string text { get; set; }
public string category { get; set; }
public static List<Countries> GetCountries()
{
List<Countries> country = new List<Countries>();
country.Add(new Countries { text = "Austria", category = "A" });
country.Add(new Countries { text = "Australia", category = "A" });
country.Add(new Countries { text = "Antarctica", category = "A" });
country.Add(new Countries { text = "Bangladesh", category = "B" });
country.Add(new Countries { text = "Brazil", category = "B" });
country.Add(new Countries { text = "Canada", category = "C" });
country.Add(new Countries { text = "Cuba", category = "C" });
country.Add(new Countries { text = "Denmark", category = "D" });
country.Add(new Countries { text = "Dominica", category = "D" });
return country;
}
}
}
```

Output for accessibility ComboBox control is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



How To

Configure the Cascading ComboBox

The cascading ComboBox is a series of ComboBox, where the value of one ComboBox depends upon the another value. This can be configured by using the change event of the parent ComboBox. Within that change event handler, data has to be loaded to the child ComboBox based on the selected value of the parent ComboBox.

The following example shows the cascade behavior of the country, state, and city

ComboBox. Here, the dataBind method is used to reflect the property changes immediately

to the ComboBox.

HTML

```
<div class="frame">
<div class="row">
<div class="col-xs-8 col-sm-4">
<span class="txt">Select Group</span>
@Html.EJ().ComboBox("groupsList").Datasource((IEnumerable<groups>)ViewBag.da
tasource).ComboBoxFields(f =>
f.Value("parentId").Text("text")).ClientSideEvents(e =>
e.Change("onChange")).Placeholder("Select")
</div>
<div class="col-xs-8 col-sm-4" >
<span class="txt">Select Country</span>
@Html.EJ().ComboBox("countryList").Datasource((IEnumerable<Countries>)ViewBa
g.datasource1).ComboBoxFields(f=>f.Text("text")).Enabled(false)
</div>
</div>
</div>
<script type="text/javascript">
function onChange(e) {
var country = $('#countryList').data("ejComboBox");
if (e.model.value == null) country.option({ enabled: false });
```

```
else country.option({ enabled: true, query: new ej.Query().where('parentId',
'equal', e.model.value), value: null });
}
</script>
```

C#

```
List<groups> group = new List<groups>();
List<Countries> country = new List<Countries>();
public ActionResult Cascading()
{
group.Add(new groups { parentId = "a", text = "Group A" });
group.Add(new groups { parentId = "b", text = "Group B" });
group.Add(new groups { parentId = "c", text = "Group C" });
group.Add(new groups { parentId = "d", text = "Group D" });
group.Add(new groups { parentId = "e", text = "Group E" });
ViewBag.datasource = group;
country.Add(new Countries { value = 11, parentId = "a", text = "Algeria" });
country.Add(new Countries { value = 12, parentId = "a", text = "Armenia"});
country.Add(new Countries { value = 13, parentId = "a", text = "Bangladesh"
});
country.Add(new Countries { value = 14, parentId = "a", text = "Cuba"});
country.Add(new Countries { value = 15, parentId = "b", text = "Denmark"});
country.Add(new Countries { value = 16, parentId = "b", text = "Egypt" });
country.Add(new Countries { value = 17, parentId = "c", text = "Finland" });
country.Add(new Countries { value = 18, parentId = "c", text = "India" });
country.Add(new Countries { value = 19, parentId = "c", text = "Malaysia"
});
country.Add(new Countries { value = 20, parentId = "d", text = "New Zealand"
});
country.Add(new Countries { value = 21, parentId = "d", text = "Norway" });
country.Add(new Countries { value = 22, parentId = "d", text = "Romania" });
country.Add(new Countries { value = 23, parentId = "e", text = "Singapore"
});
country.Add(new Countries { value = 24, parentId = "e", text = "Thailand"
});
country.Add(new Countries { value = 25, parentId = "e", text = "Ukraine"});
ViewBag.datasource1 = country;
return View();
}
}
}
```

Output for ComboBox control is as follows.

Show the list items with icons

You can render **icons** to the list items by mapping the

IconCss field. This IconCss field create a span in the list item with mapped class name to allow styling as per your need.

In the following sample, icon classes are mapped with IconCss field.

HTML

```
<div class="frame">
<div class="control">
@Html.EJ().ComboBox("maillots").Datasource((IEnumerable<IconCss>)ViewBag.dat
asource).ComboBoxFields(f =>
f.Text("Name").IconCss("IconClass")).Placeholder("Select a
icon").Width("100%")
</div>
</div>
<style>
.mail {
display: block;
background-image: url('../../Images/dropdownlist/iconsapps.png');
height: 25px;
width: 25px;
background-position: center center;
background-repeat: no-repeat;
}
.mail.done {
background-position: 0 0;
}
.mail.moveto {
background-position: 0 -22px;
}
.mail.categorize {
background-position: 0 -46px;
}
.mail.flag {
background-position: 0 -70px;
}
.mail.forward {
background-position: 0 -94px;
}
.mail.new {
background-position: 0 -116px;
```

Copyright © 2001 - 2020 Syncfusion Inc.

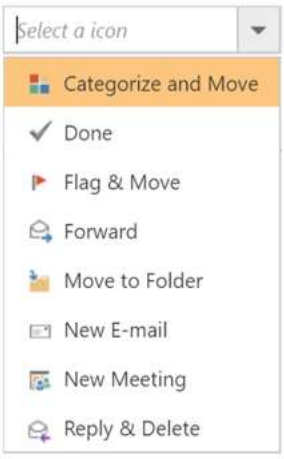
```
}
.mail.reply {
background-position: 0 -140px;
}
.mail.meeting {
background-position: 0 -164px;
}
.control {
margin-left: 20px;
}
.ctrllabel {
padding-bottom: 3px;
}
</style>
```

C#

```
public string Name { get; set; }
public string IconClass { get; set; }
public static List<IconCss> GetIconList()
{
List<IconCss> icon = new List<IconCss>();
icon.Add(new IconCss { Name = "Categorize and Move", IconClass = "mail
categorize" });
icon.Add(new IconCss { IconClass = "mail done", Name = "Done" });
icon.Add(new IconCss { IconClass = "mail flag", Name = "Flag & Move" });
icon.Add(new IconCss { IconClass = "mail forward", Name = "Forward" });
icon.Add(new IconCss { IconClass = "mail moveto", Name = "Move to Folder"
});
icon.Add(new IconCss { IconClass = "mail new", Name = "New E-mail" });
icon.Add(new IconCss { IconClass = "mail meeting", Name = "New Meeting" });
icon.Add(new IconCss { IconClass = "mail reply", Name = "Reply & Delete" });
return icon;
}
public ActionResult Icons()
{
ViewBag.datasource = IconCss.GetIconList();
return View();
}
}
}
```

Output for ComboBox control is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



AutoFill supported with ComboBox

The ComboBox supports the AutoFill behavior with the help of AutoFill property. Whenever you change the input value,

the ComboBox will autocomplete your data by matching the typed character. If no matches found, the ComboBox will not suggest any item.

In the following sample, showcase that how to work autofill with ComboBox.

HTML

```
<div class="frame">
<div class="control">
@{
Html.EJ()
.ComboBox("groupingCountry")
.Datasource((IEnumerable<Countries>)ViewBag.datasource)
.Width("100%")
.ComboBoxFields(fields => fields.Text("text"))
.Placeholder("Select a country")
.AutoFill(true)
.Render();
}
</div>
</div>
```

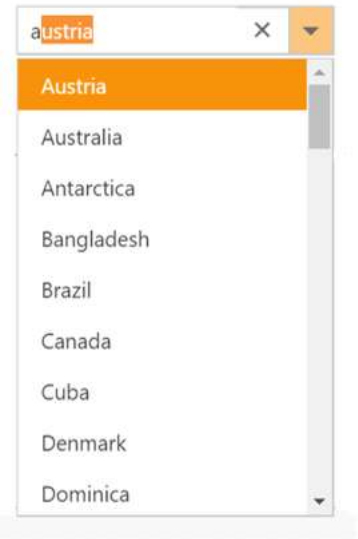
C#

```
public string text { get; set; }
public string category { get; set; }
public static List<Countries> GetCountries()
{
List<Countries> country = new List<Countries>();
country.Add(new Countries { text = "Austria", category = "A" });
country.Add(new Countries { text = "Australia", category = "A" });
country.Add(new Countries { text = "Antarctica", category = "A" });
country.Add(new Countries { text = "Bangladesh", category = "B" });
country.Add(new Countries { text = "Brazil", category = "B" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
country.Add(new Countries { text = "Canada", category = "C" });
country.Add(new Countries { text = "Cuba", category = "C" });
country.Add(new Countries { text = "Denmark", category = "D" });
country.Add(new Countries { text = "Dominica", category = "D" });
return country;
}
}
}
```

Output for grouping ComboBox control is as follows.



Validation of ComboBox using jQuery Validator

Validation of ComboBox can be done on form submission using jQuery Validations by adding name attribute for ComboBox through htmlAttributes property. Also, you can remove this error message during item selection through select or change event of ComboBox

Note: jquery.validate.min script file should be referred for validation, for more details, refer here.

HTML

```
<form id="form1">
<div class="frame">
<div class="row">
<div class="col-xs-8 col-sm-4">
<span class="txt">Select Country</span>
@Html.EJ().ComboBox("countryList").Datasource((IEnumerable<CountryList>)View
Bag.datasource1).ComboBoxFields(h =>
h.Text("text")).AutoFill(true).Placeholder("Select").HtmlAttributes(new
Dictionary<string, object> { { "name", "select" }
}).ClientSideEvents(e=>e.Select("select"))
</div>
<label class="message"></label>
</div>
<button type="submit" id="valid" onclick="validate()"> Validate</button>
</div>
<script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
function validate()
{
var rules = {};
$("form[id$=form1] input[name$=select]").each(function () {
rules[this.name] = "required";
});
$('form[id$="form1"]').validate({
rules: rules,
errorPlacement: function (error, element) {
$(error).insertAfter($(".message"));
}
});
}
function select(args)
{
if(args.value!="")
{
$("label.error").css("display", "none")  //hide error message when value is
selected.
}
}
</script>
</form>
```

Render ComboBox from code behind

ComboBox can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of ComboBox using ComboBox properties from code behind.

RAZOR

```
@{Html.EJ().ComboBox("Customer", Model).Render(); }
```

C#

```
public ActionResult Index()
{
ComboBoxProperties combobox = new ComboBoxProperties();
combobox.DataSource =
"http://js.syncfusion.com/ejServices/wcf/NorthWind.svc/";
combobox.Query = "ej.Query().from('Suppliers').select('SupplierID',
'ContactName').take(10)";
combobox.ComboBoxFields.Text = "ContactName";
combobox.ComboBoxFields.Value = "SupplierID";
combobox.Width = "300";
return View(combobox);
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

CurrencyTextBox

Overview

Essential ASP.NET MVC CurrencyTextBox is used to display only currency values. It has Spin buttons to increase or decrease the values in the Text Box.

Key Features

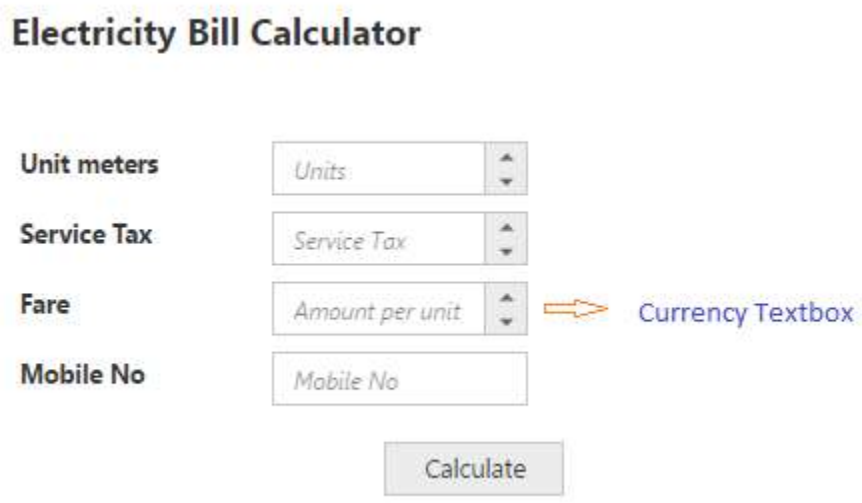
- Min and Max Values—Specifies value range for the textbox.
- Spin Buttons—Enable you to increase or decrease the current value in the textbox.
- Step Value—Enables you to increment or decrement the current value by step value.
- Globalization— EJ MVC CurrencyTextBox has globalization support. It use ej.globalize.js file to globalize the number format, and parse numbers according to the culture.
- Keyboard Navigation—You can interact with CurrencyTextBox by using keyboard.
- RTL Support—Support for right to left alignment of textbox input.
- Decimal Values—You can configure the textbox to accept decimal values.
- Themes—CurrencyTextBox consist of 17 built-in themes , and also support custom skins for creating user-defined themes.

Getting Started

This section explains briefly about how to create a EJMVC CurrencyTextBox in ASP.NET MVC platform.

Create your first CurrencyTextBox in MVC

From the following steps you can learn how to create and use CurrencyTextBox in your application. Here we have showcased, a small Electric bill calculator application using EJMVC Editors widgets.The Essential ASP.NET MVC Editors control includes Numeric, Percentage, Currency and MaskEdit textbox controls. This will guide you to use the wide range of Editors functionalities to complete this application.



Electricity Bill Calculator

Create Editors

ASP.NET MVC Editors renders built-in features like keyboard navigation, min and max range and flexible API's.

Copyright © 2001 - 2020 Syncfusion Inc.

1. Create a MVC Project and add necessary Dll's and Scripts. Refer MVC-Getting Started.
2. Add necessary helper elements to render the Editor components.

HTML

```
<div class="editors">
<div class="element-text" style="">Electricity Bill Calculator</div>
<br />
<table class="editors">
<tbody>
<tr>
<td>
<label>Unit meters</label>
</td>
<td>    @* NumericTextBox creation with watermark text *@
@Html.EJ().NumericTextbox("numeric").WatermarkText("Units")
</td>
</tr>
<tr>
<td>
<label>Service Tax</label>
</td>
<td>     @* PercentageTextBox creation with watermark text *@
@Html.EJ().PercentageTextbox("percent").WatermarkText("Tax")
</td>
</tr>
<tr>
<td>
<label>Fare</label>
</td>
<td>    @* CurrencyTextBox creation with watermark text *@
@Html.EJ().CurrencyTextbox("currency").WatermarkText("Amount per unit")
</td>
</tr>
<tr>
<td>
<label>Mobile No</label>
</td>
<td>    @* MaskEditTextBox creation with watermark text *@
@Html.EJ().MaskEdit("maskedit").WatermarkText("Phone number")
</td>
</tr>
</tbody></table>
<div class="pay-bill">
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("Calculate")
</div>
</div>
```

3. The following styles are added to arrange the Editors.

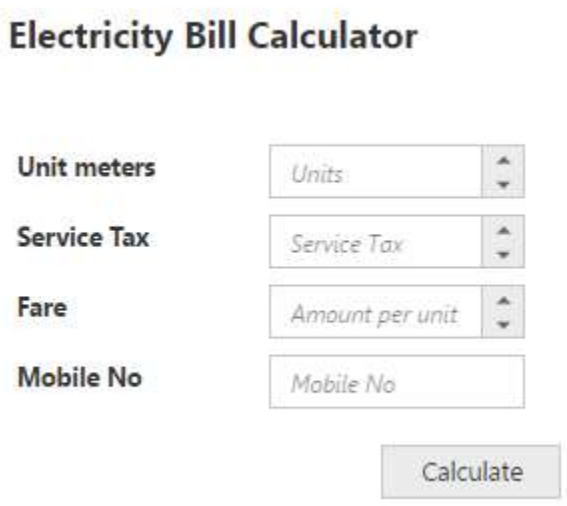
CSS

```
<style type="text/css" class="cssStyles">
.element-text
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
display: inline-block;
font-size: 20px;
font-weight: bolder;
height: 50px;
position: relative;
text-align: center;
top: -20px;
}
.editors
{
max-width: 400px;
border: 2px solid #DDDDDD;
}
.editors table
{
border:0px;
padding-left:50px;
}
.pay-bill
{
margin:15px 0px 10px 208px;
}
.editors label
{
display: block;
width: 130px;
}
</style>
```

4. Execute the code to render Editors as follows



CurrencyTextBox with watermark text

Set MinValue, MaxValue and value in CurrencyTextBox

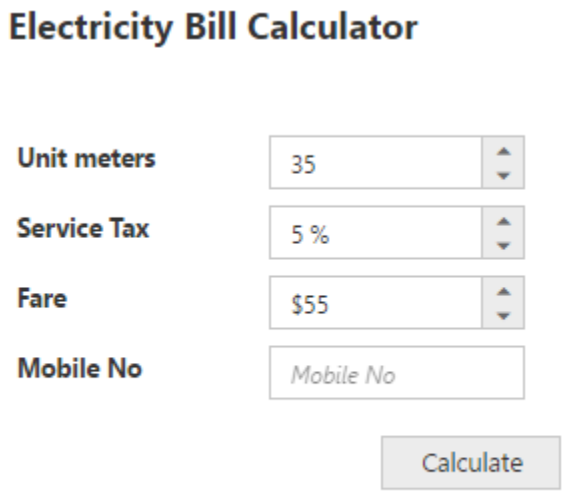
You can set the “MinValue”,“MaxValue” and “Value” in Currency, Percentage and Currency text boxes for maintaining the range in Editors widgets. In this scenario, you have to enter the values between the default ranges and enter the phone number in the MaskEdit widget by using the ”MaskFormat” property. By using DecimalPlaces property for CurrencyTextBox you can get decimal values. The following code example illustrates how to achieve this.

HTML

```
<div class="editors">
<div class="element-text" style="">Electricity Bill Calculator</div>
<br />
<table class="editors">
<tbody>
<tr>
<td>
<label>Unit meters</label>
</td>
<td>
@Html.EJ().NumericTextbox("numeric").WatermarkText("Units").MinValue(1).MaxV
alue(10000).Value("70")
</td>
</tr>
<tr>
<td>
<label>Service Tax</label>
</td>
<td>
@Html.EJ().PercentageTextbox("percent").WatermarkText("Tax").MinValue(5).Max
Value(100).Value("15")
</td>
</tr>
<tr>
<td>
<label>Fare</label>
</td>
<td>
@Html.EJ().CurrencyTextbox("currency").WatermarkText("Amount per
unit").MinValue(0.00).MaxValue(100000.00).Value("350.00").DecimalPlaces(2)
</td>
</tr>
<tr>
<td>
<label>Mobile No</label>
</td>
<td>
@Html.EJ().MaskEdit("maskedit").WatermarkText("Phone
number").MaskFormat("99-999-99999").Value("9090909090")
</td>
</tr>
</tbody>
</table>
<div class="pay-bill">
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("Calculate")
</div>
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot illustrates the output of the above code examples.



CurrencyTextBox with Min/Max Value ranges

Setting the Strict Mode Option

You can set the “StrictMode” option to restrict entering values defined outside the range. The following code example illustrates how to set strict mode option.

HTML

```
<div class="editors">
<div class="element-text" style="">ElectricityBill Calculator</div><br />
<table class="editors">
<tbody>
<tr>
<td>
<label>Unit meters</label>
</td>
<td>
@Html.EJ().NumericTextbox("numeric").WatermarkText("Units").MinValue(1).MaxV
alue(10000).Value("70").EnableStrictMode(true)
</td>
</tr>
<tr>
<td>
<label>Service Tax</label>
</td>
<td>
@Html.EJ().PercentageTextbox("percent").WatermarkText("Tax").MinValue(5).Max
Value(100).Value("15")
</td>
</tr>
<tr>
<td>
<label>Fare</label>
```

```
</td>
<td>
@Html.EJ().CurrencyTextbox("currency").WatermarkText("Amount per
unit").MinValue(0.00).MaxValue(100000.00).Value("350.00").DecimalPlaces(2)
</td>
</tr>
<tr>
<td>
<label>Mobile No</label>
</td>
<td>
@Html.EJ().MaskEdit("maskedit").WatermarkText("Phone
number").MaskFormat("99-999-99999").Value("9090909090")
</td>
</tr>
</tbody>
</table>
<div class="pay-bill">
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("Calculate").
</div>
</div>
```

Run the above code example and you can see that it restricts entering a value exceeding the MinValue and MaxValue range mentioned in the Numeric textbox.

Set Calculation process with CurrencyTextBox Widgets

You can use events to calculate the total and displays the value. You can achieve this with the help of Click event in the button widget. The calculation steps are written in the call back function of Click event button.

To customize the button, you can set the ContentType as TextAndImage to include the icon before the text and add the ClientSideEvents for click event.

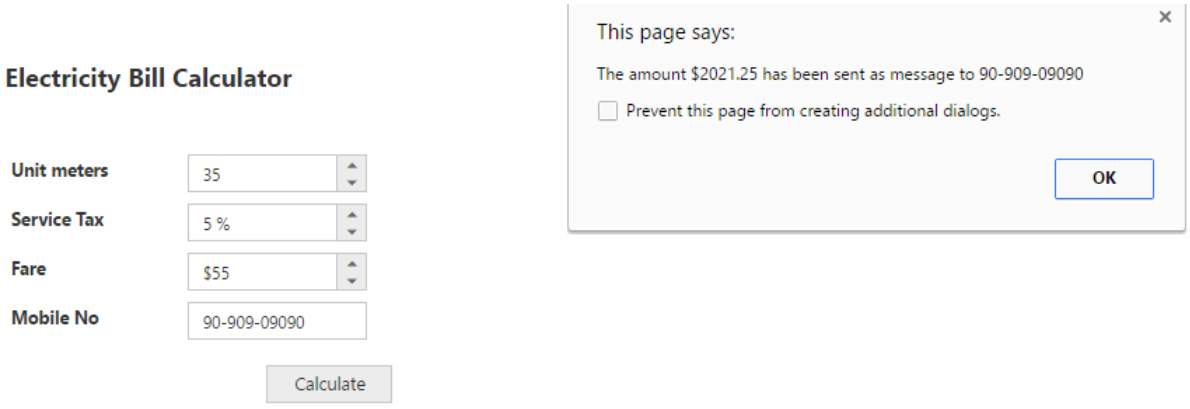
JS

```
<div class="editors">
@* Please refer the table format for textboxes customization *@
<div class="pay-bill">
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("Calculate").ClientSide
Events(c=>c.Click("calculateBill"))
</div>
</div>
<script type="text/javascript">
function calculateBill() {
// Declares Necessary variable creation
var unitMeter, serviceTax, amountPerKm;
unitMeter = $("#numeric").data("ejNumericTextbox");// Object of Numeric
serviceTax = $("#percent").data("ejPercentageTextbox");// Object of
Percentage
amountPerKm = $("#currency").data("ejCurrencyTextbox"); // Object of
Currency
mobileNumber = $("#maskedit").data("ejMaskEdit"); // Object of MaskEdit
// This is used to calculate the Net amount
var netAmount = unitMeter.model.value * amountPerKm.model.value;
// This is used to calculate the service tax amount
var sTax = (netAmount * serviceTax.model.value) / 100;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
// This shows the calculated amount for the units
alert("The amount $" + (netAmount + sTax) + " has been sent as message to "
+ mobileNumber.model.value + ".");
}
</script>
```

Run the above code sample, fill the required Textbox fields and click the Calculate button. The values are displayed and an alert message is shown. The following screen shot illustrates the final output of the Electricity bill calculator.



Electricity bill calculator with alert

Behavior Settings

Decimal Places

DecimalPlaces property specifies number of values allowed after the decimal point.The default value of DecimalPlaces property is 0 i.e., by default you cannot specify decimal value in CurrencyTextBox. We need to add this property to allow decimal values. To set the DecimalPlaces to “-1”, that allows the decimals without any limit in CurrencyTextBox control.

Configure Decimal Places

1. In the View page add CurrencyTextBox helper, and configure the DecimalPlaces property as follows.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").DecimalPlaces(4).Value("555")
```

The output is as follows.

CurrencyTextBox with decimalPlaces

Persistence Support

CurrencyTextBox provides state maintenance support. You can maintain the previous changes made in the control after a page loads.

Copyright © 2001 - 2020 Syncfusion Inc.

Configure Persistence Support

In the View page add CurrencyTextBox helper, and configure the EnablePersistence property as follows.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Value("33").EnablePersistence(true)
```

Output of CurrencyTextBox with EnablePersistence is as follows.

CurrencyTextBox at initial load

CurrencyTextBox after changing the value and after page refresh

Strict Mode Support

CurrencyTextBox allows you to use the strict mode option by setting the EnableStrictMode property. You can set the MinValue and MaxValue to the controls to enable strict mode functionality. Default value of this property is false. When the textbox value exceeds the MaxValue, it restricts the exceeded value and returns the MaxValue. Likewise when the textbox value goes below MinValue, it restricts the new value and returns the MinValue. When this property is enabled, it will not restrict the specified value and an error class will be added to indicate wrong value is provided to the textbox.

Configure Strict Mode Support

In the View page add CurrencyTextBox helper, and configure the EnableStrictMode property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").MinValue(-
1).MaxValue(8).Value(10).EnableStrictMode(true)
```

Output when EnableStrictMode is “true” is as follows.

Currency with EnableStrictMode

Enabled or Disabled

CurrencyTextBox has an option to enable or disable its element. You can set the Enabled property as “false” to enable the Textbox controls.

Also you can enable/disable the **CurrencyTextBox** by using enable and disable methods.

Configure Enabled or Disabled

In the View page add CurrencyTextBox helper, and configure the Enabled property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Value("3").Enabled(false)
```

Output when Enabled is “true” and when Enabled is “false”.

Copyright © 2001 - 2020 Syncfusion Inc.

CurrencyTextBox with enabled as false

CurrencyTextBox with enabled as true

Adjusting Textbox Size

CurrencyTextBox size can be modified by using the Height and Width properties.

Configure Height and Width

In the View page add CurrencyTextBox helper, and configure the Height and Width property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Width("100").Height("50").Value("1")
```

Output of CurrencyTextBox after setting “Height” and “Width” is as follows.

CurrencyTextBox with height and width

Increment Step

The IncrementStep property is used to increase or decrease the amount of value in the Currency textbox.

Configure Increment Step

In the View page add CurrencyTextBox helper, and configure the IncrementStep property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").IncrementStep(4).Value("1")
```

Output of Currency textbox with IncrementStep is as follows.

CurrencyTextBox at initial load

CurrencyTextBox after increasing two step

Define Name

When you have placed the CurrencyTextBox in a form, the Name property is used to send the field value at form submission. The default value of the Name property is null.

Configure Name

In the View page add CurrencyTextBox helper, and configure the Name property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Name("Currency")
```

Define Value

The value of CurrencyTextBox can be assigned by using the Value property. The default value for Value property is null.

You can get the value of **CurrencyTextBox** by using getValue method.

Configure Value

In the View page add CurrencyTextBox helper, and configure the Value property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Value("33")
```

Output of CurrencyTextBox with the value property is as follows.

CurrencyTextBox with value

Define MaxValue and MinValue

MaxValue

The maximum limit value can be assigned to the CurrencyTextBox by using the MaxValue property. The default value of MaxValue property is 1.7976931348623157e+308.

MinValue

The minimum limit value can be assigned to the CurrencyTextBox by using the MinValue property. The default value of MinValue property is -1.7976931348623157e+308.

Configure MaxValue and MinValue

In the View page add CurrencyTextBox helper, and configure the MinValue and MaxValue property. .

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Value("4").MinValue(-3).MaxValue(4)
```

Output of CurrencyTextBox with MaxValue and MinValue is as follows.

CurrencyTextBox with maxValue

CurrencyTextBox with minValue

Read Only Support

CurrencyTextBox supports read only option. When you enable the ReadOnly property to the control, the value cannot be changed in the CurrencyTextBox. You can set the ReadOnly property as “true” to enable this option.

Copyright © 2001 - 2020 Syncfusion Inc.

Configure Read Only

In the View page add CurrencyTextBox helper, and configure the ReadOnly property.

@Html.EJ().CurrencyTextbox("currency").Value("3").ReadOnly(true)

Output of CurrencyTextBox when ReadOnly is “true” is as follows. CurrencyTextBox values cannot be edited or changed.

CurrencyTextBox with readOnly

Appearance

Theme

CurrencyTextBox control’s style and appearance can be controlled based on CSS classes. In order to apply styles you need to refer 2 files namely, ej.widgets.core.min.css and ej.theme.min.css. If the file ej.web.all.min.css is referred, then it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.web.all.min.css is the combination of these two.

By default, there are 17 themes support available namely:

- bootstrap
- flat-azure
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark
- high-contrast-01
- high-contrast-02
- material
- office-365

CSS Class

The CSS can be customized by using the CssClass in the CurrencyTextBox. You can customize the CurrencyTextBox with CssClass property to appear like your desired control.

Configure CSS Class

In the View page add CurrencyTextBox helper, and configure the CssClass property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Value("3").CssClass("customCss")
```

Copyright © 2001 - 2020 Syncfusion Inc.

1. Customize the CSS properties in custom CSS class.

CSS

```
<style>
.customCss .e-box {
border-color: #9d241b;
}
.customCss .e-input {
background-color: #f6db8d;
}
.customCss .e-select {
background-color: #ecf6ac;
border-color: #3c36e7;
}
</style>
```

Output of CurrencyTextBox after applying CssClass is as follows.

CurrencyTextBox with cssClass

Rounded Corner Support

CurrencyTextBox provides you with rounded corner support whose appearance is different from normal textbox controls.

Configure Rounded Corner Support

In the View page add CurrencyTextBox helper, and configure the ShowRoundedCorner property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Value("3").ShowRoundedCorner(true)
```

Output of CurrencyTextBox when ShowRoundedCorner is “true”.

CurrencyTextBox with ShowRoundedCorner

Spin Button Support

CurrencyTextBox provides you the option as to whether to display the spin button in the widget or remove it from the control by using showSpinButton property.

Configure Spin Button

In the View page add CurrencyTextBox helper, and configure the ShowSpinButton property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Value("3").ShowSpinButton(false)
```

Output of CurrencyTextBox when ShowSpinButton is “false”.

Copyright © 2001 - 2020 Syncfusion Inc.

CurrencyTextBox with ShowSpinButton is false

Water Mark Text Support

The CurrencyTextBox provide water mark text support. You can display the initial value in the control by water mark.

Configure Water Mark Text

In the View page add CurrencyTextBox helper, and configure the ShowSpinButton property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").WatermarkText("Currency")
```

Output of CurrencyTextBox after applying WaterMarkText is as follows.

CurrencyTextBox with watermark text

Globalization Support

Globalization is language support based on the culture in CurrencyTextBox. You can achieve the **Globalization** using "**locale"** property in CurrencyTextBox.

The CurrencyTextBox widget provides multi-language support using globalization. You can customize the CurrencyTextBox with your own language style by using this feature. You can change the globalization by using the **locale** property. The default value for **locale** property is **en-US** in CurrencyTextBox controls. Also you can specify the currencySymbol property when the user wants to overwrite the currency symbol commonly instead of the current culture symbol.

More than 350 culture specific files are available to localize the value. To know more about EJ globalize support, please refer the below link

http://help.syncfusion.com/js/localization

Note: All the culture-specific script files are available within the below specified location, once you have installed Essential Studio in your machine, therefore it is not necessary to download these files explicitly.

'(installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n'
For example, If you have installed the Essential Studio package within C:\Program Files (x86), then navigate to the below location, C:\Program Files (x86)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n

Refer the below German culture file in head section of HTML page after the reference of **ej.web.all.min.js** file.

JAVASCRIPT

```
<script src="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/i18n/ej.culture.de-DE.min.js"></script>
```

You can dynamically change the language based on their culture.

Configure Localization

The following example describes the way to use localization in CurrencyTextBox.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Value("33").Locale("de-DE")
```

Output of CurrencyTextBox with localization.

CurrencyTextBox with de-DE locale

CurrencyTextBox with default (en-US) locale

RTL Support

CurrencyTextBox provides RTL (Right-To-Left) support. The alignment of CurrencyTextBox can be changed from Left-To-Right into Right-To-Left.

Enable RTL

In the View page add CurrencyTextBox helper, and configure the EnableRTL property.

ASPX-CS

```
@Html.EJ().CurrencyTextbox("currency").Value("33").EnableRTL(true)
```

Output of CurrencyTextBox when EnableRTL is “true” is as follows.

CurrencyTextBox with enableRTL

Keyboard Interaction

With the keyboard navigation enabled in the CurrencyTextBox control, it is possible to control the actions with the provided shortcut keys. Almost all the CurrencyTextBox functionality that are done through mouse can be controlled with shortcut keys.

The various keyboard shortcuts available within the CurrencyTextBox control are discussed in the following table.

Shortcut Key	Description
Access key + j	Focuses the control
Up	Increments the value
Down	Decrements the value
Tab	Focus the next element

Copyright © 2001 - 2020 Syncfusion Inc.

Configuring Keyboard Navigation

The following steps explain the implementation of keyboard interaction in CurrencyTextBox.

In the View page add CurrencyTextBox helper. Set the access key property to the CurrencyTextBox for focusing the control while key is pressed. We need to use 'HtmlAttributes' property to add the "access key" attribute to the Editor elements. 'HtmlAttributes' property is used to add HTML attributes like, id, class etc.. to the components. We need to use IDictionary<string,object> to specify the HTML attributes. Please check the below code.

ASPX-CS

```
@{IDictionary<string, object> currencyAttribute = new Dictionary<string,
object>();
currencyAttribute.Add("accesskey", "l");
}
@Html.EJ().CurrencyTextbox("currency").Name("currency").Value("33").HtmlAttr
ibutes(currencyAttribute)
```

Run the above example and press Access key + j key to focus the CurrencyTextBox widget. Perform provided functionality by using keyboard shortcuts.

CurrencyTextBox focused with keyboard shortcut

DataManager

DataManager

DataManager helps in managing relational data in the ASP.NET MVC. Its rich features make querying data sources easier. The ODataClient supports OData queries that are enabled in the Web API & WCF data services.

DataManager supports different types of data binding such as:

1. JSON
2. Web Services
3. OData

Basically, all services that have JSON acts as a transport.

Key Features

DataManager has many abilities and responsibilities, among which to:

1. **DataManager** - Communicates with data source and returns the desired result based on the Query provided.
2. **JavaScript Query** – **DataManager** have APIs for generating JavaScript data query with ease.
3. **CRUD in individual requests and Batch** – **CRUD** operations are fully supported. The options are enabled to commit the data as a single or multiple requests.
4. **Adaptors** – **Adaptors** are specific dataSource type aware interfaces that are used by **DataManager** to communicate with DataSource. Three adaptors are created. They are, ODataAdaptor, JsonAdaptor and UrlAdaptor

Copyright © 2001 - 2020 Syncfusion Inc.

5. **Model binding** – Simple model binding is made using **DataManager**. You can directly bind Query result to **HTML** element.
6. Calculate and maintain aggregates, sorting order and paging

In other words, the DataManager fully supports CRUD (Create, Read, Update, Destroy) data operations, and provides both client-side and server-side support for sorting, paging, filtering, grouping, and aggregates.

Getting Started

Create your DataManager in the ASP.NET MVC

DataManager is used to manage relational data. It supports CRUD (Create, Read, Update, and Destroy) in individual requests and Batch. DataManager uses DataManager control for processing and ej.Query for serving the data. DataManager control communicates with data source and ej.Query generates data queries that are read by DataManager.

Configure Demo Application

This section briefly describes how to make a connection to WCF “Northwind” OData service and generate a report with top five orders from customer HANAR with higher Freight charges. In this application scenario, you can learn how to bind the DataManager to the Grid control to do paging, filtering and sorting with Grid control in the DataManager by using ej.Query.

Create Connection

To define connection to data source, you can use the DataManager control. The data source can be local or remote. Local data source is the local data and remote data source is any web service.

The local data is set as data source by using the following code example.

ASPX-CS

```
<%--connection local reference--%>
@(Html.EJ().DataManager("FlatData").URL("Home/DataSource").Adaptor(AdaptorTy
pe.UrlAdaptor))
public class HomeController : Controller
{
public ActionResult Index()
{
return View();
}
public ActionResult DataSource(Syncfusion.JavaScript.DataManager
dataManagerObj)
{
var DataSource = OrderRepository.GetAllRecords();
DataResult result = new DataResult();
result.result =
DataSource.Skip(dataManagerObj.Skip).Take(dataManagerObj.Take).ToList();
result.count = DataSource.Count();
return Json(result, JsonRequestBehavior.AllowGet);
}
public class DataResult
{
public IEnumerable<EditableOrder> result { get; set; }
public int count { get; set; }
}
}
```

In this application, as you have web service for Northwnd database, you can assign the web service URL link to the URL property of DataManager, and you can enable crossDomain to retrieve data from another domain.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders/").CrossDomain(true)
```

You can use the ej.Query to generate the report from web service.

Binding with Grid Control

You can bind the DataManager with Grid by defining the ID of DataManager in the DataManagerID property of the Grid control.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders/").CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData") //DataManagerID(DataManager ID)
.Query("new ej.Query().take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
}))
```

When you run, the following table is displayed.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

DataManager with Grid Control

Filter

You can generate the Filter query to filter the CustomerID column based on VINET value and it is ran by using the DataManager.

The where function is used to filter the records based on the specified filter condition.

Copyright © 2001 - 2020 Syncfusion Inc.

The select property of ejQuery is used to retrieve the specified columns from the data source.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders/").CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID', 'ShipCity', 'Freight']).where('CustomerID', 'equal', 'VINET').take(5)")
//where(fieldName, operator, value, [ignoreCase])
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
}))
```

When you run the filter query and bind the result to the Grid, the following table is displayed.

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10274	VINET	6	Reims	6.0100
10295	VINET	2	Reims	1.1500
10737	VINET	2	Reims	7.7900
10739	VINET	3	Reims	11.0800

Data with Filtering

Sort

You can generate the Sort query to sort the Freight column in descending order and that is executed by using the DataManager.

The sortBy property of ejQuery is used to sort the records based on the field and direction specified.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders/").CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID', 'ShipCity', 'Freight']).where('CustomerID', 'equal', 'VINET').sortBy('Freight desc').take(5)")
//sortBy(field direction)
.Columns(col =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
}))
```

When you run the sort query and bind the result to the table, the following table is displayed.

Order ID	Customer ID	Employee ID	Ship City	Freight
11078	VINET	5	Reims	32.3800
11908	VINET	5	Reims	32.3800
12738	VINET	5	Reims	32.3800
13568	VINET	5	Reims	32.3800
14398	VINET	5	Reims	32.3800

Data with Sorting

Page

You can generate the Paging query to get the top four orders and it is ran by using the DataManager.

The Page property of ejQuery is used to retrieve the records based on the given pageIndex and pageSize.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/Orders/").CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).where('CustomerID', 'equal',
'VINET').sortBy('Freight desc').page(3,5)")
//page(pageIndex,pageSize)
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
}))
```

Copyright © 2001 - 2020 Syncfusion Inc.

Order ID	Customer ID	Employee ID	Ship City	Freight
10739	VINET	3	Reims	11.0800
11569	VINET	3	Reims	11.0800
12399	VINET	3	Reims	11.0800
13229	VINET	3	Reims	11.0800
14059	VINET	3	Reims	11.0800

In this section, you can learn how to enable basic properties available in the DataManager and the usage of the various queries in the DataManager.

Data Binding

Local

A data source can be bound to a Grid through the DataManager. The DataManager supports JSON array binding. It is useful to bind records in a client-side by using JSON data that is very helpful in Single Page Application (SPA) and in feature rich web application. To achieve this, you can refer to the following code example.

ASPX-CS

```
//connection local reference
@(Html.EJ().DataManager("FlatData").URL("Home/DataSource").Adaptor(AdaptorTy
pe.UrlAdaptor))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).where('CustomerID', 'equal', 'VINET').take(5)")
//where(fieldName, operator, value, [ignoreCase])
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

C#

```
public class HomeController : Controller
{
public ActionResult Index()
{
return View();
}
public ActionResult DataSource(Syncfusion.JavaScript.DataManager
dataManagerObj)
{
```

```
var DataSource = OrderRepository.GetAllRecords();
DataResult result = new DataResult();
result.result =
DataSource.Skip(dataManagerObj.Skip).Take(dataManagerObj.Take).ToList();
result.count = DataSource.Count();
return Json(result, JsonRequestBehavior.AllowGet);
}
public class DataResult
{
public IEnumerable<EditableOrder> result { get; set; }
public int count { get; set; }
}
}
```

The result of the above code example is illustrated as follows.

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

Binding local data to grid

REST Services

OData binding

OData is a standardized protocol for creating and consuming data. You can retrieve data from OData service by using DataManager. You can refer to the following code example of remote Data binding by using the OData service.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

The result of the above code example is illustrated as follows.

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

OData binding

OData V4

The OData v4 is an improved version of OData protocols and the DataManager can also retrieve and consume OData v4 services. For more details on OData v4 Services, refer to the odata documentation.

You can refer to the following code example for consuming OData v4 services and bind the result to the Grid. In the the following code, crossDomain is enabled to make cross domain request.

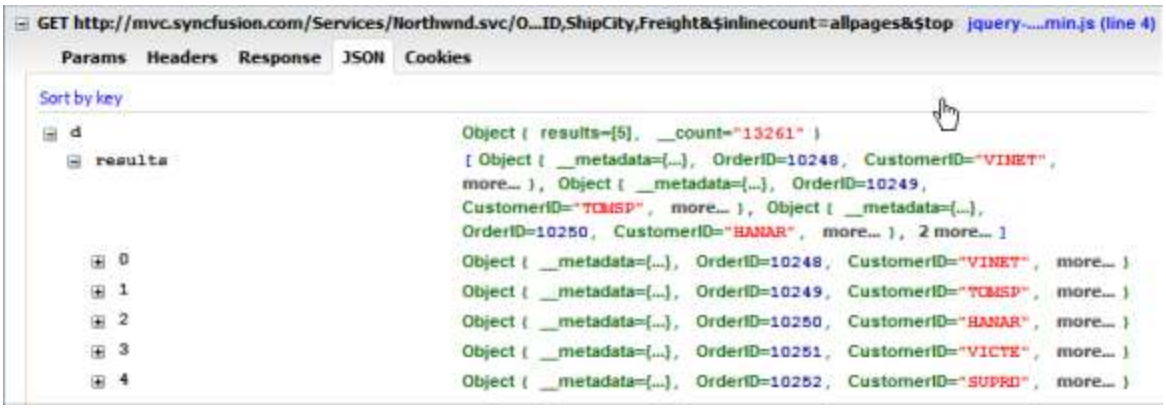
HTML

```
@Html.EJ().DataManager("FlatData").URL("http://services.odata.org/V4/Northwi
nd/Northwind.svc/Orders").Adaptor(AdaptorType.ODataV4Adaptor).CrossDomain(tr
ue)
@(Html.EJ().Grid<object>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

The request and response to the service from the DataManager are illustrated as follows.

The result of the above code example is illustrated as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



OData v4 request and response

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

OData v4 binding

WebAPI binding

The Web API is a programmatic interface to define the request and response messages system that is mostly exposed in JSON or XML. The DataManager contains default adaptor to handle the Web API request and responses. The WebApiAdaptor is discussed briefly in the Adaptor section.

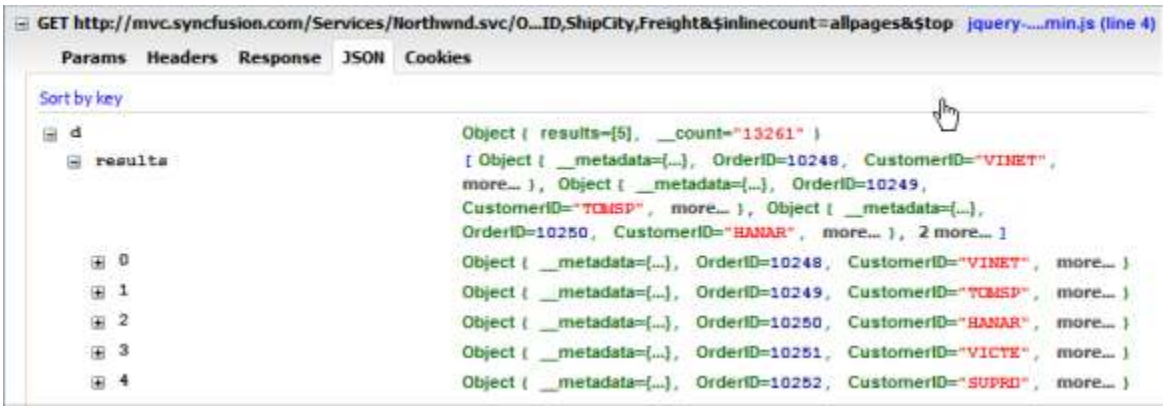
Refer to the following code example for consuming the Web API data by using the DataManager.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/UGService/
api/Orders").Adaptor(AdaptorType.WebApiAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).where('CustomerID', 'equal', 'VINET').take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

The request to the Web API and response is illustrated as follows.



Web API adaptor request and response

The result for the above code example is illustrated as follows.

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

Web API data binding

Other Web Services binding

The DataManager can also retrieve data from the ASP.NET Web methods and ASP.NET MVC Controller`s action. You can achieve this by using the UrlAdaptor of the DataManager. The UrlAdaptor is discussed briefly in the adaptor section. By default, the URL Adaptor is used when accessing remote data.

Refer to the following code example to know how the DataManager can be used to consume data from the web method.

Create a sample using ASP.NET Web Services

HTML

```
public class WebService1 : System.Web.Services.WebService
{
static string cons =
ConfigurationManager.ConnectionStrings["SQLConnectionString"].ConnectionStri
ng;
static SqlConnection con = new SqlConnection(cons);
[WebMethod]
public DataTable Get()
{
SqlCommand getData = new SqlCommand();
getData.CommandText = "USP_DEV_ChangeLog_Select"; // Stored procedure for
retrieve data from suppliers table
getData.CommandType = CommandType.StoredProcedure;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
getData.Connection = con;
if (con.State != ConnectionState.Open)
con.Open();
DataTable sqlData = new DataTable();
SqlDataAdapter sqlAdapter = new SqlDataAdapter(getData);
sqlData.TableName = "Suppliers";
sqlAdapter.Fill(sqlData);
return sqlData;
}
}
```

In the above code snippet, we have created web services by using the ASP.NET web service and bound dataSource to Grid, in code behind GetDataSource method.

HTML

```
[WebMethod]
[ScriptMethod(ResponseFormat = ResponseFormat.Json)] // Return the JSON
formatted result
public static object GetDataSource()
{
CRUD_Service.WebService1 service = new CRUD_Service.WebService1();
var sqlData = service.Get();   // Get data from web services
DataResult result = new DataResult();
List<EditableCustomer> data = (from demand in sqlData.AsEnumerable() //
Perform skip take for on demand load paging
select new EditableCustomer
{
OrderID = demand.ItemArray[0].ToString(),
CustomerID = demand.ItemArray[1].ToString(),
EmployeeID = demand.ItemArray[5].ToString(),
Freight = demand.ItemArray[7].ToString(),
ShipCity = demand.ItemArray[8].ToString()
}).ToList();
con.Close();
return data;
}
```

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("WebService1.asmx/GetDataSource"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

ASP.NET Web service binding

Complex Data Sorting

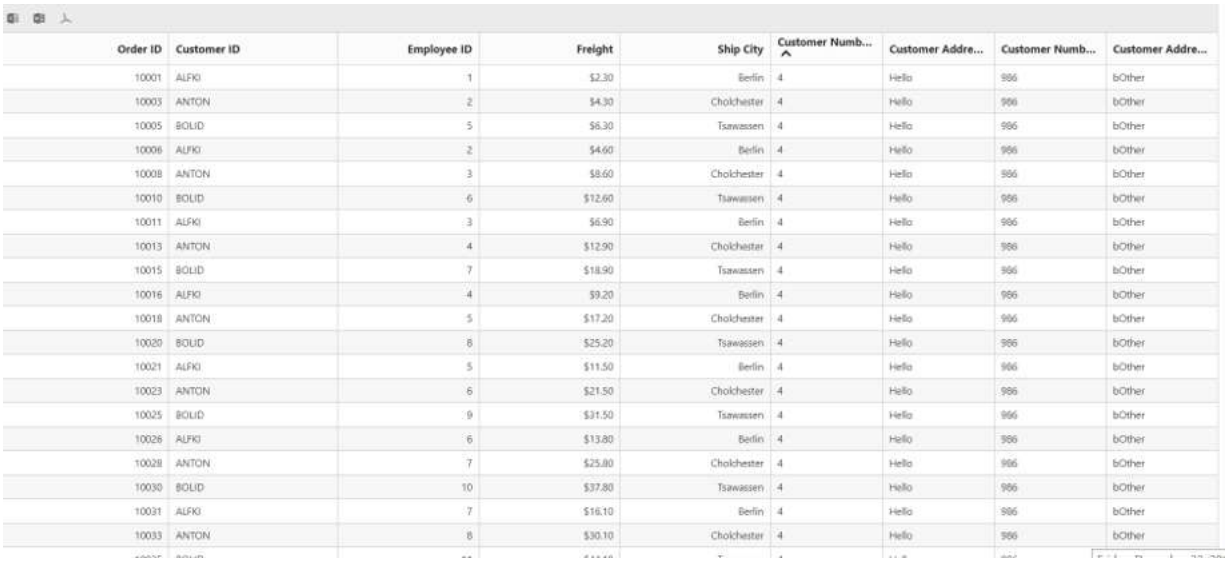
You can perform a data operation based on nested column data and bind to the data control. Here, if you want to perform the server side data operation for the nested dataSource like sorting, grouping, filtering, searching, take, or skip then we have to define the generic type of dataSource.

ASPX-CS

```
@(Html.EJ().Grid<object>("FlatGrid")
.Datasource(ds => ds.URL("GetData").Adaptor(AdaptorType.UrlAdaptor))
.ToolbarSettings(toolBar => toolBar.ShowToolbar().ToolbarItems(items =>
{
items.AddTool(ToolBarItems.ExcelExport);
items.AddTool(ToolBarItems.WordExport);
items.AddTool(ToolBarItems.PdfExport);
}))
.AllowSorting()
.AllowPaging()
.IsResponsive()
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(90).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(90).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship
City").TextAlign(TextAlign.Right).Width(80).Add();
for (int i = 0; i < 2; i++)
{
col.Field("customer." + i + ".CustomerNumber").HeaderText("Customer Number "
+ i).Width(60).Add();
col.Field("customer." + i + ".OtherAddress").HeaderText("Customer Address2 "
+ i).Width(60).Add();
}
})
)
```

C#

```
public ActionResult GetData(Syncfusion.JavaScript.DataManager dataManager)
{
BindDataSource();
IEnumerable<Orders> Data =order;
Syncfusion.JavaScript.DataSources.DataOperations operation = new
Syncfusion.JavaScript.DataSources.DataOperations();
if (dataManager.Sorted != null && dataManager.Sorted.Count > 0) //Sorting
{
Data = operation.PerformSorting(Data,dataManager.Sorted);
}
int count=Data.AsQueryable().Count();
return JSON(new { result = Data, count = count },
JsonRequestBehavior.AllowGet);
}
```



Order ID	Customer ID	Employee ID	Freight	Ship City	Customer Numb...	Customer Addre...	Customer Numb...	Customer Addre...

Data Adaptors

DataManger uses adaptors to process data. There are three types of adaptors in the DataManger. They are

- JSON Adaptor
- URL Adaptor
- OData Adaptor

Here, you can learn when and how each adaptor is used.

JSON Adaptor

JSONAdaptor is used to process JSON data. It contains methods to process the given JSON data based on the queries. The following code example illustrates on how to use the JSONAdaptor.

JSONAdaptor has the following unique in-built methods,

Properties	Parameters	Description

Copyright © 2001 - 2020 Syncfusion Inc.

<table>
<tr><td>processQuery(dataManagerObj, query)</td><td><table><tr><td>dataManagerObj</td><td>Object</td><td>ej.DataManager object</td></tr><tr><td>query</td><td>ej.Query</td><td>Sets the default query for the data source</td></tr></table></td><td>Used to prepare query string for the request data</td></tr>
<tr><td>processResponse(data, dataObj, query, xhr)</td><td><table><tr><td>data</td><td>Object</td><td>JSON data or JSON array</td></tr><tr><td>dataObj</td><td>Object</td><td>ej.DataManager object</td></tr><tr><td>query</td><td>ej.Query</td><td>Sets the default query for the data source</td></tr><tr><td>xhr</td><td>Object</td><td>XMLHTTPRequest object</td></tr></table></td><td>Used to precess the response which is return from the Data Source</td></tr>
<tr><td>insert(dataManagerObj, data)</td><td><table><tr><td>data</td><td>Object</td><td>JSON data or JSON array</td></tr><tr><td>dataManagerObj</td><td>Object</td><td>ej.DataManager object</td></tr></table></td><td>Inserts a data item in the data table.</td></tr>
<tr><td>remove(dataManagerObj, keyField, value, tableName)</td><td><table><tr><td>dataManagerObj</td><td>Object</td><td>ej.DataManager object</td></tr><tr><td>keyField</td><td>String</td><td>KeyColumn to find the data</td></tr><tr><td>String</td><td>Object</td><td>Specified value for the keyField</td></tr><tr><td>tableName</td><td>String</td><td>Name of the source table</td></tr></table></td><td>It is used to remove the data from the dataSource</td></tr>
<tr><td>update(dataManagerObj, keyField, value, tableName)</td><td><table><tr><td>dataManagerObj</td><td>Object</td><td>ej.DataManager object</td></tr><tr><td>keyField</td><td>String</td><td>KeyColumn to find the data</td></tr><tr><td>String</td><td>Object</td><td>Specified value for the keyField</td></tr><tr><td>tableName</td><td>String</td><td>Name of the source table</td></tr></table></td><td>Updates existing record and saves the changes to the table..</td></tr>
</table>

C#

```
public ActionResult GridFeatures()
{
var DataSource = new NorthwindDataContext().OrdersViews.ToList();
ViewBag.dataSource = DataSource;
return View();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
```

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").Json((IEnumerable<object>)ViewBag.dataSo
urce))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

The result of above code example is illustrated as follows.

Order ID	Customer ID	Employee ID	Ship City	Freight
10001	TOMSP	1	Münster	2.3
10002	HANAR	3	Rio de Janeiro	3.3
10003	VICTE	2	Lyon	4.3
10004	VINET	4	Reims	5.3
10005	SUPRD	5	Charleroi	6.3

JSON adaptor

URL Adaptor

URL Adaptor of the DataManager can be used when you are required to use remote service to retrieve data. It interacts with server-side for all DataManager Queries and CRUD operations. Now, in the following code example, the data is retrieved from the MVCController.

UrlAdaptor has the following unique in-built methods,

Properties	Parameters			Description
processQuery(dataManagerObj, query, hierarchyFilters)	dataManagerObj	Object	ej.DataManager object	Used to prepare query string for the request data
	query	ej.Query	Sets the default query for the data source	

<table>
<tr><td></td><td><table><tr><td>hierarchyFilters</td><td>ej.Query</td><td>The hierarchical query can be provided by using the hierarchical function.</td></tr></table></td><td></td></tr>
<tr><td>processResponse(data, dataObj, query, xhr, request, changes)</td><td><table><tr><td>data</td><td>Object</td><td>JSON data or JSON array of Result</td></tr><tr><td>dataObj</td><td>Object</td><td>ej.DataManager object</td></tr><tr><td>query</td><td>ej.Query</td><td>Sets the default query for the data source</td></tr><tr><td>xhr</td><td>Object</td><td>XMLHTTPRequest object</td></tr><tr><td>request</td><td>Object</td><td>request object to the Data Source</td></tr><tr><td>changes</td><td>Object</td><td>Specified changes to the Data Source</td></tr></table></td><td>Used to precess the response which is return from the Data Source</td></tr>
<tr><td>insert(dataManagerObj, data, tableName, query)</td><td><table><tr><td>data</td><td>Object</td><td>JSON data or JSON array</td></tr><tr><td>dataManagerObj</td><td>Object</td><td>ej.DataManager object</td></tr><tr><td>tableName</td><td>String</td><td>Name of the source table</td></tr><tr><td>query</td><td>ej.Query</td><td>Sets the default query for the data source</td></tr></table></td><td>Inserts a data item in the data table.</td></tr>
<tr><td>remove(dataManagerObj, keyField, value, tableName, query)</td><td><table><tr><td>dataManagerObj</td><td>Object</td><td>ej.DataManager object</td></tr><tr><td>keyField</td><td>String</td><td>KeyColumn to find the data</td></tr><tr><td>String</td><td>Object</td><td>Specified value for the keyField</td></tr><tr><td>tableName</td><td>String</td><td>Name of the source table</td></tr><tr><td>query</td><td>ej.Query</td><td>Sets the default query for the data source</td></tr></table></td><td>It is used to remove the data from the dataSource</td></tr>
<tr><td>update(dataManagerObj, keyField, value, tableName, query)</td><td><table><tr><td>dataManagerObj</td><td>Object</td><td>ej.DataManager object</td></tr></table></td><td>Updates existing record and saves the</td></tr>
</table>

Copyright © 2001 - 2020 Syncfusion Inc.

	keyField	String	KeyColumn to find the data	changes to the table..
	String	Object	Specified value for the keyField	
	tableName	String	Name of the source table	
	query	ej.Query	Sets the default query for the data source	

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("Home/DataSource").Adaptor(AdaptorTy
pe.UrlAdaptor))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

C#

```
public class HomeController : Controller
{
public ActionResult Index()
{
return View();
}
public ActionResult DataSource(Syncfusion.JavaScript.DataManager
dataManagerObj)
{
var DataSource = OrderRepository.GetAllRecords();
DataResult result = new DataResult();
result.result =
DataSource.Skip(dataManagerObj.Skip).Take(dataManagerObj.Take).ToList();
result.count = DataSource.Count();
return Json(result, JsonRequestBehavior.AllowGet);
}
public class DataResult
{
public IEnumerable<EditableOrder> result { get; set; }
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public int count { get; set; }
}
}
```

The result of the above code example is illustrated as follows.

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

URL Adaptor

OData Adaptor

OData Adaptor that is extended from URL Adaptor is used for consuming data through OData Service. You can use the following code example to use OData adaptor.

ODataAdaptor has the following unique in-built methods,

<table>
<tr><th>Properties</th><th colspan="3">Parameters</th><th>Description</th></tr>
<tr><td rowspan="5">processResponse(data, dataObj, query, xhr, request, changes)</td><td>data</td><td>Object</td><td>JSON data or JSON array</td><td rowspan="5">Used to precess the response which is return from the Data Source</td></tr>
<tr><td>dataObj</td><td>Object</td><td>ej.DataManager object</td></tr>
<tr><td>query</td><td>ej.Query</td><td>Sets the default query for the data source</td></tr>
<tr><td>xhr</td><td>Object</td><td>XMLHTTPRequest object</td></tr>
<tr><td>request</td><td>Object</td><td>request object to the Data Source</td></tr>
<tr><td>changes</td><td>Object</td><td>Specified changes to the Data Source</td></tr>
<tr><td rowspan="3">insert(dataManagerObj, data, tableName)</td><td>data</td><td>Object</td><td>JSON data or JSON array</td><td rowspan="3">Inserts a data item in the data table.</td></tr>
<tr><td>dataManagerObj</td><td>Object</td><td>ej.DataManager object</td></tr>
<tr><td>tableName</td><td>String</td><td>Name of the source table</td></tr>
</table>

OData adaptor

WebAPI Adaptor

WebAPIAdaptor extended from the UrlAdaptor of the DataManager is used for retrieving data from WebAPI service. Refer to the following code example.

WebApiAdaptor has the following unique in-built methods,

Properties	Parameters			Description
processResponse(data, dataObj, query, xhr, request, changes)	data	Object	JSON data or JSON array	Used to precess the response which is return from the Data Source
	dataObj	Object	ej.DataManager object	
	query	ej.Query	Sets the default query for the data source	
	xhr	Object	XMLHTTPRequest object	
	request	Object	request object to the Data Source	
	changes	Object	Specified changes to the Data Source	
insert(dataManagerObj, data, tableName)	data	Object	JSON data or JSON array	Inserts a data item in the data table.
	dataManagerObj	Object	ej.DataManager object	
	tableName	String	Name of the source table	
remove(dataManagerObj, keyField, value, tableName)	dataManagerObj	Object	ej.DataManager object	It is used to remove the data from the dataSource
	keyField	String	KeyColumn to find the data	

Copyright © 2001 - 2020 Syncfusion Inc.

	String	Object	Specified value for the keyField	
	tableName	String	Name of the source table	
update(dataManagerObj, keyField, value, tableName)	dataManagerObj	Object	ej.DataManager object	Updates existing record and saves the changes to the table..
	keyField	String	KeyColumn to find the data	
	String	Object	Specified value for the keyField	
	tableName	String	Name of the source table	

C#

```
public class EmployeeController : ApiController
{
static readonly IEmployeeRepository repository = new EmployeeRepository();
// GET API/<controller>
[HttpGet]
public object Get()
{
var data = repository.GetAll().ToList();
return new { Items = data, Count = data.Count() };
}
}
```

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("/api/Employee").Adaptor(AdaptorType
.WebApiAdaptor))
@(Html.EJ().Grid<Sample.Models.Employee>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['EmployeeID', 'FirstName', 'LastName'])")
.Columns(col =>
{
col.Field("EmployeeID").HeaderText("EmployeeID").IsPrimaryKey(true).Width(75
).Add();
col.Field("FirstName").HeaderText("FirstName").Width(80).Add();
col.Field("LastName").HeaderText("LastName").Add();
})
)
```

Result of the above code example is illustrated as follows.

Employee	FirstName	LastName
1	Nancy	Davolio
2	Andrew	Fuller
3	Janet	Leverling
4	Margaret	Peacock
5	Steven	Buchanan
6	ANGEL	Reims

Insert

Web API Adaptor

RemoteSave Adaptor

RemoteSaveAdaptor extended from the JsonAdaptor of theDataManager is used for binding local data and performs all DataManager queries in client-side. It interacts with server-side only for CRUD operations to pass the modified records. Refer to the following code example.

RemoteSaveAdaptor has the following unique in-built methods,

Properties	Parameters			Description
insert(dataManagerObj, data, tableName, query)	data	Object	JSON data or JSON array	Inserts a data item in the data table.
	dataManagerObj	Object	ej.DataManager object	
	tableName	String	Name of the source table	
	query	ej.Query	Sets the default query for the data source	
remove(dataManagerObj, keyField, value, tableName, query)	dataManagerObj	Object	ej.DataManager object	It is used to remove the data from the dataSource
	keyField	String	KeyColumn to find the data	
	String	Object	Specified value for the keyField	
	tableName	String	Name of the source table	

Copyright © 2001 - 2020 Syncfusion Inc.

	query	ej.Query	Sets the default query for the data source	
update(dataManagerObj, keyField, value, tableName, query)	dataManagerObj	Object	ej.DataManager object	Updates existing record and saves the changes to the table..
	keyField	String	KeyColumn to find the data	
	String	Object	Specified value for the keyField	
	tableName	String	Name of the source table	
	query	ej.Query	Sets the default query for the data source	

RAZOR

```
@(Html.EJ().Grid<object>("FlatGrid")
.Datasource(dataSource =>
dataSource.Json((IEnumerable<object>)ViewBag.datasource).UpdateURL("/Home/Update")
.InsertURL("/Home/Insert").RemoveURL("/Home/Remove").Adaptor(AdaptorType.RemoteSaveAdaptor))
.AllowPaging()
.EditSettings(edit => { edit.AllowAdding().AllowDeleting().AllowEditing();
})
.ToolbarSettings(toolbar =>
{
toolbar.ShowToolbar().ToolbarItems(items =>
{
items.AddTool(ToolBarItems.Add);
items.AddTool(ToolBarItems.Edit);
items.AddTool(ToolBarItems.Delete);
items.AddTool(ToolBarItems.Update);
items.AddTool(ToolBarItems.Cancel);
});
})
.Columns(col =>
{
col.Field("OrderID").IsPrimaryKey(true).Add();
col.Field("EmployeeID").Add();
col.Field("CustomerID").Add();
col.Field("ShipCountry").Add();
col.Field("Freight").Add();
})
)
```

C#

```
namespace EJGrid.Controllers
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
public class HomeController : Controller
{
public ActionResult Index()
{
var data = OrderRepository.GetAllRecords();
ViewBag.dataSource = data;
return View();
}
public ActionResult Update(EditableOrder value)
{
OrderRepository.Update(value);
var data = OrderRepository.GetAllRecords();
return Json(data, JsonRequestBehavior.AllowGet);
}
public ActionResult Insert(EditableOrder value)
{
OrderRepository.Add(value);
var data = OrderRepository.GetAllRecords();
return Json(data, JsonRequestBehavior.AllowGet);
}
public ActionResult Remove(int key)
{
OrderRepository.Delete(key);
var data = OrderRepository.GetAllRecords();
return Json(data, JsonRequestBehavior.AllowGet);
}
}
}
```

Result of the above code example is illustrated as follows.

RemoteSave Adaptor

Custom Adaptor

Custom Adaptor is a key technique to customize adaptors in the DataManager. It is useful to write own adaptor. Normally ej.Adaptor is base class for all adaptors. Therefore, first inherit the ej.Adaptor to develop the customized one and then override functionality in Custom Adaptor with base class. The following code example illustrates you how to create the Custom Adaptor.

HTML

```
@(Html.EJ().DataManager("FlatData"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
<script type="text/javascript">
$(function () {// Document is ready.
//new custom adaptor implementation
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//able to implement more option in custom adaptor other than insert
var customAdaptor = new ej.Adaptor().extend({
insert: function (dataManagerObj, data) {
return dataManagerObj.dataSource.json.push(data);
},
processQuery: ej.JsonAdaptor.prototype.processQuery // reused process query
from json adaptor
});
window.FlatData.Adaptor = new customAdaptor()
window.FlatData.insert({ OrderID: 10240, CustomerID: "HANAR", EmployeeID: 3,
ShipCity: "Reims", Freight: "23.4" });
window.FlatData.insert({ OrderID: 10241, CustomerID: "HANAR", EmployeeID: 2,
ShipCity: "Reims", Freight: "21.4" });
window.FlatData.insert({ OrderID: 10242, CustomerID: "VINET", EmployeeID: 5,
ShipCity: "Lyon", Freight: "13.4" });
var obj = $("#FlatGrid").ejGrid("instance");
obj.dataSource(window.FlatData.executeLocal(new ej.Query().take(7)));
})
</script>
```

Result of above code example is as follows.

Order ID	Customer ID	Employee ID	Ship City	Freight
10240	HANAR	3	Reims	23.4
10241	HANAR	2	Reimse	21.4
10242	VINET	5	Lyon	13.4

Custom adaptor

Using Custom Adaptor, you can override the existing method of Extended Adaptor,

Properties	Description
beforeSend	Custom headers can be set using pre-request callback beforeSend, by using the setRequestHeader method can be used to modify the XMLHTTPRequest
processQuery	Used to prepare query string for the request data
processResponse	Used to precess the response which is return from the Data Source
insert	The insert method of the data manager is used to add a new record to the table
remove	The remove action submits the data items that should be deleted
update	The update method is used to update the modified changes made to a record in the data source of the DataManager.

Cache Adaptor

Cache Adaptor is used to cache the data of the visited pages. It prevents new requests for the previously visited pages. It can be enabled by using the EnableCaching property. You can configure cache page

Copyright © 2001 - 2020 Syncfusion Inc.

size and duration of caching by using CachingPageSize and TimeTillExpiration properties of the "DataManager".

CacheAdaptor has the following unique in-built methods,

Properties	Parameters			Description
processQuery(dataManagerObj, query, hierarchyFilters)	dataManagerObj	Object	ej.DataManager object	Used to prepare query string for the request data
	query	ej.Query	Sets the default query for the data source	
	hierarchyFilters	ej.Query	The hierarchical query can be provided by using the hierarchical function.	
processResponse(data, dataObj, query, xhr, request, changes)	data	Object	JSON data or JSON array	Used to precess the response which is return from the Data Source
	dataObj	Object	ej.DataManager object	
	query	ej.Query	Sets the default query for the data source	
	xhr	Object	XMLHTTPRequest object	
	request	Object	Sets the default query for the data source	
	changes	Object	XMLHTTPRequest object	
insert(dataManagerObj, data, tableName)	data	Object	JSON data or JSON array	Inserts a data item in the data table.
	dataManagerObj	Object	ej.DataManager object	
	tableName	String	Name of the source table	
remove(dataManagerObj, keyField, value, tableName)	dataManagerObj	Object	ej.DataManager object	It is used to remove the data from the dataSource
	keyField	String	KeyColumn to find the data	
	String	Object	Specified value for the keyField	
	tableName	String	Name of the source table	

Copyright © 2001 - 2020 Syncfusion Inc.

<table>
<tr>
<td>update(dataManagerObj, keyField, value, tableName)</td>
<td>
<table>
<tr><td>dataManagerObj</td><td>Object</td><td>ej.DataManager object</td></tr>
<tr><td>keyField</td><td>String</td><td>KeyColumn to find the data</td></tr>
<tr><td>String</td><td>Object</td><td>Specified value for the keyField</td></tr>
<tr><td>tableName</td><td>String</td><td>Name of the source table</td></tr>
</table>
</td>
<td>Updates existing record and saves the changes to the table..</td>
</tr>
</table>

ASPX-CS

```
@(Html.EJ().Grid<OrdersView>("Grid")
.Datasource(dataSource => dataSource.URL(@Url.Action("DataSource"))
.EnableCaching()
.CachingPageSize(4)
.TimeTillExpiration(120000)
.Adaptor(AdaptorType.UrlAdaptor))
.AllowPaging()
.Columns(col =>
{
col.Field(p => p.OrderID).HeaderText("Order ID").Add();
col.Field(p => p.CustomerID).HeaderText("Customer
ID").TextAlign(TextAlign.Left).Add();
col.Field(p => p.EmployeeID).HeaderText("Employee ID").Add();
col.Field(p => p.Freight).HeaderText("Freight").Format("{0:C2}").Add();
})
)
```

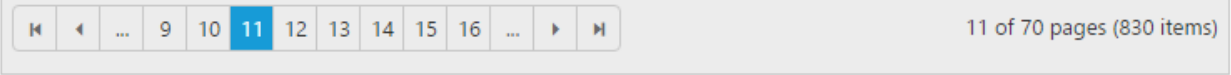
C#

```
//Refer the Syncfusion DataSource assembly
using Syncfusion.JavaScript;
using Syncfusion.JavaScript.DataSources;
public IEnumerable OrderData = new
NorthwindDataContext().OrdersViews.ToList();
public ActionResult GridFeatures()
{
return View();
}
public ActionResult DataSource(DataManager dataManagerObj)
{
IEnumerable data = OrderData;
DataOperations operation = new DataOperations();
if (dataManagerObj.Sorted != null && dataManagerObj.Sorted.Count > 0)
//Sorting
{
data= operation.PerformSorting(data, dataManagerObj.Sorted);
}
if (dataManagerObj.Where != null && dataManagerObj.Where.Count > 0)
//Filtering
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
data= operation.PerformWhereFilter(data, dataManagerObj.Where,
dataManagerObj.Where[0].Operator);
}
int count = data.Cast<OrdersView>().Count();
if (dataManagerObj.Skip != 0)
{
data= operation.PerformSkip(data, dataManagerObj.Skip);
}
if (dataManagerObj.Take != 0)
{
data= operation.PerformTake(data, dataManagerObj.Take);
}
return Json(new { result = data, count = count });
}
}
```

Order ID	Customer ID	Employee ID	Freight
10746	CHOPS	1	$31.43
10731	CHOPS	7	$96.65
10966	CHOPS	4	$27.19
11029	CHOPS	4	$47.84
11041	CHOPS	3	$48.22
11042	COMMI	2	$29.99
10969	COMMI	1	$0.21
10466	COMMI	4	$11.93
10494	COMMI	4	$65.99
10290	COMMI	8	$79.70
10435	CONSH	8	$9.21
10462	CONSH	2	$6.17



Cache Adaptor

Cache Adaptor has the following unique properties,

Properties	Description
TimeTillExpiration	Specifies the duration of cached pages in milliseconds
CachingPageSize	A number of pages to be cached

Query

DataManager provides support for multiple queries in order to perform various operations like filtering, sorting, cloning, expanding, searching, grouping etc., in the data source. Here, you can learn the query options in detail.

Select

The select query of the DataManager is used to select only some particular fields or columns from the data source. The following code example illustrates on how to select only particular fields by using the select query.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID', 'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

Result of using “select”

From

The from query of the DataManager is used to select the table from where the data is retrieved and bound to the table. The following code example illustrates how to use the from query.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Query("new ej.Query().from('Orders').select(['OrderID', 'CustomerID',
'EmployeeID', 'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

Result of using “from”

Clone

The clone query of the DataManager is used to duplicate the query. The following code example illustrates how to clone a query.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().from('Orders').select(['OrderID', 'CustomerID',
'EmployeeID', 'ShipCity', 'Freight']).take(15)")
.ClientSideEvents(e => e.ActionComplete("onComplete"))
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
<script type="text/javascript" class="jsScript">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
var flag = true;
function OnComplete() {
if (flag) {
flag = false;
var query = ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)
var query1 = query.clone();
var proxy = $("#FlatGrid").ejGrid("instance");
var dataManagerObj = window.FlatData.executeQuery(query1).done(function (e1)
{
proxy.dataSource(e1.result);
})
}
}
</script>
```

Result of the above code example is illustrated as follows.

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

Result of using “clone”

Expand

The expand query of the DataManager is used to perform complex data binding.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().from('Orders').select(['OrderID', 'CustomerID',
'EmployeeID', 'ShipCity', 'Freight']).take(5).expand('Employee')")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("Employee.FirstName").HeaderText("Employee
Name").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.

Order ID	Customer ID	Emp Name	Ship City	Freight
10248	VINET	Nancy	STOCKHOLM	6.0000
10249	TOMSP	Michael	MOSCOW	18.0000
10250	HANAR	Anne	OTTAWA	8.0000
10251	VICTE	Janet	KIEV	43.0000
10252	SUPRD	Margaret	COPENHAGEN	28.0000

Result of using “expand”

Sorting

Default

Sorting is basic query in the DataManager. It enables you to view the items or records in ascending or descending order based on a particular field and sorting direction. The query parameter of the DataManager enables you to retrieve the data in the sorted fashion and thus utilizing the resultant data obtained.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().sortBy('CustomerID', ej.sortOrder.Ascending, false).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10643	ALFKI	6	Berlin	29.4600
10692	ALFKI	4	Berlin	61.0200
10702	ALFKI	4	Berlin	23.9400
10835	ALFKI	1	Berlin	69.5300
10952	ALFKI	1	Berlin	40.4200

Sorting

Copyright © 2001 - 2020 Syncfusion Inc.

SortByDesc

The sortByDesc query of the DataManager is used to sort the specified field in descending order, by default. You can use the following code example for sortByDesc query.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().sortByDesc('EmployeeID').take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10250	HANAR	9	OTTAWA	8.0000
10255	RICSU	9	MOSCOW	148.0000
10263	ERNSH	9	Graz	146.0600
10324	SAVEA	9	Boise	214.2700
10331	BONAP	9	Marseille	10.1900

Sort in descending order

Dynamic sorting

The table can be dynamically sorted by using an external button click event. The value of the column to be sorted can be obtained by the sortBy query and thus the sorted data is retrieved and bounded to the table. The following code example illustrates you to dynamically sort the data source.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().sortByDesc('EmployeeID').take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
<input id="field" type="text" placeholder="fieldName" />
@Html.EJ().Button("submit").Text("Sort").ClientSideEvents(e => {
e.Click("onClick"); })
<script type="text/javascript" class="jsScript">
function onClick(e) {
var field = $("#field").val();
var obj = $("#FlatGrid").ejGrid("instance")
var query = ej.Query().sortByDesc(field).take(5)
var dataManagerObj = window.FlatData.executeQuery(query).done(function (e1)
{
obj.dataSource(e1.result);
})
}
</script>
```

Result of above code example is illustrated as follows.

Dynamic sorting

Multi sorting

Multi sorting is a special technique, where you can sort multiple fields by adding multiple sorting queries to the DataManager.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().sortByDesc('CustomerID').sortBy('EmployeeID',
'ascending').take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
```

```
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10258	ERNSH	1	Graz	140.5100
10270	WARTH	1	Oulu	136.5400
10275	MAGAA	1	Bergamo	26.9300
10285	QUICK	1	Cunewalde	76.8[illegible]0

Multi sorting

Searching

Searching is a basic query technique in the Data Manager. It is used to filter the records from the entire data source based on the search key parameter.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().search(4, 'EmployeeID').take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of above code example is illustrated as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10004	VINET	4	Reims	5.3
10007	HANAR	4	Rio de Janeiro	6.6
10013	VICTE	4	Lyon	12.899999999999
10016	TOMSP	4	Münster	9.2

Searching

Filtering

Filtering is a basic technique in the DataManager query. The where query is used to filter some particular or related records from the data source to review details of records.

Filter Operators

Filter operators are generally used to specify the filter type. The various filter operators corresponding to the type of the column are listed in the following table.

Filter Operators

Column type	Filter operators
Number	ej.FilterOperators.greaterThan ej.FilterOperators.greaterThanOrEqual ej.FilterOperators.lessThan ej.FilterOperators.lessThanOrEqual ej.FilterOperators.equal
String	ej.FilterOperators.startsWith ej.FilterOperators.endsWith ej.FilterOperators.contains ej.FilterOperators.equal ej.FilterOperators.notEqual
Boolean	ej.FilterOperators.equal ej.FilterOperators.notEqual
Date	ej.FilterOperators.greaterThan ej.FilterOperators.greaterThanOrEqual ej.FilterOperators.lessThan ej.FilterOperators.lessThanOrEqual ej.FilterOperators.equal

lessThan

This operator is used to get the records with values lesser than the filter value.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Query("new ej.Query().where('OrderID', 'lessThan', 10252, false)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000

Filter using “lessThan” operator

greaterThan

This operator is used to get the records with values greater than that of the filter value.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().where('OrderID', 'greaterThan', 10252,
false).take(5)")
.Columns(col =>        {
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10253	HANAR	3	Juneau	35.0000
10254	CHOPS	5	STOCKHOLM	28.0000
10255	RICSU	9	MOSCOW	148.0000

10257	HILAA	4	San Cristóbal	81.9100

Filter using “greaterThan” operator

lessThanOrEqual

This operator is used to get the records with values lesser than or equal to the filter value.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().where('OrderID', 'lessThanOrEqual', 10252, false)")
.Columns(col =>        {
col.Field("OrderID").HeaderText("Order ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

Filter using “lessThanOrEqual” operator

greaterThanOrEqual

This operator is used to get the records with values greater than or equal to the filter value.

Lambda Operators

all

The ALL operator returns true if all the sub query values meet the condition. This operator used to fetch the records of the fields match with the given value's fields.

HTML

```
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCountry").HeaderText("Ship Country").Width(110).Add();
})
)
```

JAVASCRIPT

```
setTimeout(function () {
var gridData = [{ OrderID: 10248, CustomerID: "VINET", EmployeeID: 5,
OrderDate: new Date(8364186e5), ShipName: "Vins et alcools Chevalier",
ShipCity: "Reims", ShipAddress: "59 rue de l'Abbaye", ShipRegion: null,
ShipPostalCode: "51100", ShipCountry: "France", Freight: 32.38, Verified: !0
}];
var data = [{ OrderID: 10248, CustomerID: "VINET", EmployeeID: 5, OrderDate:
new Date(8364186e5), ShipName: "Vins et alcools Chevalier", ShipCity:

ShipPostalCode: "51100", ShipCountry: "France", Freight: 32.38, Verified: !0
}];
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
var dataManager = ej.DataManager(gridData);
var dataSource = ej.DataManager(data);
var result = ej.Query().select("ShipCountry")
var ShipCountry = dataSource.executeLocal(result);
var query = ej.Query()
.where("ShipCountry", "equal all", ShipCountry, false).select("OrderID",
"CustomerID", "EmployeeID", "Freight", "ShipCountry");
var execute = dataManager.executeLocal(query); // executing query
var obj = $("#FlatGrid").ejGrid("instance");
obj.dataSource(execute);
}, 1000);
```

Order ID	Customer ID	Employee ID	Freight	Ship Country
10248	VINET	5	32.38	France

any

The ANY operator returns true if any of the sub query values meet the condition. The returned data match with any one of the field in existing table.

HTML

```
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCountry").HeaderText("Ship Country").Width(110).Add();
})
)
```

JAVASCRIPT

```
setTimeout(function () {
var gridData = window.gridData;
var data = [{ OrderID: 10343, CustomerID: "LEHMS", EmployeeID: 4, OrderDate:
new Date(8467002e5), ShipName: "Lehmanns Marktstand", ShipCity: "Frankfurt
a.M.", ShipAddress: "Magazinweg 7", ShipRegion: null, ShipPostalCode:
"60528", ShipCountry: "Germany", Freight: 110.37, Verified: !0 }, { OrderID:
10344, CustomerID: "WHITC", EmployeeID: 4, OrderDate: new Date(8467866e5),
ShipName: "White Clover Markets", ShipCity: "Seattle", ShipAddress: "1029 -
12th Ave. S.", ShipRegion: "WA", ShipPostalCode: "98124", ShipCountry:
"USA", Freight: 23.29, Verified: !1 }];
var dataManager = ej.DataManager(gridData);
var dataSource = ej.DataManager(data);
var result = ej.Query().select("ShipCountry")
var ShipCountry = dataSource.executeLocal(result);
var query = ej.Query()
.where("ShipCountry", "equal any", ShipCountry, false).select("OrderID",
"CustomerID", "EmployeeID", "Freight", "ShipCountry");
```

Grouping

Grouping technique is also supported in the DataManager. When you want to analyze any particular record based on its category, simply you can group that column and analyze the records based on category. The following code example illustrates the grouping behavior in table.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().page(1,5).group('CustomerID')")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Result of the above code example is illustrated as follows.

Grouping

CRUD Data Operations

The DataManager fully supports the CRUD (Create, Read, Update, Destroy) data operations. However, it must be combined with some user interface or another Syncfusion UI widget such as the Grid, ListView, etc.

Local CRUD Operations

The information in this section is applicable to scenarios, in which the data is already available on the client, or when it is you that is going to take care of its retrieval and submission. In other words, DataManager will not make any HTTP requests on its own.

Insert

The insert method of the data manager is used to add a new record to the table. The JSON data passed as a parameter to the insert method that is inserted to the data source of the data manager.

C#

```
public static List<Employee> employee = new List<Employee>();
public ActionResult Insert()
{
BindDataSource();
ViewBag.data = order;
return View();
}
public void BindDataSource()
{
int code = 10000;
order.Add(new OrderDetails(code + 1, "ALFKI", 1 + 0, 2.3 * 1, "Berlin"));
order.Add(new OrderDetails(code + 2, "ANATR", 1 + 2, 3.3 * 1, "Madrid"));
order.Add(new OrderDetails(code + 3, "ANTON", 1 + 1, 4.3 * 1,
"Cholchester"));
order.Add(new OrderDetails(code + 4, "BLONP", 1 + 3, 5.3 * 1, "Marseille"));
order.Add(new OrderDetails(code + 5, "BOLID", 1 + 4, 6.3 * 1, "Tsawassen"));
}
public class OrderDetails
{
public OrderDetails()
{
```

```
}
public OrderDetails(int OrderID, string CustomerId, int EmployeeId, double
Freight, string ShipCity)
{
this.OrderID = OrderID;
this.CustomerID = CustomerId;
this.EmployeeID = EmployeeId;
this.Freight = Freight;
this.ShipCity = ShipCity;
}
public int? OrderID { get; set; }
public string CustomerID { get; set; }
public int? EmployeeID { get; set; }
public double? Freight { get; set; }
public string ShipCity { get; set; }
}
```

C#

```
@(Html.EJ().DataManager("FlatData").Json((IEnumerable<object>)ViewBag.data).
Adaptor(AdaptorType.JsonAdaptor))
@Html.EJ().Button("submit").Text("Insert").ClientSideEvents(e => {
e.Click("onClick"); })
@(Html.EJ().Grid<object>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight'])")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
<script type="text/javascript" class="jsScript">
function onClick(e) {
var record = { OrderID: 10253, CustomerID: "ANGEL", EmployeeID: 4, ShipCity:
"Reims", Freight:23.1 };
window.FlatData.insert(record)
var obj = $("#FlatGrid").ejGrid("instance");
obj.dataSource(window.FlatData.executeLocal(ej.Query().sortByDesc("OrderID")
));
}
</script>
```

Insert

Update

The update method is used to update the modified changes made to a record in the data source of the DataManager.

C#

```
public static List<Employee> employee = new List<Employee>();
public ActionResult Update()
{
BindDataSource();
ViewBag.data = order;
return View();
}
public void BindDataSource()
{
int code = 10000;
order.Add(new OrderDetails(code + 1, "ALFKI", 1 + 0, 2.3 * 1, "Berlin"));
order.Add(new OrderDetails(code + 2, "ANATR", 1 + 2, 3.3 * 1, "Madrid"));
order.Add(new OrderDetails(code + 3, "ANTON", 1 + 1, 4.3 * 1,
"Cholchester"));
order.Add(new OrderDetails(code + 4, "BLONP", 1 + 3, 5.3 * 1, "Marseille"));
order.Add(new OrderDetails(code + 5, "BOLID", 1 + 4, 6.3 * 1, "Tsawassen"));
}
public class OrderDetails
{
public OrderDetails()
{
}
public OrderDetails(int OrderID, string CustomerId, int EmployeeId, double
Freight, string ShipCity)
{
this.OrderID = OrderID;
this.CustomerID = CustomerId;
this.EmployeeID = EmployeeId;
this.Freight = Freight;
this.ShipCity = ShipCity;
}
public int? OrderID { get; set; }
```

Remove

The remove function receives the items to be deleted in the Data Table. The function should remove the provided items from the data source of the DataManager.

C#

```
public static List<Employee> employee = new List<Employee>();
public ActionResult Remove()
{
BindDataSource();
ViewBag.data = order;
return View();
}
public void BindDataSource()
{
int code = 10000;
order.Add(new OrderDetails(code + 1, "ALFKI", 1 + 0, 2.3 * 1, "Berlin"));
order.Add(new OrderDetails(code + 2, "ANATR", 1 + 2, 3.3 * 1, "Madrid"));
order.Add(new OrderDetails(code + 3, "ANTON", 1 + 1, 4.3 * 1,
"Cholchester"));
order.Add(new OrderDetails(code + 4, "BLONP", 1 + 3, 5.3 * 1, "Marseille"));
order.Add(new OrderDetails(code + 5, "BOLID", 1 + 4, 6.3 * 1, "Tsawassen"));
}
public class OrderDetails
{
public OrderDetails()
{
}
public OrderDetails(int OrderID, string CustomerId, int EmployeeId, double
Freight, string ShipCity)
{
this.OrderID = OrderID;
this.CustomerID = CustomerId;
this.EmployeeID = EmployeeId;
this.Freight = Freight;
this.ShipCity = ShipCity;
}
public int? OrderID { get; set; }
public string CustomerID { get; set; }
public int? EmployeeID { get; set; }
public double? Freight { get; set; }
public string ShipCity { get; set; }
}
```

C#

```
@(Html.EJ().DataManager("FlatData").Json((IEnumerable<object>)ViewBag.data).
Adaptor(AdaptorType.JsonAdaptor))

Remove

Remote CRUD Operations

The information in this section is applicable to scenarios, in which the data should be retrieved from and submitted to a remote data service via HTTP requests made by the DataManager.

CRUD operations with remote data rely on server code to perform the read, update, create and destroy actions. Instead of configuring client functions, the DataManager defines remote service URLs and the expected format in which data should be sent and received. Theoretically, it is possible to use remote CRUD operations with transport functions, similar to the above examples that use local data, but this is rarely required.

Each of the CRUD operation settings—read, update, create, destroy—provides some common settings that need to be set accordingly:

- The client request type can be "get" or "post".
- Additional optional headers parameters can be sent to the server if needed.
- The client request and expected server response dataType can be "json", "jsonp", "odata", etc.

Copyright © 2001 - 2020 Syncfusion Inc.

Insert

The insert method of the data manager is used to add a new record to the table. The JSON data passed as a parameter to the insert method that is inserted to the data source of the data manager.

C#

```
//Employee Model class
public class Employee
{
public int EmployeeID { get; set; }
public string FirstName { get; set; }
public string LastName { get; set; }
public Employee()
{
}
public Employee(int id, string LN, string FN)
{
this.EmployeeID = id;
this.LastName = LN;
this.FirstName = FN;
}
}
//Employee Repository interface
interface IEmployeeRepository
{
IEnumerable<Employee> GetAll();
Employee Get(int EmployeeID);
Employee Add(Employee employee);
void Remove(int EmployeeID);
bool Update(Employee employee);
}
//EmployeeRepository class
public class EmployeeRepository : IEmployeeRepository
{
private List<Employee> employee = new List<Employee>();
public EmployeeRepository()
{
employee.Add(new Employee(1, "Davolio", "Nancy"));
employee.Add(new Employee(2, "Fuller", "Andrew"));
employee.Add(new Employee(3, "Leverling", "Janet"));
employee.Add(new Employee(4, "Peacock", "Margaret"));
employee.Add(new Employee(5, "Buchanan", "Steven"));
}
public IEnumerable<Employee> GetAll()
{
return employee;
}
public Employee Get(int id)
{
return employee.Find(p => p.EmployeeID == id);
}
public Employee Add(Employee eObj)
{
if (eObj == null)
{
throw new ArgumentNullException("eObj");
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
employee.Add(eObj);
return eObj;
}
public void Remove(int id)
{
employee.RemoveAll(p => p.EmployeeID == id);

3	Janet	Leverling
4	Margaret	Peacock
5	Steven	Buchanan
6	ANGEL	Reims

Insert

Update

The update method is used to update the modified changes made to a record in the data source of the DataManager.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("/api/Employee").Adaptor(AdaptorType
.WebApiAdaptor))
@(Html.EJ().Grid<Sample.Models.Employee>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['EmployeeID', 'FirstName', 'LastName'])")
.Columns(col =>
{
col.Field("EmployeeID").HeaderText("EmployeeID").IsPrimaryKey(true).Width(75
).Add();
col.Field("FirstName").HeaderText("FirstName").Width(80).Add();
col.Field("LastName").HeaderText("LastName").Add();
})
)
@Html.EJ().Button("submit").Text("Update").ClientSideEvents(e => {
e.Click("onClick"); })
<script type="text/javascript" class="jsScript">
function onClick(e) {
var record = { EmployeeID: 1, FirstName: "Nancy", LastName: "Kamal" };
window.FlatData.update("ItemID", record);
setTimeout(function () {
var query = ej.Query();
var dataSource = window.FlatData.executeQuery(query).done(function (args) {
var obj = $("#FlatGrid").ejGrid("instance");
obj.dataSource(args.result);
// renderTable(args.result);
}).fail(function (args) {
//error handling
});
}, 2000);
}
</script>
```

Employee	FirstName	LastName
2	Andrew	Fuller
3	Janet	Leverling
4	Margaret	Peacock
5	Steven	Buchanan
6	ANGEL	Reims
1	Nancy	Kamal

Update

Remove

The remove action submits the data items that should be deleted, or just its IDs.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("/api/Employee").Adaptor(AdaptorType
.WebApiAdaptor))
@(Html.EJ().Grid<Sample.Models.Employee>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['EmployeeID', 'FirstName', 'LastName'])")
.Columns(col =>
{
col.Field("EmployeeID").HeaderText("EmployeeID").IsPrimaryKey(true).Width(75
).Add();
col.Field("FirstName").HeaderText("FirstName").Width(80).Add();
col.Field("LastName").HeaderText("LastName").Add();
})
)
@Html.EJ().Button("submit").Text("Remove").ClientSideEvents(e => {
e.Click("onClick"); })
<script type="text/javascript" class="jsScript">
function onClick(e) {
window.FlatData.remove("EmployeeID", 2);
setTimeout(function () {
var query = ej.Query();
var dataSource = window.FlatData.executeQuery(query).done(function (args) {
var obj = $("#FlatGrid").ejGrid("instance");
obj.dataSource(args.result);
// renderTable(args.result);
}).fail(function (args) {
//error handling
});
}, 2000);

Remove

Batch Edit

Batch Editing is a unique feature, where requests to add, remove and change are handled altogether at a time rather than passing the request separately for each operation.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").Adaptor(AdaptorType.JsonAdaptor))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("ej.Query().take(5)")
.Columns(col =>
{
col.Field("EmployeeID").HeaderText("EmployeeID").IsPrimaryKey(true).TextAlig
n(TextAlign.Right).Width(75).Add();
col.Field("FirstName").HeaderText("FirstName").Width(80).Add();
col.Field("LastName").HeaderText("LastName").TextAlign(TextAlign.Right).Widt
h(75).Add();
})
)
```

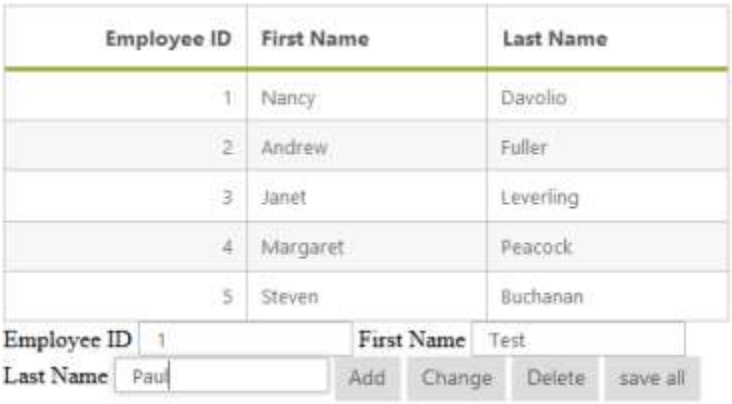
ASPX-CS

```
Employee ID
<input id="EmployeeID" class="e-ejinputtext" type="text" value="" />
First Name
<input id="FirstName" class="e-ejinputtext" type="text" value="" />
Last Name
<input id="LastName" class="e-ejinputtext" type="text" value="" />
@Html.EJ().Button("submit").Text("Add").ClientSideEvents(e => {
e.Click("onClick"); })
@Html.EJ().Button("submit").Text("Change").ClientSideEvents(e => {
e.Click("onClick"); })
@Html.EJ().Button("submit").Text("Delete").ClientSideEvents(e => {
e.Click("onClick"); })
@Html.EJ().Button("submit").Text("Save All").ClientSideEvents(e => {
e.Click("onClick"); })
<script type="text/javascript" class="jsScript">
window.changes = { changed: [], added: [], deleted: [] };
function Click(args) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
if (document.activeElement.value == "Change") {
data = window.FlatData.executeLocal(ej.Query().where("EmployeeID",
ej.FilterOperators.equal, parseInt($("#EmployeeID").val(), 10)));
if (data.length) {
data[0].FirstName = $("#FirstName").val();
window.changes.changed.push(data);
}
}
else if (document.activeElement.value == "Add") {
window.changes.added.push({
EmployeeID: parseInt($("#EmployeeID").val(), 10),
FirstName: $("#FirstName").val(),
LastName: $("#LastName").val(),
});
}
else if (document.activeElement.value == "Delete") {
data = window.FlatData.executeLocal(ej.Query().where("EmployeeID",
ej.FilterOperators.equal, parseInt($("#EmployeeID").val(), 10)));
if (data.length)
window.changes.deleted.push(data[0]);
}
else {
var obj = $("#MainContent_OrdersGrid").ejGrid("instance");
window.FlatData.saveChanges(window.changes, "EmployeeID");
(window.FlatData.dataSource.json);
}
}
</script>
</asp:Content>
```

Result of the above code example is illustrated as follows.



Batch Editing

Paging

Paging is a very important query in the DataManager used to display only some records from the large data source. Here, you can learn the paging query in detail.

Default

The paging index and the paging size parameters of the paging query determine the number of records to be retrieved from the data source of the DataManager.

Copyright © 2001 - 2020 Syncfusion Inc.

Refer to the following code example for the paging options.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().page(5,5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result for the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10268	GROSR	8	Caracas	66.2900
10269	WHITC	5	Seattle	4.5600
10270	WARTH	1	Oulu	136.5400
10271	SPLIR	6	Lander	4.5400
10272	RATTC	6	Albuquerque	98.0300

Paging

Dynamic Paging

The paging operation can be dynamically performed by using the DataManager. With the help of an external button click event, the required page records can be obtained and processed accordingly. The following code example illustrates the dynamic paging.

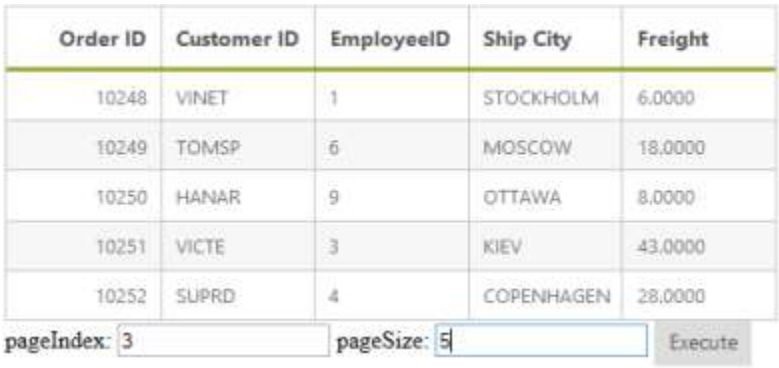
ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/Orders/").CrossDomain(true))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).page(1,3)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
pageIndex: <input id="pageIndex" type="text" placeholder="pageIndex" />
pageSize:  <input id="pageSize" type="text" placeholder="pageSize" />
@Html.EJ().Button("submit").Text("Execute").ClientSideEvents(e => {
e.Click("onClick"); })
<script type="text/javascript" class="jsScript">
function onClick(e) {
var from = parseInt($("#pageIndex").val());
var to = parseInt($("#pageSize").val());
var obj = $("#FlatGrid").ejGrid("instance")
tempQuery = new ej.Query();
tempQuery.page(from, to);
var dataManagerObj = window.FlatData.executeQuery(tempQuery).done(function
(e1) {
obj.dataSource(e1.result);
})
}
</script>
```

Result of above code example is illustrated as follows.



Dynamic Paging

Custom paging

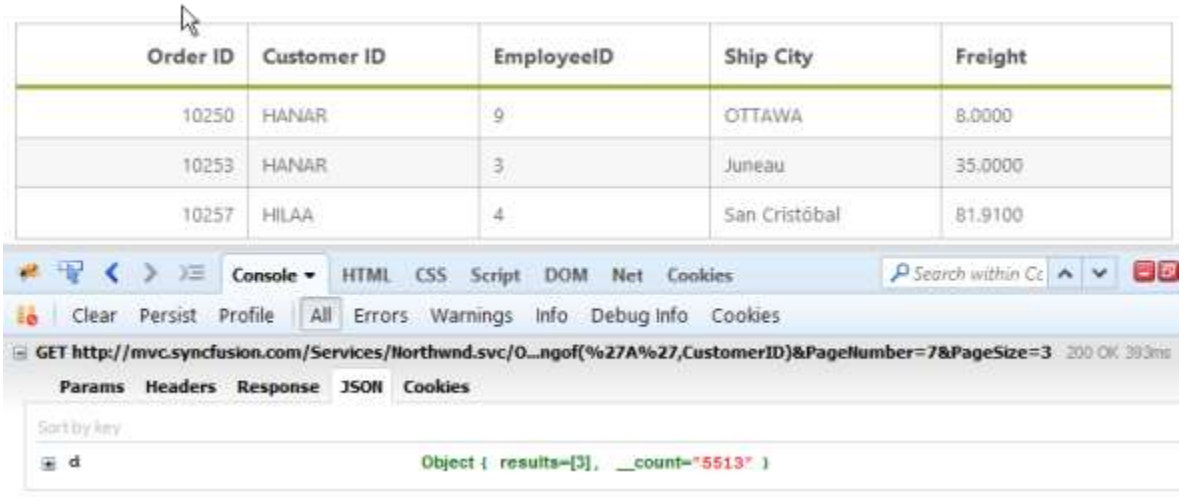
In this section, you can learn how to use the customized paging. The following code example illustrates the custom paging.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select('OrderID', 'CustomerID', 'EmployeeID',
'Freight',
'ShipCity').addParams('PageNumber',7).addParams('PageSize',3).where('Custome
rID', 'contains', 'A', false)")
.Columns(col =>
{
```

```
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of above code example is illustrated as follows.



Custom Paging

Skip

The skip query is used to skip some number of records.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select('OrderID', 'CustomerID', 'EmployeeID',
'Freight', 'ShipCity').skip(100).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Result of the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10348	WANDK	4	Stuttgart	0.7800
10349	SPLIR	7	Lander	8.6300
10350	LAMAI	6	Toulouse	64.1900

By using Skip

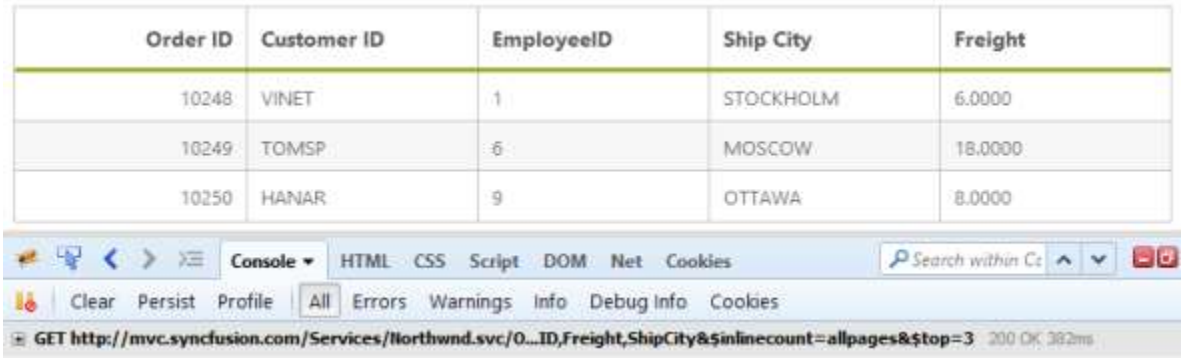
Take

The take query is used to get some number of records from the data source of the DataManager.

HTML

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select('OrderID', 'CustomerID', 'EmployeeID',
'Freight', 'ShipCity').take(3)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.



Order ID	Customer ID	EmployeeID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000

By using take

Copyright © 2001 - 2020 Syncfusion Inc.

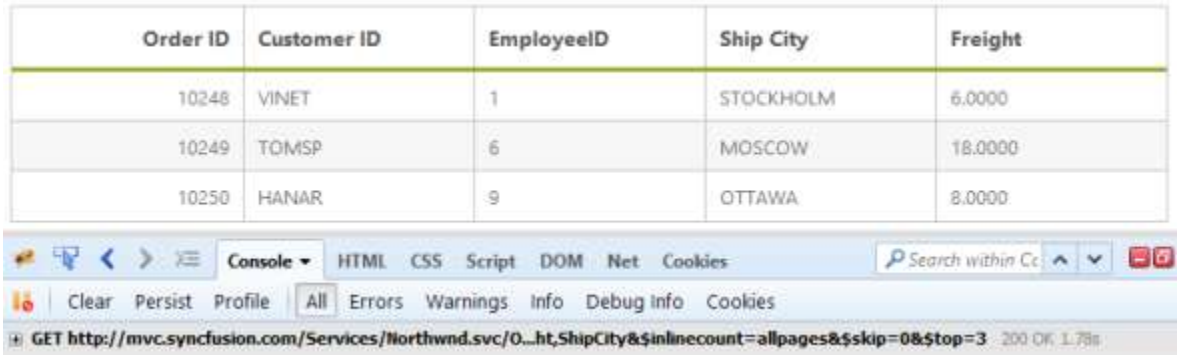
RequiresCount

The requiresCount query is used to get the count of the total number of records in the data source of the DataManager.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select('OrderID', 'CustomerID', 'EmployeeID',
'Freight', 'ShipCity').page(1,3).requiresCount()")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.



By using requireCount

Range

The range query is used to get some particular range of records from the data source of the DataManager.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select('OrderID', 'CustomerID', 'EmployeeID',
'Freight', 'ShipCity').range(25,30)")
.Columns(col =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10273	QUICK	3	Cunewalde	76.0700
10274	VINET	6	Reims	6.0100
10275	MAGAA	1	Bergamo	26.9300
10276	TORTU	8	México D.F.	13.8400
10277	MORGK	2	Leipzig	125.7700

By using range

Summary

Summary is a key feature in the DataManager that helps to aggregate any data. DataManager provides several summary type by default, they are as follows.

- Sum
- Average
- Minimum
- Maximum
- Distinct

The ej provides several data utilization methods to achieve summary.

Sum

The Sum summary type provides the sum of the data. The Sum data utilization method accepts two parameters, they are JSON data and the fieldname where the sum is calculated. The following code example illustrates the Default Summary Types.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
```

```
.Query("new ej.Query().select('OrderID', 'CustomerID', 'EmployeeID',
'Freight', 'ShipCity').range(25,30)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
<script type="text/javascript" class="jsScript">
setTimeout(function () {
var proxy = $("#FlatGrid").ejGrid("instance");
var data = proxy._currentJsonData;
var sum = ej.sum(data, "EmployeeID");//Calculates the sum Freight
$("body").append("<span>Sum:" + sum + "</spn>");
}, 3000);
</script>
```

The result of the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10273	QUICK	3	Cunewalde	76.0700
10274	VINET	6	Reims	6.0100
10275	MAGAA	1	Bergamo	26.9300
10276	TORTU	8	México D.F.	13.8400
10277	MORGK	2	Leipzig	125.7700

Sum:20

Summary - Sum

Min

The Minimum of a particular field can be calculated by using the ej.min data utilization method and this method accepts the arguments such as JSON data/array, field name and the comparer used for the comparison. When the data to the min method is a JSON array, then the whole record is returned.

The minimum of particular field can be calculated as follows.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select('OrderID', 'CustomerID', 'EmployeeID',
'Freight', 'ShipCity').range(25,30)")
.Columns(col =>
{
```

```
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
<script type="text/javascript" class="jsScript">
setTimeout(function () {
var proxy = $("#FlatGrid").ejGrid("instance");
var data = proxy._currentJsonData;
var min = ej.min(data, "EmployeeID");//Calculates the min Freight
$("body").append("<span>Min:" + min.EmployeeID + "</spn>");
}, 3000);
</script>
```

The result of the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10273	QUICK	3	Cunewalde	76.0700
10274	VINET	6	Reims	6.0100
10275	MAGAA	1	Bergamo	26.9300
10276	TORTU	8	México D.F.	13.8400
10277	MORGK	2	Leipzig	125.7700

Min:1

Summary- Minimum

Max

The Maximum of a particular field can be calculated by using the ej.max data utilization method and this method accepts the arguments such as JSON data/array, field name and the comparer used for the comparison. When the data to the max method is a JSON array, then the whole record is returned.

The maximum of particular field can be calculated as follows.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select('OrderID', 'CustomerID', 'EmployeeID',
'Freight', 'ShipCity').range(25,30)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
<script type="text/javascript" class="jsScript">
setTimeout(function () {
var proxy = $("#FlatGrid").ejGrid("instance");
var data = proxy._currentJsonData;
var max = ej.max(data, "EmployeeID"); //Calculates the max Freight
$("body").append("<span>Max:" + max.EmployeeID + "</spn>");
}, 3000);
</script>
```

The result for the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10273	QUICK	3	Cunewalde	76.0700
10274	VINET	6	Reims	6.0100
10275	MAGAA	1	Bergamo	26.9300
10276	TORTU	8	México D.F.	13.8400
10277	MORGK	2	Leipzig	125.7700

Max:8

Summary - Maximum

Avg

The Average summary type provides the average of the given data. The Average data utilization method accepts two parameters, they are JSON/Array data and the fieldname where the sum is calculated. Use the following code example for calculating the average of the given JSON data.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select('OrderID', 'CustomerID', 'EmployeeID',
'Freight', 'ShipCity').range(25,30)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
<script type="text/javascript" class="jsScript">
setTimeout(function () {
var proxy = $("#FlatGrid").ejGrid("instance");
var data = proxy._currentJsonData;
var avg = ej.avg(data, "EmployeeID");//Calculates the avg Freight
$("body").append("<span>Avg:" + avg + "</spn>");
}, 3000);
</script>
```

The result of the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10273	QUICK	3	Cunewalde	76.0700
10274	VINET	6	Reims	6.0100
10275	MAGAA	1	Bergamo	26.9300
10276	TORTU	8	México D.F.	13.8400

Avg:4

Summary - Average

Distinct

In a data, a field may contain many duplicate values; and sometimes you are required only to list the different (distinct) values. This can be achieved by using the ej.distinct method. This method accepts three parameters such as JSON/Array data, fieldname that you want to fetch as distinct and the third Boolean parameter set as true, returns the whole record when the data is a JSON array.

The following code example illustrates how to use the ej.distinct method. In the following code, the third parameter of distinct method is set as true and hence it fetches the whole record from the provided data.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select('OrderID', 'CustomerID', 'EmployeeID',
'Freight', 'ShipCity').range(25,35)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
<script type="text/javascript" class="jsScript">
setTimeout(function () {
var proxy = $("#FlatGrid").ejGrid("instance");
var data = proxy._currentJsonData;
var distinct = ej.distinct(data, "EmployeeID", true);//Calculates the
distinct
proxy.dataSource(distinct);
}, 3000);
</script>
```

The result for the above code example is illustrated as follows.

Order ID	Customer ID	EmployeeID	Ship City	Freight
10273	QUICK	3	Cunewalde	76.0700
10274	VINET	6	Reims	6.0100
10275	MAGAA	1	Bergamo	26.9300
10276	TORTU	8	México D.F.	13.8400
10277	MORGK	2	Leipzig	125.7700
10281	ROMEY	4	Madrid	2.9400

Summary - Distinct

Hierarchical Query

The DataManager contains support to manage the hierarchical query. The hierarchical queries are commonly required when you use foreign key binding. The hierarchical query can be provided by using the hierarchical function. This method accepts two parameters such as the query and the selector function.

foreignKey

The foreignkey method of ej.Query can be used to refer to another table fields. The foreignkey method accepts one parameter, the foreign key value.

The following code example illustrates the hierarchical query and foreignkey method.

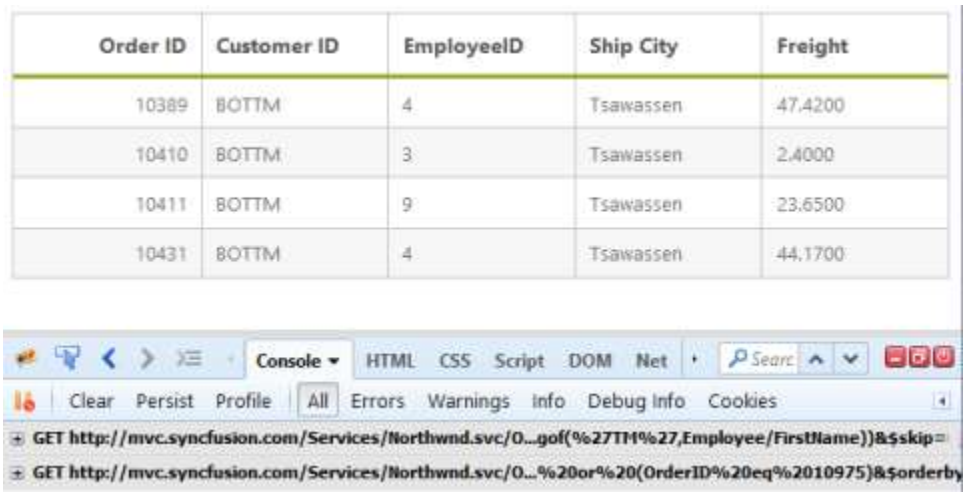
ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc"))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("ej.Query().from('Orders').search('TM', ['CustomerID',
'Employee.FirstName']).page(1,
4).hierarchy(ej.Query().foreignKey('OrderID').from('Order_Details').sortBy('
Quantity'),function () {return [10410, 10492, 10949, 10742, 10975]})")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

The result for the above code example is illustrated as follows.



Hierarchical Query and foreignkey method

Helper Functions

ej.parseJSON

This method is used to parse the string to **JSON**.

ej.parseTable

This method is used to parse the **HTML** element into the **JSON** Array and is used commonly in element binding using **DataManager**.

ej.getGuid

This method returns the globally unique identifier and it generates unique identifier with the prefix provided as parameter.

ej.merge

The ej.merge is used to merge two arrays and the result is merged in the first array.

ej.support

The ej.support property contains a collection of properties representing different browser features or bugs. The property are as follows.

1. cors – represents the cross browser support.
2. enableLocalizedSort – enables the localized sort operation.
3. stableSort – enables stable sort operation.
4. outerHTML – represents the outerHTML support.

Copyright © 2001 - 2020 Syncfusion Inc.

ej.swap

This method is used to swap the position of element in an array. It accepts three arguments such as input array and two swap positions.

ej.serverTimezoneOffset

This property is used to set the time-zone offset from UTC, in hours

Note: Suppose, application has been hosted in EST time zone and client may be in IST, GMT etc. in that case, date will differ from database. The below given solution will fix the conflict.

Property Name: ej.serverTimezoneOffset Data type: number Default Value: 0

Note: By default, The server time zone will be in UTC, if its other than the UTC, set the proper format time zone offset value to the ej.serverTimezoneOffset property.

Please refer the online (link)[https://en.wikipedia.org/wiki/Time*zone#List*of*UTC*offsets] for time zone offset values.

Time-zone offset calculation from UTC: ej.serverTimezoneOffset = serverTimeZoneDifference(in hours) + ClientSideTimeZoneDiff(in hours);

HTML

```
<div class="content-container-fluid">
<div class="row">
<div class="cols-sample-area">
<div id="Grid"></div>
</div>
</div>
</div>
<script type="text/javascript">
var serverTimeZoneDifference = -5.0   // if your server is in EST time zone
(UTC -5.0) (in hours)
var serverTimeZoneDifference = new Date().getTimezoneOffset() / 60; // get
client time zone differences and convert it to hours;
ej.serverTimezoneOffset = serverTimeZoneDifference +
serverTimeZoneDifference;
$(function () {
var dataManagerObj = ej.DataManager({ url:
"http://mvc.syncfusion.com/services/Northwnd.svc/Orders" });
$("#Grid").ejGrid({
dataSource: dataManagerObj,
allowPaging: true,
columns: ["OrderID", "EmployeeID", "CustomerID", "OrderDate", "Freight"]
});
});
</script>
```

Note: When the Daylight saving time mode is enabled in the sever, take care about this time adjustment with the server time-zone offset calculation.

Copyright © 2001 - 2020 Syncfusion Inc.

The countries that are using Eastern Standard Time (EST) when observing standard time (autumn/winter) are 5 hours behind Coordinated Universal Time (UTC−05:00).

Eastern Daylight Time (EDT), when observing daylight saving time DST (spring/summer) is 4 hours behind Coordinated Universal Time (UTC−04:00).

Let see an example, when they observe the Daylight saving time.

HTML

```
<div class="content-container-fluid">
<div class="row">
<div class="cols-sample-area">
<div id="Grid"></div>
</div>
</div>
</div>
<script type="text/javascript">
var serverTimeZoneDifference = -4.0  // if your server is in EDT time zone
(UTC -4.0) (in hours)
var serverTimeZoneDifference = new Date().getTimezoneOffset() / 60; // get
client time zone differences and convert it to hours;
ej.serverTimezoneOffset = serverTimeZoneDifference +
serverTimeZoneDifference;
$(function () {
var dataManagerObj = ej.DataManager({ url:
"http://mvc.syncfusion.com/services/Northwnd.svc/Orders" });
$("#Grid").ejGrid({
dataSource: dataManagerObj,
allowPaging: true,
columns: ["OrderID", "EmployeeID", "CustomerID", "OrderDate", "Freight"]
});
});
</script>
```

KO ResultSet

The DataManager contains a default method to subscribe the view model properties as KO observable. This is done at the success of the executeQuery by using the getKnockoutModel. You can also provide computed properties to the view model by using the getKnockoutModel.

The following code example illustrates how the model is made observable and updated.

ASPX-CS

```
<div class="datatable" style="padding:10px">
<div class="row">
<div class="col-md-7">
<table id="table1" class="table table-striped table-bordered"
style="width:700px">
<thead>
<tr>
<th>EmployeeID</th>
<th>Full Name</th>
</tr>
</thead>
<tbody data-bind="foreach: employees">
<tr>
```

```
<td data-bind="text: EmployeeID"></td>
<td data-bind="text: FullName"></td>
</tr>
</tbody>
</table>
</div>
<div class="col-md-5">
<form class="form-horizontal" role="form">
<div class="form-group">
<label class="col-sm-4 control-label">EmployeeID</label>
<div class="col-sm-8">
<input type="text" class="form-control" id="employeeId">
</div>
</div>
<div class="form-group">
<label class="col-sm-4 control-label">FirstName</label>
<div class="col-sm-8">
<input type="text" class="form-control" id="first">
</div>
</div>
<div class="form-group">
<label class="col-sm-4 control-label">LastName</label>
<div class="col-sm-8">
<input type="text" class="form-control" id="last">
</div>
</div>
<div class="form-group">
<div class="col-sm-offset-4 col-sm-4">
<button type="button" id="formSubmit" class="btn btn-
default">Change</button>
</div>
</div>
</form>
</div>
</div>
</div>
@(Html.EJ().DataManager("FlatData").Json((IEnumerable<object>)ViewBag.dataso
urce).Adaptor(AdaptorType.JsonAdaptor))
<script src="~/Scripts/knockout.min.js"></script>
<script src="~/Scripts/ej/ej.widget.ko.min.js"></script>
<script type="text/javascript">
setTimeout( function (){
window.pageModel = {
employees: []
};
var query = ej.Query();
var promise = window.FlatData.executeQuery(query);
promise.done(function (e) {
pageModel.employees = e.getKnockoutModel({
FullName: function () {
return this.FirstName() + " " + this.LastName();
}
});
ko.applyBindings(pageModel);
});
}, 1000);
$("#formSubmit").click(function (e) {
```

```
var employeeId = parseInt($("#employeeId").val(), 10);
var fName = $("#first").val();
var lName = $("#last").val();
employee = window.pageModel.employees()[employeeId - 1];
employee.FirstName(fName);
employee.LastName(lName);
});
</script>
```

The result of the above code example is illustrated as follows.

Before changing the model, EmployeeID 1 has FullName value as Nancy Davolio. After changing, the result is as follows.

EmployeeID	Full Name
1	Kate Beckett
2	Andrew Fuller
3	Janet Leverling
4	Margaret Peacock
5	Steven Buchanan
6	Michael Suyama

Knockout ResultSet

Table Model

The **DataManager** contains a default support to bind a TableModel to the element. You can make the data observable using the **getTableModel** method. The **getTableModel** method also accept extra properties or properties with computed value that can be added to the TableModel. In the view, you can create a simple view by using the bindings **getTableModel**

Then the model is bound with the element using the **bindTo.**

ASPX-CS

```
<div class="datatable" style="padding:10px">
<div class="row">
<div class="col-md-7">
<table id="table1" class="table table-striped table-bordered"
style="width:700px">
<thead>
<tr>
<th>EmployeeID</th>
<th>Full Name</th>
</tr>
</thead>
<tbody id="tbody1">
<tr>
<td ej-observe="EmployeeID"></td>
<td ej-computed="FullName"></td>
</tr>
</tbody>
</table>
</div>
```

```
<div class="col-md-5">
<form class="form-horizontal" role="form">
<div class="form-group">
<label class="col-sm-4 control-label">EmployeeID</label>
<div class="col-sm-8">
<input type="text" class="form-control" id="employeeId">
</div>
</div>
<div class="form-group">
<label class="col-sm-4 control-label">FirstName</label>
<div class="col-sm-8">
<input type="text" class="form-control" id="first">
</div>
</div>
<div class="form-group">
<label class="col-sm-4 control-label">LastName</label>
<div class="col-sm-8">
<input type="text" class="form-control" id="last">
</div>
</div>
<div class="form-group">
<div class="col-sm-offset-4 col-sm-4">
<button type="button" id="formSubmit" class="btn btn-
default">Change</button>
</div>
</div>
</form>
</div>
</div>
</div>
@(Html.EJ().DataManager("FlatData").Json((IEnumerable<object>)ViewBag.dataso
urce).Adaptor(AdaptorType.JsonAdaptor))
<script type="text/javascript">
setTimeout(function () {
window.employees = [];
var query = ej.Query();
var promise = window.FlatData.executeQuery(query);
promise.done(function (e) {
employees = e.getTableModel({
FullName: {
value: function () {
return this.FirstName + ' ' + this.LastName;
},
deps: ["FirstName", "LastName"]
}
});
employees.bindTo($("#tbody1"));
});
}, 1000);
$("#formSubmit").click(function (e) {
var employeeId = parseInt($("#employeeId").val(), 10);
var fName = $("#first").val();
var lName = $("#last").val();
employee = employees.get(employeeId - 1);
employee.set("FirstName",fName);
employee.set("LastName",lName);
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</script>
```

The result for the above code example is illustrated as follows.

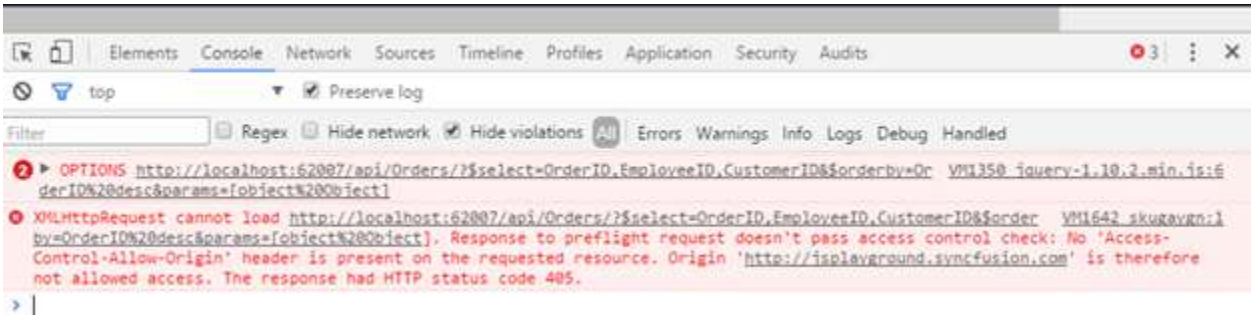
EmployeeID	Full Name
1	Kate Beckett
2	Andrew Fuller
3	Janet Leverling
4	Margaret Peacock
5	Steven Buchanan
6	Michael Suyama

CORS Data Fetching

The Cross-Origin Resource Sharing (CORS) mechanism enable secure cross-domain data transfers.

SAME-ORIGIN POLICY

This policy defined the rule for, “how a web page can be accessed by an external resource”. Browsers wont permits a request to access the resources who origin is differ than the current page. To overcome the restriction of same-origin policy, we can use a technique called Cross-origin resource sharing.



Access-Control-Allow-Origin

Cross-domain requests require common procedure between the Web page and the server. Initiate a cross-domain request in a web page and opening a connection to the mentioned domain. The browser will request the service (i.e data) from the domain’s server by sending an Origin header with the value of the origin. It will only complete the connection if the server responds with an Access-Control-Allow-Origin header of either * or the exact URL of the requesting page.

When you set, Access-Control-Allow-Origin value as “Testing1.com”.

With this rule, only scripts that originate from http://“Testing1.com are allowed to load resources. Any other domain trying to use AJAX to load resources will be given the security error message.

By using this rule, the domain owners can restrict which domains are allowed to use the resource.

Alternatively, the owners can grant wide-open access with the always ready to party asterisk: **Access-Control-Allow-Origin: ***.

HTML

```
<system.webServer>
<httpProtocol>
```

```
<customHeaders>
<add name="Access-Control-Allow-Origin" value="*" />
</customHeaders>
</httpProtocol>
</system.webServer>
```

Now, any website that wants to load a resource using AJAX can do so without getting the security error.

Access-Control-Request-Method

The Access-Control-Request-Method is used when issuing a preflight request to let the server know what HTTP method will be used when the request is made.

HTML

```
<httpProtocol>
<customHeaders>
<add name="Access-Control-Allow-Methods" value="GET, POST, PUT, DELETE,
OPTIONS" />
</customHeaders>
</httpProtocol>
```

Note:

Preflightedrequests:

Setting custom headers to XHR triggers a preflight request. With simple words this mean that preflight request first sends an HTTP request by the OPTIONS method to the resource on the remote domain, to make sure that the request is safe to send. According W3C for non-same origin requests using the HTTP GET method a preflight request is made when headers other than Accept and Accept-Language are set.

Access-Control-Request-Headers

The Access-Control-Request-Headers header is used when issuing a preflight request to let the server know what HTTP headers will be used when the request is made.

HTML

```
<httpProtocol>
<customHeaders>
<add name="Access-Control-Allow-Headers" value="*" />
</customHeaders>
</httpProtocol>
```

For more details, please refer to this link:

Advanced Functionalities

Offline Support

Offline support allows data-bound Syncfusion UI widgets to function without active server connection. Users can continue working with the data.

With offline as true, the DataManager requests the server only once and further data manipulation operation can be done at client side itself.

In the following code example, the offline property of the DataManager is set as true.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/Orders/").Offline(true))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

The result of the above code example is illustrated as follows.

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

Figure offline mode

Load on demand

Load on demand is powerful technique to reduce band width size of consuming data. It allow you to retrieve the required range of data alone from the server and this feature helps you when the server contains large amount of data.

You can use the following code example for implementing load on demand using DataManager.

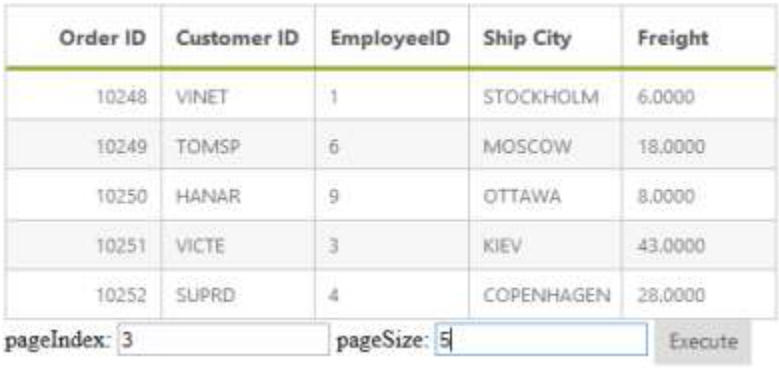
ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/Orders/").CrossDomain(true))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).page(1,3)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
pageIndex: <input id="pageIndex" type="text" placeholder="pageindex" />
pageSize:  <input id="pageSize" type="text" placeholder="pageSize" />
@Html.EJ().Button("submit").Text("LoadOnDemand").ClientSideEvents(e => {
e.Click("onClick"); })
<script type="text/javascript" class="jsScript">
function onClick(e) {
var from = parseInt($("#pageIndex").val());
var to = parseInt($("#pageSize").val());
var obj = $("#FlatGrid").ejGrid("instance")
tempQuery = new ej.Query();
tempQuery.page(from, to);
var dataObj = window.FlatData.executeQuery(tempQuery).done(function (e1) {
obj.dataSource(e1.result);
})
}
</script>
```

The result of the above code example is illustrated as follows.



Load on demand

The request and the response for the above code are sent as follows.

Demanded data

Custom Request Headers

You can add custom request headers using **DataManager** and the headers can be added to the request headers in three ways that is illustrated in the following code example.

Adding Custom Request Headers to every Request using headers

You can add custom request headers to every request made by the **DataManager** using the headers property. Refer to the following code example for setting the custom request headers using the headers property.

C#

```
public ActionResult GridFeatures()
{
var DataSource = new NorthwindDataContext().OrdersViews.ToList();
ViewBag.data = DataSource;
return View();
}
```

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").Json((IEnumerable<object>)ViewBag.data).
Headers(new { myData = 3232323 }))
@(Html.EJ().Grid<object>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

The above method generates the request header with custom header as follows.

*Adding Custom Request Headers to every Request using pre-request callback **beforeSend***

You can set the custom headers using pre-request callback **beforeSend** as follows. The **setRequestHeader** method can be used to modify the **XMLHTTPRequest**.

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
public static List<OrderDetails> order = new List<OrderDetails>();
public ActionResult DataSource()
{
int code = 10000;
for (int i = 1; i < 10; i++)
{
order.Add(new OrderDetails(code + 1, "ALFKI", i + 0, 2.3 * i, "Berlin"));
order.Add(new OrderDetails(code + 2, "ANATR", i + 2, 3.3 * i, "Madrid"));
order.Add(new OrderDetails(code + 3, "ANTON", i + 1, 4.3 * i,
"Cholchester"));
order.Add(new OrderDetails(code + 4, "BLONP", i + 3, 5.3 * i, "Marseille"));
order.Add(new OrderDetails(code + 5, "BOLID", i + 4, 6.3 * i, "Tsawassen"));
code += 5;
}
var list = order.ToList();
DataResult result = new DataResult();
result.result = list;
result.count = list.Count;
return Json(result, JsonRequestBehavior.AllowGet);
}
public class DataResult
{
public IEnumerable<OrderDetails> result { get; set; }
public int count { get; set; }
}
public class OrderDetails
{
public OrderDetails()
{
}
public OrderDetails(int OrderID, string CustomerId, int EmployeeId, double
Freight, string ShipCity)
{
this.OrderID = OrderID;
this.CustomerID = CustomerId;
this.EmployeeID = EmployeeId;
this.Freight = Freight;
this.ShipCity = ShipCity;
}
public int? OrderID { get; set; }
public string CustomerID { get; set; }
public int? EmployeeID { get; set; }
public double? Freight { get; set; }
public string ShipCity { get; set; }
}
```

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("DataSource"))
@(Html.EJ().Grid<object>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)")
.Columns(col =>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

JAVASCRIPT

```
<script type="text/javascript">
setTimeout(function () {
var customAdaptor = new ej.UrlAdaptor().extend({
beforeSend: function (request, settings) {
settings.setRequestHeader("myData1", "Syncfusion");
settings.setRequestHeader("myData2", 23243);
}
});
window.FlatData.adaptor = new customAdaptor();
var gridObj = $("#FlatGrid").ejGrid("instance");
gridObj.dataSource(window.FlatData.executeQuery(new ej.Query().take(7)));
}, 3000);
</script>
```

The above method generates the request header with custom header as follows.

*Adding Custom Request Headers using **addParams** method*

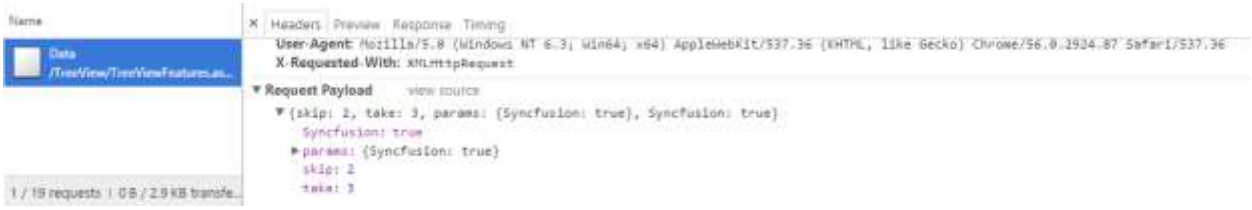
You can use the addParams method of ej.Query class, to add custom parameter to the data request.

ASPX-CS

```
@Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/N
orthwnd.svc/Orders/").Adaptor(AdaptorType.ODataAdaptor).CrossDomain(true)
@(Html.EJ().Grid<object>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5).addParams('Syncfusion', true)")
.Columns(col =>
{
```

```
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

The custom parameter will be passed along with the data request of the grid as follows.



Cross domain & JSONP

The **DataManager** contains support for creating cross domain request, you can achieve this by using crossDomain and jsonp property of the **DataManager**. The following code example illustrate on how to create cross domain request.

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Services/
Northwnd.svc/Orders/").CrossDomain(true))
@(Html.EJ().Grid<MVCdoc.OrdersView>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(5)")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
```

Result of above code example is illustrated as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Order ID	Customer ID	Employee ID	Ship City	Freight
10248	VINET	1	STOCKHOLM	6.0000
10249	TOMSP	6	MOSCOW	18.0000
10250	HANAR	9	OTTAWA	8.0000
10251	VICTE	3	KIEV	43.0000
10252	SUPRD	4	COPENHAGEN	28.0000

Cross domain

HTML Table

Other than **JSON** and **Remote** datasource, the **DataManager** can also fetch and use data from **HTML** element. You can achieve this by using the **table** property of the **DataManager**. The **DataManager** can fetch data from the **HTML** table element.

Refer to the following code example for the **HTML** element binding using **DataManager**.

ASPX-CS

```
<script id="_table1" type="text/template">
<table id="datasource" style="display:none">
<thead>
<tr>
<th>OrderID</th>
<th>EmployeeID</th>
<th>CustomerID</th>
</tr>
</thead>
<tbody>
<tr><td>10248</td><td>VINET</td><td>5</td></tr>
<tr><td>10249</td><td>TOMSP</td><td>6</td></tr>
<tr><td>10250</td><td>HANAR</td><td>4</td></tr>
<tr><td>10251</td><td>VICTE</td><td>3</td></tr>
<tr><td>10252</td><td>SUPRD</td><td>4</td></tr>
</tbody>
</table>
</script>
@(Html.EJ().DataManager("FlatData").Table("#_table1"))
@(Html.EJ().Grid<object>("FlatGrid")
.DataManagerID("FlatData")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
})
)
```

The result of the above code example is illustrated as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Order ID	Customer ID	Employee ID
10248	VINET	5
10249	TOMSP	6
10250	HANAR	4
10251	VICTE	3
10252	SUPRD	4

HTML Table element binding

WebAPI Batch Edit

WebAPI Batch Editing is a unique feature, where requests to add, remove and change are handled altogether at a time rather than passing the request separately for each operation.Use the Save changes button to process all changes at once and cancel button to discard the changes.

Configuration

Below are listed the steps for you to follow when configuring the DataManager for ASP.NET MVC to do batch updates.

In order to using batch in Web API, you should register a route with a batch handler or create an OWIN server. The below code creates the server and configures a web API route and a batch route.

C#

```
using Microsoft.Owin;
using Owin;
using System.Web.Http;
using System.Web.Http.Batch;
[assembly: OwinStartupAttribute(typeof(Sample.Startup))]
namespace Sample
{
public partial class Startup
{
public void Configuration(IAppBuilder app)
{
ConfigureAuth(app);
HttpConfiguration config = new HttpConfiguration();
config.MapHttpAttributeRoutes();
HttpServer server = new HttpServer(config);
config.Routes.MapHttpBatchRoute(
routeName: "batch",
routeTemplate: "api/batch",
batchHandler: new DefaultHttpBatchHandler(server));
app.UseWebApi(config);
app.UseStaticFiles();
}
}
}
```

Web API uses route templates to determine which controller and action method to execute. At least one route template must be added into route table in order to handle various HTTP requests.

Copyright © 2001 - 2020 Syncfusion Inc.

Route (WebApiConfig.cs):

C#

```
config.Routes.MapHttpRoute(
name: "api",
routeTemplate: "api/{controller}/{id}",
defaults: new { id = RouteParameter.Optional }
);
```

Add a new class to the ~/Models folder. Name it Employee.

C#

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;
namespace Sample.Models
{
interface IEmployeeRepository
{
IEnumerable<Employee> GetAll();
Employee Get(int EmployeeID);
Employee Add(Employee employee);
void Remove(int EmployeeID);
bool Update(Employee employee);
}
public class Employee
{
public int EmployeeID { get; set; }
public string FirstName { get; set; }
public string LastName { get; set; }
public Employee()
{
}
public Employee(int id, string LN, string FN)
{
this.EmployeeID = id;
this.LastName = LN;
this.FirstName = FN;
}
}
}
```

Add a new Repository Data Model class. Name it EmployeeRepository.

C#

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;
namespace Sample.Models
{
public class EmployeeRepository : IEmployeeRepository
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
private List<Employee> employee = new List<Employee>();
public EmployeeRepository()
{
employee.Add(new Employee(1, "Davolio", "Nancy"));
employee.Add(new Employee(2, "Fuller", "Andrew"));
employee.Add(new Employee(3, "Leverling", "Janet"));
employee.Add(new Employee(4, "Peacock", "Margaret"));
employee.Add(new Employee(5, "Buchanan", "Steven"));
}
public IEnumerable<Employee> GetAll()
{
return employee;
}
public Employee Get(int id)
{
return employee.Find(p => p.EmployeeID == id);
}
public Employee Add(Employee eObj)
{
if (eObj == null)
{
throw new ArgumentNullException("eObj");
}
employee.Add(eObj);
return eObj;
}
public void Remove(int id)
{
employee.RemoveAll(p => p.EmployeeID == id);
}
public bool Update(Employee eObj)
{
if (eObj == null)
{
throw new ArgumentNullException("eObj");
}
int index = employee.FindIndex(p => p.EmployeeID == eObj.EmployeeID);
if (index == -1)
{
return false;
}
employee.RemoveAt(index);
employee.Add(eObj);
return true;
}
}
}
```

Add a new ApiController name it as EmployeeController.cs and add a new Post/Put/Delete method which will return the Employee as JSON. The DataManager will make requests to this action based on route name.

C#

```
using System;
using System.Collections.Generic;
```

```
using System.Linq;
using System.Net;
using System.Net.Http;
using System.Web.Http;
using Sample.Models;
using System.Web;
using System.Threading.Tasks;
namespace Sample.Controllers
{
public class EmployeeController : ApiController
{
static readonly IEmployeeRepository repository = new EmployeeRepository();
[Route("get")]
public async Task<object> Get()
{
await Task.Delay(1000);
var queryString = HttpContext.Current.Request.QueryString;
var data = repository.GetAll().ToList();
return new { Items = data, Count = data.Count() };
}
public Employee GetEmployee(int id)
{
Employee employee = repository.Get(id);
if (employee == null)
{
throw new HttpResponseException(HttpStatusCode.NotFound);
}
return employee;
}
[Route("post")]
public async Task<IHttpActionResult> Post([FromBody] Employee employee)
{
if (employee == null)
{
return BadRequest(ModelState);
}
employee = repository.Add(employee);
return Content(HttpStatusCode.OK, employee);
}
[Route("put")]
public async Task<IHttpActionResult> Put([FromBody] Employee employee)
{
await Task.Delay(1000);
if (employee == null)
{
return BadRequest(ModelState);
}
else
{
if (!repository.Update(employee))
{
throw new HttpResponseException(HttpStatusCode.NotFound);
}
return Content(HttpStatusCode.OK, employee);
}
}
[Route("delete/{id}")]
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public async Task<IHttpActionResult> Delete(int id)
{
Employee employee = repository.Get(id);
await Task.Delay(1000);
if (employee == null)
{
return NotFound();
}
else
{
repository.Remove(id);
return StatusCode(HttpStatusCode.OK);
}
}
}
}
```

In the view, configure the Data manager to use the Post/Put/Delete methods created in the previous steps.

C#

```
@(Html.EJ().DataManager("FlatData").BatchURL("/api/batch").UpdateURL("/put")
.RemoveURL("/delete").InsertURL("/post").Adaptor(AdaptorType.WebApiAdaptor))
@(Html.EJ().Grid<Sample.Models.Employee>("FlatGrid")
.DataManagerID("FlatData")
.Query("new ej.Query().select(['EmployeeID', 'FirstName', 'LastName'])")
.EditSettings(edit => {
edit.AllowAdding().AllowDeleting().AllowEditing().EditMode(EditMode.Batch);
})
.ToolbarSettings(toolbar =>
{
toolbar.ShowToolbar().ToolbarItems(items =>
{
items.AddTool(ToolBarItems.Add);
items.AddTool(ToolBarItems.Edit);
items.AddTool(ToolBarItems.Delete);
items.AddTool(ToolBarItems.Update);
items.AddTool(ToolBarItems.Cancel);
});
})
.Columns(col =>
{
col.Field("EmployeeID").HeaderText("EmployeeID").IsPrimaryKey(true).Width(75
).Add();
col.Field("FirstName").HeaderText("FirstName").Width(80).Add();
col.Field("LastName").HeaderText("LastName").Add();
})
)
```

Run the sample and perform batch operation. You can notice that the changes are reflected in the Database Table too.

Copyright © 2001 - 2020 Syncfusion Inc.

IEnumerable

IEnumerable will execute **select** query on server side, load data in-memory on client side and then filter data.IEnumerable can be used for querying data from in-memory collections like List, Array etc.

Data Binding

The **DataManager** contains a default support to bind data from a IEnumerable list to a control.

Refer the below given code to bind data from IEnumerable list through datamanager to Grid

C#

```
public ActionResult DataSource(Syncfusion.JavaScript.DataManager
dataManagerObj)
{
IEnumerable data = OrderRepository.GetAllRecords();
var count = data.AsQueryable().Count();
DataOperations ds = new DataOperations();
data = ds.Execute(data, dataManagerObj);
return Json(new { result=data , count = count },
JsonRequestBehavior.AllowGet);
}
```

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("Home/DataSource").Adaptor(AdaptorTy
pe.UrlAdaptor))
@(Html.EJ().Grid<object>("FlatGrid")
.DataManagerID("FlatData") // pass the datamanager Id
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight']).take(10)") // query to be executed
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
)
```

The result of above code example is illustrated as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Order ID	Customer ID	Employee ID	Freight	Ship City
10248	VINET	5	$32.38	Reims
10249	TOMSP	6	$11.61	Münster
10250	HANAR	4	$65.83	Rio de Janeiro
10251	VICTE	3	$41.34	Lyon
10252	SUPRD	4	$51.30	Charleroi
10253	HANAR	3	$58.17	Rio de Janeiro
10254	CHOPS	5	$22.98	Bern
10255	RICSU	9	$148.33	Genève
10256	WELLI	3	$13.97	Resende
10257	HILAA	4	$81.91	San Cristóbal

Filtering Sorting and Searching with IEnumerable

We can perform filtering ,sorting and searching by passing the corresponding query through datamanager.

Refer the below given code to perform these actions

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("/Home/DataSource").Adaptor(AdaptorT
ype.UrlAdaptor))
@(Html.EJ().Grid<object>("FlatGrid")
.DataManagerID("FlatData") // pass the datamanager Id
.Query("new ej.Query().sortByDesc('OrderID').sortBy('EmployeeID',
'ascending').search(4, 'EmployeeID').where('OrderID', 'lessThan', 10435,
false).take(10)") // query to be executed
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").IsPrimaryKey(true).TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("EmployeeID").HeaderText("Employee
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("Freight").HeaderText("Freight").TextAlign(TextAlign.Right).Width(
75).Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Width(110).Add();
})
)
)
```

The result of above code example is illustrated as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Order ID	Customer ID	Employee ID	Freight	Ship City
10431	BOTTM	4	$44.17	Tsawassen
10430	ERNSH	4	$458.78	Graz
10427	PICCO	4	$31.29	Salzburg
10426	GALED	4	$18.69	Barcelona
10419	RICSU	4	$137.35	Genève
10418	QUICK	4	$17.55	Cunewalde
10417	SIMOB	4	$70.29	Kobenhavn
10403	ERNSH	4	$73.79	Graz
10389	BOTTM	4	$47.42	Tsawassen
10382	ERNSH	4	$94.77	Graz

IQueryable

IQueryable is derived from IEnumerable and this executes select query on server side with all filters.IQueryable can be used for querying data from out-memory like remote database, service collections.

IQueryable support in DataManager

The DataManager now allows to execute a query against a specific data source by using the QueryableDataOperations. It can perform the IQueryable server side operation such as filtering, paging and sorting.

Refer the below code for performing these actions using IQueryable in Grid

C#

```
public ActionResult DataSource(Syncfusion.JavaScript.DataManager data)
{
IQueryable<OrdersView> datasource = new NorthwindDataContext().OrdersViews;
if (data.Where != null) // for filtering
datasource = QueryableDataOperations.PerformWhereFilter(datasource,
data.Where, data.Where[0].Condition);
if (data.Sorted != null)//for sorting
datasource = QueryableDataOperations.PerformSorting(datasource,
data.Sorted);
if (data.Search != null)
datasource = QueryableDataOperations.PerformSearching(datasource,
data.Search);
if (data.Skip >= 0)//for paging
datasource = QueryableDataOperations.PerformSkip(datasource, data.Skip);
if (data.Take > 0)//for paging
datasource = QueryableDataOperations.PerformTake(datasource, data.Take);
int count = datasource.Count();
return Json(new { result = datasource.ToList(), count = count },
JsonRequestBehavior.AllowGet);
}
```

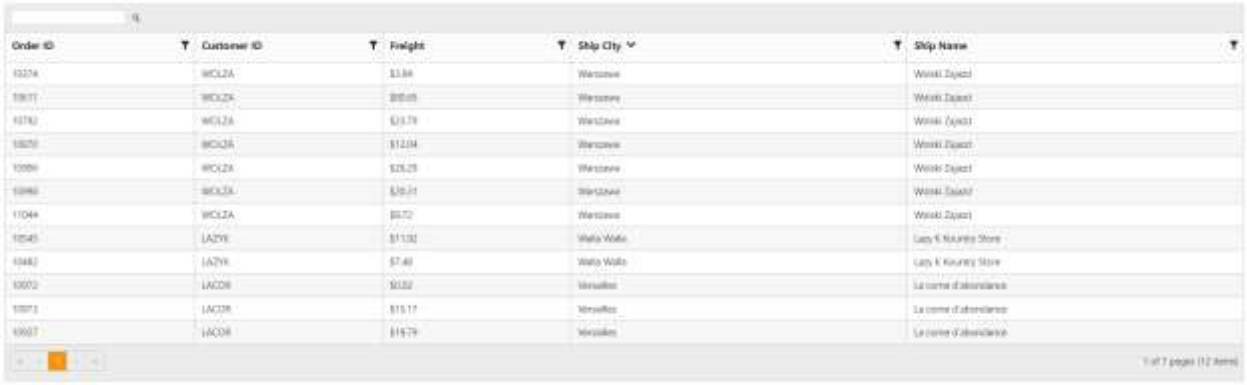
ASPX-CS

```
@(Html.EJ().Grid<OrdersView>("QueryableGrid")
.Datasource(ds =>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
ds.URL("/Home/DataSource").Adaptor(AdaptorType.UrlAdaptor);
})
.AllowScrolling()
.AllowSorting()
.AllowMultiSorting()
.AllowFiltering()
.AllowSearching()
.ToolbarSettings(set1 => set1.ShowToolbar(true).ToolbarItems(new
List<ToolBarItems>() { ToolBarItems.Search }))
.AllowPaging()
.SortSettings(sort => sort.SortedColumns(col =>
col.Field("ShipCity").Direction(SortOrder.Descending).Add()))
.FilterSettings(filter => { filter.FilterType(FilterType.Menu); })
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order ID").Add();
col.Field("CustomerID").HeaderText("Customer ID").AllowSorting().Add();
col.Field("Freight").HeaderText("Freight").Format("{0:C}").Add();
col.Field("ShipCity").HeaderText("Ship City").Add();
col.Field("ShipName").HeaderText("Ship Name").Add();
})
)
```

The result of above code example is illustrated as follows.



Anti-forgery Token

Anti-forgery tokens prevents anyone from submitting requests to your site while postback the data that are generated by a malicious script not generated by the actual user.

For this purpose, the input element with hidden value field and name attribute is created. The value from the input element stored in cookies. To enable the anti-forgery, set enableAntiForgery property as true.

HTML

```
<input type="hidden" name="_ejRequestVerifyToken" value="f2cd20a3-5ae1-4e19-
be61-d409191be3b1">
```

HTML

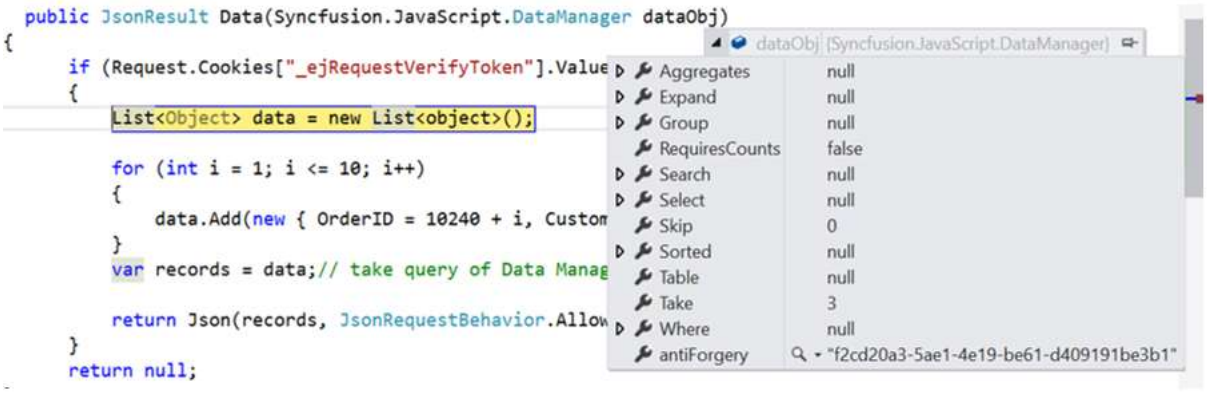
```
<div class="datatable">
```

```
<table id="table1" class="table table-striped table-bordered"
style="width:700px">
<thead>
<tr>
<th>Order ID</th>
<th>Customer ID</th>
<th>Employee ID</th>
</tr>
</thead>
<tbody></tbody>
</table>
</div>
@Html.EJ().DataManager("data").URL("Data").EnableAntiForgery(true).Adaptor(A
daptorType.UrlAdaptor).Render();
<script type="text/javascript">
$(function () {
var query = ej.Query();
var execute = window.data.executeQuery(query) // executing query
.done(function (e) {
$("#table1 tbody").html($("#tableTemplate").render(e.result));
});
});
</script>
<script id="tableTemplate" type="text/x-jsrender">
<tr>
<td>{{>OrderID}}</td>
<td>{{>CustomerID}}</td>
<td>{{>EmployeeID}}</td>
</tr>
</script>
```

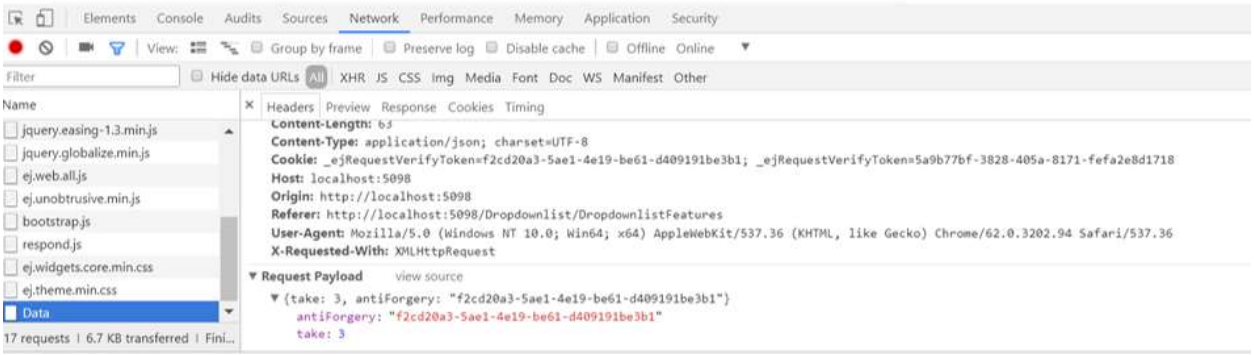
C#

```
public JsonResult Data(Syncfusion.JavaScript.DataManager dataObj)
{
if (Request.Cookies["_ejRequestVerifyToken"].Value == dataObj.antiForgery)
{
List<Object> data = new List<object>();
for (int i = 1; i <= 10; i++)
{
data.Add(new { OrderID = 10240 + i, CustomerID = "Customer" + i, EmployeeID
= i });
}
var records = data;// take query of Data Manager
return Json(records, JsonRequestBehavior.AllowGet);
}
return null;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



In the header, You can find the anti-forgery token value



DatePicker

Overview

The Essential ASP.NET MVC (EJMVC) DatePicker component provides the support for displaying calendar in web page and allows the user to pick or directly enter the date value as like EJ DatePicker, since EJMVC DatePicker is a server side wrapper of EJ DatePicker.

Key features

- Formatting the date value.
- Globalization.
- Range the date value to pick.
- Quick picking date by drill down or up.
- State persistence.
- Strongly typed HTML editor
- Responsive dimension.
- Flexible customization.
- Custom styling.
- Built-in jQuery validation.
- Accessibility (keyboard and ARIA).

Copyright © 2001 - 2020 Syncfusion Inc.

Getting Started

A new MVC application and required assemblies with dependent files

To get start with Essential ASP.NET MVC DatePicker, create a new MVC application and add the required assemblies in references and then refer the below specified dependent CSS file as well as scripts

To create a MVC project and add necessary assemblies you can use the help of the given MVC-Getting Started Documentation.

CSS file

- [ej.web.all.min.css](http://cdn.syncfusion.com/{{ site.releaseversion }}/js/web/flat-azure/ej.web.all.min.css) includes all widgets styles (To know more about theme refer Theming in Essential JavaScript Component)

External script files

- jQuery (from the version 1.7.1 to 3.1.0)

jQuery.easing external dependency has been removed from version 14.3.0.49 onwards. Kindly include this jQuery.easing dependency for versions lesser than 14.3.0.49 in order to support animation effects.

Internal script files

File	Description / Usage
ej.core.min.js	Includes only the widget basic functions and Framework features. Must be referred always before using all the JS controls
ej.globalize.min.js	To support the globalization.
ej.datepicker.min.js	DatePicker plugin.

Note: From V13.4.0.53 onwards, jQuery.globalize.min.js file has been replaced with our script file ej.globalize.min.js to support the globalization for our widgets. For version lower than 13.4.0.53, refer jQuery.globalize.min.js.

You can make use of **ej.web.all.min.js** file which encapsulates all EJMVC components and frameworks in single file.

- [ej.web.all.min.js](http://cdn.syncfusion.com/{{ site.releaseversion }}/js/web/ej.web.all.min.js) - includes all web widgets.

If you are using NuGet packages, then required files to render the EJMVC components, will get included in corresponding location automatically in your application.

Note: In production, we highly recommend you to use our custom script generator to create custom script file with required controls and its dependencies only. Also to reduce the file size further please use GZip compression in your server.

Copyright © 2001 - 2020 Syncfusion Inc.

Below is a simple Layout CSHTML file with required CSS and script reference added to create the Essential ASP.NET MVC DatePicker

ASPX-CS

```
<head>
<meta charset="utf-8" />
<meta name="viewport" content="width=device-width, initial-scale=1.0">
<title>@ViewBag.Title - My ASP.NET MVC Application</title>
<link rel="stylesheet" href="http://cdn.syncfusion.com/{{
site.releaseversion }}/js/web/flat-azure/ej.web.all.min.css" />
<script src="https://code.jquery.com/jquery-1.10.2.min.js"></script>
<script src="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/ej.web.all.min.js"> </script>
<script src="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/common/ej.unobtrusive.min.js"></script>
</head>
```

DatePicker Initialization

The Essential ASP.NET MVC DatePicker can be created using HTML helper like below code example (Razor code)

ASPX-CS

```
@Html.EJ().DatePicker("datePicker")
```

Note: DatePicker is a form control, so on form submitting its value can be received by its name, and normally id has been treated as name. If you want to set the name manually you can use our HtmlAttributes property. You can get this property related information from here

Get / Set value

The Essential ASP.NET MVC DatePicker provides an options to configure all its properties and to get its value. DatePicker value can be assigned during initialization or at run time. Below code shows how to assign values at initialization.

ASPX-CS

```
@Html.EJ().DatePicker("datePicker").Value(System.DateTime.Now).DateFormat("y
yyy/MM/dd")
```

You can assign values to existing EJMVC DatePicker using its instance. Consider that you going to set date value at button click, refer the below code example.

JS

```
<script>
//bind below onClick action to button
function onClick() {
//create instance for datePicker.
// only after control creation we can get dateObj otherwise it throws
exception.
var dateObj = $("#datePicker").ejDatePicker('instance');
//set value using date object
dateObj.option('value', new Date());
//get value using date object and displays in alert box
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
alert(dateObj.option('value'));
}
</script>
```

Note: Existing DatePicker instance can be created by jQuery.data() and you can control the API's of DatePicker behavior.

Client Side Events

You can handle the all available client side events in Essential JavaScript DatePicker. Refer the below code example to use the client side event in EJMVC DatePicker

ASPX-CS

```
@Html.EJ().DatePicker("datePicker").Value(System.DateTime.Now).ClientSideEve
nts(e => e.Change("onChange"))
<script>
function onChange(args) {
//args contains entire model of DatePicker to get the value of all
properties.
//alert popup shows the previous date and selected date.
alert(" previous date is : " + args.prevDate + " \n selected date is : " +
args.value);
}
</script>
```

Strongly Typed HTML Helper

EJMVC DatePicker can be created using DatePickerFor extension, which behaves as strongly typed HTML helper. This reduce the run time issues while using model values in DatePickerFor , since it will find the issues if any in compilation time itself. Also, to know about the setting model properties to DatePickerFor control, please refer the link:

https://www.syncfusion.com/kb/4670/how-to-define-properties-for-for-controls

Please refer the below code to create the DatePickerFor control in your application

ASPX-CS

```
@Html.EJ().DatePickerFor(model => model.datepicker,
(Syncfusion.JavaScript.Models.DatePickerProperties)ViewData["date"])
@Html.ValidationMessageFor(model => model.datepicker1)
```

Behavior Settings

The Essential ASP.NET MVC DatePicker has some default behavior settings which helps to perform more operation by built-in.

Selected Date

The Essential ASP.NET MVC DatePicker value can be selected through picking date from DatePicker calendar or you can set it by using "Value" property.

EJMVC DatePicker allows only the valid date to be entered and it should be within the specified range. By default, strict mode is enabled in DatePicker, so it will restrict invalid date and resets to previous date if it's not valid. Also the valid date should be defined in specified range or else it resets to min or

Copyright © 2001 - 2020 Syncfusion Inc.

maximum date when the entered date is out of range. To know more about strict mode refer Strict Mode

Date Range

EJMVC DatePicker provides an option to restrict the user to pick the date from specified range of value. You can utilize this option by make use of 'MinDate' and 'MaxDate' property.

MinDate - specifies the minimum date to be picked in DatePicker calendar by disabling below date of minDate.

MaxDate - specifies the maximum date to be picked in DatePicker calendar by disabling above date of maxDate.

Refer below example to set min and max date range in DatePicker at initialization (You can change the **'MinDate'** and **'MaxDate'** value dynamical as like 'Value' property)

ASPX-CS

```
@*sets min and max date to be pick able in datepicker*@
@Html.EJ().DatePicker("datePicker").Value(System.DateTime.Now).MinDate("2014
/06/03").MaxDate("2014/06/19")
```

Note: You can change the **MinDate** and **MaxDate** value dynamically like **Value** property

Start and Depth Level

Start and depth represents the view of Essential ASP.NET MVC DatePicker calendar. DatePicker calendar has four different level of views, which are month, year, decade and century. It allows you to quick pick date from different months and years by navigating through different views.

By default DatePicker starts with month view and can be drill down into year, decade and century. You can also change the start and depth level view by using StartLevel and DepthLevel property. So that you can initiate DatePicker calendar to view at any level and control the navigation.

- "MonthÂ•" - shows the days in month to pick.
- "Year" - shows the months in year to pick.
- "Decade" - shows the years in decade to pick.
- "Century" - shows the decades in century to pick.

ASPX-CS

```
@*sets the start view and defines when the DatePicker calendar to return
date*@
@Html.EJ().DatePicker("datePicker").Value(System.DateTime.Now).StartLevel(Pe
riod.Year).DepthLevel(Period.Year).DateFormat("MMMM yyyy")
```

Display Inline Mode

The Essential ASP.NET MVC DatePicker provides an option to act as calendar by setting the DisplayInline property as true. In this mode the DatePicker calendar has been placed open state constantly to pick the date.

Refer below code example to represent DatePicker as calendar.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@*sets inline to represent datePicker as DatePicker calendar*@
@Html.EJ().DatePicker("datePicker").Value(System.DateTime.Now).DisplayInline
(true)
```

Strict Mode

Strict mode in Essential ASP.NET MVC DatePicker allows you to enter valid or invalid date in input textbox, but an error class will get added to exhibit if it is an invalid date. When you set EnableStrictMode to false, DatePicker allows you to enter only the valid date or else it will resets with previous value.

Also the valid date should be defined in specified range or else it resets to min or maximum date when the entered date is out of range

By default **EnableStrictMode•** is true, so you can enter any value other than date too, but an **error** class ("**e - error**") will get added to wrapper to highlight the invalid date.

ASPX-CS

```
@*sets active strict mode*@
@Html.EJ().DatePicker("datePicker").Value(System.DateTime.Now).EnableStrictM
ode(false)
```

You can also override the **error** class to highlight when invalid date is entered.

ASPX-CS

```
@*sets inactive strict mode*@
@Html.EJ().DatePicker("datePicker").Value(System.DateTime.Now).EnableStrictM
ode(true)
```

CSS

```
<style>
/* error class to highlight invalid date */
.e-error .e-input {
color: Red; /* highlights invalid date font color in input */
}
</style>
```

Formatting

Formatting is the way of displaying the date or number as string in some standard format which is based on culture specific or user need.

Below table shows the patterns to format date value.

Format Pattern	Description	Result
d	The day of the month between 1 and 31	"1" to "31"
dd	The day of the month with leading zero if required.	"01" to "31"
ddd	Abbreviated day name.	"Mon" to "Sun"

Copyright © 2001 - 2020 Syncfusion Inc.

dddd	The full day name	"Monday" to "Sunday"
M	The month of the year between 1 - 12	"1" to "12"
MM	The month of the year with leading zero if required	"01" to "12"
MMM	Abbreviated month name	"Jan" to "Dec"
MMMM	The full month name	"January" to "December"
yy	The year as a two-digit number	"99" or "08"
yyyy	The full four digit year	"1999" or "2008"

Date Format

Each culture has some specific date format. Date format defines a format or structure of the displayed date in the textbox of EJMVC DatePicker component. You can change the date format by using DateFormat property

The standard formats are listed as follows

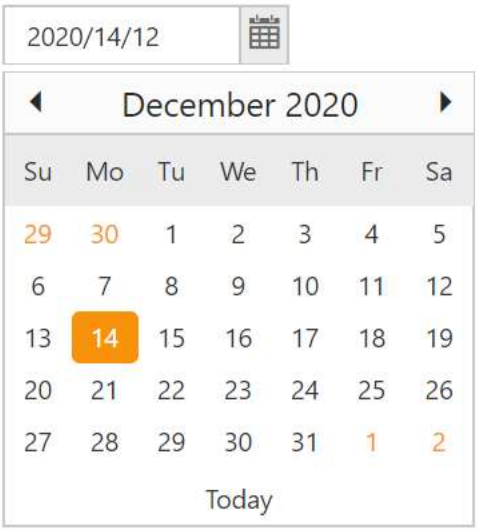
Format Name	Formats	Input Date	Formatted Date
Default	M/d/yyyy	"12/01/2020"	"12/1/2020"
Short	"d M, y"	"12/14/2020"	"14 12,20"
Medium	"d MM, y"	"12/14/2020"	"14 12, 20"
Full	dddd, d MMMM, yy	"12/14/2020"	"Monday, 14 December, 20"
UTC	yyyy-MM-dd	"12/14/2020"	"2020-12-14"

By default **en-US** culture Date format is "M/d/yyyy".

ASPX-CS

```
@*sets en-US culture with specified date format*@
@Html.EJ().DatePicker("datePicker").Value(System.DateTime.Now).Locale("en-
US").DateFormat("yyyy/dd/MM")
```

Copyright © 2001 - 2020 Syncfusion Inc.



To get the culture and date format of DatePicker, refer the below code example

JS

```
// create instance for datePicker
// only after control creation we can get dateObj otherwise it throws
exception
var dateObj = $("#datePicker").ejDatePicker('instance');
dateObj.option('locale'); //returns the culture in string
dateObj.option('dateFormat');// returns the date Format in string
```

Note: By default date format is based on culture specific. You have to refer the required culture specific files in layout page of your web application in order to localize DatePicker and customize different format for that culture. Refer this link to know more about this functionality support in DatePicker.

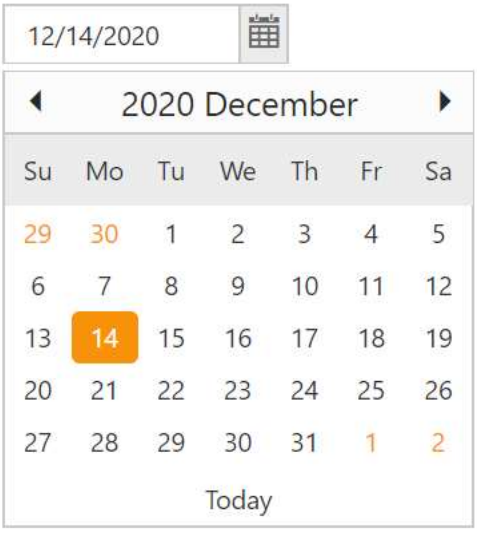
Header Format

EJMVC DatePicker calendar consists of header, day header, days and footer section. In which header section shows the current view of DatePicker calendar by displaying the selected day or month or year. It can be formatted as like date format by using HeaderFormat property.

ASPX-CS

```
@*sets the selected header format to display in header*@
@Html.EJ().DatePicker("datePicker").HeaderFormat("yyyy
MMMM").Value("12/14/2020")
```

Copyright © 2001 - 2020 Syncfusion Inc.

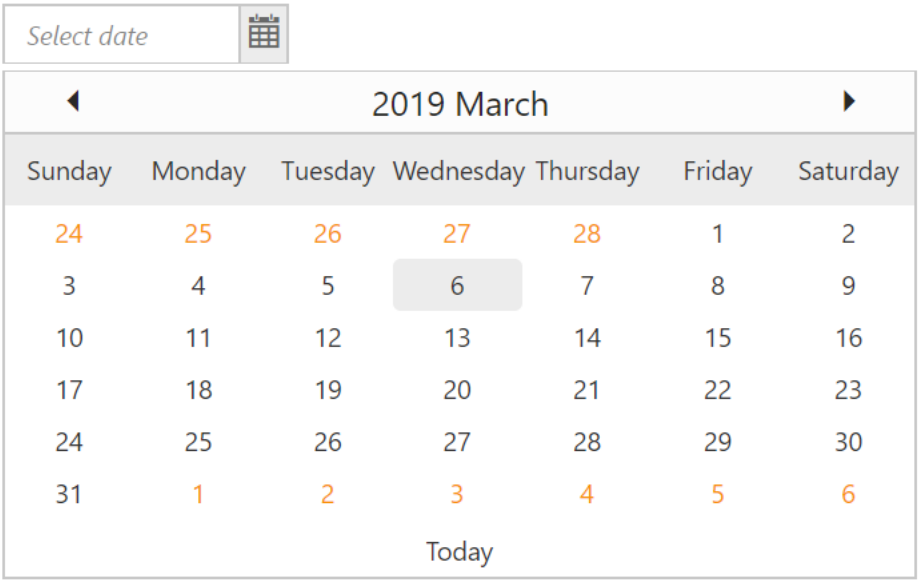


Day Header

Day header determines the days name to be displayed in terms of short, medium and long in EJMVC DatePicker calendar by using DayHeaderFormat property. Also the DatePicker calendar size varies with this specified values.

ASPX-CS

```
@*sets the day header as long*@
@Html.EJ().DatePicker("datePicker").DayHeaderFormat(Header.Long)
```



Tooltip with Formatting

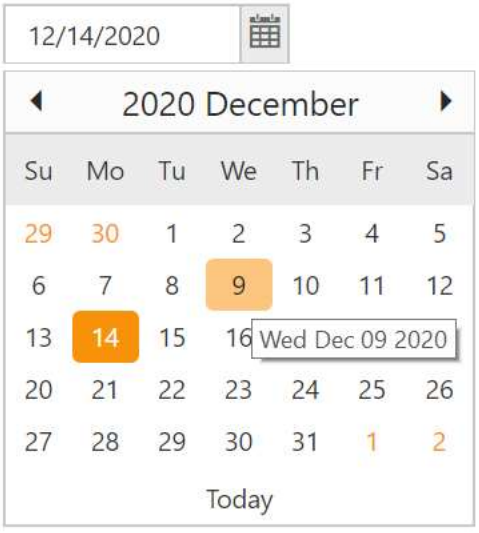
The EJMVC DatePicker calendar shows tooltip on hovering the date by specifying the formatted date of hovered date. Its helps you to get clear view about the date going to select. You can show or hide this tooltip option by using ShowTooltip property.

Copyright © 2001 - 2020 Syncfusion Inc.

You can also change the format of tooltip by using TooltipFormat property. Below codes example allows to show tooltip and format its value.

ASPX-CS

```
@*sets and shows tooltip on hovering date on calendar*@
@Html.EJ().DatePicker("datePicker").ShowTooltip(true).TooltipFormat("dd/MM/yy").Value("12/14/2020")
```



Globalization

Essential ASP.NET MVC DatePicker has been provided with built-in localization support, so that it will be able adapt based on culture specific locale defined for it.

More than 350 culture specific files are available to localize the date. To know more about EJ globalize support, please refer the below link

http://help.syncfusion.com/js/localization

Note: Seven culture-specific script files are available in the below specified location. For all other culture files, please download from the GitHub location.

(installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n
For example, If you have installed the Essential Studio package within C:\Program Files (x86), then navigate to the below location, C:\Program Files (x86)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n

To translate our control content from default English to any of the culture, say For example - German language, then you need to refer the ej.culture.de-DE.min.js file in your application,

The **en-US** locale is currently being used as default culture in DatePicker. You can set any other culture to DatePicker by using **Locale** property. Below code example shows German cultured DatePicker.

Refer the below German culture file in head section of HTML page after the reference of **ej.web.all.min.js** file.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script src="https://cdn.syncfusion.com/js/assets/i18n/ej.culture.de-DE.min.js"></script>
```

Set German culture to DatePicker at initialization.

ASPX-CS

```
@Html.EJ().DatePicker("datePicker").Value(System.DateTime.Now).Locale("de-DE")
```

Watermark and Today Button Text

By default the EJMVC DatePicker input has “select date” as watermark text, you can change this value by using WatermarkText property. Also there’s a today button in DatePicker calendar which allows you to quick select the current date, you can change this value by using **ButtonText** property.

ASPX-CS

```
@*sets watermark text and button text*@
@Html.EJ().DatePicker("datePicker").Value(System.DateTime.Now).WatermarkText("enter the date value").ButtonText("current date")
```

Based on culture specific, only date gets localized but by changing the watermark and button text, you can completely localize the DatePicker UI too.

Refer below code example to update those value based some culture say for example English and German.

JS

```
//create instance for datePicker.
// only after control creation we can get dateObj otherwise it throws exception.
var dateObj = $("#datePicker").ejDatePicker('instance');
//condition to check English culture and change watermark and button text using dateObj.
if (ej.cultureObject.name == "en-US") {
dateObj.option({ buttonText: "Today", watermarkText: "select date" })
}
//condition to check German culture and change watermark and button text using dateObj.
if (ej.cultureObject.name == "de-DE") {
dateObj.option({ buttonText: "heute", watermarkText: "Datum auswählen" })
}
```

Customization

EJMVC DatePicker appearance can be customized using below listed properties.

Set Dimension

By default DatePicker has standard height and width (height: "30" and width: "143"). You can change this height and width by using Height and Width property respectively.

ASPX-CS

```
@*sets height and width of the datepicker control*@
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().DatePicker("datePicker").Height("50px").Width("300px")
```

Since EJMVC DatePicker is a form control and you can make it as responsive by specifying its width as **100%**.

ASPX-CS

```
@*sets width as 100 percentage*@
@Html.EJ().DatePicker("datePicker").Width("100%")
```

Show Footer

You can show or hide the footer of EJMVC DatePicker calendar by using ShowFooter property.

ASPX-CS

```
@*hides the footer in popup calendar*@
@Html.EJ().DatePicker("datePicker").ShowFooter(false)
```

Note: Footer contains the today button to quickly navigate to the current date. By turning off it, you have to select current date by manually.

Show Popup Button

EJMVC DatePicker input textbox contains a button to open the DatePicker calendar. You can hide this DatePicker calendar button using ShowPopupButton value as false.

By hiding this button, you can open the DatePicker by focusing the input textbox element itself.

ASPX-CS

```
@*hides the popup calendar button*@
@Html.EJ().DatePicker("datePicker").ShowPopupButton(false)
```

Show Other Months

You can show or hide the other month days from EJMVC DatePicker calendar by using ShowOtherMonths property.

ASPX-CS

```
@*hides the days of other months in calendar*@
@Html.EJ().DatePicker("datePicker").ShowOtherMonths(false)
```

Highlight Special Date

The Essential ASP.NET MVC DatePicker allows you to highlight the special dates in EJMVC DatePicker calendar by using SpecialDates property. It receives the list of "dataSpecial" date fields such as, in which the data should contain the date value, icon CSS class and tooltip as field values with any names.

Special Date property has following properties,

Members	Description
Date	It specifies the mapping field of special date

Copyright © 2001 - 2020 Syncfusion Inc.

IconClass	It specifies the mapping field of icon CSS class.
Tooltip	It specifies the mapping field of tool tip text.

ASPX-CS

```
@*sets the special date in datepicker calendar*@
@Html.EJ().DatePicker("datePicker").SpecialDates(SpecialDate => {
SpecialDate.Add().Date("28/06/2015").IconClass("birthday").Tooltip("John
birthday"); })
```

Validation

EJMVC DatePicker provides very cool way to validate the value by custom rules and messages before its get processing. Enhanced APIs and built-in validation support in EJWEB DatePicker provides the quick validation in client side itself which provides the easy customization and better user experience than the validating the values in server side. Most common client side validation plugin is jQuery Validation.

DatePicker supports this validation by built-in, so you can do client validation with simple steps to validate and respond validation message. The jQuery validate plugin rules and custom methods can be used in the DatePicker control with the help of two properties,ValidationRules and ValidationMessage.

Before using those properties, you need to add the jQuery validate plugin to your HTML page.

Refer the below jQuery validation plugin script after jQuery script reference.

ASPX-CS

```
<script
src="http://ajax.aspnetcdn.com/ajax/jquery.validate/1.14.0/jquery.validate.m
in.js"></script>
```

jQuery validation library contains some default settings for validating the form. By default, it ignores hidden elements in from validation. But some of our EJ components (“Checkbox”, “MaskEdit”, ”NumericTextbox”, “CurrencyTextbox”, “PercentageTextbox”, “RTE”, “Dropdownlist”) contains hidden fields with values, these

values need to be validated at here. So to perform the validation properly, you have to set “[]” in “ignore” API of “$.validator.setDefaults”.

If validation gets fail, in-built “error” class will be added to corresponding element. Here you can specify a custom class with your own style using “errorClass” API and you can place the error message in necessary position using “errorPlacement” API. Refer following code block to customize the default jQuery validation settings.

JAVASCRIPT

```
$.validator.setDefaults({
//if we don’t set custom class, default “error” class will be added
errorClass: 'e-validation-error',
//it specifies the error message display position
errorPlacement: function (error, element) {
$(error).insertAfter(element.closest(".e-widget"));
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
});
```

ASPX-CS

```
<!--form to submit-->
@using (Html.BeginForm())
{
//Sets the field to be required with validation message
@Html.EJ().DatePicker("datePicker").ValidationRules(rule =>
rule.AddRule("required", true)).ValidationMessage(msg =>
msg.AddMessage("required", "Required Date value"));
<input type="submit" value="click here!" />
}
```

Note: jQuery validation works only within the form element.

State Persistence

You can sustain the entire widget model of EJMVC DatePicker even after form post or browser refresh by using EnablePersistence property. So the entire model values such as

- Selected date
- Highlighted date
- Start and depth level

are stored in local storage / cookies of browser before page refreshes and reinitialized with the restored model after refresh.

ASPX-CS

```
@*persists the DatePicker model*@
@Html.EJ().DatePicker("datePicker").EnablePersistence(true)
```

Miscellaneous

Start Day

By default EJMVC DatePicker calendar starts with "Sunday"• and ends with "Monday". You can redefine this start day by using StartDay property.

Refer below code to start Wednesday as start day.

ASPX-CS

```
@*sets start day as Wednesday in calendar*@
@Html.EJ().DatePicker("datePicker").StartDay(3)
```

Step Months

The EJMVC DatePicker calendar allows you to quick navigate back and forth from one month to previous or next month by clicking the arrow button. By default it is navigate one by one month. You can also navigate by skipping months in odd or even or any count by using StepMonths property.

ASPX-CS

```
@*skips the one months from current month(July to Sept to Nov)*@
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().DatePicker("datePicker").StepMonths(2)
```

Read Only

You can make EJMVC DatePicker as read only by setting ReadOnly property as true. It allows only to read the value and it cannot be changed by interaction.

ASPX-CS

```
@*sets DatePicker as read only*@
@Html.EJ().DatePicker("datePicker").ReadOnly(true)
```

Enable or Disable

You can enable or disable the EJMVC DatePicker textbox by using Enabled property. In inline mode DatePicker calendar also gets enabled or disabled.

ASPX-CS

```
@*disables the DatePicker textbox*@
@Html.EJ().DatePicker("datePicker").Enabled(false)
```

How to?

Customizing template with range selection between two DatePicker.

You can customize the date field to emphasize the particular dates in EJMVC DatePicker calendar with help of SpecialDates and set the date range using MinDate and MaxDate property.

Validating the date value in server side

The EJMVC DatePicker control, is a form control which allows us to validate the date value in client side and server side actions. Please refer from the validation to know more about this with EJMVC DatePicker control.

Localize DatePicker with browser specific culture

You can get the browser culture name at page load or document ready state. Based on the culture name, EJMVC DatePicker can be initiated with that specific culture value by assigning to Locale property.

Disable specific dates to restrict user

EJMVC DatePicker allows you to restrict date selection in specific range by using date range option. But you can also restrict selective date in DatePicker calendar by utilizing BeforeDateCreate event. This event will get triggered at each date creation. So you can disable the selective date in this event to restrict the user.

ASPX-CS

```
@*handler to listen each date create*@
@Html.EJ().DatePicker("datePicker").ClientSideEvents(clientSideEvent =>
clientSideEvent.BeforeDateCreate("restrictDate"))
<script>
//event get triggered for each date create.
function restrictDate(args) {
//date to disable in calendar to restrict selection.
var disableDate = new Date("09/22/2015");
//compares two and adds the disable class.
if (+args.date === +disableDate)
args.element.addClass('e-disable');
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
// args contains current date and its element.
}
</script>
```

How to add clear button with DatePicker?

Clear button can be included in the DatePicker control. In the create event of DatePicker, clear button element should be appended in the input element and event for clearing the value should bind with the clear button element. Refer the sample from the link Clear button to know how to add the clear button with the DatePicker component. Based, on theme loaded you can adjust the styles of the clear button.

ASPX-CS

```
@Html.EJ().DatePicker("date").ClientSideEvents(e =>
e.Create("Created")).Value(System.DateTime.Now)
<script>
function Created() {
if (this.innerWrapper.find('.e-clear-date').length == 0) {
this.innerWrapper.append("<span class='e-clear-date e-icon'></span>"); //
create and append the 'div' element to the calendar
this._on($('.e-clear-date', this.innerWrapper), "click", function () {
this.option('value', null); if (!this.model.displayInline) this.hide(); });
// bind the 'Click' event to that 'div' element
}
}
</script>
<style>
/*styles for clear button*/
.e-clear-date {
text-align: center;
position: absolute;
right: 24px;
top: 0;
background: #ececec;
width: 21px !important;
height: 100% !important;
margin-top: -16px !important;
}
.e-clear-date:hover {
background: #86cbea;
cursor: pointer;
}
.e-clear-date:before {
content: "\e605";
font-size: 16px;
line-height: 1.8;
}
/*end of styles*/
</style>
```

How to integrate with bootstrap grid system?

EJMVC DatePicker is responsive control, you have to just set the input element width as 100%. In Bootstrap grid layout use the below code example to get responsive textbox

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@*sets the height and width to 100%*@
@Html.EJ().DatePicker("datePicker").Height("100%").Width("100%")
```

Render Datepicker from Code behind

DatePicker can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of DatePicker properties in the controller.

C#

```
//Namespace to get the JavaScript (DatePicker) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class DatePickerController : Controller
{
// GET: DatePicker
public ActionResult DatePickerFeatures()
{
//Initializing the DatePicker model
DatePickerProperties DateObj = new DatePickerProperties();
//Initializing the datasource and other properties
DateObj.Width = "300px";
DateObj.Value = "12/12/2018";
//Passing DatePicker properties using the ViewData
ViewData["DateModel"] = DateObj;
return View();
}
}
}
```

Binding the DatePicker properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().DatePicker("searchCustomer",(Syncfusion.JavaScript.Models.DatePick
erProperties)ViewData["DateModel"]).Render();
}
```

DateRangePicker

DateRangePicker

The Essential ASP.NET MVC DateRangePicker control allows the user to select date range from two calendars in the popup. Also, DateRangePicker has the flexible options to navigate back and forth from month and years and pick the start and end date in any month.DateRangePicker provides the easiest way to get the details within the date ranges in application.

Key Features

- Values formatting.
- Globalization.

Copyright © 2001 - 2020 Syncfusion Inc.

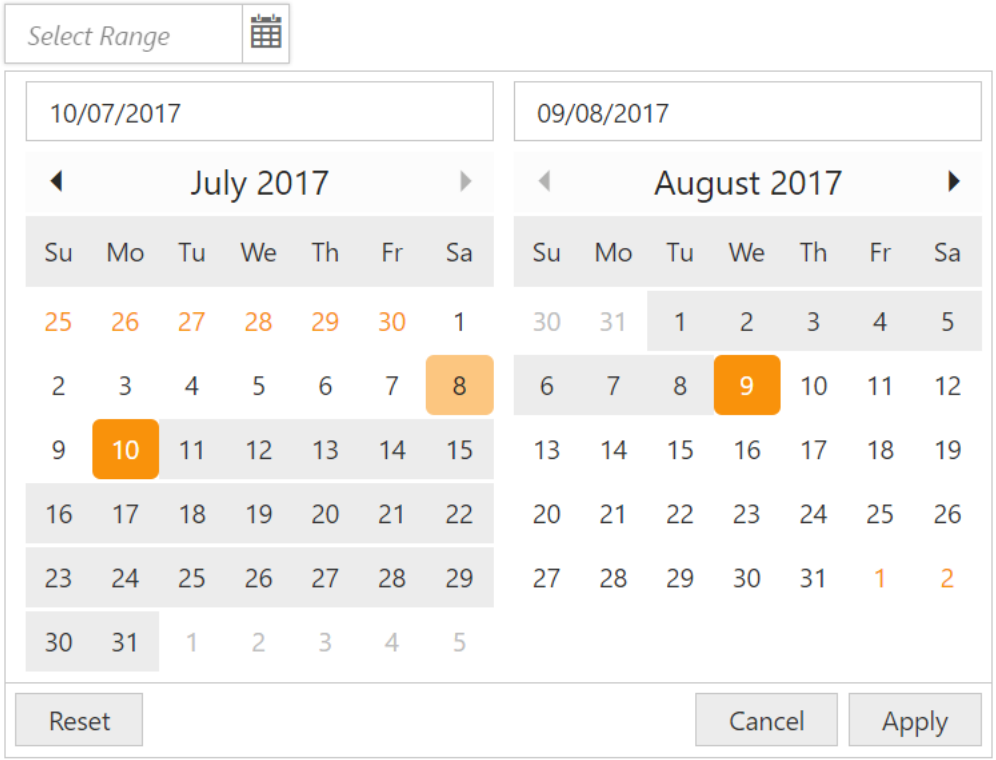
- Preset Ranges.
- Time Picker option.
- Drilldown navigation support.
- State persistence.
- Responsive dimension.
- Flexible customization.
- Custom Styling.

Getting Started

This section explains briefly about how to render a DateRangePicker in your application with ASP.NET MVC.

Create your first DateRangePicker in MVC

The Essential ASP.NET MVC DateRangePicker supports to display two calendars in the webpage and allows you pick date range from the calendars. Refer the following guidelines to customize the DateRangePicker. The following screenshot illustrates the functionality of DateRangePicker.



DateRangePicker

In the above screenshot, you can see the start date and end date selection of a date range in DateRangePicker. This control offers easy way to navigate and select desired date range from one month as start date to other month as end date or we can pick both the start date and end date from the same month.

Create a DateRangePicker

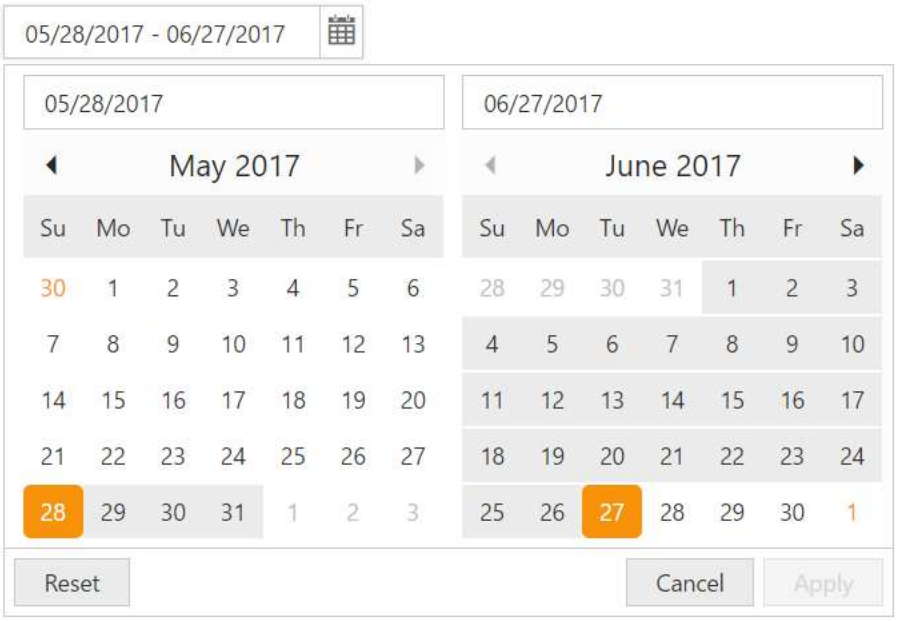
ASP.NET MVC DateRangePicker widget basically renders with built-in features like navigation between two calendars in popup with animations and flexible APIs. You can easily create the DateRangePicker widget using simple DateRangePicker elements as follows.

1. Create an MVC Project, add necessary assemblies and scripts.
2. Refer [MVC-Getting Started] (https://help.syncfusion.com/aspnetmvc/getting-started).
3. Add the following code to the corresponding view page to render DateRangePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateRangePicker widget*@
@Html.EJ().DateRangePicker("DateRangePick").Value("05/28/2017-
06/27/2017").DateFormat("dd/MM/yyyy").Width("200px")
```

Execute the above code to render the following output.



DateRangePicker

Start Date

Start Date can be selected from any calendar in the popup of DateRangePicker. The date which is selected in the calendar in any following cases will be considered as StartDate of a date range,

1. Click on any date in an calendar of dateRange popup where there is no selection in calendars.
2. Click on date which is lesser than existing start date
3. Click on calendar when already there is start date and end date is updated.In this case exiting selection will be cleared fully and clicked date will be set as StartDate to form new range.

Start Date of range can be set using API called **StartDate**, please refer the below code example:

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateRangePicker widget with start date *@
@Html.EJ().DateRangePicker("DateRangePick").StartDate("5/1/2017")
```

Copyright © 2001 - 2020 Syncfusion Inc.

And also, StartDate can be set to popup, by entering the date value into first input box in popup.

End Date

End Date of the date range can be selected from popup directly. Else this can be also updated by using the API called EndDate.

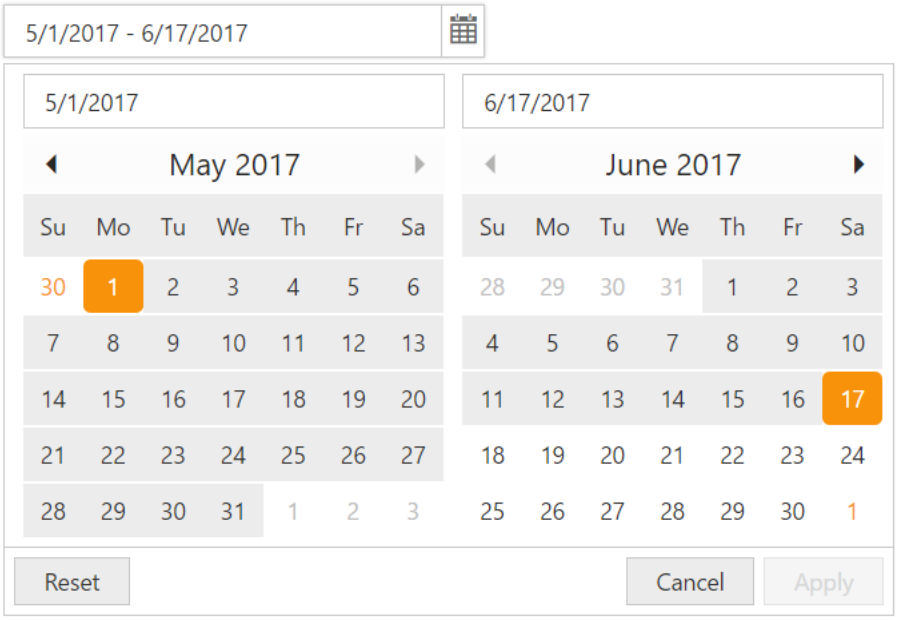
The Selection next to the **StartDate** will be considered as end date. This selected date should be higher or equal date than the existing start date. Else this selection will be considered **StartDate** as we have mentioned in StartDate section above.

Below code will explain to use the **EndDate** API to set the end Date in popup.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateRangePicker widget with customized Start Date and  End Date*@
@Html.EJ().DateRangePicker("DateRangePick").Width("25%").StartDate("5/1/2017
").EndDate("6/17/2017")
```

Execute the above code to render the following output.



DateRangePicker with StartDate and EndDate

End Date can be set to popup by entering the date into the second input box in popup.

Behavior-Settings

DateRangePicker has some default behavior settings which helps you to perform more operations by built-in.

Value

DateRangePicker value can be selected through picking two date values from available two calendars on popup or you can set it by using **Value** property.

Add the following code in your CSHTML page to render DateRangePicker with value.

ASPX-CS

```
@Html.EJ().DateRangePicker("DateRangePick").Value("5/12/2017 -
12/5/2017").ClientSideEvents(p => p.Change("onChange"))
```

ASPX-CS

```
function onChange(args) {
//args contains entire model of DateRangePicker to get the value of all
properties.
//alert DateRangePicker shows the start date and end date.
alert(" start date is : " + args.startDate + " \n end date is : " +
args.endDate);
}
```

Separator

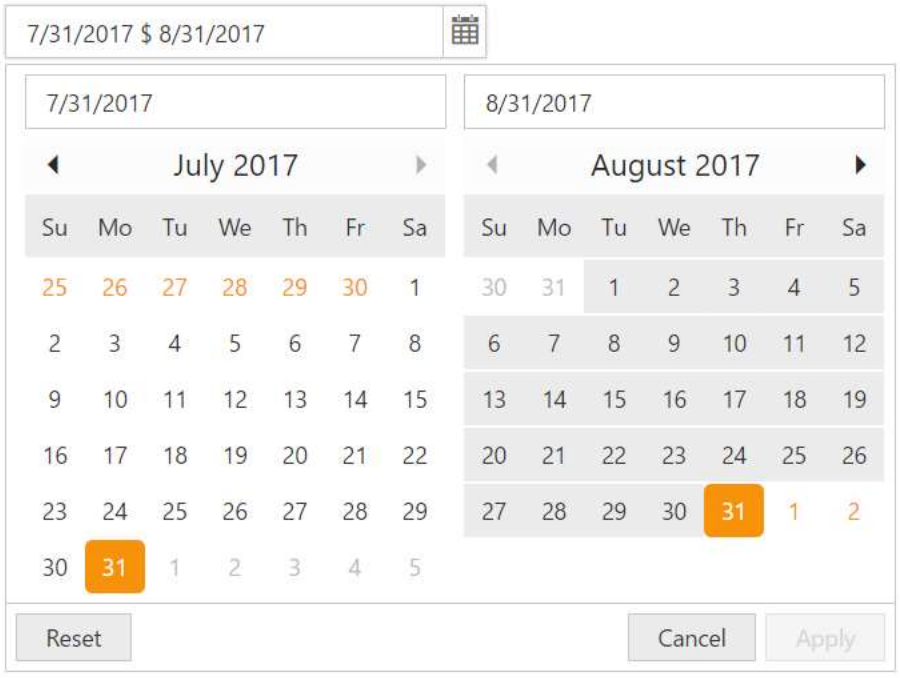
The value of the DateRangePicker popup will be presented with two date strings which is separated by **Separator** (e.g “11/1/2016 - 11/2/2017”).By default , the symbol "-" separates the two date strings of the value and this can be changed using API called **Separator**. Please check with below code example to set the separator using **Separator** API.

Add the following code in your CSHTML page to render DateRangePicker widget with value separated by separator.

ASPX-CS

```
@Html.EJ().DateRangePicker("DateRangePick").Value("7/31/2017 $
8/31/2017").Width("25%").Separator("$")
```

Execute the above code to render the following output.



DateRangePicker

Localization

DateRangePicker, has built in support with Localization. so, it allows users to use culture specified DateRangePicker component with their application using locale API.

Essential ASP.NET MVC DateRangePicker has been provided with built-in localization support, so that it can adapt based on culture specific locale defined for it.

More than 350 culture specific files are available to localize the DateRangePicker. To know more about EJ globalize support, please refer the below link

http://help.syncfusion.com/js/localization

Note: Seven culture-specific script files are available in the below specified location. For all other culture files, please download from the GitHub location.

(installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n
For example, If you have installed the Essential Studio package within C:\Program Files (x86), then navigate to the below location, C:\Program Files (x86)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n

To translate our control content from default English to any of the culture, say For example - French language, then you need to refer the ej.culture.fr-FR.min.js file in your application,

The **en-US** locale is currently being used as default culture in **DateRangePicker**. You can set any other culture to DateRangePicker using **Locale** property. Below code example shows French cultured DateRangePicker.

Refer the below French culture file in head section of HTML page after the reference of **ej.web.all.min.js** file.

JAVASCRIPT

```
<script src="https://cdn.syncfusion.com/js/assets/i18n/ej.culture.fr-FR.min.js"></script>
```

If you want to change month names to your culture month just replace month names with your culture month names or your customized format.

The following example is used to set DateRangePicker in French language.

ASPX-CS

```
calendars: {
standard: {
'/': '/',
':': ':',
firstDay: 1,
days: {
names: ["dimanche","lundi","mardi","mercredi","jeudi","vendredi","samedi"],
namesAbbr: ["dim.","lun.","mar.","mer.","jeu.","ven.","sam."],
namesShort: ["di","lu","ma","me","je","ve","sa"]
},
months: {
```

Copyright © 2001 - 2020 Syncfusion Inc.

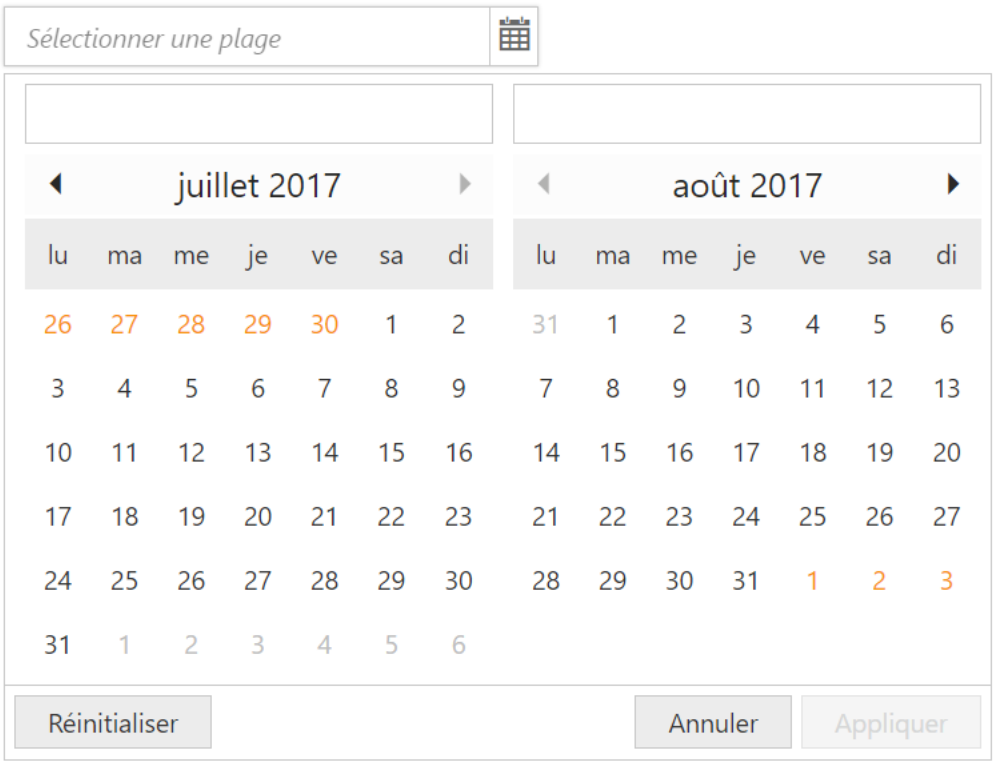
```
names:
["janvier","février","mars","avril","mai","juin","juillet","août","septembre
","octobre","novembre","décembre",""],
namesAbbr:
["janv.","févr.","mars","avr.","mai","juin","juil.","août","sept.","oct.","n
ov.","déc.",""]
},
AM: null,
PM: null,
eras: [{"name":"ap. J.-C.","start":null,"offset":0}],
patterns: {
d: "dd/MM/yyyy",
D: "dddd d MMMM yyyy",
t: "HH:mm",
T: "HH:mm:ss",
f: "dddd d MMMM yyyy HH:mm",
F: "dddd d MMMM yyyy HH:mm:ss",
M: "d MMMM"
}
}
}
```

Add the following code in your CSHTML page to render DateRangePicker widget.

ASPX-CS

```
@Html.EJ().DateRangePicker("DateRange").Locale("fr-FR").Width("25%")
```

The following screenshot displays the output for the above code.



Showcase for DateRangePicker with French culture

Customization

Customization of DateRangePicker will be easier with its flexible customization options.

Setting Dimension

Height and width of the DateRangePicker can be changed using corresponding API (**Height**,**Width**) like below code examples.

Add the following code in your CSHTML page to render DateRangePicker with customized **Height** and **Width**.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateRangePicker widget with customized height and width*@
@Html.EJ().DateRangePicker("DateRange").Height("50").Width("300")
```

Rounded Corners

ShowRoundedCorner property is used to add rounded borders to the input and popup elements. By default, ShowRoundedCorners property will be disabled state. we can enable the property by setting **ShowRoundedCorner** as **true**.

Add the following code in your CSHTML page to render DateRangePicker widget with rounded corners.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateRangePicker widget with rounded corners*@
@Html.EJ().DateRangePicker("DateRange").ShowRoundedCorner(true)
```

Persistence

The value of DateRangePicker can be sustained even after form post back and page refreshing by enabling the **EnablePersistence** API like below code example.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to enable
state persistence in rendered DateRangePicker widget*@
@Html.EJ().DateRangePicker("DateRange").EnablePersistence(true)
```

The DateRangePicker Model value will be stored in local storage / cookies of browser before page refreshes and reinitialized with the restored model after refresh.

Preset Ranges

We can make use of **Ranges** API for easy selection of preset ranges from the popup. Each preset range will have a label which will be displayed on the right side of the popup with user-defined name. By clicking the labels the associated date ranges will get updated in the popup, automatically.

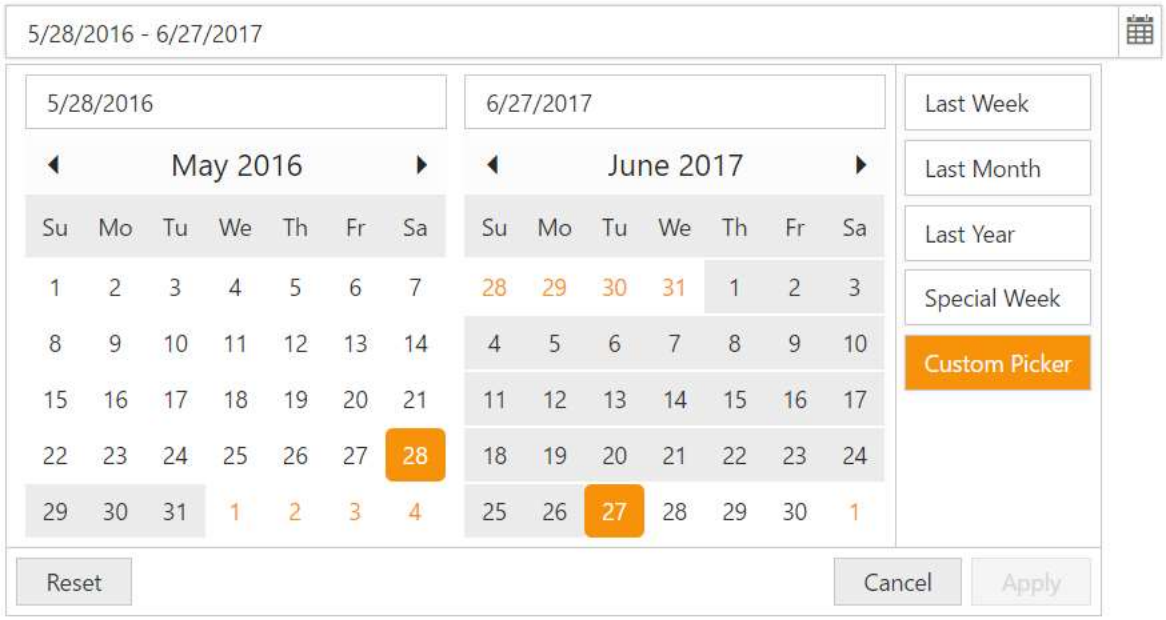
ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to enable
state persistence in DateRangePicker widget*@
@{List<Object> lastWeek = new List<Object>() { DateTime.Today.AddDays(-
7),DateTime.Today.AddDays(-1)};}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@{List<Object> lastMonth = new List<Object>() { DateTime.Today.AddMonths(-
1), DateTime.Today.AddDays(-1) };}
@{List<Object> lastYear = new List<Object>() { DateTime.Today.AddYears(-1),
DateTime.Today.AddDays(-1) };}
@{List<Object> special = new List<Object>() { "12/25/2017", "1/1/2018" };}
@Html.EJ().DateRangePicker("DateRange").Value("05/28/2016-
06/27/2017").Ranges(e => e.Add().Label("Last
Week").Range(lastWeek)).Ranges(p => p.Add().Label("Last
Month").Range(lastMonth)).Ranges(m=>m.Add().Label("Last
Year").Range(lastYear)).Ranges(n => n.Add().Label("Special
Week").Range(special)).Width("60%")
```

Execute the above code to render the following output.



DateRangePicker with preset ranges

TimePicker Option

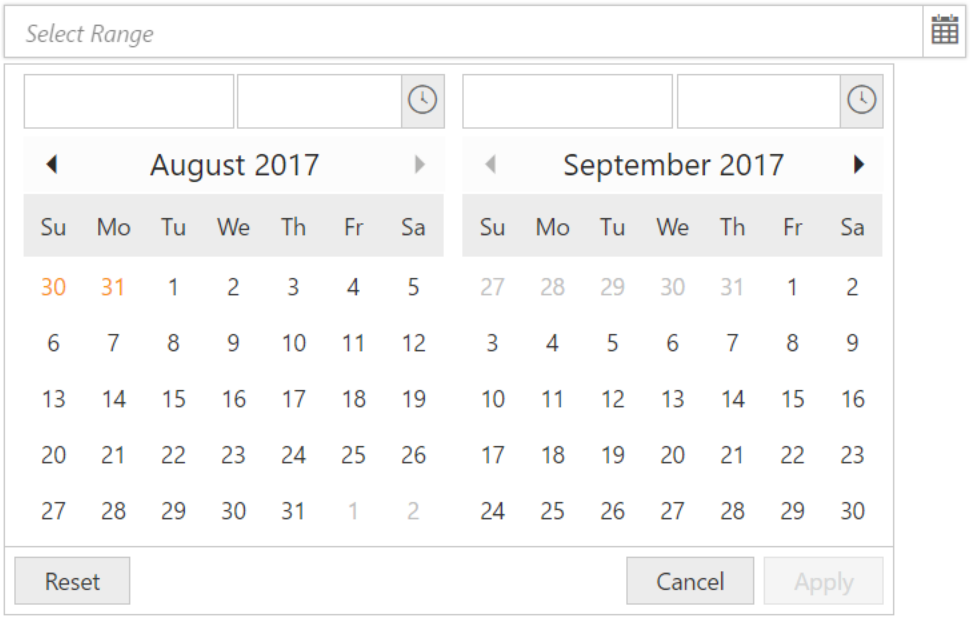
The date ranges can also be selected with start time and end time by enable the TimePicker in popup using **EnableTimePicker** API. Each calendar will have separate Time Pickers in which we can select start time along with start date and end time along with end date. Please check with the below code example to enable the time picker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateRangePicker with TimePicker widget*@
@Html.EJ().DateRangePicker("DateRange").EnableTimePicker(true)
```

Execute the above to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.



DateRangePicker with TimePicker option

Allow Editing

Editing in input box can be disabled by setting the false value to **AllowEdit** API. By default this property will be true and we can edit the value in input box.

ASPX-CS

```
@Html.EJ().DateRangePicker("DateRange").AllowEdit(false)
```

Enable/Disable

The control can be enabled / disabled using public methods, **enable** or **disable**.

ASPX-CS

```
@Html.EJ().DateRangePicker("DateRange").Value("05/28/2016-
06/27/2016").ClientSideEvents(p => p.Create("Create"))
<script>
//Create event triggers after DateRangePicker created successfully.
function Create() {
$("#DateRange").ejDateRangePicker('disable');
}
</script>
```

Clear Ranges

To clear the all selection and ranges in a popup we can make use of **clearRanges** method.

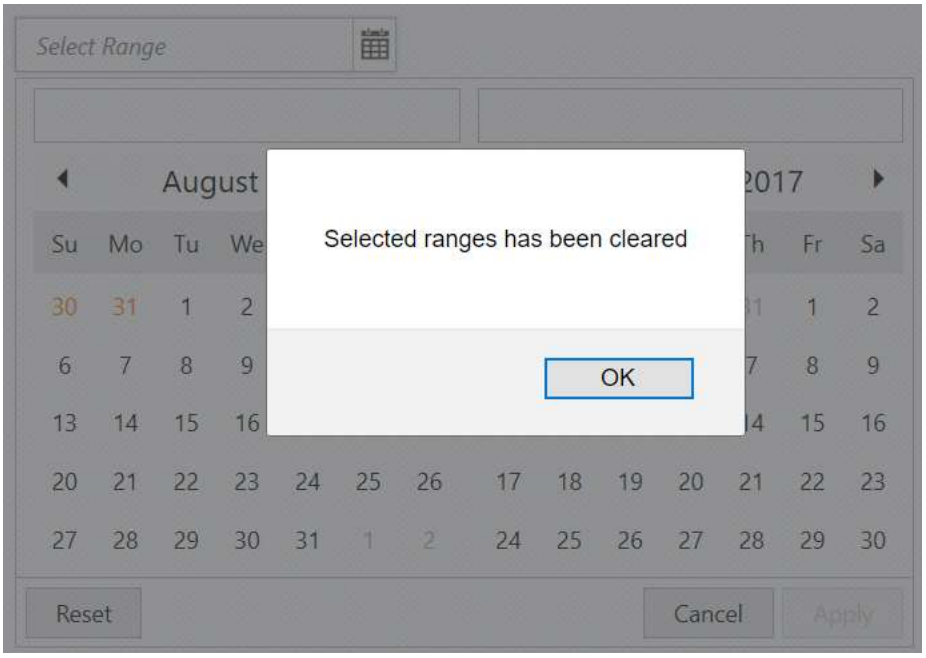
ASPX-CS

```
@Html.EJ().DateRangePicker("DateRange").ClientSideEvents(c=>c.BeforeClose("C
lear"))
<script>
//BeforeClose event triggers before closing DateRangePicker popup
function Clear() {
$("#DateRange").ejDateRangePicker('clearRanges');
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
</script>
```

The following screenshot displays the output for the above code.



BeforeClose Event of DateRangePicker

How to?

Render DateRangePicker from Code behind

DateRangePicker can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of DateRangePicker properties in the controller.

C#

```
//Namespace to get the JavaScript (DateRangePicker) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class DateRangePickerController : Controller
{
// GET: DateRangePicker
public ActionResult DateRangePickerFeatures()
{
//Initializing the DateRangePicker model
DateRangePickerProperties DateObj = new DateRangePickerProperties();
//Initializing the datasource and other properties
DateObj.Width = "300px";
DateObj.StartDate = "2/2/2018";
DateObj.EndDate = "2/25/2018";
//Passing DateRangePicker properties using the ViewData
ViewData["DateModel"] = DateObj;
return View();
```

```
}
}
}
```

Binding the DateRangePicker properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().DateRangePicker("searchCustomer",(Syncfusion.JavaScript.Models.Dat
eRangePickerProperties)ViewData["DateModel"]).Render();
}
```

DateTimePicker

DateTimePicker

The Essential ASP.NET MVC DateTimePicker control is used to input the date and time with a specific format. The DateTimePicker control combines the DatePicker and TimePicker controls so that users can select the date and time with their desired format.

Key Features

- DateTime format: Supports all valid date and time formats.
- Localization: Supports localization to different cultures.
- Persist: Supports state maintenance during page refresh.
- RTL: Support for Right to Left alignment of content in DateTimePicker control.
- Themes: Essential ASP.NET MVC controls consist of 12 built-in themes (6 – flat and 6 – gradient effects), and also support custom skin options to set user-defined themes.

Note: As the DateTimePicker inherits the functionalities of the DatePicker and TimePicker controls, it supports the basic functionalities of both controls.

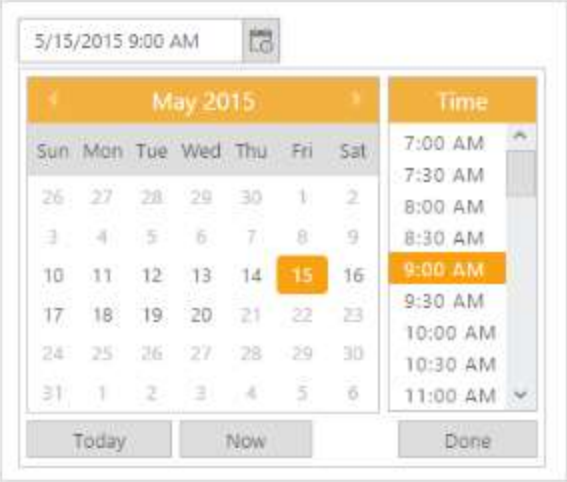
Getting Started

This section explains briefly about how to create a DateTimePicker in your application with ASP.NET MVC.

Create your first DateTimePicker in MVC

The ASP.NET MVC DateTimePicker provides support to display the calendar within your web page and allows you to pick date and time from the calendar. Refer the following guidelines to customize date and time pickers for a real time appointment booking scenario that helps you to book an appointment, within a limited number of days. The following screenshot illustrates the functionality of DatePicker with date range.

Copyright © 2001 - 2020 Syncfusion Inc.



DateTimePicker

In the above screenshot, you can select a date and time, within a week ranging from the current date. This helps you to avoid booking an appointment beyond the current date and mentioned date range.

Create a DateTimePicker

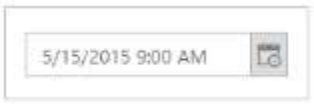
ASP.NET MVC DateTimePicker widget basically renders built-in features like Month and Time Navigation, with animations and flexible APIs. You can easily create the DateTimePicker widget using simple DateTimePicker element as follows.

1. Create a MVC Project and add necessary assemblies and scripts.
2. Refer MVC-Getting Started.
3. Add the following code to the corresponding view page to render DateTimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render DateTimePicker widget*@
@Html.EJ().DateTimePicker("Datetime").Width("175px").Value("05/15/2015 09:00 AM")
```

Execute the above code to render the following output.



DateTimePicker

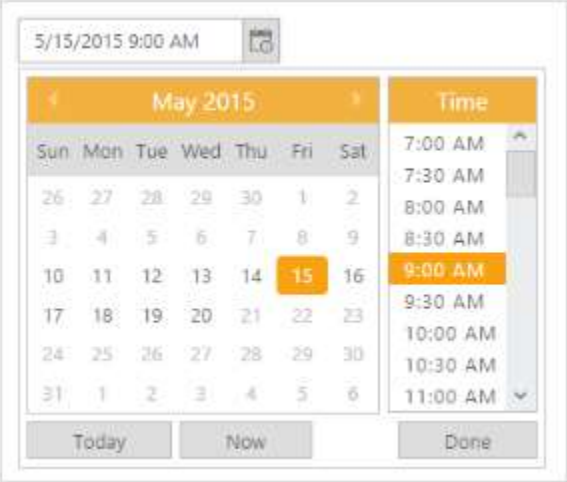
Set the Min/Max Date and Time Intervals

In a real-time appointment booking scenario, the booking is open only for a limited number of days. You can select the date from the given range. This is achieved using the properties MinDateTime and MaxDateTime. Only the dates ranging between MinDateTime and MaxDateTime are enabled in the date picker. Using the Interval property, you can set the interval.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@*Add the following code example to the corresponding CSHTML page to render
DateTimePicker widget with customized Min time and Max time*@
@Html.EJ().DateTimePicker("DateTime").MinDateTime("5/10/2015 09:00
AM").MaxDateTime("5/20/2015 06:00
PM").Interval(30).Width("175px").Value("5/15/2015 09:00 AM")
```



DateTimePicker with Min/Max Date and Time Interval

Display format

DateTime format

DateTimePicker allows you to define the text representation of a date and time value to be displayed in the DateTimePicker control. The format specified is achieved by the DateTimeFormat property. Default value of this property is “M/d/yyyy h: mm tt”. To change the “Time Popup” display format, “TimeDisplayFormat” is used here. The default value of this property is “h:mm t”.

If your company’s website is going to be used all over the world, following the UTC time is better. Main benefit of UTC Time is that the time is always guaranteed to be *consistent*. In other words, whenever the time zone of customer is changed you don't have to go back or forth in time from the logging time of the customer to your time zone.

DateTime format

Format	Display in DateTimePicker
Short Date and Timeâ€“ d/M/yy h:mm tt	9/12/2014 2:04 PM
Medium Date-d MMM yy h:mm tt	12 Sep 14 2:04: PM
Full Date and short time - dddd, MMMM dd, yyyy HH:mm tt	Friday, September 12,2014 2:04 PM
Full Date and Long Time - dddd, MMMM dd, yyyy HH:mm:ss tt	Friday, September 12,2014 2:04:00 PM
UTC - yyyy-MM-dThh:mm:ssz	2014-09-12T2:04:00+5

You can also customize the format. Refer the following list to create your custom format for DateTimePicker.

Copyright © 2001 - 2020 Syncfusion Inc.

- d - Day of the month.
- ddd - Short name of day of the week.
- dddd - Full name of day of the week.
- M – The month, from 1 through 12.
- MMM- Short name of Month.
- MMMM- Long name of the Month.
- yy - Last two digit if year.
- yyyy - Full Year.
- hh – Hour.
- mm – Minutes.
- ss – Seconds.
- tt - The AM/PM designator.

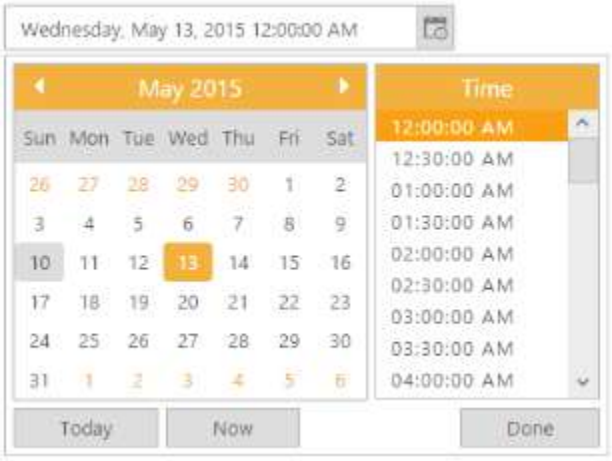
In the following example, set DateTimeFormat to full datetime format.

1. Add the following code in your CSHTML page to render DateTimePicker widget.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render DateTimePicker widget with customized date time format*@
@Html.EJ().DateTimePicker("DateTime").TimePopupWidth(150).TimeDisplayFormat("hh:mm:ss tt").Width("300px").DateTimeFormat("dddd, MMMM dd, yyyy hh:mm:ss tt")
```

2. The following screenshot displays the output for the above code.



Showcase of DateTimePicker with UTC time format

Day Header Format

You can change the format for the days of the week names using DayHeaderFormat property. By default in our DateTimePicker day of the week format in ShowHeaderMin format. For example, Sun for Sunday. To know the different types of day format refer the following table.

DayHeaderFormat

Header Format types	Description
ShowHeaderNone	Removes the day header
ShowHeaderShort	Shows the day header format in min like Su, Mo, Tu â€¦
ShowHeaderMin	Shows the day header format in short like Sun, Mon, Tue â€¦
ShowHeaderLong	Shows the day header format in long like Sunday, Monday, Tuesday â€¦

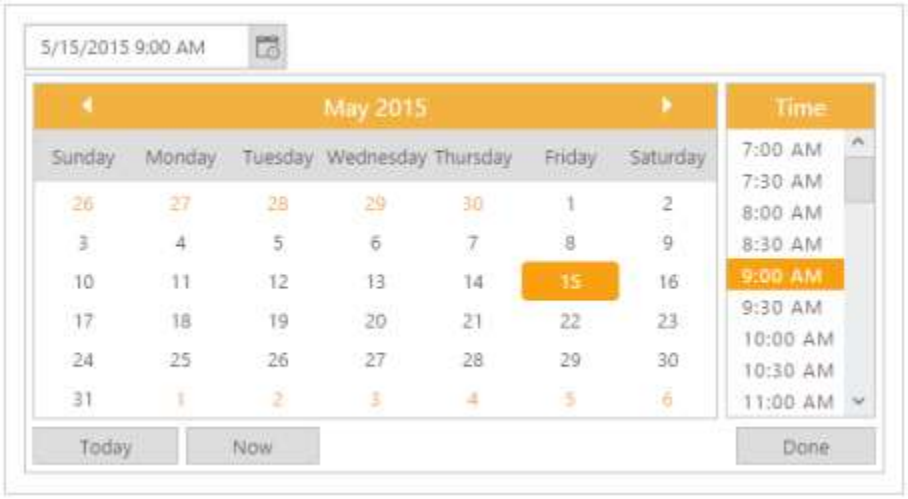
You can also customize the format according to your needs. This is achieved by changing the day names information in the culture script file. This is explained later under the Localization section of this document. In the following sample is displayed, the short name of the day of the week, by setting day header format as ShowHeaderLong.

1. Add the following code in your CSHTML page to render DateTimePicker widget.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateTimePicker widget with customized day header format*@
@Html.EJ().DateTimePicker("DateTime").DayHeaderFormat(Header.ShowHeaderLong)
.Width("175px").Value("5/15/2015 09:00 AM")
```

2. The following screenshot displays the output for the above code.



Showcase of DateTimePicker with short name of day of the week

Date Range

Date Range between two dates is achieved by MinDateTime, MaxDateTime property of DateTimePicker.

In DateTimePicker, a property called EnableStrictMode is available.When this property is set to false, it does not allow wrong values and corrects the entered value automatically. If it is true, then DateTimePicker allows values with error class to indicate the selected date is wrong.

Copyright © 2001 - 2020 Syncfusion Inc.

MinDateTime - Sets the minimum value to the DateTimePicker. Based on the EnableStrictMode value behind the minimum value an error class is added to the wrapper element or it is corrected automatically to the nearest correct date value.

MaxDateTime - Sets the maximum value to the DateTimePicker. Based on the EnableStrictMode value beyond the maximum value an error class is added to the wrapper element or it is corrected automatically to the nearest correct date value.

Sometimes, you can give restrictions on selecting the date before or after the particular date. Consider you are going to make a project for hotel reservation system. The “In DateTime” has to be lesser than the “Out DateTime” and vice versa. So you have to set “In DateTime” as minimum DateTime and “Out DateTime” as maximum DateTime for selection in DateTimePicker control.

The dates before min date and after the max date are considered as invalid dates and it is disabled for selection.

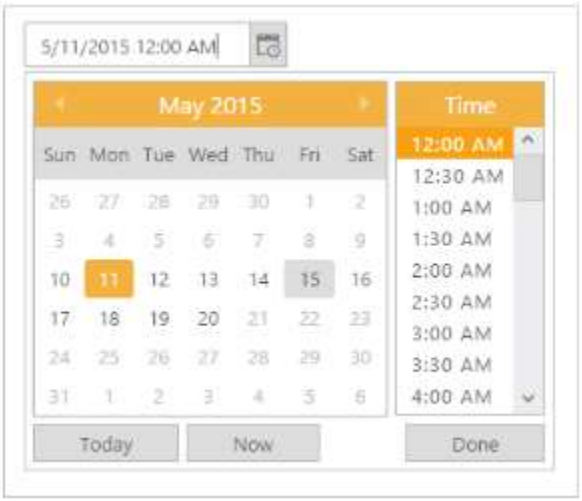
In the following example May 10, 2015 09:00 AM is set as MinDateTime and May 20, 2015 09:00 PM set as MaxDateTime.

1. Add the following code in your CSHTML page to render DateTimePicker widget.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateTimePicker widget with customized Min time and Max time*@
@Html.EJ().DateTimePicker("DateTime").MinDateTime("05/10/2015 09:00
AM").MaxDateTime("05/20/2015 09:00 PM").Interval(30).Width("175px")
```

2. The following screenshot displays the output for the above code.



Showcase of min and max dates in DateTimePicker

Copyright © 2001 - 2020 Syncfusion Inc.

Start and Depth level

Start Level

DateTimePicker allows you to change the starting level view of Calendar inside the DateTimePicker popup. Consider you are creating a login form for your blog. If the “Birth date” field in the form starts from year, it is easy to select date from year, month and date. By default, the Start Level of DateTimePicker is “Month” level view. The “StartLevel” property receives “enum” value. The “Period” class contains four types of levels. Refer the following table to know the different types of start level.

Start Level

StartLevel	Syntax	Description
Month	StartLevel(Period.Month)	Starts from month level view.
Year	StartLevel(Period.Year)	Starts from year level view.
Decade	StartLevel(Period.Decade)	Starts from year decade level view.
Century	StartLevel(Period.Century)	Starts from century level view.

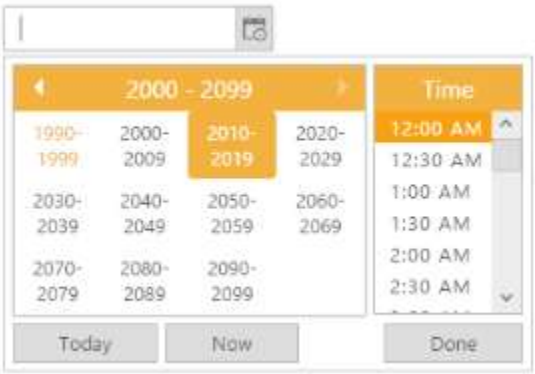
In the following example DateTimePicker popup Start level view is set to “century level” when you drop down the DateTimePicker popup.

1. Add the following code in your CSHTML page to render DateTimePicker widget.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render DateTimePicker widget with customized Start level*@
@Html.EJ().DateTimePicker("DateTime").StartLevel(Period.Century).Width("175px")
```

2. The following screenshot displays the output for the above code.



Showcase of DateTimePicker with short name of day of the week

Copyright © 2001 - 2020 Syncfusion Inc.

Depth Level

DateTimePicker enables you to set the drill down level of DateTimePicker. Consider, you are going to take the monthly report of sales in your company. In that case, there is no need for selecting date from month view. You can restrict the drill-down of DateTimePicker popup to month view.

In the following example, start level is set from century and drill down is set to year view. So drill-down to month is restricted. So you can avoid selecting the day of the month. By default, the current day of the month is maintained in the day number field. Refer the following code to set drill down value to year view.

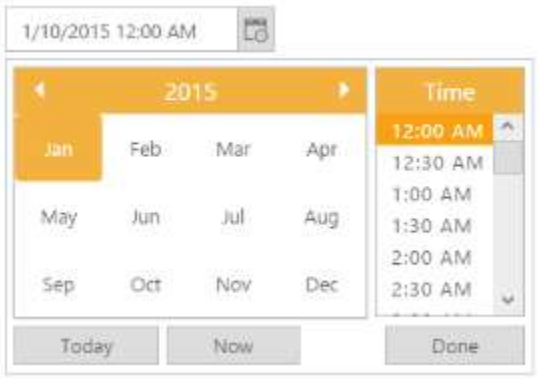
The following code snippet is set to DepthLevel in DateTimePicker.

1. Add the following code in your CSHTML page to render DateTimePicker widget.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateTimePicker widget with customized Depth level*@
@Html.EJ().DateTimePicker("DateTime").StartLevel(Period.Century).DepthLevel(
Period.Year) .Width("175px")
```

2. The following screenshot displays the output for the above code.



Showcase of DateTimePicker with Depth level

Date in other months

DateTimePicker calendar can display the dates in other months at the start or end of the current month. To enable or disable the display of other month dates in the current month, you can use the property called ShowOtherMonths. By setting this property value as “true” you can display the dates in other months at the start or end of the current month. By default the value of this property is “true”.

Consider you are going to calculate the monthly report of your company’s employee attendance. To avoid the mistake of selecting other month dates while calculating current month report, you can disable showing other month dates in the current month. You can achieve this requirement by setting ShowOtherMonths value as “false”.

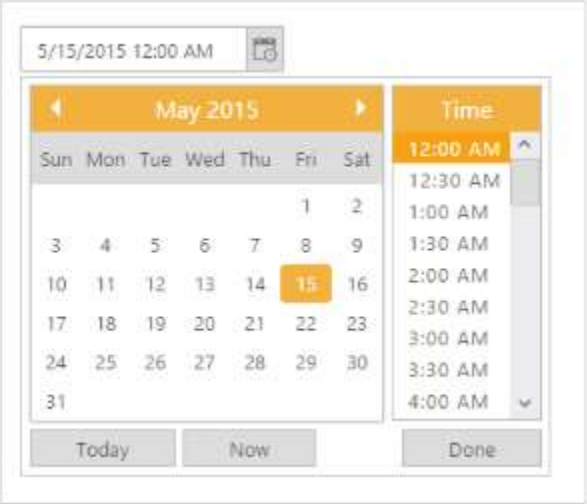
1. Add the following code in your CSHTML page to render DateTimePicker widget.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateTimePicker widget with customized other months*@
@Html.EJ().DateTimePicker("DateTime").ShowOtherMonths(false).Width("175px")
```

2. The following screenshot displays the output for the above code.



Showcase for DateTimePicker without other month dates

Time Interval

You can set time interval between two adjacent time values in the time popup manually using the “Interval” property. By default the value of the “Interval” property is 30 minutes. Setting this value as 60 is considered as 1 hour. Sometimes you need to update for every hour work log reports. In that case to select time from time popup window with 1 hour interval to update the every 1 hour report you can use Interval option by setting time interval value as “60 minutes”.

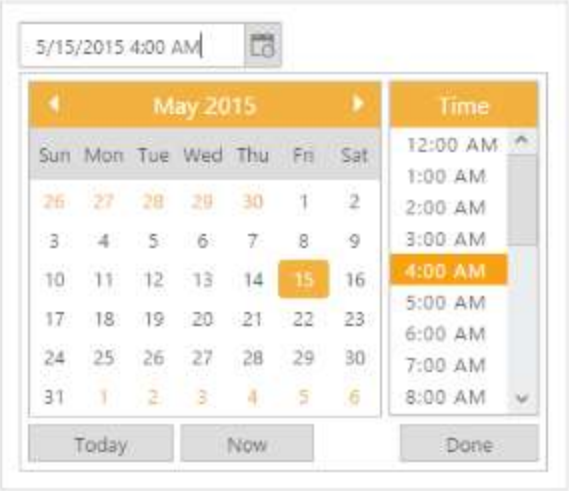
1. Add the following code in your CSHTML page to render DateTimePicker widget.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateTimePicker widget with customized interval*@
@Html.EJ().DateTimePicker("DateTime").Interval(60).Width("175px")
```

2. The following screenshot displays the output for the above code.

Copyright © 2001 - 2020 Syncfusion Inc.



Showcase for DateTimePicker with I hour interval in time picker popup

Localization

You can globalize your DateTimePicker control. People of different culture can make use of it. All culture files are supported by Syncfusion components

Essential ASP.NET MVC DateTimePicker has been provided with built-in localization support, so that it can adapt based on culture specific locale defined for it.

More than 350 culture specific files are available to localize the datetime. To know more about EJ globalize support, please refer the below link

http://help.syncfusion.com/js/localization

Note: Seven culture-specific script files are available in the below specified location. For all other culture files, please download from the GitHub location.

(installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n
For example, If you have installed the Essential Studio package within C:\Program Files (x86), then navigate to the below location, C:\Program Files (x86)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n

To translate our control content from default English to any of the culture, say For example - Spanish language, then you need to refer the ej.culture.es-ES.min.js file in your application,

The **en-US** locale is currently being used as default culture in DateTimePicker. You can set any other culture to DateTimePicker using **Locale** property. Below code example shows Spanish cultured DateTimePicker.

Refer the below Spanish culture file in head section of HTML page after the reference of **ej.web.all.min.js** file.

JAVASCRIPT

```
<script src="https://cdn.syncfusion.com/js/assets/i18n/ej.culture.es-ES.min.js"></script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

If you want to change month names to your culture month just replace month names with your culture month names or your customized format.

The following code example is used to set DateTimePicker in Spanish language.

ASPX-CS

```
calendars: {
standard: {
firstDay: 1,
days: {
names: ["domingo","lunes","martes","miércoles","jueves","viernes","sábado"],
namesAbbr: ["do.","lu.","ma.","mi.","ju.","vi.","sá."],
namesShort: ["D","L","M","X","J","V","S"]
},
months: {
names:
["enero","febrero","marzo","abril","mayo","junio","julio","agosto","septiembre","octubre","noviembre","diciembre",""],
namesAbbr:
["ene.","feb.","mar.","abr.","may.","jun.","jul.","ago.","sep.","oct.","nov.","dic.",""]
},
AM: null,
PM: null,
eras: [{"name":"d. C.","start":null,"offset":0}],
patterns: {
d: "dd/MM/yyyy",
D: "dddd, d' de 'MMMM' de 'yyyy",
t: "H:mm",
T: "H:mm:ss",
f: "dddd, d' de 'MMMM' de 'yyyy H:mm",
F: "dddd, d' de 'MMMM' de 'yyyy H:mm:ss",
M: "d' de 'MMMM",
Y: "MMMM' de 'yyyy"
}
}
}
```

The following code example can be used to get Spanish culture in DateTimePicker.

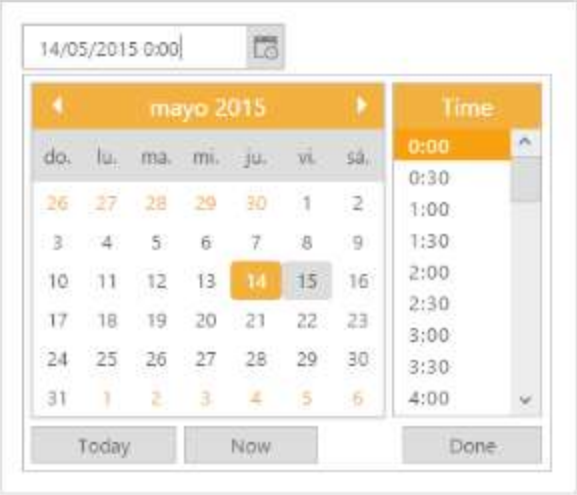
3. Add the following code in your CSHTML page to render DateTimePicker widget.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render DateTimePicker widget with customized localization*@
@Html.EJ().DateTimePicker("DateTime").Locale("es-ES").Width("175px")
```

4. The following screenshot displays the output for the above code.

Copyright © 2001 - 2020 Syncfusion Inc.



Showcase for DateTimePicker with Spanish culture

Right-to-Left

RTL control supports right-to-left functionality and features for languages that work right-to-left for selecting and editing date and time. You can change your popup and textbox display to read right-to-left. Arabic and Hebrew are written from right to left. The customer who has a right to left writing style can use this feature. You can achieve this in your DateTimePicker by using EnableRTL property. Setting this property to “true” allows you to write in the right to left format. Position of the toolbars are also changed to right to left.

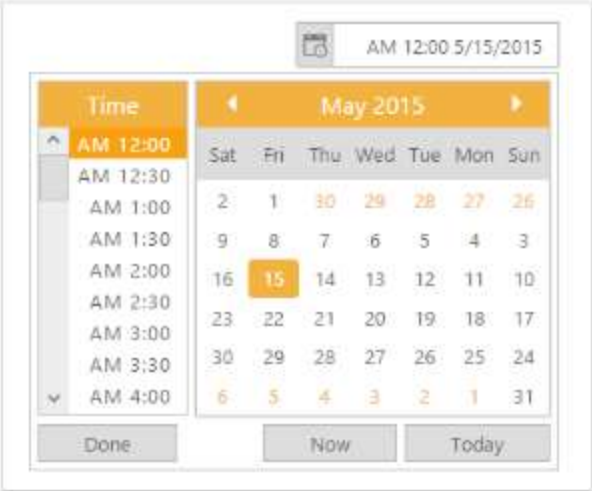
1. Add the following code in your CSHTML page to render DateTimePicker widget.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to render
DateTimePicker widget with right to left appearance*@
@Html.EJ().DateTimePicker("DateTime").EnableRTL(true).Width("175px")
```

2. The following screenshot displays the output for the above code.

Copyright © 2001 - 2020 Syncfusion Inc.



Showcase of DateTimePicker with Right to Left appearance

Appearance and Styling

Theme

DateTimePicker control support rich appearance. This control consist of six flat themes and six gradient themes. To use these twelve themes, refer the themes files in HTML file.

You need two style sheets to apply styles to DateTimePicker control; one ej.widgets.core.min.css and one ej.theme.min.css. If you use ej.widgets.all.min.css then you don't need to use ej.widgets.core.min.css and ej.theme.min.css because ej.widgets.all.min.css is a combination of these two.

The core style sheet applies styles related to positioning and size, but are not related to the color scheme and always require the control to look correct and function properly. The theme style sheet applies theme-specific styles like colors and backgrounds.

The following list is of the twelve themes supported by DateTimePicker:

- default-theme
- flat-azure-dark
- flat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

1. Add the following code in your CSHTML page to render DateTimePicker widget.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@*Add the following code example to the corresponding CSHTML page to render
DateTimePicker widget with right to left appearance*@
@Html.EJ().DateTimePicker("DateTime").Width("175px")
```

2. The following screenshot displays the output for the above code.

Showcase of DateTimePicker with gradient lime dark theme

CSS Class

DateTimePicker control also allows you to customize its appearance using user-defined CSS and custom skin options such as colors and backgrounds. To apply custom themes you have a property called CssClass. CssClass property sets the root class for DateTimePicker theme.

Using this CssClass you can override the existing styles under the theme style sheet. The theme style sheet applies theme-specific styles like colors and backgrounds. In the following example, the value of CssClass property is set as “Purple-dark”. Purple-dark is added as root class to DateTimePicker control at the runtime. From this root class you can customize the DateTimePicker control theme.

1. Add the following code in your CSHTML page to render the DateTimePicker.

ASPX-CS

```
@*Add the following code in your view page to render the DateTimePicker.*@
@Html.EJ().DateTimePicker("dt").CssClass("Purple-dark").Width("175px")
```

In the following style sheet the exiting theme style sheet file has been over-ridden using root class “Purple-dark”.

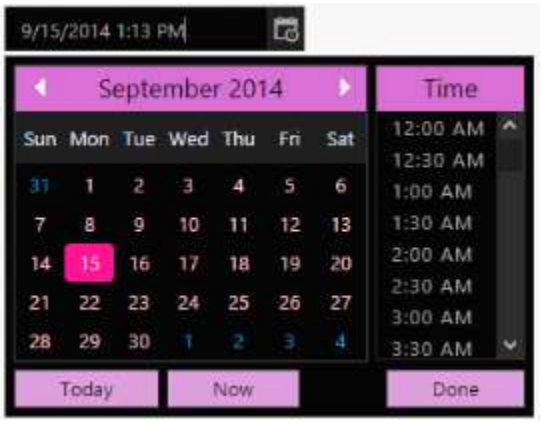
2. Add the following code in your style section.

CSS

```
.Purple-dark .e-week-header {
color: #EBADD6;
}
.Purple-dark .e-text {
color: black;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
.Purple-dark .e-state-default {
color: pink;
}
.Purple-dark .e-active {
background-color: #FF1975;
}
.Purple-dark .e-state-default:hover {
color: #EBADD6;
}
.Purple-dark .e-dt-button {
color: black;
background-color: #E085C2;
}
.Purple-dark .e-header {
background-color: #E085C2;
color: black;
}
.Purple-dark .e-timecontainer .e-header {
background-color: #E085C2;
color: black;
}
```



Showcase for DateTimePicker with cssClass “Purple-dark”

How to?

Render DateTimePicker from Code behind

DateTimePicker can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of DateTimePicker properties in the controller.

C#

```
//Namespace to get the JavaScript (DateTimePicker) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class DateTimePickerController : Controller
{
// GET: DateTimePicker
public ActionResult DateTimePickerFeatures()
```

```
{
//Initializing the DateTimePicker model
DateTimePickerProperties DateObj = new DateTimePickerProperties();
//Initializing the datasource and other properties
DateObj.Width = "300px";
DateObj.Value = "05/15/2015 09:00 AM";
//Passing DateTimePicker properties using the ViewData
ViewData["DateModel"] = DateObj;
return View();
}
}
}
```

Binding the DateTimePicker properties passed via **ViewData** from the controller in the client side as below.

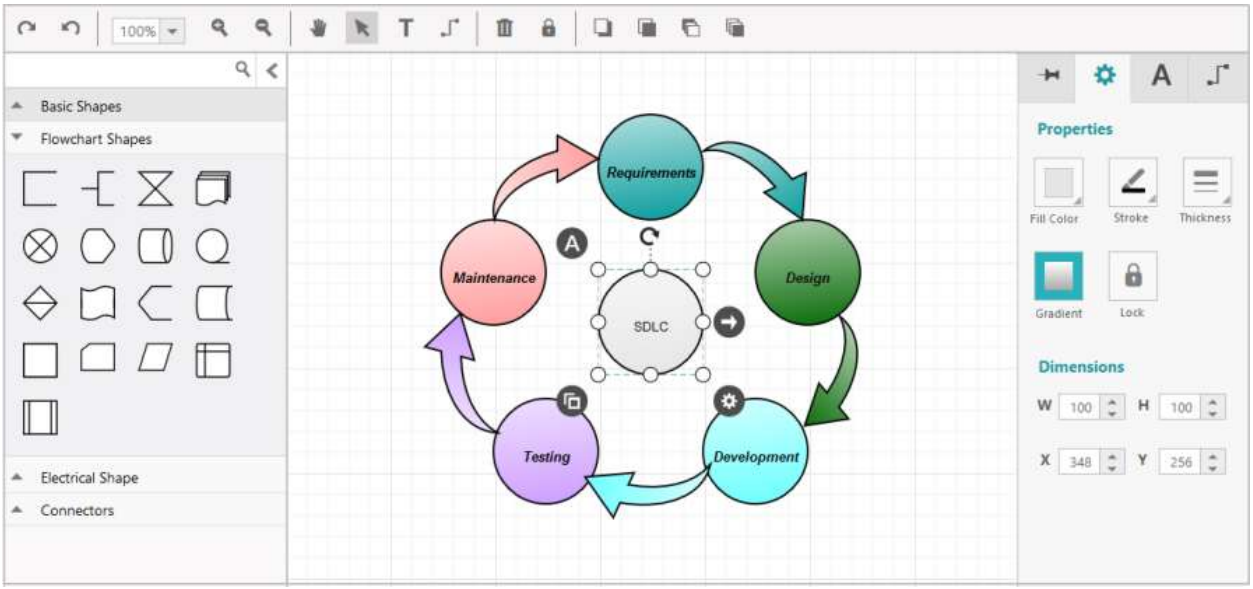
ASPX-CS

```
@{
Html.EJ().DateTimePicker("searchCustomer",(Syncfusion.JavaScript.Models.Date
TimePickerProperties)ViewData["DateModel"]).Render();
}
```

Diagram

Diagram

EssentialDiagram ASP.NET MVC creates rich Visio-like applications. Its Framework comprises of many Elements that helps you to create an application easily. The rich feature set of the Diagram control includes Snapping, Guidelines, Gridlines, Serialization and Zooming.



Diagram

The list of features of the Diagram control in ASP.NET MVC are as follows.

- Node, Connector, Group, Port, and Label: Elements used to compose the Diagram.
- Symbol Palette: It holds a list of symbols dropped over the Diagram.
- Clipboard Commands: Performs Cut, Copy and Paste operations.
- Undo/Redo: Performs correction in recent change.
- Serialization: Saves current state of the Diagram, and loads them back when required.
- Snapping: Snaps the Diagram elements towards the nearest elements.
- Gridlines: Visual horizontal/vertical lines that help align elements on Diagram.
- Interaction: Zoom, pan, multiple selections, keyboard shortcuts, and snapping.
- Layout: Arranges nodes in a tree-like structure based on a relationship between the Nodes.

Getting Started

Getting started with your MVC Diagram is easy. You can start by creating a simple flow chart.

Flow Diagram

Initialize Diagram

1\. Create an ASP.NET MVC application. You can refer MVC Getting Started documentation to create a new project and to add necessary assemblies and script files. 2\. Add a placeholder div element to initialize diagram control

RAZOR

```
<div>
@Html.EJ().Diagram("diagram").Width("100%").Height("600px")
</div>
```

3\. This creates an empty diagram

Create and add Node

Let us create and add a node with specific position, size, label and shape.

RAZOR

```
@*Initializes diagram control*@
<div>
@Html.EJ().Diagram("diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
</div>
```

C#

```
DiagramProperties model = new DiagramProperties();
FlowShape start = CreateNode("Start", 140, 50, 300, 50,
FlowShapes.Terminator, "Start");
model.Nodes.Add(start);
ViewData["diagramModel"] = model;
FlowShape CreateNode(string name, int width, int height, int offsetX, int
offsetY, FlowShapes shape, string text)
{
FlowShape node = new FlowShape()
{
Shape = shape,
Name = name,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Width = width,
Height = height,
OffsetX = offsetX,
OffsetY = offsetY,
Labels = new Collection() { new Label() { Text = text } }
};
return node;
}
```

Note: Labels property is an array, which indicates that more than one label can be added to a node.

Added node will be displayed in diagram as shown below.

Connect nodes

- Create another node with another set of data.

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(CreateNode("Start", 140, 50, 300, 50, FlowShapes.Terminator,
"Start"));
model.Nodes.Add(CreateNode("Init", 140, 50, 300, 140, FlowShapes.Process,
"var i = 0;"));
ViewData["diagramModel"] = model;
FlowShape CreateNode(string name, int width, int height, int offsetX, int
offsetY, FlowShapes shape, string text)
{
FlowShape node = new FlowShape()
{
Shape = shape,
Name = name,
Width = width,
Height = height,
OffsetX = offsetX,
OffsetY = offsetY,
Labels = new Collection() { new Label() { Text = text } }
};
return node;
}
```

Connect these two nodes by adding a connector into Connectors collection with reference to source and target end.

C#

```
//Add a connector to `Connectors` collection of diagram model
model.Connectors.Add(ConnectNodes("connector1", "Start", "Init"));
Connector ConnectNodes(string name, string source, string target)
{
return new Connector()
{
Name = name,
```

```
SourceNode = source,
TargetNode = target,
Segments = new Collection() {
new Segment(Segments.Orthogonal)
}
};
}
```

- Connector connects the two nodes as shown below.

- Default values for all nodes and connectors can be set using default settings. For example if all nodes have same Width and Height, we can move such properties into DefaultSettings. Above code can be rewritten as shown below.

C#

```
DiagramProperties model = new DiagramProperties();
//Default Settings
model.DefaultSettings.Node = new Node() { Type = Shapes.Flow, Width = 140,
Height = 50, OffsetX = 300 };
model.DefaultSettings.Connector = new Connector()
{
Labels = new Collection() { new Label() { FillColor = "white" } },
Segments = new Collection() { new Segment(Segments.Orthogonal) }
};
//Create Nodes
model.Nodes.Add(CreateNode("Start", 50, FlowShapes.Terminator, "Start"));
model.Nodes.Add(CreateNode("Init", 140, FlowShapes.Process, "var i = 0;"));
//Connect Nodes
model.Connectors.Add(ConnectNodes("connector1", "Start", "Init"));
ViewData["diagramModel"] = model;
Connector ConnectNodes(string name, string source, string target)
{
return new Connector()
{
Name = name,
SourceNode = source,
TargetNode = target
};
}
FlowShape CreateNode(string name, int width, int height, int offsetX, int
offsetY, FlowShapes shape, string text)
{
FlowShape node = new FlowShape()
{
Shape = shape,
Name = name,
OffsetY = offsetY,
Labels = new Collection() { new Label() { Text = text } }
};
return node;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Complete flow diagram

Similarly we can add required nodes and connectors to form a complete flow diagram.

C#

```
//Initialize model properties
DiagramProperties model = new DiagramProperties();
//Default Settings
model.DefaultSettings.Node = new Node() { Type = Shapes.Flow, Width = 140,
Height = 50, OffsetX = 300 };
model.DefaultSettings.Connector = new Connector()
{
Labels = new Collection() { new Label() { FillColor = "white" } },
Segments = new Collection() { new Segment(Segments.Orthogonal) }
};
//Create Nodes
model.Nodes.Add(CreateNode("Start", 50, FlowShapes.Terminator, "Start"));
model.Nodes.Add(CreateNode("Init", 140, FlowShapes.Process, "var i = 0;"));
model.Nodes.Add(CreateNode("Condition", 230, FlowShapes.Decision, "i <
10?"));
model.Nodes.Add(CreateNode("Print", 320, FlowShapes.PreDefinedProcess, "i <
10?"));
model.Nodes.Add(CreateNode("Increment", 410, FlowShapes.Process, "i <
10?"));
model.Nodes.Add(CreateNode("End", 500, FlowShapes.Terminator, "i < 10?"));
//Connect Nodes
model.Connectors.Add(ConnectNodes("connector1", "Start", "Init"));
model.Connectors.Add(ConnectNodes("connector2", "Init", "Condition"));
model.Connectors.Add(ConnectNodes("connector3", "Condition", "Print",
"Yes"));
model.Connectors.Add(ConnectNodes("connector4", "Condition", "End", "No",
new Segment() { Type = Segments.Orthogonal, Direction = "right", Length = 30
}));
model.Connectors.Add(ConnectNodes("connector5", "Print", "Increment"));
model.Connectors.Add(ConnectNodes("connector5", "Increment", "Condition",
"",
new Segment() { Type = Segments.Orthogonal, Direction = "left", Length = 30
}));
ViewData["diagramModel"] = model;
//Helper methods
Connector ConnectNodes(string name, string source, string target, string
text = "", Segment segment = null)
{
Connector connector = new Connector()
{
Name = name,
SourceNode = source,
TargetNode = target,
Labels = new Collection() { new Label() { Text = text } }
};
if (segment != null) connector.Segments = new Collection() { segment };
return connector;
}
FlowShape CreateNode(string name, int offsetY, FlowShapes shape, string
text)
```

```
{
FlowShape node = new FlowShape()
{
Shape = shape,
Name = name,
OffsetY = offsetY,
Labels = new Collection() { new Label() { Text = text } }
};
return node;
}
```

Final flow chart will looks as shown below.

Automatic organization chart

In 'Flow Diagram' section we saw how to create a diagram manually, now let us see how to create and position diagram automatically.

Initialize diagram

Initializing diagram is already discussed in Flow Diagram > Initialize diagram section.

Business object (Employee information)

- Define Employee Information as JSON data. The following code example shows an employee array whose,
- `Name` is used as a unique identifier and
- `ReportingPerson` is used to identify the person to whom an employee report to, in the organization.

RAZOR

```
//Initialize data source - Saved in a JSON file...
{
data: [
{ Name: "Elizabeth", Role: "Director" },
{ Name: "Christina", ReportingPerson: "Elizabeth", Role: "Manager" },
{ Name: "Yoshi", ReportingPerson: "Christina", Role: "Lead" },
{ Name: "Philip", ReportingPerson: "Christina", Role: "Lead" },
{ Name: "Yang", ReportingPerson: "Elizabeth", Role: "Manager" },
{ Name: "Roland", ReportingPerson: "Yang", Role: "Lead" },
{ Name: "Yvonne", ReportingPerson: "Yang", Role: "Lead" }
]
}
```

Map data source

- You can configure this "Employee Information" with Diagram, so that the node and connector are automatically generated using mapping properties. The following code examples show how dataSourceSetting is used to map id and parent with property name identifiers for employee information.

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
DiagramProperties model = new DiagramProperties();
model.DataSourceSettings.DataSource = GetEmployeeData();
model.DataSourceSettings.Id = "Name";
model.DataSourceSettings.Parent = "ReportingPerson";
Array GetEmployeeData()
{
string text =
System.IO.File.ReadAllText(Server.MapPath("~/App_Data/employee.json"));
Dictionary<string, object> data = (Dictionary<string, object>)new
JavaScriptSerializer().DeserializeObject(text);
return (Array)data["data"];
}
```

Visualize employee

Following code examples indicate how to define the default appearance of node and connector using defaultSettings. The NodeTemplate is used to update each node based on employee data.

C#

```
DiagramProperties model = new DiagramProperties();
//Configure data source
model.DataSourceSettings.DataSource = GetEmployeeData();
model.DataSourceSettings.Id = "Name";
model.DataSourceSettings.Parent = "ReportingPerson";
//Default Settings
model.DefaultSettings.Node = new Node()
{
Width = 70,
Height = 30,
Shape = { Type = Shapes.Rectangle, CornerRadius = 5 },
Labels = new Collection() { new Label() { FontSize = 11, Bold = true,
FontFamily = "Segoe UI", FontColor = "white" } }
};
model.DefaultSettings.Connector = new Connector()
{
Segments = new Collection() { new Segment(Segments.Orthogonal) }
};
model.NodeTemplate = "nodeTemplate";
ViewData["diagramModel"] = model;
```

RAZOR

```
//To represent the roles
var codes = {
Director: "rgb(0, 139,139)",
Manager: "rgb(30, 30,113)",
Lead: "rgb(0, 100,0)"
}
// Bind custom data with node
function nodeTemplate(diagram, node) {
node.labels[0].text = node.Name;
node.fillColor = codes[node.Role];
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Apply org chart layout

- Next you need to arrange nodes in an organizational chart structure, and to do this you can apply layout as shown in following code example. You can see that spacing, margin and orientation are defined, that can also be customized based on the needs.

C#

```
DiagramProperties model = new DiagramProperties();
model.Layout.Type = LayoutTypes.OrganizationalChart;
model.Layout.MarginX = 10;
model.Layout.MarginY = 50;
model.Layout.HorizontalSpacing = 50;
model.Layout.VerticalSpacing = 50;
model.Layout.Orientation = LayoutOrientations.TopToBottom;
```

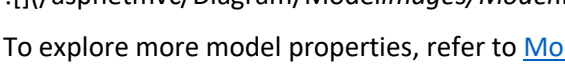
- The Employee details are displayed in the Diagram as follows.

Model

The Diagram model represents the data to render the Diagram and to manipulate the Diagram elements. The following code illustrates how to define Diagram model.

RAZOR

```
//Creates diagram
<div>
@Html.EJ().Diagram("diagram").Width("100%").Height("100%").PageSettings(s=>s
.PageWidth(2000).PageHeight(2000))
</div>
```

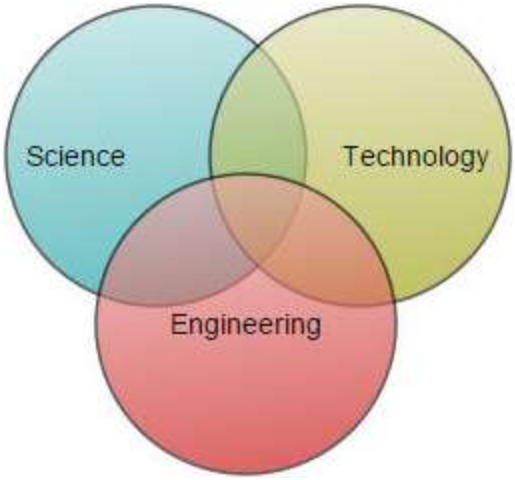


To explore more model properties, refer to Model Properties.

Node

Nodes are graphical object that represent visual data to be placed on the page.

Copyright © 2001 - 2020 Syncfusion Inc.



Create Node

A node can be created and added to the Diagram, either programmatically or interactively. Nodes are stacked on the Diagram area from bottom to top in the order they are added.

Add node through nodes collection

To create a node, You have to create the node object and add that to Nodes collection of the Diagram Model. The following code example illustrates how to add a node to the Diagram.

C#

```
//Initializes Diagram
DiagramProperties Model = new DiagramProperties();
Model.Height = "600px";
Model.Width = "900px";
BasicShape Node = new BasicShape();
//Name of the node
Node.Name = "node1";
//Sets the size
Node.Width = 100;
Node.Height = 100;
//Sets the position
Node.OffsetX = 250;
Node.OffsetY = 250;
//Customizes the appearance
Node.FillColor = "darkcyan";
Node.BorderWidth = 2;
//Adds node to nodes collection
Model.Nodes.Add(Node);
```

Copyright © 2001 - 2020 Syncfusion Inc.

Add node at runtime

Nodes can be added at runtime by using public method, add. The following code illustrates how to add a node.

JS

```
// Defines JSON to create a node
var node = {
name: "node1",
width: 100,
height: 100,
//Sets position
offsetX: 250,
offsetY: 250,
fillColor: "darkcyan",
borderWidth: 2
};
var diagram = $("#diagram").ejDiagram("instance");
// Adds node to the Diagram
diagram.add(node);
```

Add node from palette

Nodes can be predefined and added to palette and can be dropped into the Diagram when needed. For more information about adding nodes from symbol palette, refer to Symbol Palette.

Create node through data source

Nodes can be generated automatically with the information provided through data source. The default properties for these nodes are fetched from default settings. For more information about data source, refer to Data Binding.

Draw nodes

Nodes can be interactively drawn by clicking and dragging the Diagram surface by using **DrawingTool**. For more information about drawing nodes, refer to Draw Nodes.

Update Node at runtime

The client side method updateNode is used to update the nodes at run time. The following code example illustrates how to update a node at runtime.

JS

```
var diagram = $("#DiagramContent").ejDiagram("instance");
diagram.updateNode("nodeName", {
fillColor: "#1BA0E2",
borderWidth: 5,
borderColor: "#000000"
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

Position

Position of a node is controlled by using its OffsetX and OffsetY properties. By default, these offset properties represent the distance between origin of the Diagram's page and node's center point. You may expect this Offset values to represent the distance between page origin and node's top left corner instead of center. Pivot property helps solve this problem. Default value of node's Pivot point is (0.5, 0.5), that means center of Node.

The following table illustrates how pivot relates offset values with node boundaries.

| Pivot | Offset |

|---|---|

| (0.5,0.5) | OffsetX and OffsetY values are considered as the node's center point. |

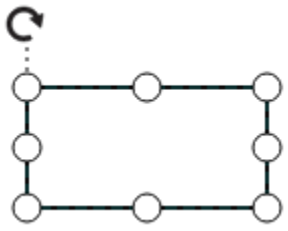
| (0,0) | OffsetX and OffsetY values are considered as the top left corner of node |

| (1,1) | OffsetX and OffsetY values are considered as the bottom right corner of the node. |

The following code illustrates how to change the Pivot value.

C#

```
//Initializes Diagram
DiagramProperties Model = new DiagramProperties();
Model.Height = "600px";
Model.Width = "900px";
BasicShape Node = new BasicShape();
//Name of the node
Node.Name = "node1";
//Sets the size
Node.Width = 100;
Node.Height = 50;
//Sets the position
Node.OffsetX = 100;
Node.OffsetY = 100;
//Sets pivot point
Node.Pivot = new DiagramPoint(0, 0);
//Adds node to nodes collection
Model.Nodes.Add(Node);
```



Types

Diagram allows to add different kind of nodes. To explore the types of nodes, refer to Types of Nodes.

Appearance

You can customize the appearance of a node by changing its font, fill colors, patterns, line weight and style, or shadow. The following code illustrates how to customize the appearance of the shape.

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
//Initializes Diagram
DiagramProperties Model = new DiagramProperties();
Model.Height = "600px";
Model.Width = "900px";
BasicShape Node = new BasicShape();
Node.Name = "node1";
Node.Width = 100;
Node.Height = 100;
Node.OffsetX = 100;
Node.OffsetY = 100;
//Sets styles to a node to customize the appearance
Node.FillColor = "darkcyan";
Node.BorderWidth = 2;
Node.BorderColor = "black";
Node.BorderDashArray = "5 5";
//Adds node to nodes collection
Model.Nodes.Add(Node);
```

Gradient

There are two types of gradients.

- **Linear gradient -** Defines a smooth transition between a set of colors (so-called "stops") on a line.
- **Radial gradient -** Defines a smooth transition between stops on a circle.

The Gradient property of Node allows you to define and applies the gradient effect to that node.

C#

```
BasicShape Node = new BasicShape();
Node.Name = "node1";
Node.Width = 100;
Node.Height = 100;
Node.OffsetX = 100;
Node.OffsetY = 100;
//Initialize the radial gradient
RadialGradient Radial = new RadialGradient();
Radial.CX = 50;
Radial.CY = 50;
Radial.FX = 50;
Radial.FY = 50;
//Initialize the stops
Collection Stops = new Collection();
Stop Stop = new Stop();
Stop.Color = "white";
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Stop.Offset = 0;
Stops.Add(Stop);
Stop = new Stop();
Stop.Color = "darkCyan";
Stop.Offset = 100;
Stops.Add(Stop);
Radial.Stops = Stops;
//Initialize the linear gradient
LinearGradient Linear = new LinearGradient();
Linear.X1 = 0;
Linear.X2 = 50;
Linear.Y1 = 0;
Linear.Y2 = 50;
//Initialize the stops
Stops = new Collection();
Stop = new Stop();
Stop.Color = "white";
Stop.Offset = 0;
Stops.Add(Stop);
Stop = new Stop();
Stop.Color = "darkCyan";
Stop.Offset = 100;
Stops.Add(Stop);
Linear.Stops = Stops;
//Sets the node gradient as linear gradient
Node.Gradient = Linear;
Model.Nodes.Add(Node);
```

Linear Gradient

Radial Gradient

Shadow

Diagram provides support to add **shadow** effect to a node that is disabled by default. It can be enabled with the Constraints property of node. The following code illustrates how to drop shadow.

C#

```
// Defines the node
BasicShape Node = new BasicShape();
Node.Name = "node1";
Node.Width = 100;
Node.Height = 100;
Node.OffsetX = 100;
Node.OffsetY = 100;
//Enables Shadow effect for a node.
Node.Constraints = NodeConstraints.Default | NodeConstraints.Shadow;
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following code illustrates how to disable shadow effect at runtime.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
var node = diagram.findNode("node");
var nodeConstraints = ej.datavisualization.Diagram.NodeConstraints;
//Disables Shadow effect for a node.
constraints = node.constraints & ~nodeConstraints.Shadow;
diagram.updateNode("node", { constraints: constraints });
```

Customizing Shadow

The angle, translation, and opacity of the Shadow can be customized with the Shadow property of node. The following code example illustrates how to customize shadow.

C#

```
// Defines the node
BasicShape Node = new BasicShape();
Node.Name = "node1";
Node.Width = 100;
Node.Height = 100;
Node.OffsetX = 100;
Node.OffsetY = 100;
//Enables Shadow effect for a node.
Node.Constraints = NodeConstraints.Default | NodeConstraints.Shadow;
//Customize the Node's Shadow effect
Node.Shadow.Opacity = .8f;
Node.Shadow.Angle = 50;
Node.Shadow.Distance = 9;
```

Interaction

Diagram provides support to drag, resize, or rotate the node interactively. For more information about editing a node at runtime, refer to Edit Nodes.

Copyright © 2001 - 2020 Syncfusion Inc.

Constraints

The constraints property of node allows you to enable/disable certain features. For more information about node constraints, refer to Node Constraints.

Connector

Connectors are objects used to create link between two points, nodes or ports to represent the relationships between them.

Create Connector

Connector can be created by defining the start and end points. The path to be drawn can be defined with a collection of segments.

To explore the properties of a Connector, refer to Connector Properties.

Add connectors through connectors collection

The SourcePoint and TargetPoint properties of connector allow you to define the end points of a Connector. The following code example illustrates how to add a connector through connector collection.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
//Name of the connector
Name = "Connector",
//Sets source and target points
SourcePoint = new DiagramPoint(100f, 100f),
TargetPoint = new DiagramPoint(200f, 200f),
};
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```

Add connector at run time

Connectors can be added at runtime with the client side method, add. The following code example illustrates how to add connector at runtime.

JS

```
// Defines JSON
var connector = {
name: "connector",
sourcePoint: {
x: 100,
y: 100
},
targetPoint: {
x: 200,
y: 200
}
};
var diagram = $("#DiagramContent").ejDiagram("instance");
// Adds to the Diagram
diagram.add(connector);
```

Connectors from palette

Connectors can be predefined and added to the symbol palette. You can drop those connectors into the Diagram, when required.

For more information about adding connectors from symbol palette, refer to Symbol Palette.

Connectors through data source

Connectors are automatically generated based on the relationships defined through the data source.

The default properties for these connectors are fetched from default settings.

For more information about data source, refer to Data Binding.

Draw connectors

Connectors can be interactively drawn by clicking and dragging on the Diagram surface by using **DrawingTool**. For more information about drawing connectors, refer to Draw Connectors.

Update Connector at runtime

The client side method, updateConnector is used to update the connectors at run time. The following code example illustrates how to update a connector at runtime.

JS

```
var diagram = $("#DiagramContent").ejDiagram("instance");
diagram.updateConnector("connectorName", {
lineColor: "#1BA0E2",
lineWidth: 5,
lineDashArray: "5,5"
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

Connect nodes

The SourceNode and TargetNode properties allow to define the nodes to be connected. The following code example illustrates how to connect two nodes.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
FlowShape task1 = new FlowShape(){
Name = "task1", OffsetX = 200, OffsetY = 200, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 1" } }
};
FlowShape task1 = new FlowShape(){
Name = "task2", OffsetX = 400, OffsetY = 200, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 2" } }
};
//Sets nodes collection to the Diagram model
model.Nodes.Add(task1);
model.Nodes.Add(task2);
Connector connector = new Connector() {
Name = "flow1",
//Sets source and target node
SourceNode = "task1",
TargetNode = "task2"
};
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
//Defines the properties that carry the common values
model.DefaultSettings.Node = new Node() {
Width = 100, Height = 50, FillColor = "darkCyan",
BorderColor = "black", Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { FontColor = "white" } }
};
ViewData["diagramModel"] = model;
return View();
}
```

Note: By default, connections are created at the intersecting point of segments and node bounds. The connection between any specific point of source and target nodes can be achieved with connection ports.

Connections with ports

The SourcePort and TargetPort properties allow to create connections between some specific points of source/target nodes. The following code example illustrates how to create port to port connections.

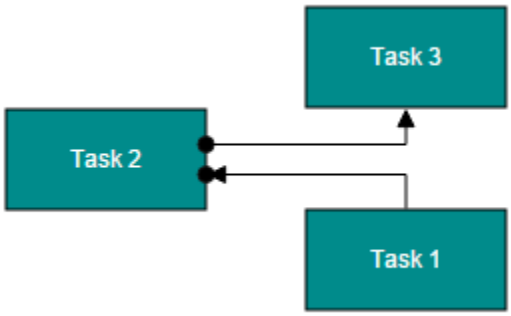
Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
FlowShape task1 = new FlowShape(){
Name = "task1", OffsetX = 350, OffsetY = 300, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 1" } }
};
FlowShape task2 = new FlowShape(){
Name = "task2", OffsetX = 200, OffsetY = 250, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 2" } },
//Defines ports for task2
Ports = new Collection() {
new Port(){
Name="in", Offset= new DiagramPoint(1f, 0.65f), Shape = PortShapes.Circle,
Visibility = PortVisibility.Visible, FillColor = "black"
},
new Port(){
Name="out", Offset= new DiagramPoint(1f, 0.35f), Shape = PortShapes.Circle,
Visibility = PortVisibility.Visible, FillColor = "black"
}
}
};
FlowShape task3 = new FlowShape(){
Name = "task3", OffsetX = 350, OffsetY = 200, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 1" } }
};
//Sets nodes collection to the Diagram model
model.Nodes.Add(task1);
model.Nodes.Add(task2);
model.Nodes.Add(task3);
Connector connector = new Connector() {
Name = "flow1",
//Sets source and target node
SourceNode = "task1",
TargetNode = "task2",
//Name of the target port defined in the target node
TargetPort = "in"
};
Connector connector = new Connector() {
Name = "flow2",
//Sets source and target node
SourceNode = "task2",
TargetNode = "task3",
//Name of the target port defined in the target node
SourcePort = "out"
};
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
//Defines the properties that carry the common values
model.DefaultSettings.Node = new Node() {
Width = 100, Height = 50, FillColor = "darkCyan",
BorderColor = "black", Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { FontColor = "white" } }
};
model.DefaultSettings.Connector = new Connector(){
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Segments = new Collection(){ new Segment(){ Type = Segments.Orthogonal }}
}
ViewData["diagramModel"] = model;
return View();
}
```



Segments

The path of the connector is defined with a collection of segments. There are three types of segments.

Straight

Straight segment allows to create a straight line.

To create a straight line, you should specify the Type of the segment as "straight" and add a straight segment to Segments collection. The following code example illustrates how to create a default straight segment.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
Name = "Connector1",
SourcePoint = new DiagramPoint(100f, 100f),
TargetPoint = new DiagramPoint(200f, 200f),
//Defines segment collection
//When there is no previous segment, line starts from source point
//When the end point is not specified, line ends at target point
//Defines the type of the segment
Segments = new Collection() { new Segment() { Type = Segments.Straight }}
};
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

The Point property of straight segment allows you to define the end point of it. The following code example illustrates how to define the end point of a straight segment.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
Name = "Connector1",
SourcePoint = new DiagramPoint(100f, 100f),
TargetPoint = new DiagramPoint(200f, 300f),
//Defines segment collection
//When there is no previous segment, line starts from source point
//When the end point is not specified, line ends at target point
//Defines the type of the segment
Segments = new Collection() { new Segment() {
Type = Segments.Straight,
// Defines the end point of the segment
// Additional straight line will be drawn from this end point to the target
point
Point = new DiagramPoint(100f, 200f)
}}
}
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

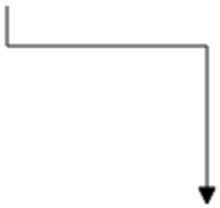
Orthogonal

Orthogonal segments are used to create segments that are perpendicular to each other.

Set the segment Type as "Orthogonal" to create a default orthogonal segment. The following code example illustrates how to create a default orthogonal segment.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
Name = "Connector1",
SourcePoint = new DiagramPoint(100f, 100f),
TargetPoint = new DiagramPoint(200f, 200f),
//Defines segment collection
//Defines the type of the segment
Segments = new Collection() { new Segment() { Type = Segments.Orthogonal }}
}
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```



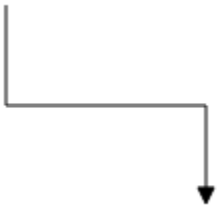
The Length and Direction properties allow to define the flow and length of segment. The following code example illustrates how to create customized orthogonal segments.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
Name = "Connector1",
SourcePoint = new DiagramPoint(100f, 100f),
TargetPoint = new DiagramPoint(200f, 200f),
//Defines segment collection
Segments = new Collection() { new Segment() {
//Defines the type of the segment
Type = Segments.Orthogonal,
// Orthogonal segment of 50px length to the bottom
Length = 50,
// Additional orthogonal segments will be added from the end of the last
segment to the target point
Direction = "right"
}}
```

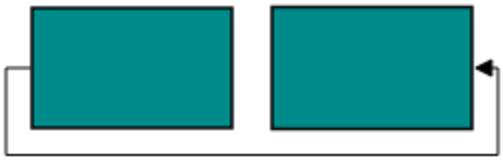
Copyright © 2001 - 2020 Syncfusion Inc.

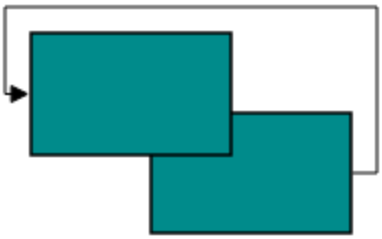
```
}
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```



Avoid overlapping

Orthogonal segments are automatically re-routed, in order to avoid overlapping with the source and target nodes. The following images illustrate how orthogonal segments are re-routed.





Note: Overlapping with source and target nodes are only avoided. Other nodes are not considered as obstacles.

Bezier

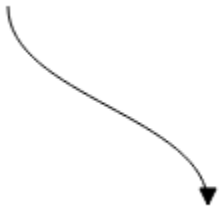
Bezier segments are used to create curve segments and the curves are configurable either with the control points or with vectors.

To create a bezier segment, the Segment.Type is set as Bezier. The following code example illustrates how to create a default Bezier segment.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
Name = "Connector1",
SourcePoint = new DiagramPoint(100f, 100f),
TargetPoint = new DiagramPoint(200f, 200f),
```

```
//Defines segment collection
Segments = new Collection() { new Segment() {
//Defines the type of the segment
Type = Segments.Bezier
}}
}
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```

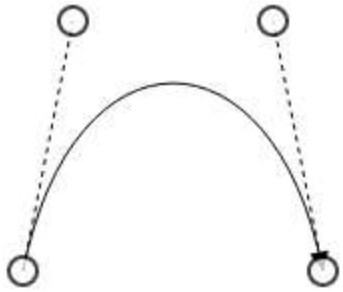


The Point1 and Point2 properties of bezier segment enable you to set the control points. The following code example illustrates how to configure the Bezier segments with control points.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
Name = "Connector1",
SourcePoint = new DiagramPoint(100f, 200f),
TargetPoint = new DiagramPoint(250f, 200f),
//Defines segment collection
Segments = new Collection() { new Segment() {
//Defines the type of the segment
Type = Segments.Bezier,
//First control point: an absolute position from the page origin
Point1 = new DiagramPoint(125f, 75f),
//Second control point: an absolute position from the page origin
Point2 = new DiagramPoint(225f, 75f)
}}
}
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



The Vector1 and Vector2 properties of bezier segment enable you to define the vectors. The following code illustrates how to configure a bezier curve with vectors.

JS

```
//Defines JSON
var connector = {
name: "connector",
sourcePoint: { x: 100, y: 200 },
targetPoint: { x: 250, y: 200 },
//Defines segment collection
segments: [
{
// Defines the type of the segment
type: "bezier",
// Length and angle between the source point and the first control point
vector1: { angle: 270, distance: 75 },
// Length and angle between the target point and the second control point
vector2: { angle: 270, distance: 75 }
}]
};
connectors.push(connector);
```

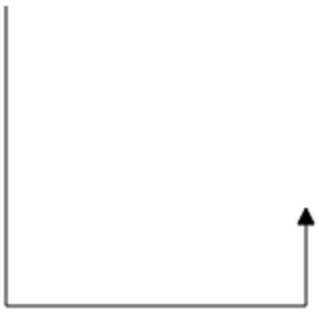
Complex segments

Multiple segments can be defined one after another. To create a connector with multiple segments, define and add the segments to Connector.Segments collection. The Following code example illustrates how to create a connector with multiple segments.

C#

```
public ActionResult Index()
{
```

```
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
Name = "Connector1",
SourcePoint = new DiagramPoint(100f, 200f), TargetPoint = new
DiagramPoint(250f, 300f),
//Defines segment collection
Segments = new Collection() {
// Segment of length 100px to the bottom
new Segment() { Type = Segments.Orthogonal, Length = 100, Direction =
"bottom" },
// Segment of length 150px to the bottom
//Additional orthogonal segments will be added from the end of the last
segment to the target point
new Segment() { Type = Segments.Orthogonal, Length = 150, Direction =
"right" }
}
}
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```



Decorator

Start and end points of a connector can be decorated with some customizable shapes like arrows, circles, diamond or path. You can decorate the connection end points with the SourceDecorator and TargetDecorator properties of connector.

To explore the properties of decorators, refer to Decorator Properties.

The Shape property of decorator allows to define the shape of the decorators. The following code example illustrates how to create decorators of various shapes.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector1 = new Connector() {
Name = "connector1",SourcePoint = new DiagramPoint(100f, 100f), TargetPoint
= new DiagramPoint(200f, 200f),
//Decorator shape - Circle
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
SourceDecorator = new Decorator() { Shape = DecoratorShapes.Circle, Width =
10, Height = 10 },
//Decorator shape - Arrow
TargetDecorator = new Decorator() { Shape = DecoratorShapes.Arrow, Width =
10, Height = 10 }
};
Connector connector2 = new Connector() {
Name = "connector2",SourcePoint = new DiagramPoint(300f, 100f), TargetPoint
= new DiagramPoint(400f, 200f),
//Decorator shape - Diamond
SourceDecorator = new Decorator() { Shape = DecoratorShapes.Diamond, Width =
10, Height = 10 },
//Decorator shape - Open Arrow
TargetDecorator = new Decorator() { Shape = DecoratorShapes.OpenArrow, Width
= 10, Height = 10 }
};
Connector connector3 = new Connector() {
Name = "connector3",SourcePoint = new DiagramPoint(500f, 100f), TargetPoint
= new DiagramPoint(600f, 200f),
//Decorator shape - Path
TargetDecorator = new Decorator() { Shape = DecoratorShapes.Path, PathData =
"M 376.892,225.284L 371.279,211.95L 376.892,198.617L 350.225,211.95L
376.892,225.284 Z" }
};
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector1);
model.Connectors.Add(connector2);
model.Connectors.Add(connector3);
ViewData["diagramModel"] = model;
return View();
}
```

Padding

Padding is used to leave space between the Connector's end point and the object to where it is connected.

The SourcePadding and TargetPadding properties of connector define the space to be left between the connection end points and the source and target nodes of connector. The following code example illustrates how to leave space between the connection end points and source, target nodes.

C#

```
public ActionResult Index()
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
DiagramProperties model = new DiagramProperties();
FlowShape task1 = new FlowShape(){
Name = "task1", OffsetX = 200, OffsetY = 200, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 1" } }
};
FlowShape task2 = new FlowShape(){
Name = "task2", OffsetX = 400, OffsetY = 200, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 2" } }
};
model.Nodes.Add(task1);
model.Nodes.Add(task2);
model.Nodes.Add(new Connector() {
Name = "flow1", SourceNode = "task1", TargetNode = "task2",
//Space between source point and source object
SourcePadding = 5,
//Space between target point and target object
TargetPadding = 10
});
//Defines the properties that carry the common values
model.DefaultSettings.Node = new Node() {
Width = 100, Height = 50, BorderColor = "black", FillColor = "darkCyan",
Labels = new Collection() { new Label() { FontColor = "white" } }
}
ViewData["diagramModel"] = model;
return View();
}
```

The ConnectorPadding property of node defines the space to be left between the node bounds and its edges. The following code example illustrates how to leave the space between a node and its connections.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
FlowShape task1 = new FlowShape() {
Name = "task1", OffsetX = 200, OffsetY = 200, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 1" } },
//Space between the node and its edges
ConnectorPadding = 5
};
FlowShape task2 = new FlowShape() {
Name = "task2", OffsetX = 400, OffsetY = 200, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 2" } }
};
model.Nodes.Add(task1);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
model.Nodes.Add(task2);
model.Connectors.Add( new Connector() { Name = "flow1", SourceNode =
"task1", TargetNode = "task2" });
//Sets the default properties for nodes
model.DefaultSettings.Node = new Node() {
Width = 100, Height = 50, BorderColor = "black", FillColor = "darkCyan",
Labels = new Collection() { new Label() { FontColor = "white" } }
};
ViewData["diagramModel"] = model;
return View();
}
```

The ConnectorPadding property of port defines the space between the ports and its in/out edges. The following code example illustrates how to leave the space between ports and its connections.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
FlowShape task1 = new FlowShape() {
Name = "task1", OffsetX = 200, OffsetY = 200, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 1" } }
};
FlowShape task2 = new FlowShape() {
Name = "task2", OffsetX = 400, OffsetY = 200, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 2" } },
//Defines ports for task2
Ports = new Collection() {
new Port(){
Name = "port", Offset = new DiagramPoint(0f, 0.5f), Shape =
PortShapes.Circle,
Visibility = PortVisibility.Visible, FillColor = "black",
//Space between port and its edges
ConnectorPadding = 5
}
}
};
model.Nodes.Add(task1);
model.Nodes.Add(task2);
model.Connectors.Add(new Connector() { Name = "flow1", SourceNode = "task1",
TargetNode = "task2", TargetPort = "port"});
//Sets the default properties for nodes
model.DefaultSettings.Node = new Node() {
Width = 100, Height = 50, BorderColor = "black", FillColor = "darkCyan",
Labels = new Collection() { new Label() { FontColor = "white" } }
}
ViewData["diagramModel"] = model;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
return View();
}
```

Bridging

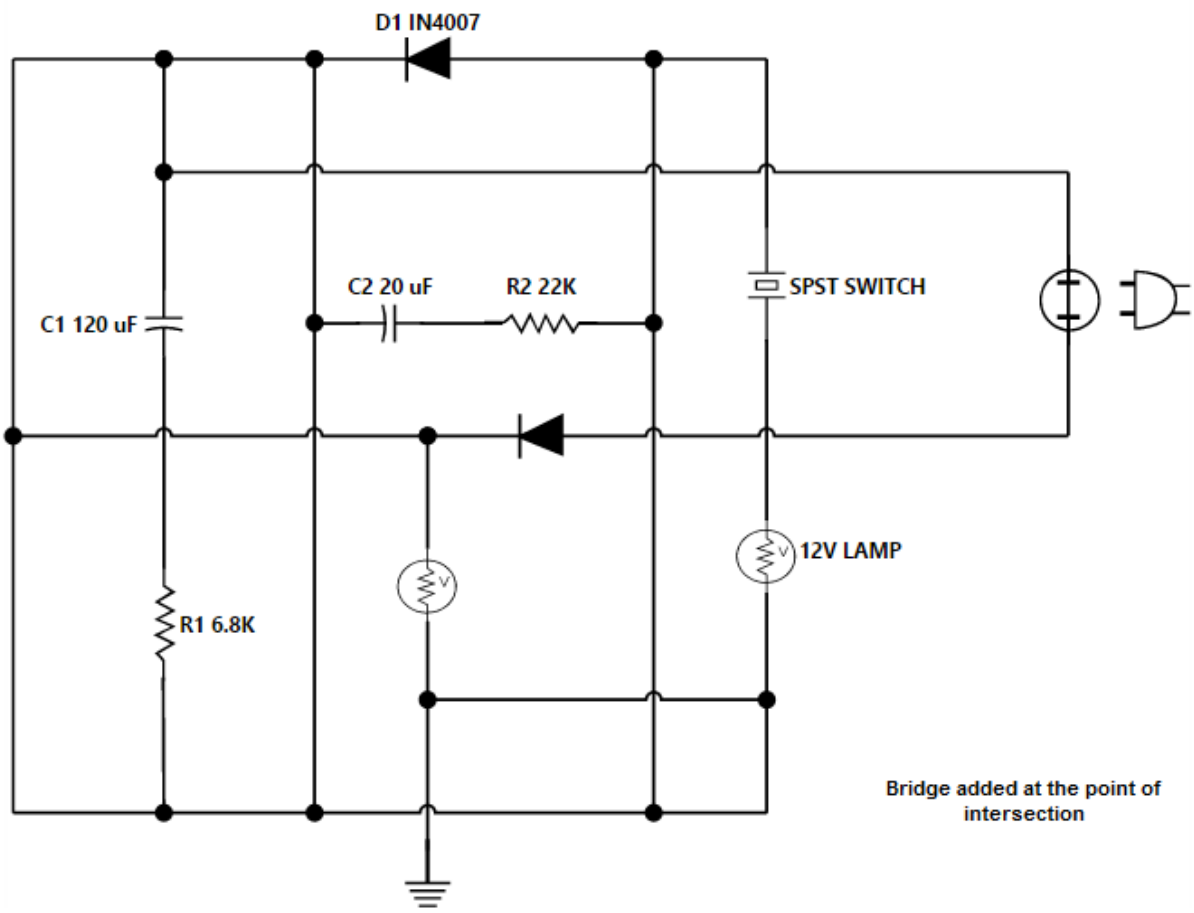
Line Bridging creates a bridge for lines to smartly cross over other lines, at points of intersection. When two line connectors meet each other, the line with the higher z-order (upper one) draws an arc over the underlying connector.

Bridging can be enabled/disabled either with the Connector.Constraints or Diagram.Constraints. The following code example illustrates how to enable line bridging.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
Name = "Connector1", SourcePoint = new DiagramPoint(100f, 100f), TargetPoint
= new DiagramPoint(200f, 200f),
//Removes inherit bridging or else bridging is enabled/disabled based on the
Diagram constraints
//And includes bridging
Constraints = ConnectorConstraints.Default &
~ConnectorConstraints.InheritBridging | ConnectorConstraints.Bridging
};
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



The direction of the bridge can be customized with the property BridgeDirection. BridgeDirection defines the intersecting segment where the bridge has to be inserted. By default, the bridge direction points to the top.

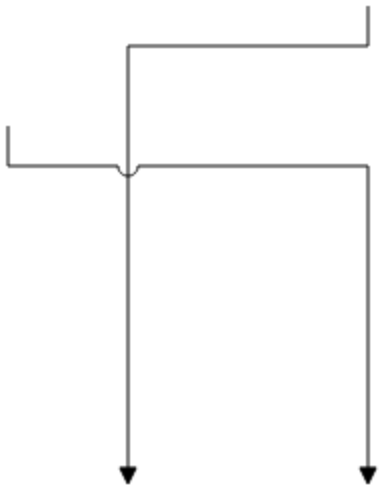
To explore the bridge directions, refer to Bridge Directions.

The following code example illustrates how to draw the bridge at the bottom direction.

RAZOR

```
@using Syncfusion.JavaScript.DataVisualization.DiagramEnums
@using Syncfusion.JavaScript.DataVisualization.Models.Diagram
@(Html.EJ().Diagram("Diagram").Width("100%").Height("600px")
@*Sets the bridge direction*@
.BridgeDirection(BridgeDirection.Bottom)
@*Enables bridging for every connector added in the model*@
.Constraints(DiagramConstraints.Default | DiagramConstraints.Bridging)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Limitation: Bezier segments do not support bridging.

Corner radius

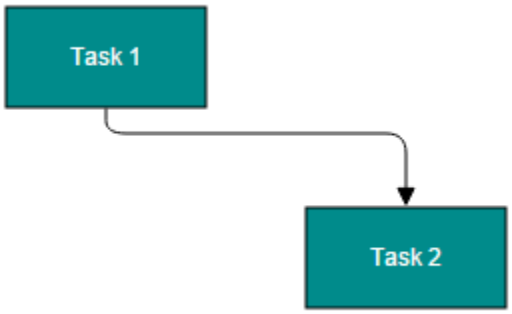
Corner radius allows to create connectors with rounded corners. The radius of the rounded corner is set with CornerRadius property.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
FlowShape task1 = new FlowShape() {
Name = "task1", OffsetX = 200, OffsetY = 200, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 1" } }
};
FlowShape task1 = new FlowShape() {
Name = "task2", OffsetX = 350, OffsetY = 300, Shape = FlowShapes.Process,
Labels = new Collection() { new Label() { Text = "Task 2" } },
};
Connector connector = new Connector() {
Name = "flow1",
SourceNode = "task1",
TargetNode = "task2",
//Sets the radius for the rounded corner
CornerRadius = 10
};
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
//Sets the default properties for nodes
model.DefaultSettings.Node = new Node() {
Width = 100, Height = 50, BorderColor = "black", FillColor = "darkCyan",
Labels = new Collection() { new Label() { FontColor = "white" } }
};
model.DefaultSettings.Connector = new Connector(){
Segments = new Collection(){ new Segment(){ Type = Segments.Orthogonal }}
}
ViewData["diagramModel"] = model;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
return View();
}
```



Appearance

Stroke width, stroke color, and style of the lines and decorators can be customized with a set of defined properties.

Segment Appearance

The following code example illustrates how to customize the segment appearance.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
Name = "connector", SourcePoint = new DiagramPoint(100f, 100f), TargetPoint
= new DiagramPoint(200f, 200f),
//Stroke width of the line
LineWidth = 2,
//Stroke color
LineColor = "green",
//Line style
LineDashArray = "2,2",
//Opacity of the line
Opacity = 0.8,
};
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```

Decorator Appearance

The following code example illustrates how to customize the appearance of the decorator.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector = new Connector() {
//Customizes the appearance of decorator
```

```
TargetDecorator = = new Decorator(){
//Defines the shape
Shape = DecoratorShapes.Arrow,
//Fills color of the decorator
FillColor = "red",
//Stroke color
BorderColor = "green",
//Stroke width
BorderWidth = 2,
Width = 10,
Height = 10
}
};
//Sets connectors collection to the Diagram model
model.Connectors.Add(connector);
ViewData["diagramModel"] = model;
return View();
}
```

Interaction

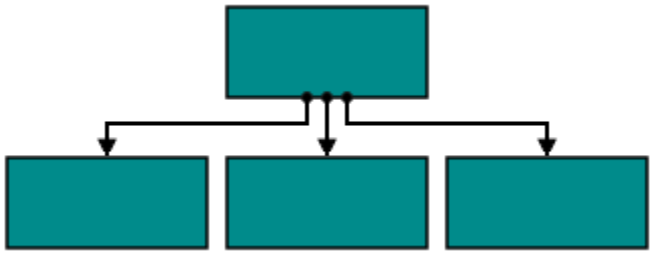
Diagram allows to edit the connectors at runtime. To edit the connector segments at runtime, refer to Connection Editing.

Constraints

The Constraints property of connector allows to enable/disable certain features of connectors. For more information about constraints, refer to Connector Constraints.

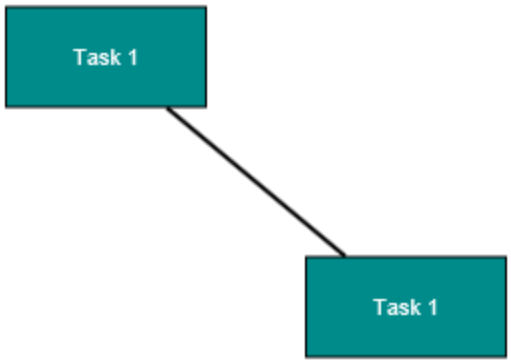
Port

Essential Diagram for JS provides support to define custom ports for making connections.

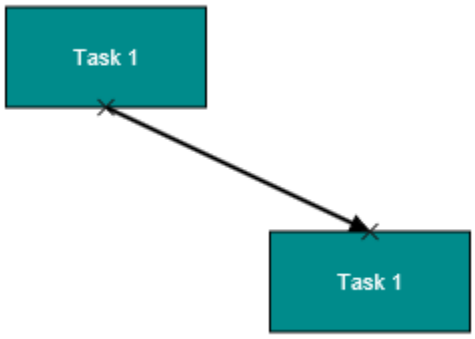


When a connector is connected between two nodes, its end points are automatically docked to node's nearest boundary as shown in the following image.

Copyright © 2001 - 2020 Syncfusion Inc.



Ports act as the connection points of node and allows to create connections with only those specific points as shown in the following image.



Create Port

Add ports when initializing nodes

To add a connection port, you need to define the port object and add it to node's Ports collection. The Offset property of port accepts an object of fractions and used to determine the position of ports. The following code illustrates how to add ports when initializing the node.

C#

```
BasicShape Node = new BasicShape();
Node.Name = "node1";
Node.Width = 100;
Node.Height = 100;
Collection Ports = new Collection();
Port port = new Port();
port.Name = "port1";
port.Offset = new DiagramPoint(0, 0.5f);
Node.Ports = Ports;
Model.Nodes.Add(Node);
```

Add ports at runtime

You can add ports at runtime by using the client side method addPorts. The following code illustrates how to add ports to node at runtime.

JS

```
// Defines a collection of ports that have to be added at runtime
var ports = [
{
name: "port1",
// Specifies the port offset - fraction value relative
to node bounds - determines the position of port on node
offset: {
x: 0,
y: 0.5
}
},
{ name: "port2",offset: {x: 1,y: 0.5 }},
{ name: "port3",offset: {x: 0.5,y: 0 }},
{ name: "port4",offset: {x: 0.5,y: 1 }}
];
// Gets the instance for the Diagram
var diagram = $("#diagram").ejDiagram("instance");
// Adds the ports to the node of name "node"
diagram.addPorts("node", ports)
```

To explore the set of properties for defining a port, refer to Port Properties

Update Port at runtime

The client side API updatePort is used to update the ports at run time. The following code example illustrates how to change the port properties.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
var selectedObject = diagram.model.selectedItems.children[0];
var visibility = ej.datavisualization.Diagram.PortVisibility.Visible;
diagram.updatePort(selectedObject.name, selectedObject.ports[0], {
fillColor: "red", visibility: visibility });
```

Connect with ports

Connector's SourcePort and TargetPort properties allow to create connections between some specific points of source/target nodes.

For more information about creating connections with port, refer to Connections with ports

Appearance

You can change the shape of port by using its Shape property. To explore the different types of port shapes, refer to Port Shapes.

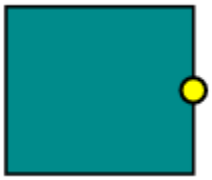
The appearance of ports can be customized with a set of style specific properties.

The following code illustrates how to change the appearance of port.

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
BasicShape Node = new BasicShape();
Collection Ports = new Collection();
Port Port = new Port();
//Defines the shape of port
Port.Shape = PortShapes.Circle;
//Specifies the port visibility
Port.Visibility = PortVisibility.Visible;
//Customizes the appearance
Port.FillColor = "yellow";
Port.Size = 12;
Port.BorderColor = "black";
Port.BorderWidth = 2;
// Specifies the port position
Port.Name = "port1";
Port.Offset = new DiagramPoint(1, 0.5f);
Node.Ports = Ports;
Model.Nodes.Add(Node);
```



Constraints

The Constraints property allows to enable/disable certain behaviors of ports. For more information about port constraints, refer to Port Constraints

Label

Label is a block of text that can be displayed over a node or connector. Label is used to textually represent an object with a string that can be edited at run time. You can add Multiple Labels to a node/connector.

Create Label

You can add a label to a node/connector by defining the label object and adding that to the Labels collection of node/connector. The Text property of label defines the text to be displayed. The following code illustrates how to create a Label.

RAZOR

```
@*Initializes diagram control*@
<div>
@Html.EJ().Diagram("diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
</div>
```

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(new BasicShape()
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
//Initializes labels collection
Labels = new Collection(){
new Label()
{
//Defines the text to be displayed
Text= "Label"
}
}
});
model.Connectors.Add(new Connector()
{
Name = "connector1",
SourcePoint = new DiagramPoint(200, 50),
TargetPoint = new DiagramPoint(300, 150),
Segments = new Collection() {
new Segment() { Type = Segments.Orthogonal, Direction = "bottom", Length =
50 } },
//Initializes labels collection
Labels = new Collection(){
new Label()
{
//Defines the text to be displayed
Text= "Label",
FillColor = "white"
}
}
});
ViewData["diagramModel"] = model;
```

To explore more label properties, refer to Label Properties.

Update Label at runtime

The client side API updateLabel is used to update the labels at run time.

The following code example illustrates how to change the label properties.

C#

```
var diagram = $("#diagram").ejDiagram("instance");
var selectedObject = diagram.model.selectedItems.children[0];
diagram.updateLabel(selectedObject.name, selectedObject.labels[0], { text:
"label", fillColor: "red" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

Alignment

Label can be aligned relative to the node boundaries. It has margin, offset, horizontal and vertical alignment settings. It is quite tricky when all four alignments are used together but gives you more control over alignment.

Offset

The Offset property of label is used to align the labels based on fractions. 0 represents top/left corner, 1 represents bottom/right corner, and 0.5 represents half of width/height.

The following image shows the relationship between the label position (black colored circle) and offset (fraction values).

Horizontal and vertical alignments

The HorizontalAlignment property of label is used to set how the label is horizontally aligned at the label position determined from the fraction values. The VerticalAlignment property is used to set how label is vertically aligned at the label position.

The following tables illustrates all the possible alignments visually with **offset (0, 0).**

| Horizontal Alignment | Vertical Alignment | Output with Offset(0,0) |

|---|---|---|

| Left | Top | |

| Center | | |

| Right | | |

| Left | Center | |

| Center | | |

| Right | | |

| Left | Bottom | |

| Center | | |

| Right | | |

The following codes illustrates how to align labels.

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
Labels = new Collection(){
new Label(){
Text= "Label",
```

```
// Sets offset to label
Offset= new DiagramPoint(0,0.5f),
// Sets to align label horizontally relative to given offset
HorizontalAlignment= HorizontalAlignment.Left,
// Sets to align label vertically relative to given offset
VerticalAlignment= VerticalAlignment.Center,
// Sets text alignment to label
TextAlign= TextAlign.Center
}
}
});
ViewData["diagramModel"] = model;
```

Margin

Margin is an absolute value used to add some blank space in any one of its four sides. You can displace the labels with the Margin property.

The following code example illustrates how to align a label based on its Offset, HorizontalAlignment, VerticalAlignment and Margin values.

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
Labels = new Collection(){
new Label(){
Text= "Label",
Offset=new DiagramPoint(0.5f,1),
HorizontalAlignment= HorizontalAlignment.Center,
VerticalAlignment= VerticalAlignment.Top,
//Sets margin to add label outside a node
Margin= new LabelMargin(){Top=10}
}
}
});
ViewData["diagramModel"] = model;
```

Text Alignment

The TextAlign property of label allows you to set how the text should be aligned (left, right, center, or justify) inside the text block. The following codes illustrate how to set textAlign for a label.

C#

```
DiagramProperties model = new DiagramProperties();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
Labels = new Collection(){
new Label(){
Text= "Text Align is set as Left",
// Sets text alignment for a label
TextAlign = TextAlign.Left
}
}
});
ViewData["diagramModel"] = model;
```

| TextAlign | Image |

|---|---|

| Left | |

| Right | |

| Center | |

| Justify | |

Wrapping

When text overflows node boundaries, you can control it by using text wrapping. So, it is wrapped into multiple lines. The Wrapping property of label defines how the text should be wrapped. The following code illustrates how to wrap a text in a node.

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
Labels = new Collection(){
new Label(){
Text= "Text-Wrapping",
//Enables Text-wrapping
Wrapping = TextWrapping.Wrap
}
}
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
ViewData["diagramModel"] = model;
```

| Values | Description | Image |

|---|---|---|

| NoWrap | Text will not be wrapped |  |

| Wrap | Text-wrapping occurs when the text overflows beyond the available node width. |  |

| WrapWithOverflow (Default) | Text-wrapping occurs when the text overflows beyond the available node width. However, the text may overflow beyond the node width in the case of a very long word. |  |

Appearance

You can change the font style of the labels with the font specific properties(`FontSize`,`FontFamily`,`FontColor`.,). The following code illustrates how to customize the appearance of a label.

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
Labels = new Collection(){
new Label(){
Text= "Label Text",
//Sets styles to a label
FontSize= 12,
FontFamily= "TimesNewRoman",
FontColor= "black",
Bold= true,
Italic= true,
TextDecoration= TextDecorations.Underline
}
}
});
ViewData["diagramModel"] = model;
```

The fill and border appearances of the text can also be customized with appearance specific properties of label.The following code illustrates how to customize background and border of a label.

C#

```
DiagramProperties model = new DiagramProperties();
```

```
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
Labels = new Collection(){
new Label(){
Text= "Label Text",
//Customizes background and borders of a label
FillColor= "white",
BorderColor= "black",
BorderWidth= 1
}
}
});
ViewData["diagramModel"] = model;
```

Drag

A **Label** can be displaced from its original position to any preferred location interactively. Dragging is disabled by default. You can enable label dragging with the Constraints property of node/connector. The following code illustrates how to enable label **dragging**.

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
Constraints=NodeConstraints.Default | NodeConstraints.DragLabel,
//Initializes labels collection
Labels = new Collection(){
new Label()
{
//Defines the text to be displayed
Text= "Label"
}
}
});
model.Connectors.Add(new Connector()
{
Name = "connector1",
SourcePoint = new DiagramPoint(200, 50),
TargetPoint = new DiagramPoint(300, 150),
Segments = new Collection() {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
new Segment() { Type = Segments.Orthogonal, Direction = "bottom", Length =
50 } },
Constraints=ConnectorConstraints.Default | ConnectorConstraints.DragLabel,
//Initializes labels collection
Labels = new Collection(){
new Label()
{
//Defines the text to be displayed
Text= "Label",
FillColor = "white"
}
}
});
ViewData["diagramModel"] = model;
```

Rotate

You can rotate the labels to any desired angle. Labels are rotated to the angle that is defined by the RotateAngle property of label. The following code illustrates how to rotate a label.

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
Constraints = NodeConstraints.Default | NodeConstraints.DragLabel,
//Initializes labels collection
Labels = new Collection(){
new Label()
{
Text="Label",
//Sets label's rotation Angle
RotateAngle=45
}
}
});
ViewData["diagramModel"] = model;
```

Note: There is no built-in support to rotate labels interactively.

Edit

Diagram provides support to edit a Label at runtime, either programmatically or interactively. By default, label is in **View** mode. But it can be brought to edit mode in two ways;

1. By double-clicking the label.

2. By selecting the item and pressing the **F2** key.

Double-clicking any label will enables **editing** of that. Double-clicking the node enables first label editing. When the focus of editor is lost, the label for the node is updated.

You can programmatically edit the label by changing the Mode of the label. The following code illustrates how to edit the label programmatically.

RAZOR

```
var diagram = $("#diagram").ejDiagram("instance");
var node = diagram.model.selectedItems.children[0];
//Sets label mode as Edit
var options = {
mode: ej.datavisualization.Diagram.LabelEditMode.Edit
};
diagram.updateLabel(node.name, node.labels[0], options);
```

Read Only labels

Diagram allows to create read only labels. You have to set the ReadOnly property of label to enable/disable the read only mode. The following code illustrates how to enable **readOnly** mode.

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
Constraints = NodeConstraints.Default | NodeConstraints.DragLabel,
//Initializes labels collection
Labels = new Collection(){
new Label()
{
Text="Label",
ReadOnly=true
}
}
});
ViewData["diagramModel"] = model;
```

Drag Limit

Diagram label dragging can be restricted by enabling/disabling DragLimit constraints of the connectors. Also we can define the drag limit in all direction using DragLimit property of the connector. Drag limit only applicable for connector labels.

C#

Copyright © 2001 - 2020 Syncfusion Inc.

```
DiagramProperties model = new DiagramProperties();
Collection Labels = new Collection();
Labels.Add(new Label()
{
// Defines the drag limit property in all direction
DragLimit = new LabelMargin()
{
Left = 30,
Right = 30,
Bottom = 30,
Top = 30
}
});
model.Connectors.Add(new Connector()
{
Name = "node",
// Enable DragLimit constraints to the connector.
Constraints = ConnectorConstraints.Default | ConnectorConstraints.DragLabel
| ConnectorConstraints.DragLimit,
Labels = Labels
});
ViewData["diagramModel"] = model;
```

Multiple labels

You can add any number of labels to a node or connector. The following code illustrates how to add multiple labels to a node.

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
BorderColor = "black",
FillColor = "#1BA0E2",
//Initializes labels collection
Labels = new Collection(){
new Label()
{
Text="Left",
Offset=new DiagramPoint(0.12f, 0.1f)
},
new Label(){
Text="Center",
Offset= new DiagramPoint(0.5f, 0.5f)
},
new Label(){
Text="Right",
Offset=new DiagramPoint(0.82f, 0.9f)
}
}
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
ViewData["diagramModel"] = model;
```

Limitation

- To enable faster rendering, labels are rendered in a separate layer because of this, all the labels always stay on top. When two nodes are overlapped, text of underlying node is not hidden by the overlapped node.

| Expected behavior | Current behavior |

|---|---|

| | |

Group

Group is used to cluster multiple nodes and connectors into a single element. It acts like a container for its children (nodes, groups, and connectors). Every change made to the group also affects the children. Child elements can be edited individually.

Create Group

Add group when initializing diagram

You can add a group to the Diagram model through Nodes collection. You can create Group like node and you need to add the child objects to the Children collection of the group. The following code illustrates how to create a group node.

C#

```
BasicShape node1 = new BasicShape(){
Name = "rectangle1",
OffsetX = 100,
OffsetY = 100,
Width = 100,
Height = 100,
FillColor = "darkCyan",
BorderWidth = 2,
};
node1.Labels.Add(new Label() { Text = "Rectangle1" });
BasicShape node2 = new BasicShape()
{
Name = "rectangle2",
OffsetX = 200,
OffsetY = 200,
Width = 100,
Height = 100,
FillColor = "darkCyan",
BorderWidth = 2,
};
node2.Labels.Add(new Label() { Text = "Rectangle2" });
Group group = new Group() { Name = "group1" };
group.Children.Add(node1);
group.Children.Add(node2);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Diagram.Model.Nodes.Add(group);
```

Add group at run time

You can add a group node at runtime by using the client side method add.

The following code illustrates how a group node is added at run time.

JS

```
var group = {
name: "group1",
type: "group",
children: [{
name: "rectangle1",
offsetX: 100,
offsetY: 100,
width: 100,
height: 100,
type: "node",
fillColor: "darkCyan",
borderWidth: 2,
labels: [{
text: "rectangle1"
}]
}, {
name: "rectangle2",
offsetX: 200,
offsetY: 200,
width: 100,
height: 100,
type: "node",
fillColor: "darkCyan",
borderWidth: 2,
labels: [{
text: "rectangle2"
}]
}]
};
var diagram = $("#DiagramContent").ejDiagram("instance");
// Adds group to the Diagram.
diagram.add(group);
```

Group from palette

Group nodes can be predefined and added to symbol palette. You can drop those groups into Diagram, when required.

To explore how to add groups from symbol palette, refer to Symbol Palette

Container

Containers are used to automatically measure and arrange the size and position of the child elements in a predefined manner.

There are two types of containers available.

Copyright © 2001 - 2020 Syncfusion Inc.

Canvas

- The Canvas panel supports absolute positioning and provides the least layout functionality to its contained Diagram elements.
- Canvas allows you to position its contained elements by using margin and alignment properties.
- It allows elements to be either vertically or horizontally aligned.

The `Container` property of group should be defined and its `Type` should be set as `Canvas` to create a canvas panel. The following code illustrates how to add a canvas panel.

C#

```
BasicShape node1 = new BasicShape()
{
Name = "node1",
FillColor = "darkCyan",
Width = 100,
Height = 100,
MarginTop = 0,
MarginLeft = 0,
};
BasicShape node2 = new BasicShape()
{
Name = "node2",
FillColor = "white",
Width = 100,
Height = 100,
// Sets the margin to define the space around the child node.
MarginTop = 30,
MarginLeft = 30,
};
BasicShape node3 = new BasicShape()
{
Name = "node3",
FillColor = "darkCyan",
Width = 100,
Height = 100,
MarginTop = 60,
MarginLeft = 60,
};
BasicShape node4 = new BasicShape()
{
Name = "node4",
FillColor = "white",
Width = 100,
Height = 100,
MarginTop = 90,
MarginLeft = 90,
};
Group group = new Group()
{
Name = "canvas",
OffsetX = 400,
OffsetY = 400,
//Sets the container as canvas.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Container = new Container() { Type = ContainerType.Canvas },
FillColor = "#E7EBF4",
BorderColor = "black",
//Sets the padding to give space between the group border and group content.
PaddingLeft = 30,
PaddingTop = 30,
PaddingRight = 30,
PaddingBottom = 30,
};
group.Children.Add(node1);
group.Children.Add(node2);
group.Children.Add(node3);
group.Children.Add(node4);
Diagram.Model.Nodes.Add(group);
```

Stack

- Stack panel is used to arrange its children in a single line or stack order, either vertically or horizontally.
- It controls spacing by setting margin properties of child and padding properties of group. By default, a Stack Panel's Orientation is vertical.

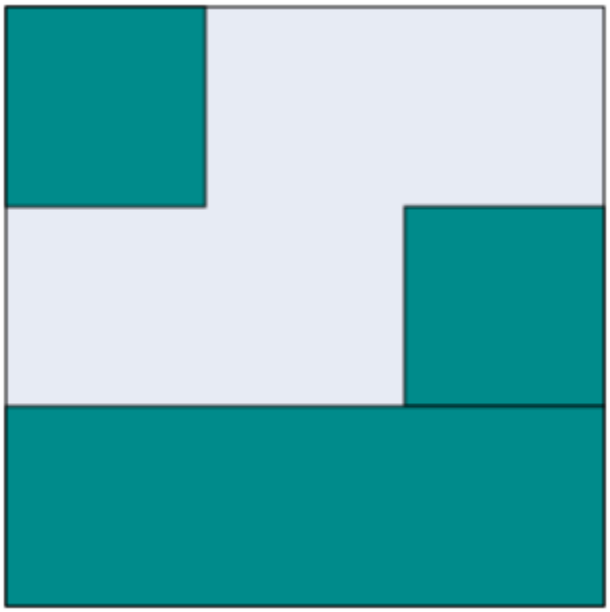
The Container property of group should be defined and its Type should be set as Stack to create a canvas panel The following code illustrates how to add a stack panel.

C#

```
Node node1 = new Node() {
Name = "node1", FillColor = "darkCyan", Width = 100, Height = 100,
//Sets the horizontal Alignment for child node.
HorizontalAlign = HorizontalAlignment.Left
};
Node node2 = new Node() {
Name = "node2", FillColor = "darkCyan", Width = 100, Height = 100,
HorizontalAlign = HorizontalAlignment.Right
};
Node node3 = new Node()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
Name = "node3", FillColor = "darkCyan", Width = 100, Height = 100,
HorizontalAlign = HorizontalAlignment.Stretch
};
Group group = new Group() {
Name = "stack",
OffsetX = 600,
OffsetY = 200,
//Sets the container as canvas.
Container = new Container() { Type = ContainerType.Stack },
FillColor = "#E7EBF4",
BorderColor = "black",
// Sets the minimum size for stack panel.
MinHeight = 300,
MinWidth = 300,
};
group.Children.Add(node1);
group.Children.Add(node2);
group.Children.Add(node3);
Diagram.Model.Nodes.Add(group);
```



Difference between a basic group and containers

| Group | Container |

|---|---|

| It arranges the child elements based on the child elementâ??s position and size properties. | Each container has a predefined behaviour to measure and arrange its child elements. Canvas and stack containers are supported in the Diagram. |

| Padding, Min and Max Size properties are not applicable for basic group. | It is applicable for container. |

| Children's margin and alignment properties are not applicable for basic group. | It is applicable for container. |

Copyright © 2001 - 2020 Syncfusion Inc.

Interaction

You can edit the group and its children at runtime. For more information about how to interact with a group, refer to Edit Groups.

Swim lane

Swim-lane Diagrams are typically used to visualize the relationship between a business process and the department responsible for it by focusing on the logical relationships between activities. Swimlanes may be arranged either horizontally or vertically.

Initialize the Diagram model

Create a Object for diagram properties model element that can be used to initialize the diagram widget as shown below.

C#

```
//Initialize the Diagram Model
DiagramProperties Model = new DiagramProperties();
```

Create a swimlane

To create a swimlane, you need to use the Swimlane class. By default, the swimlanes are arranged vertically. You can change that with the Orientation property of swimlane.

The following code example illustrates how to define a swimlane object.

C#

```
//Disables tooltip for any node/connector
DiagramProperties Model = new DiagramProperties();
SwimLane Swimlane = new SwimLane();
Swimlane.Name = "swimlaneNode";
//Changes the orientation
Swimlane.Orientation = "horizontal";
//Sets the position and size
Swimlane.OffsetX = 400;
Swimlane.OffsetY = 200;
Swimlane.Height = 100;
Swimlane.Width = 700;
//Sets the type of object as swimlane
Swimlane.IsSwimlane = true;
```

Add swimlane into diagram

Adding a swimlane to the Diagram is same as adding a node. You can add either through the Nodes collection or through the client side method add. You can also drag and drop a swimlane from symbol palette.

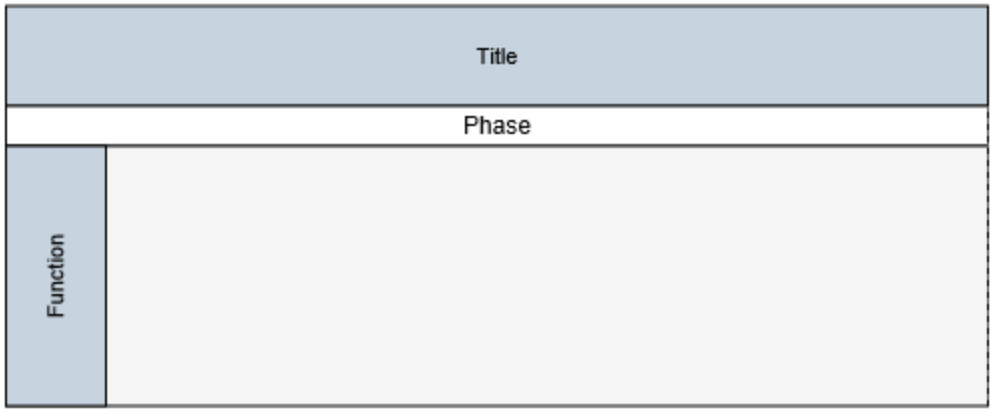
For more information about adding a node/swimlane to the Diagram, refer to Add Nodes.

The following code example illustrates how to add a swimlane to the Diagram through Nodes collection.

C#

```
//Add the swimlane in to the Nodes collection
Model.Nodes.Add(Swimlane);
```

Copyright © 2001 - 2020 Syncfusion Inc.



Headers

Swimlane allows to define a header to textually describe it. The Header property of swimlane allows you to define its textual description(Text) and to customize its appearance. The following code example illustrates how to define swimlane header.

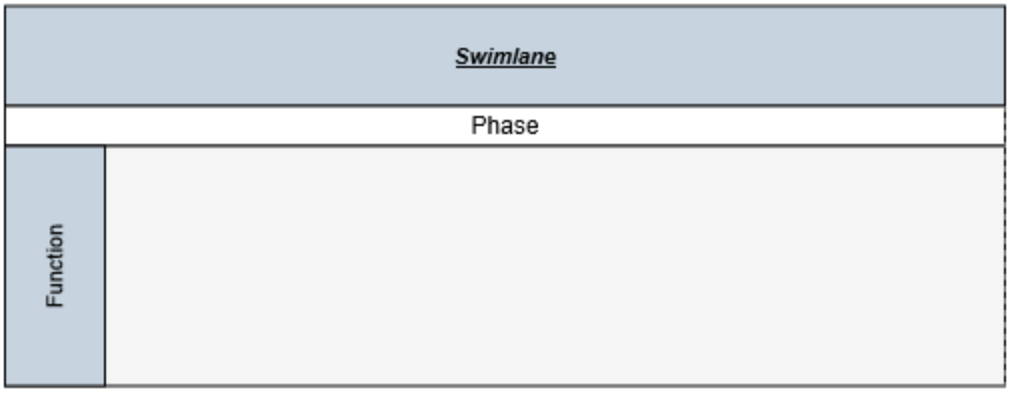
C#

```
//Defines the header and format its text
Header Header = new Header();
Header.Text = "Swimlane";
Header.Height = 50;
Header.FillColor = "#C7D4DF";
Header.FontColor = "black";
Header.FontSize = 11;
Header.FontFamily = "Arial";
Header.Italic = true;
Header.Bold = true;
Header.TextDecoration = "underline";
SwimLane Swimlane = new SwimLane();
Swimlane.Name = "swimlaneNode";
//Changes the orientation
Swimlane.Orientation = "horizontal";
//Sets the position and size
Swimlane.OffsetX = 400;
Swimlane.OffsetY = 200;
Swimlane.Height = 100;
Swimlane.Width = 700;
//Sets the type of object as swimlane
Swimlane.IsSwimlane = true;
//Sets the swimlane header
Swimlane.Header = Header;
//Add the swimlane in to the Nodes collection
Model.Nodes.Add(Swimlane);
```

JS

```
//Updates the swimlane header at runtime
var diagram = $("#diagram").ejDiagram("instance");
diagram.updateNode("swimlaneName", { header: {fontColor:"white"} })
```

Copyright © 2001 - 2020 Syncfusion Inc.



Update Header

Swimlane headers can be updated at runtime with the client side method updateNode. The following code example illustrates how to update a lane's header at runtime.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
//Defines the header and format its text
var header = {
text: "swimlane",
bold: true,
italic: true
};
diagram.updateNode("swimlane", { header: header });
```

Disable headers

You can hide the swimlane headers. The following code example illustrates how to hide headers.

C#

```
//Defines the header
Header Header = new Header();
//Sets "0" to hide header
Header.Height = 0;
```

Lane

Lane is a functional unit or a responsible department of a business process that helps to map a process within the functional unit or in between other functional units.

You can add any number of lanes to a swimlane and the lanes are automatically stacked inside a swimlane based in the order they are added.

Create an empty lane

To create an empty lane, you need to define an object with IsLane property that helps identify the object as a lane. The following example illustrates how to define a swimlane with a lane.

C#

```
SwimLane Swimlane = new SwimLane();
Swimlane.Name = "swimlaneNode";
//Changes the orientation
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Swimlane.Orientation = "horizontal";
//Sets the position and size
Swimlane.OffsetX = 400;
Swimlane.OffsetY = 200;
Swimlane.Height = 100;
Swimlane.Width = 700;
Swimlane.Header = Header;
//Sets the type of object as swimlane
Swimlane.Type = "swimlane";
//Defines an empty lanes Collection
Collection Lanes = new Collection();
Lane Lane = new Lane();
Lane.Name = "lane1";
Lane.FillColor = "#f5f5f5";
Lane.Height = 120;
//Sets the object as Lane
Lane.IsLane = true;
Lanes.Add(Lane);
Swimlane.Lanes = Lanes;
//Add the swimlane in to the Nodes collection
Model.Nodes.Add(Swimlane);
```

Create a lane with header

The Header property of the lane allows you to textually describe the lane(text) and to customize the appearance of the description. The following code example illustrates how to define a lane header.

You can limit the size of a lane with its MinWidth, MinHeight, MaxWidth, and MaxHeight properties.

C#

```
//Defines the header and format its text
Header Header = new Header();
Header.Text = "Swimlane";
Header.Height = 50;
Header.FillColor = "#C7D4DF";
Header.FontColor = "black";
Header.FontSize = 11;
Header.FontFamily = "Arial";
Header LaneHeader = new Header();
LaneHeader.Text = "Lane";
LaneHeader.Width = 50;
LaneHeader.FillColor = "#C7D4DF";
LaneHeader.FontColor = "black";
LaneHeader.FontSize = 11;
LaneHeader.FontFamily = "Arial";
//Defines an empty lanes Collection
Collection Lanes = new Collection();
Lane Lane = new Lane();
Lane.Name = "lane1";
Lane.FillColor = "#f5f5f5";
Lane.Height = 120;
//Sets the object as Lane
Lane.IsLane = true;
//Sets the object as Lane
Lane.Header = LaneHeader;
//Specifies the minimum and maximum size of the lane
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Lane.MinWidth = 500;
Lane.MaxWidth = 700;
Lane.MinHeight = 120;
Lane.MaxHeight = 200;
Lanes.Add(Lane);
SwimLane Swimlane = new SwimLane();
Swimlane.Name = "swimlaneNode";
//Changes the orientation
Swimlane.Orientation = "horizontal";
//Sets the position and size
Swimlane.OffsetX = 400;
Swimlane.OffsetY = 200;
Swimlane.Height = 100;
Swimlane.Width = 700;
Swimlane.Header = Header;
//Sets the type of object as swimlane
Swimlane.Type = "swimlane";
Swimlane.Lanes = Lanes;
//Add the swimlane in to the Nodes collection
Model.Nodes.Add(Swimlane);
```

Disable/Update header

You can disable/update the lane header at runtime with the client side method, updateNode. The following code example illustrates how to disable the lane header at run time.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
//Sets "0" to hide header
diagram.updateNode("laneName", { header: {height: 0} })
```

Add nodes to a lane

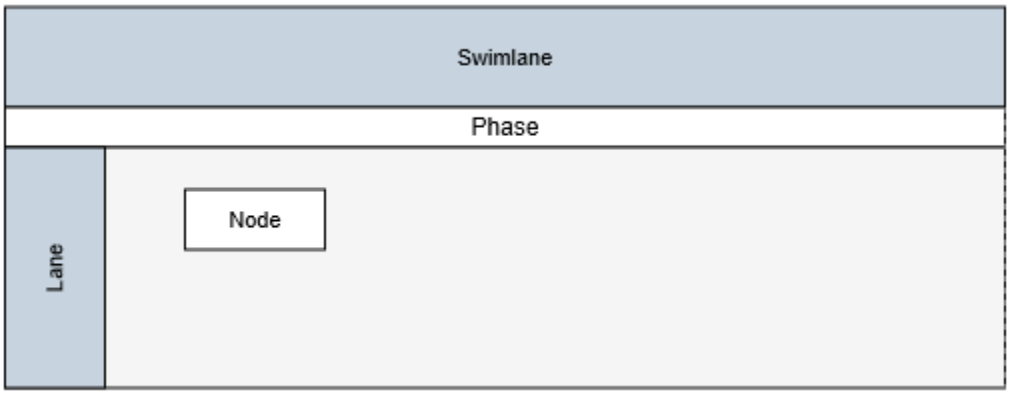
To add nodes to a lane, You need to add them to the Children collection of lane. The following code example illustrates how to add nodes to a lane.

C#

```
Label Label = new Label() { Text = "Node" };
Node Child = new Node()
{
Name = "node",
Width = 70,
Height = 30,
MarginLeft = 70,
MarginTop = 1
};
//Defines an empty lanes Collection
Collection Lanes = new Collection();
//Defines an empty Children Collection
Collection Children = new Collection();
Lane Lane = new Lane();
Lane.Name = "lane1";
Lane.FillColor = "#f5f5f5";
Lane.Height = 120;
//Sets the object as Lane
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Lane.IsLane = true;
//Sets the object as Lane
Lane.Header = LaneHeader;
//Add the Child to the children of the lane
Children.Add(Child);
Lane.Children = Children;
Lanes.Add(Lane);
SwimLane Swimlane = new SwimLane();
Swimlane.Name = "swimlaneNode";
//Changes the orientation
Swimlane.Orientation = "horizontal";
//Sets the position and size
Swimlane.OffsetX = 400;
Swimlane.OffsetY = 200;
Swimlane.Height = 100;
Swimlane.Width = 700;
Swimlane.Header = Header;
Swimlane.Lanes = Lanes;
//Add the swimlane in to the Nodes collection
Model.Nodes.Add(Swimlane);
```



Phase

Phases are the sub-processes that are used to break the swimlane into multiple smaller regions.

Add phase

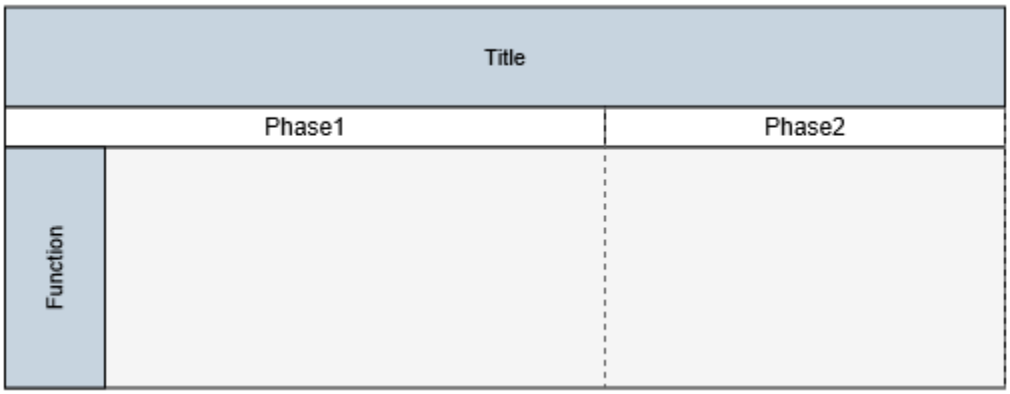
To define a phase, you have to set the length of the region to the Offset property of phase. Every region can be textually described with the Label property of phase.

The following code example illustrates how to add a phase on initializing swimlane.

C#

```
Label PhaseLabel = new Label() { Text = "Phase1" };
//Defines an empty Children Collection
Collection Phases = new Collection();
//Creates a phase
Phase Phase1 = new Phase()
{
Name = "Phase1",
//Length of the first region
Offset = 300,
//Initializes labels for phases
```

```
Label = PhaseLabel,
//Specifies the appearance of separator
LineWidth = 1,
LineDashArray = "3,3",
LineColor = "#606060"
};
PhaseLabel = new Label() { Text = "Phase2" };
Phase Phase2 = new Phase()
{
Name = "Phase2",
Label = PhaseLabel,
};
Phases.Add(Phase1);
Phases.Add(Phase2);
SwimLane Swimlane = new SwimLane();
Swimlane.Name = "swimlaneNode";
//Changes the orientation
Swimlane.Orientation = "horizontal";
//Sets the position and size
Swimlane.OffsetX = 400;
Swimlane.OffsetY = 200;
Swimlane.Height = 100;
Swimlane.Width = 700;
Swimlane.Header = Header;
//Sets the type of object as swimlane
Swimlane.Type = "swimlane";
//Sets the Lanes Collection
Swimlane.Lanes = Lanes;
//Sets the Phase Collection
Swimlane.Phases = Phases;
//Add the swimlane in to the Nodes collection
Model.Nodes.Add(Swimlane);
```



Add phase at runtime

You can add a region at runtime with the client side method, addPhase. The following code example illustrates how to add a phase at runtime.

JS

```
var phase = {
name: "Phase3",
label: { text: "Phase3" }
```

```
};
var diagram = $("#diagram").ejDiagram("instance");
diagram.addPhase("swimlaneName", phase);
```

A phase can be updated at runtime with the client side API updateNode. The following code example illustrates how to a update phase at runtime.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
var options = {
//Specifies the style of the phase to be updated
lineDashArray: "3,3",
lineColor: "#C7D4DF",
lineWidth: 2
}
diagram.updateNode("phaseName", options);
```

Note: A default phase is added, when the phase collection of the swimlane is empty. When the phase collection is initialized, a default phase is appended at the end of swimlane.

Limitations

- You cannot add connectors as the children of lanes.

Gridlines

Gridlines are the pattern of lines drawn behind the Diagram elements. It provides a visual guidance while dragging or arranging the objects on the Diagram surface.

Customize the gridlines visibility

The SnapSettings.SnapConstraints enables you to show/hide the gridlines. The following code example illustrates how to show or hide gridlines.

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
```

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
model.SnapSettings = new SnapSettings()
{
//Shows both horizontal and vertical gridlines
SnapConstraints = SnapConstraints.ShowLines
}
ViewData["diagramModel"] = model;
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

To show only horizontal/vertical gridlines or to hide gridlines, refer to Constraints

Appearance

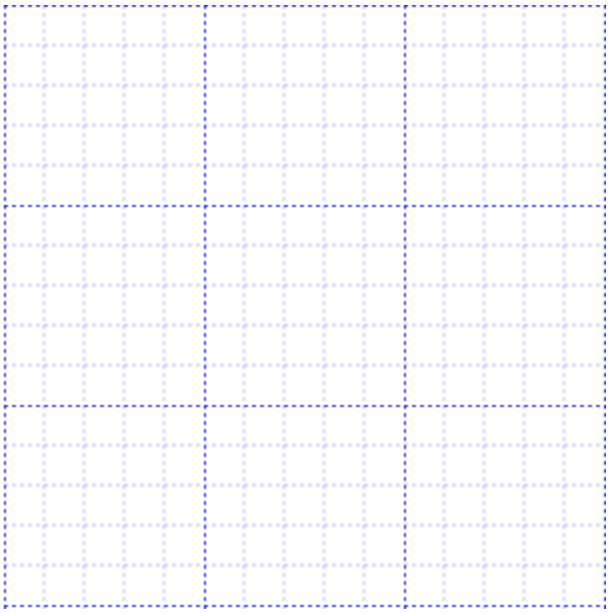
You can customize the appearance of the gridlines by using a set of predefined properties. To explore those properties, refer to Gridlines

The HorizontalGridLines and VerticalGridLines properties allow to customize the appearance of the gridlines. The following code example illustrates how to customize the appearance of gridlines.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
model.SnapSettings = new SnapSettings()
{
//Shows both horizontal and vertical gridlines
SnapConstraints = SnapConstraints.ShowLines,
// Customizes the line color and line style to the gridlines.
HorizontalGridlines = new GridLines() { LineColor = "blue", LineDashArray =
"2 2" },
VerticalGridlines = new GridLines() { LineColor = "blue", LineDashArray = "2
2" }
};
ViewData["diagramModel"] = model;
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



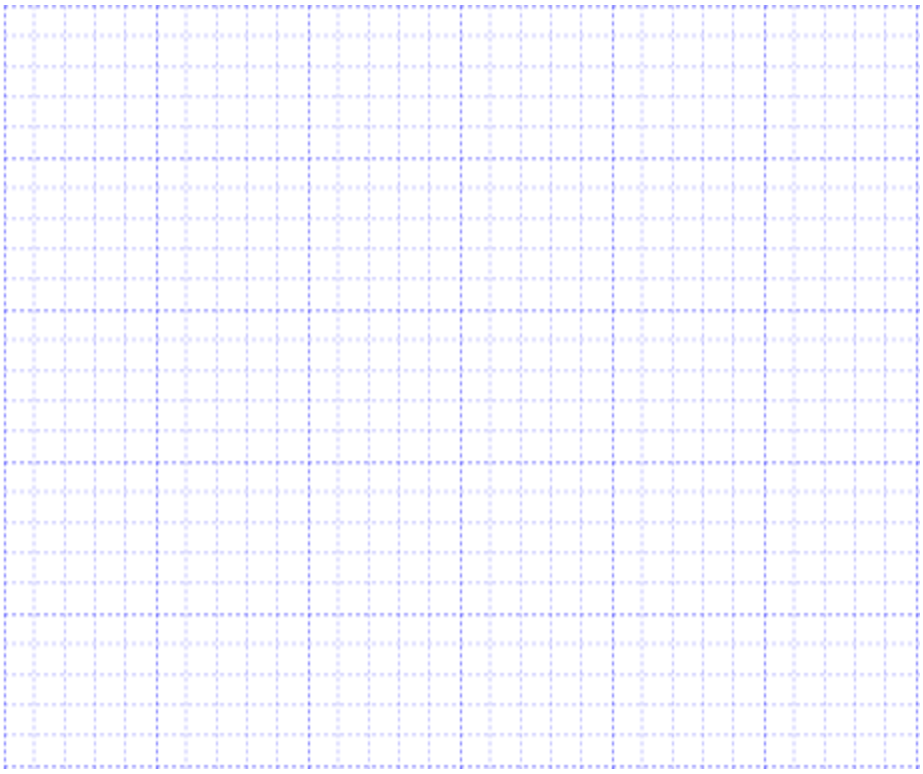
Line Intervals

Thickness and the space between gridlines can be customized by using LinesInterval property. In the linesInterval collections, values at the odd places are referred as the thickness of lines and the values at the even places are referred as the space between gridlines.

The following code example illustrates how to customize the thickness of lines and the line intervals.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
model.SnapSettings = new SnapSettings()
{
//Shows both horizontal and vertical gridlines
SnapConstraints = SnapConstraints.ShowLines,
// Customizes the line color and line style to the gridlines.
// Defines the thickness and intervals for a pattern of lines
HorizontalGridlines = new GridLines() {
LinesInterval = new List<decimal>(){1.25m, 14, 0.25m, 15, 0.25m, 15, 0.25m,
15, 0.25m, 15},
LineColor = "blue",
LineDashArray = "2 2"
},
VerticalGridlines = new GridLines() {
LinesInterval = new List<decimal>(){1.25m, 14, 0.25m, 15, 0.25m, 15, 0.25m,
15, 0.25m, 15},
LineColor = "blue",
LineDashArray = "2 2"
}
};
ViewData["diagramModel"] = model;
return View();
}
```



Snapping

Snap To Lines

This feature allows the Diagram objects to snap to the nearest intersection of gridlines while being dragged or resized. This feature enables easier alignment during layout or design.

Snapping to gridlines can be enabled/disabled with the SnapSettings.SnapConstraints. The following code example illustrates how to enable/disable the snapping to gridlines.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
model.SnapSettings = new SnapSettings()
{
//Enables snapping to both the horizontal and vertical lines.
SnapConstraints = SnapConstraints.SnapToLines,
};
ViewData["diagramModel"] = model;
return View();
}
```

To enable/disable snapping to horizontal/vertical lines, refer to Constraints

Customization of Snap Intervals

By default, the objects are snapped towards the nearest gridline. The gridline or position towards where the diagram object snaps can be customized with the property, snapInterval. The following code example illustrates how to customize the snap intervals.

RAZOR

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
model.SnapSettings = new SnapSettings()
{
HorizontalGridlines = new GridLines() { LinesInterval = new
List<decimal>(){10} },
VerticalGridlines = new GridLines() { LinesInterval = new
List<decimal>(){10} },
SnapConstraints = SnapConstraints.All
};
ViewData["diagramModel"] = model;
return View();
}
```

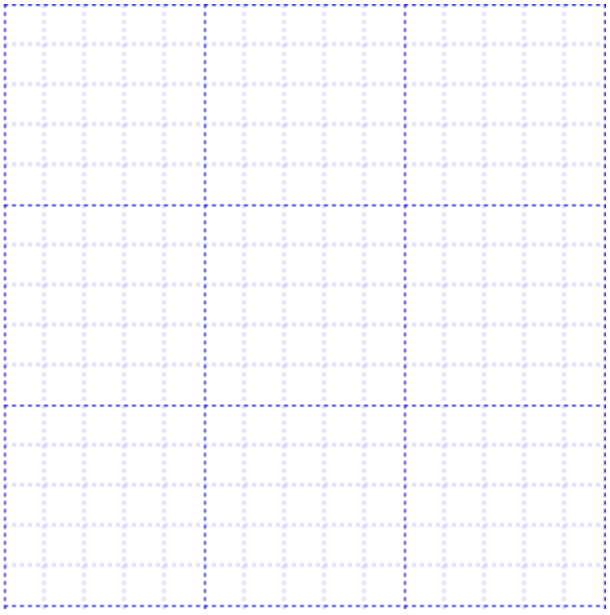
Snap To Objects

The snap-to-object provides visual cues to assist with aligning and spacing Diagram elements. A node can be snapped with its neighboring objects based on certain alignments. Such alignments are visually represented as smart guides.

The EnableSnapToObject property allows you to enable/disable smart guides. The following code example illustrates how to enable/disable the smart guides.

RAZOR

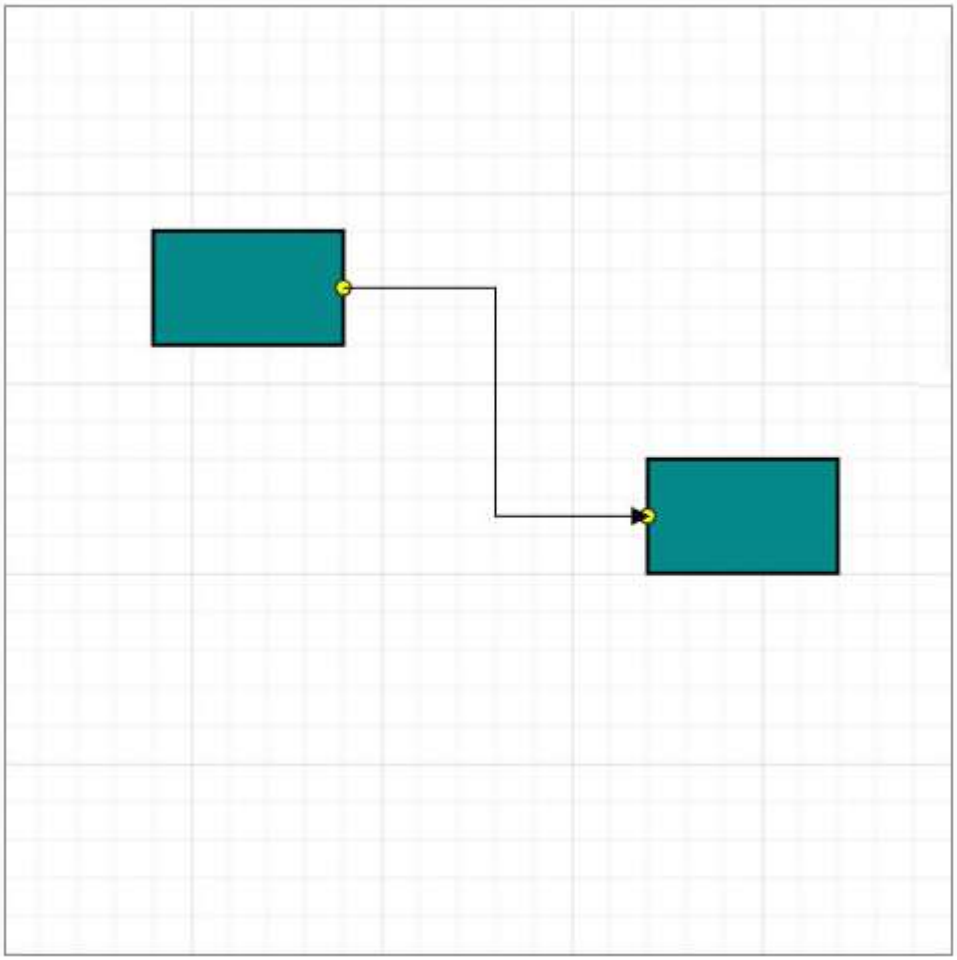
```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
model.EnableSnapToObject = true;
ViewData["diagramModel"] = model;
return View();
}
```



Copyright © 2001 - 2020 Syncfusion Inc.

Page Settings

Page settings enable to customize the appearance, width, and height of the Diagram page.



Page size and appearance

The size and appearance of the Diagram pages can be customized with the PageSettings property.

The PageWidth and PageHeight properties of page settings define the size of the page. In addition to that, you can customize the appearance of the page with a set of appearance specific properties.

To explore those properties, refer Page Settings.

You can also customize the appearance of off-page regions with the property BackgroundColor.

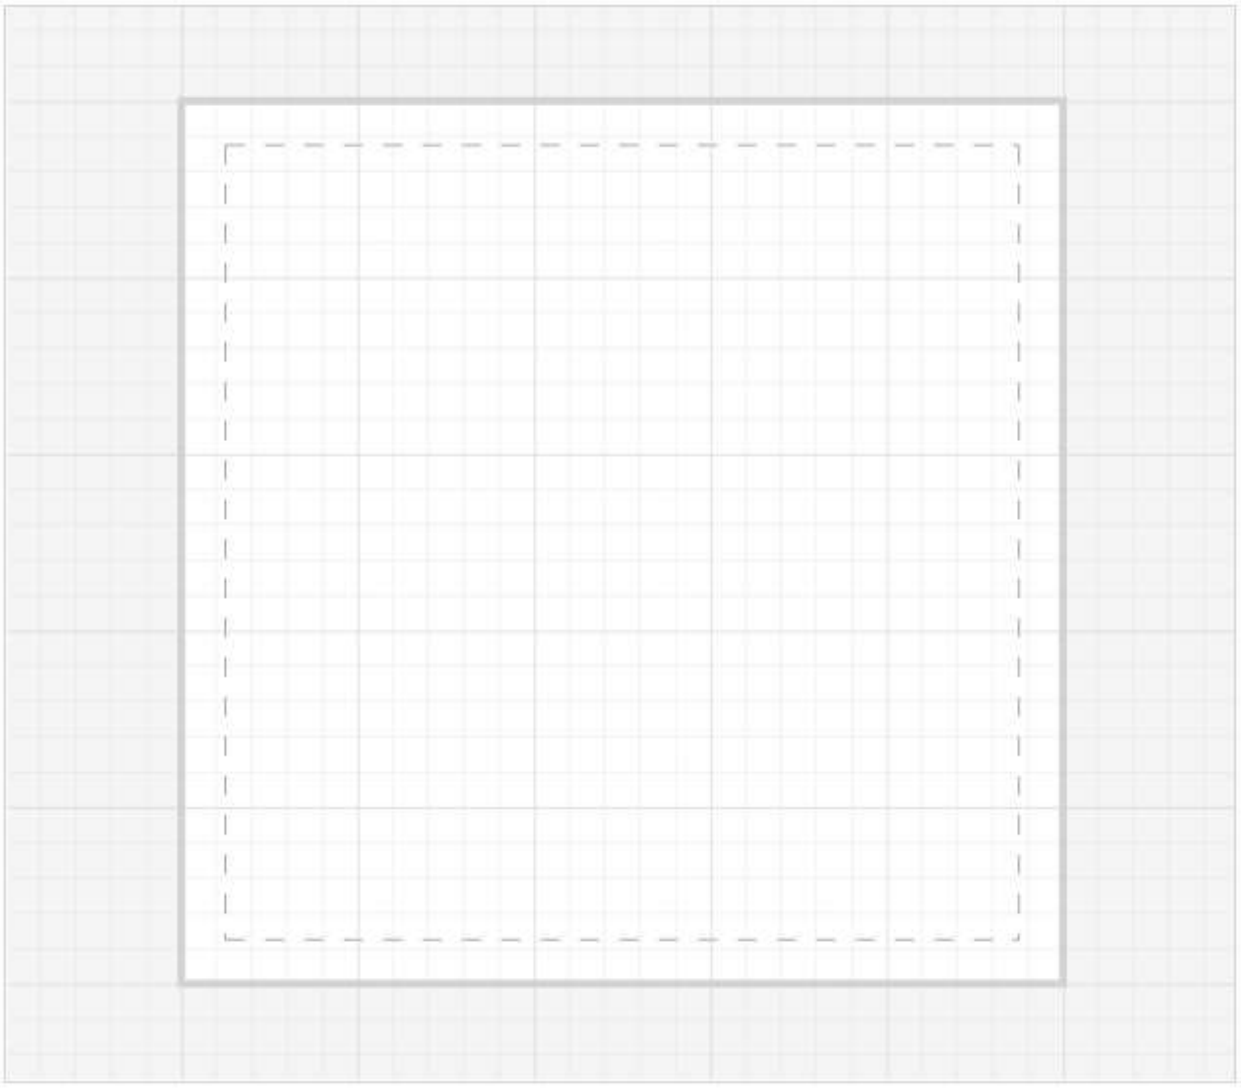
The following code illustrates how to customize the page size and the appearance of page and off-page.

C#

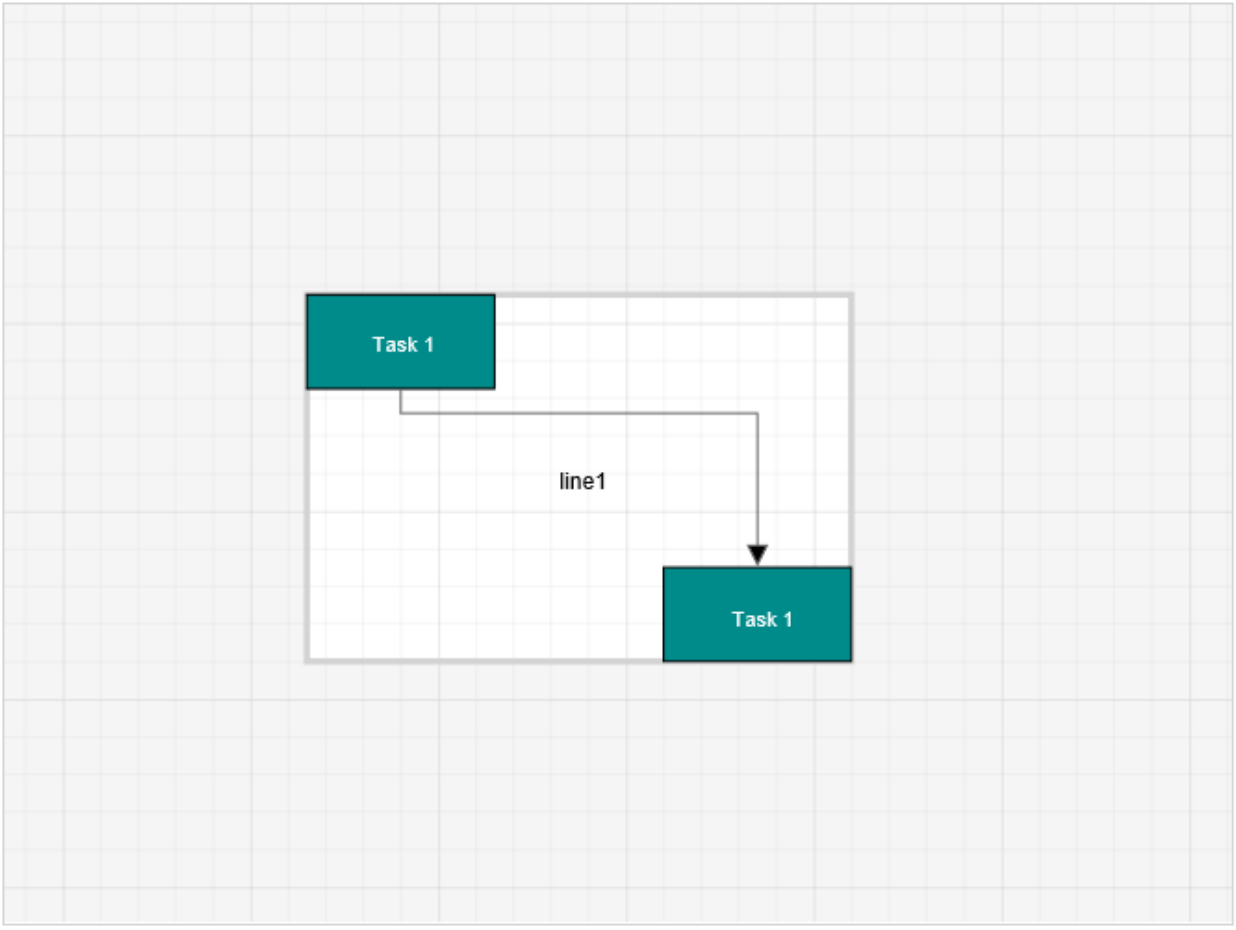
```
//Initializes Diagram
DiagramProperties Model = new DiagramProperties();
Model.Height = "600px";
Model.Width = "900px";
//Sets page size
Model.PageSettings.PageHeight = 500;
Model.PageSettings.PageWidth = 500;
//Customizes the appearance of page
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Model.PageSettings.PageBorderWidth = 4;
Model.PageSettings.PageBackgroundColor = "white";
Model.PageSettings.PageBorderColor = "lightgray";
Model.PageSettings.PageMargin = 25;
Model.PageSettings.ShowPageBreak = true;
Model.PageSettings.MultiplePage = true;
Model.PageSettings.PageOrientation = PageOrientation.Portrait;
```



Copyright © 2001 - 2020 Syncfusion Inc.

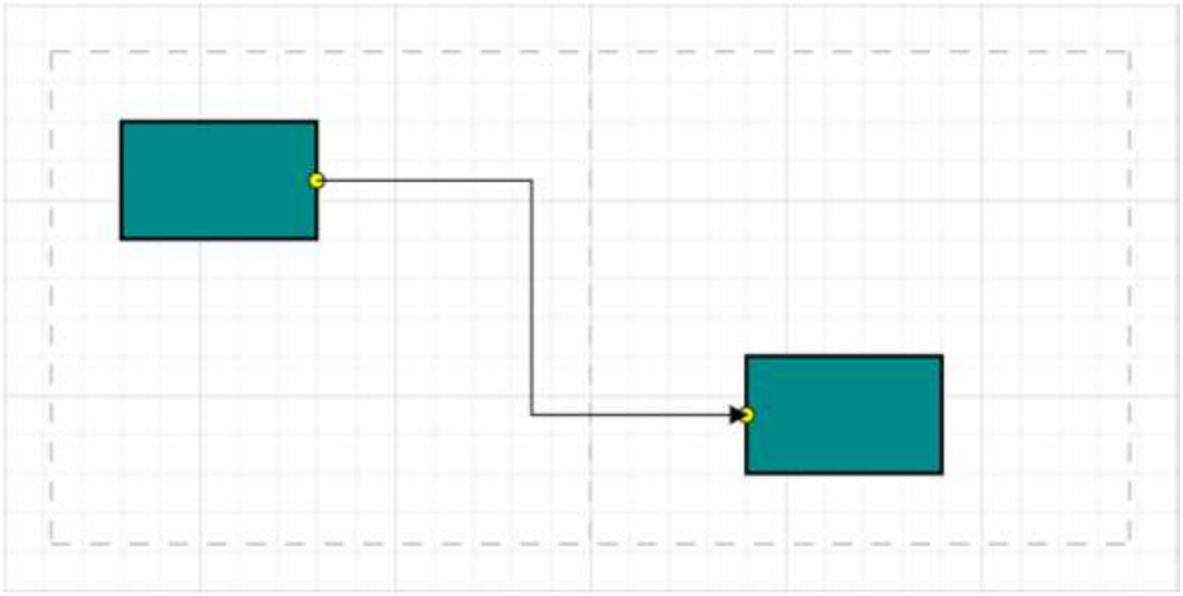


Note: When the PageWidth and PageHeight are not specified, the rectangular region that completely fits all nodes and connectors are considered as page size.

MultiplePage and PageBreaks

When MultiplePage is enabled, size of the page dynamically increases or decreases in multiples of page width and height and completely fits diagram within the page boundaries. Page Breaks is used as a visual guide to see how pages are split into multiple pages.

Copyright © 2001 - 2020 Syncfusion Inc.



MultiplePage and ShowPageBreak properties of page settings allow you to enable/disable multiple pages and page breaks respectively.

The following code illustrates how to enable multiple page and page break lines.

C#

```
//Initializes Diagram
DiagramProperties Model = new DiagramProperties();
Model.Height = "600px";
Model.Width = "900px";
//Enables the multiple page
Model.PageSettings.MultiplePage = true;
//Enables the page break lines
Model.PageSettings.ShowPageBreak = true;
```

Boundary Constraints

Diagram provides support to restrict/customize the interactive region, out of which the elements cannot be dragged, resized or rotated.

BoundaryConstraints property of page settings allows you to customize the interactive region. To explore the boundary constraints, refer refer Boundary Constraints.

The following code example illustrates how to define boundaryConstraints.

C#

```
//Initializes Diagram
DiagramProperties Model = new DiagramProperties();
Model.Height = "600px";
Model.Width = "900px";
//Allows to drag within the diagram content
Model.PageSettings.BoundaryConstraints = BoundaryConstraints.Diagram;
```

Copyright © 2001 - 2020 Syncfusion Inc.

Rulers

The Ruler provides a Horizontal and Vertical guide for measuring in the Diagram control. The Ruler can be used to measure the Diagram objects, indicate positions, and align Diagram elements. This is especially useful in creating scale models.

Adding Rulers to the Diagram

Rulers can be enabled by setting the ruler Setting's ShowRulers property for the diagram control.

Use the following code example to enable/disable the ruler to the Diagram.

C#

```
DiagramBuilderModel diagramModel = new DiagramBuilderModel();
diagramModel.Model.RulerSettings = new RulerSettings();
diagramModel.Model.RulerSettings.ShowRulers = true;
```

Customizing the Ruler

The rulerSetting's Interval property is used to define the number of tick's between two major stroke lines of the ruler.

The ruler Setting's SegmentWidth is used to defines the space between the two major tick strokes.

The ArrangeTick event will be triggered when each tick have been drawn.By using this event you can customize the length of the tick.

Use the following code example to customize the ruler's segment.

C#

```
DiagramBuilderModel diagramModel = new DiagramBuilderModel();
diagramModel.Model.RulerSettings = new RulerSettings();
diagramModel.Model.RulerSettings.ShowRulers = true;
//Customizing the horizontal ruler.
DiagramRuler HorizontalRuler = new DiagramRuler();
//Creating a custom segment with 6 intervals.
HorizontalRuler.Interval = 6;
// Customizing the ruler segment width.
HorizontalRuler.SegmentWidth = 100;
// Customizing the Ruler ticks.
HorizontalRuler.ArrangeTick = "arrangeTick";
DiagramRuler VerticalRuler = new DiagramRuler();
VerticalRuler.Interval = 6;
VerticalRuler.SegmentWidth = 100;
VerticalRuler.ArrangeTick = "arrangeTick";
diagramModel.Model.RulerSettings.HorizontalRuler = HorizontalRuler;
diagramModel.Model.RulerSettings.VerticalRuler = VerticalRuler;
```

JS

```
function arrangeTick(args) {
// Customizing the Ruler ticks.
if (args.tickInterval % 100 == 0) {
}
else if (args.tickInterval % 50 == 0) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
args.tickLength = 12.5
}
}
```

The width of the ruler can be set through Thickness property. If it's an horizontal ruler, thickness will be taken as height of the ruler.

Tick alignment can be modified using TickAlignment as either LeftOrTop or RightOrBottom.

The MarkerColor property of the ruler is used to indicate the position of the mouse cursor.

Use the following code example to customize the ruler's tick.

C#

```
DiagramBuilderModel diagramModel = new DiagramBuilderModel();
diagramModel.Model.RulerSettings = new RulerSettings();
diagramModel.Model.RulerSettings.ShowRulers = true;
//Customizing the horizontal ruler.
DiagramRuler HorizontalRuler = new DiagramRuler();
// Customizing the Ruler ticks alignment.
HorizontalRuler.TickAlignment = TickAlignment.LeftOrTop;
// Customizing the Ruler marker color
HorizontalRuler.MarkerColor = "blue";
// Customizing the thickness of the ruler bar.
HorizontalRuler.Thickness = 25;
DiagramRuler VerticalRuler = new DiagramRuler();
VerticalRuler.TickAlignment = TickAlignment.LeftOrTop;
VerticalRuler.MarkerColor = "blue";
VerticalRuler.Thickness = 25;
diagramModel.Model.RulerSettings.HorizontalRuler = HorizontalRuler;
diagramModel.Model.RulerSettings.VerticalRuler = VerticalRuler;
```

Interaction

Selection

Selector provides a visual representation of selected elements. It behaves like a container and enables you to update the size, position, and rotation angle of the selected elements through interaction and programmatically. Single or multiple elements can be selected at a time.

Single selection

An element can be selected by clicking that element. During single click, all previously selected items are cleared. The following image shows how the selected elements are visually represented.

Selecting a group

When a child element of any group is clicked, its contained group is selected instead of the child element. With consecutive clicks on the selected element, selection is changed from top to bottom in the hierarchy of parent group to its children.

Multiple selection

Multiple elements can be selected with the following ways.

Copyright © 2001 - 2020 Syncfusion Inc.

1. Ctrl+Click

During single click, any existing item in the selection list be cleared, and only the item clicked recently is there in the selection list. To avoid cleaning the old selected item, Ctrl key must be on hold when clicking.

2. Selection rectangle / Rubber band selection

Clicking and dragging the Diagram area allows to create a rectangular region. The elements that are covered under the rectangular region are selected at the end.

Multiple selected elements are visually represented as shown.

Select/Unselect elements programmatically

The client side methods addSelection, clearSelection and removeSelection help select/unselect elements at runtime. The following code example illustrates how to select/unselect an item through programmatically.

RAZOR

```
var diagram = $("#DiagramContent").ejDiagram("instance");
var node = diagram.findNode("node1");
//Selects an element
diagram.addSelection(node);
//Clears the current selection
diagram.clearSelection();
//Unselects a particular object
diagram.removeSelection(node);
```

You can get the current selected items from the children collection of selectedItems property of the Diagram model.

The client side method updateSelector helps you to change the size, position, and rotation angle of the selected elements at runtime. The following code example illustrates how to read the selected items and how to update the position, size, and rotation angle.

RAZOR

```
var diagram = $("#DiagramContent").ejDiagram("instance");
//Updates the size, position and rotateAngle of selected elements.
diagram.updateSelector({
offsetX: 200,
offsetY: 200,
width: 200,
height: 200,
rotateAngle: 200
});
//Iterates the selected elements
for (var i = 0; i < diagram.model.selectedItems.children.length; i++) {
var child = diagram.model.selectedItems.children[i];
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Note: SelectedItems's children is a read-only property. You cannot change the children collection at run time.

Drag

- An object can be dragged by clicking and dragging it. When multiple elements are selected, dragging any one of the selected elements move every selected element.
- While dragging, the objects are snapped towards the nearest objects to make better alignments. For better alignments, refer to Snapping.

Resize

- Selector is surrounded by eight thumbs. When dragging these thumbs, selected items can be resized smaller or larger.
- When one corner of the selector is dragged, opposite corner is in a static position.
- While resizing, the objects are snapped towards the nearest objects to make better alignments. For better alignments, refer to Snapping.

Rotate

- A rotate handler is placed above the selector. Clicking and dragging the handler in a circular direction lead to rotate the node.
- The node is rotated with reference to the static pivot point.
- Pivot thumb (thumb at the middle of the node) appears while rotating the node to represent the static point.
- For more information about pivot, refer to Position.

Connection editing

- Each segment of a selected connector is editable with some specific handles/thumbs.

End point handles

Source and target points of the selected connectors are represented with two handles. Clicking and dragging those handles help you to adjust the source and target points.

Straight segment editing

- End point of each straight segment is represented by a thumb that enables to edit the segment.
- Any number of new segments can be inserted into a straight line by clicking that when shift and ctrl keys are pressed. (Ctrl+Shift+Click).
- Straight segments can be removed by clicking the segment end point, when ctrl and shift keys are pressed. (Ctrl+Shift+Click).

Copyright © 2001 - 2020 Syncfusion Inc.

Orthogonal thumbs

- Orthogonal thumbs allow to adjust the length of adjacent segments by clicking and dragging it.

- When necessary, some segments are added or removed automatically, when dragging the segment. This is to maintain proper routing of orthogonality between segments.

Bezier thumbs

- Bezier segments are annotated with two thumbs to represent the control points. Control points of the curve can be configured by clicking and dragging the control thumbs.

Drag and drop nodes over other elements

Diagram provides support to drop a node/connector over another node/connector. Drop event is raised to notify that an element is dropped over another one and it is disabled by default. It can enabled with the Constraints property. The following code illustrates how to enable **dropping**.

C#

```
DiagramProperties model = new DiagramProperties();
model.Nodes.Add(new BasicShape()
{
Name = "node",
Width = 100,
Height = 100,
OffsetX = 100,
OffsetY = 100,
FillColor = "#1BA0E2",
//Allows to drop an object over the node
Constraints = NodeConstraints.Default | NodeConstraints.AllowDrop
});
model.Connectors.Add(new Connector()
{
Name = "connector1",
SourcePoint = new DiagramPoint(200, 50),
TargetPoint = new DiagramPoint(300, 150),
Segments = new Collection() { new Segment(Segments.Orthogonal) },
//Allows to drop an object over the connector
Constraints = ConnectorConstraints.Default | ConnectorConstraints.AllowDrop
});
ViewData["diagramModel"] = model;
```

The following code examples illustrates how to insert a child to a group interactively.

C#

```
DiagramProperties model = new DiagramProperties();
//Sets the drop event
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
model.Drop = "drop";
```

RAZOR

```
function drop(args) {
if (args.target && args.element) {
//Element that is being dropped
var node = args.element;
//Element over which another element is dropped
var target = args.target;
if (diagram.getObjectType(target) == "group" && diagram.getObjectType(node)
== "node") {
//Inserts the node into group
node.parent = target.name;
target.children.push(node.name);
}
}
}
```

User handles

User handles are used to add some frequently used commands around the selector. To create user handles, define and add them to the userHandles collection of selectedItems property.

The tool property of user handle should be set with any appropriate tool to enable interaction.

The following code example illustrates how to draw a user handle.

RAZOR

```
// Defines a tool to interact with the user handle
var CloneTool = (function (base) {
ej.datavisualization.Diagram.extend(CloneTool, base);
// Initializes the tool
function CloneTool(name) {
base.call(this, name);
}
// Defines the required events
CloneTool.prototype.mouseup = function (event) {
//clones the selected elements when the custom handle is clicked.
this.diagram.copy();
//Pastes the cloned elements.
this.diagram.paste();
base.prototype.mouseup.call(this, event);
};
return CloneTool;
})(ej.datavisualization.Diagram.ToolBase);
var userHandles = [];
//Initializes the handles
var cloneHandle = ej.datavisualization.Diagram.UserHandle();
// Name of the user handle.
cloneHandle.name = "Clone";
// Sets the tool that you have defined to interact with handle.
cloneHandle.tool = new CloneTool(cloneHandle.name);
userHandles.push(cloneHandle);
//Add user handles to diagram
$("#DiagramContent").ejDiagram({
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Sets user handles
selectedItems: {
userHandles: userHandles
}
});
```

Appearance

Position, size, and style of the user handle can be customized with a set of predefined properties.

The following code example illustrates how to customize the appearance of the user handle.

RAZOR

```
var UserHandlePositions = ej.datavisualization.Diagram.UserHandlePositions;
var userHandles = [];
var cloneHandle = ej.datavisualization.Diagram.UserHandle();
cloneHandle.name = "Clone";
// Sets the position of the user handle.
cloneHandle.position = UserHandlePositions.BottomLeft;
// Sets the user handle visibility.
cloneHandle.visible = true;
// Defines whether user handle should be enabled for multiple selection or
not.
cloneHandle.enableMultiSelection = true;
// Sets the size of the user handle.
cloneHandle.size = 30;
// Customizes the appearance of user handle
cloneHandle.backgroundColor = "#4D4D4D";
cloneHandle.pathColor = "white";
cloneHandle.borderColor = "red";
cloneHandle.borderWidth = "2";
cloneHandle.pathData = "M4.6350084,4.8909971 L4.6350084,9.3649971
9.5480137,9.3649971 9.5480137,4.8909971 z M3.0000062,2.8189973
L11.184016,2.8189973 11.184016,10.999997 3.0000062,10.999997 z M0,0
L7.3649998,0 7.3649998,1.4020001 1.4029988,1.4020001 1.4029988,8.0660002
0,8.0660002 0,1.4020001 0,0.70300276 z";
userHandles.push(cloneHandle);
$("#DiagramContent").ejDiagram({
selectedItems: {
userHandles: userHandles
}
});
```

Zoom pan

- When a large Diagram is loaded, only certain portion of the Diagram is visible. The remaining portions are clipped. Clipped portions can be explored by scrolling the scrollbars or panning the Diagram.
- Diagram can be zoomed in or out by using Ctrl + mouse wheel.

Copyright © 2001 - 2020 Syncfusion Inc.

Keyboard

Diagram provides support to interact with the elements with key gestures. By default, some built-in commands are bound with a relevant set of key combinations.

The following table illustrates those commands with the associated key values.

| Shortcut Key | Command | Description |

|---|---|---|

| Ctrl + A | selectAll | Select all nodes/connectors in diagram |

| Ctrl + C | copy | Copy the diagram selected elements |

| Ctrl + V | paste | Paste the copied elements |

| Ctrl + X | cut | Cut the selected elements |

| Ctrl + Z | undo | Undo(Reverse the last editing action performed on diagram) |

| Ctrl + Y | redo | Redo(Restores the last editing action when no other actions have occurred since the last undo on diagram) |

| Delete | delete | Delete the selected elements |

| Ctrl /Shift+ Click on object | | Multiple selection(Selector binds all selected nodes/connectors) |

| Up Arrow | nudge("up") | nudgeUp(move the selected elements towards up by one pixel) |

| Down Arrow | nudge("down") | nudgeDown(move the selected elements towards down by one pixel) |

| Left Arrow | nudge("left") | nudgeLeft(move the selected elements towards left by one pixel) |

| Right Arrow | nudge("right") | nudgeRight(move the selected elements towards right by one pixel) |

| Ctrl+MouseScroll | zoom | Zoom(Zoom in/Zoom out the diagram) |

| F2 | startLabelEditing | Starts to edit the label of selected element |

| Esc | endLabelEditing | Sets the label mode as View and stops editing. |

To add custom commands, configure or modify key/mouse gesture through Command Manager.

History Manager

Diagram tracks the history of actions that are performed after loading the time and provides support to reverse and restore those changes.

Undo and Redo

Diagram provides built-in support to track the changes that are made through interaction and through public APIs. The changes can be reverted or restored either through short cut keys or through commands.

Undo redo through short cut keys

Undo redo commands can be executed through short cut keys. Short cut key for undo is ctrl+z and short cut key for redo is ctrl+y.

For more information, refer to Keyboard Interactions.

Copyright © 2001 - 2020 Syncfusion Inc.

Undo redo through public APIs

The client side methods undo and redo help you to revert/restore the changes. The following code example illustrates how to undo/redo the changes through script.

JS

```
var diagram = $("#Diagram").ejDiagram("instance");
// Reverts the last action performed
diagram.undo();
// Restores the last undone action
diagram.redo();
```

Track custom changes

Diagram provides options to track the changes that are made to custom properties. For example, in case of an employee relationship Diagram, you may need to track the changes in the employee information. The HistoryManager of the Diagram model enables you to track such changes.

The following example illustrates how to track such custom property changes.

- Before changing the employee information, save the existing information to history manager by using the client side method push of historyManager.

The following code example illustrates how to save the existing property values.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
//Creates a custom entry and adds that to history manager
var entry = { object: node, prevState: node.employeeInfo };
diagram.model.historyManager.push(entry);
//Updates the new information
var newValue = { role: "New role" };
node.employeeInfo = newValue;
```

- Change the employee information

JS

```
//Updates the new information
var newValue = { role: "New role" };
node.employeeInfo = newValue;
```

- Define the methods to handle the custom changes. These methods are called when you try to revert/restore the custom changes.

You need to define the methods to handle the custom changes and you need to assign that to Undo and Redo properties of HistoryManager.

The following code example illustrates how to define methods to handle the custom changes.

C#

Copyright © 2001 - 2020 Syncfusion Inc.

```
DiagramProperties model = new DiagramProperties();
//Called to revert a custom action
model.HistoryManager.Undo = "customUndoRedo";
//Called to restore the reverted custom action
model.HistoryManager.Redo = "customUndoRedo";
ViewData["DiagramModel"] = diagram;
```

JS

```
//Method to handle the custom action
function customUndoRedo(args) {
var diagram = $("#diagram").ejDiagram("instance");
var node = args.object;
var currentState = node.employeeInfo;
//Resets the state
node.employeeInfo = args.prevState;
//Saves the previous state
args.prevState = currentState;
}
```

Group multiple changes

History manager allows to revert or restore multiple changes through a single undo/redo command. For example, you may need to revert/restore the fill color change of multiple elements at a time.

The client side method startGroupAction is used to notify the Diagram to start grouping the changes. The client side method closeGroupAction is used to notify to stop grouping the changes. The following code illustrates how to undo/redo fillColor change of multiple elements at a time.

JS

```
var group = diagram.model.selectedItems
// Start to group the changes
diagram.model.historyManager.startGroupAction();
//Makes the changes
for (var i = 0; i < group.children.length; i++) {
var option = {};
var item = group.children[i];
// Updates the fillColor for all the child elements.
option.fillColor = args.style.backgroundColor;
diagram.updateNode(item.name, option);
}
//Ends grouping the changes
diagram.model.historyManager.closeGroupAction();
```

Serialization

Serialization is the process of saving and loading for state persistence of the Diagram.

Save

The Diagram is serialized as JSON data while saving. The client side method, save helps to serialize the Diagram as JSON. The following code illustrates how to save the Diagram.

JS

```
var diagram = $("#Diagram").ejDiagram("instance");
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//save() returns serialized JSON data of the Diagram
var saveData = diagram.save();
```

This JSON data can be converted to string and stored for future use. The following snippet illustrates how to save the serialized JSON into local storage.

JS

```
//Saves the JSON object in to local storage
localStorage.setItem("diagram", JSON.stringify(json));
```

Diagram can also be saved as raster or vector image files. For more information about saving the Diagram as images, refer to Exporting.

Load

Diagram is loaded from the Serialized JSON data. The client side method, load helps you to load the Diagram from the serialized JSON. The following code illustrates how to load the Diagram from serialized JSON data.

JS

```
//Retrieves the JSON object from local storage
saveData = JSON.parse(localStorage.getItem("diagram"));
//Loads the Diagram from saved JSON data
diagram.load(json);
```

Note: Before loading a new Diagram, existing Diagram is cleared.

Limitation

There are some limitations in saving/loading the Diagrams and they are listed as follows.

- When define the events as a string, functions need to be maintained in the application level while loading the diagram.

C#

```
DiagramProperties model = new DiagramProperties();
//define the name of the function.
model.NodeCollectionChange = "nodeCollectionChange";
```

JS

```
function nodeCollectionChange(args) {
}
```

- HTML / Native template needs to be retained in the application level, while loading the native and HTML node.

HTML

```
<!-- Template content needs to be retained while loading the diagram.-->
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script id="htmlTemplate" type="text/x-jsrender">
<div>
<input type="button" value="button" style="color: #ffffff; background-color:
#fbb139; border-color: #f89b1c" />
</div>
</script>
```

JS

```
diagram.load(saveData);
```

- CSS classes have to be retained in the application level, while loading the Diagram.

HTML

```
<style>
<!-- CSS class needs to be retained while loading the Diagram.-->
.nodeCss {
fill: black;
stroke: cyan;
}
</style>
```

JS

```
diagram.load(json);
```

Commands

There are several commands available in the Diagram as follows.

- Alignment commands
- Spacing commands
- Sizing commands
- Clipboard commands
- Grouping commands
- Z-order commands
- Zoom commands
- Nudge commands
- FitToPage commands
- Undo/Redo commands

Align

Alignment commands enable you to align the selected objects such as nodes and connectors with respect to the selection boundary.

| Command | Parameter | Description |

|---|---|---|

Copyright © 2001 - 2020 Syncfusion Inc.

| align | direction (string) | Align all the nodes/connectors in the selection list with respect to specified direction of the selection boundary. |

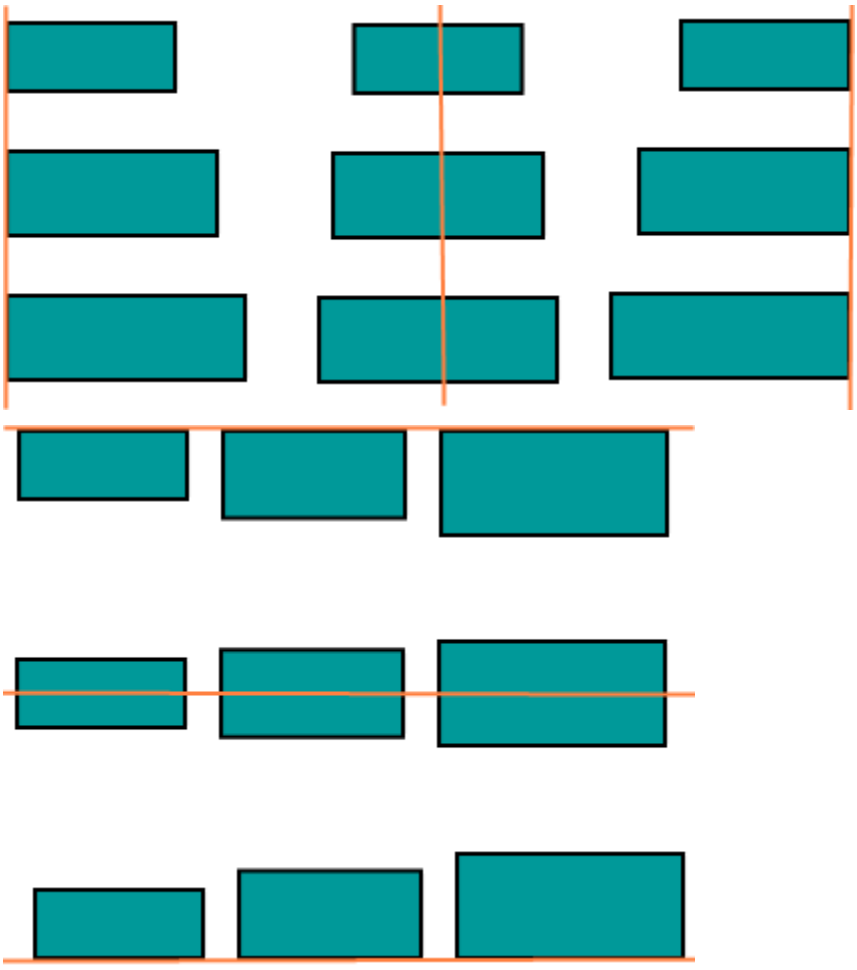
The accepted values of the argument "direction" are as follows.

- "left" - Align all the selected objects at the left of the selection boundary.
- "right" - Align all the selected objects at the right of the selection boundary.
- "center" - Align all the selected objects at the center of the selection boundary.
- "top" - Align all the selected objects at the top of the selection boundary.
- "bottom" - Align all the selected objects at the bottom of the selection boundary.
- "middle" - Align all the selected objects at the middle of the selection boundary.

The following code example illustrates how to align all the selected objects at the left side of selection boundary.

JS

```
var diagram = $("#DiagramContent").ejDiagram("instance");
//Sets direction as left
diagram.align("left");
```



Copyright © 2001 - 2020 Syncfusion Inc.

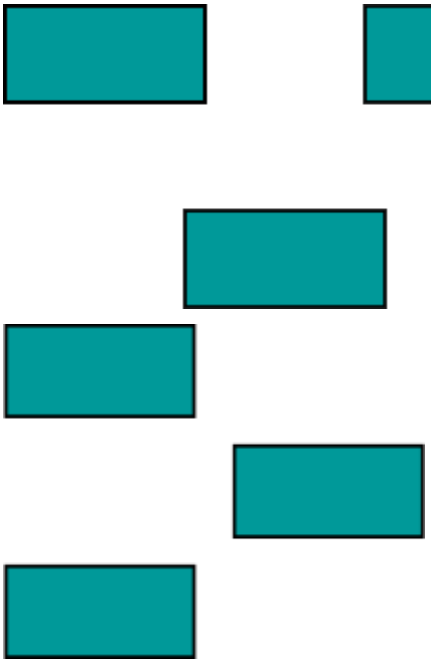
Space

Spacing commands enable you to place the selected objects on the page at equal intervals from each other. The selected objects are equally spaced within the selection boundary.

The following code example illustrates how to execute the space commands.

JS

```
var diagram = $("#DiagramContent").ejDiagram("instance");
//Equally spaces the selected nodes horizontally
diagram.spaceAcross();
//Equally spaces the selected nodes vertically
diagram.spaceDown();
```



Sizing

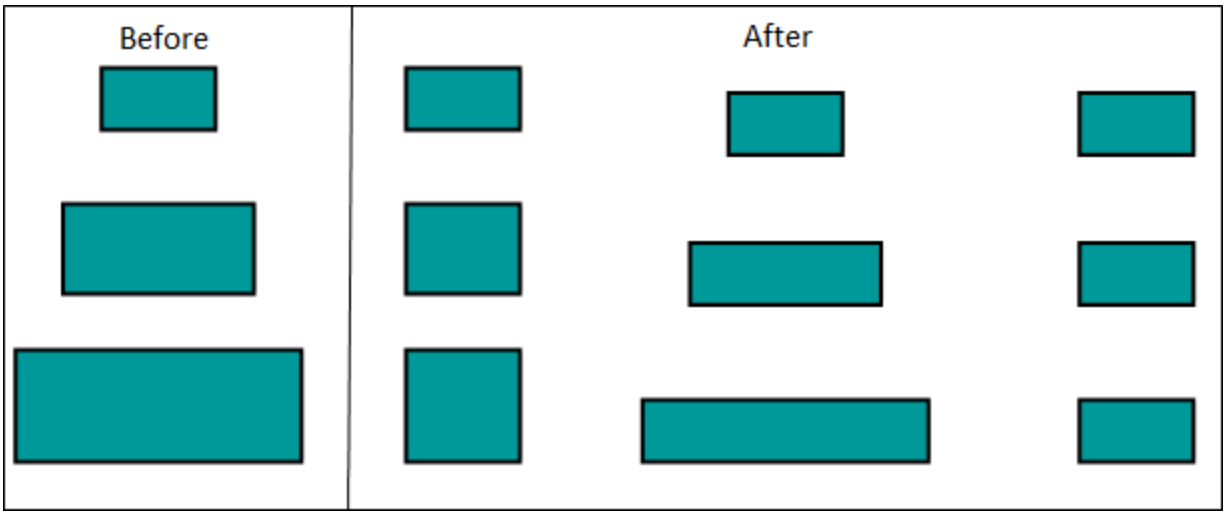
Sizing commands enable to equally size the selected nodes with respect to the first selected object.

The following code example illustrates how to execute the size commands.

JS

```
var diagram = $("#DiagramContent").ejDiagram("instance");
//Scales the selected items to the size of first selected object
diagram.sameSize();
//Vertically scales the selected items to the height of first selected
object
diagram.sameHeight();
//Horizontally scales the selected items to the width of first selected
object
diagram.sameWidth();
```

Copyright © 2001 - 2020 Syncfusion Inc.



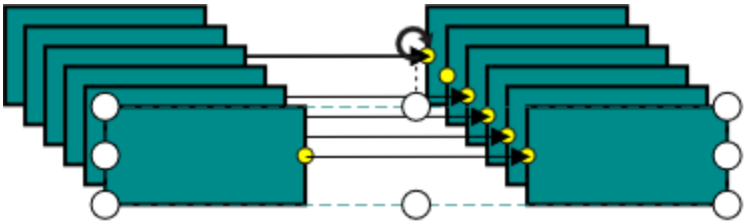
Clipboard

Clipboard commands are used to cut, copy or paste the selected elements.

The following code illustrates how to execute the clipboard commands.

JS

```
//Cuts the selected elements from the Diagram to the Diagram's clipboard
diagram.cut();
//Copies the selected elements from the Diagram to the Diagram's clipboard.
diagram.copy();
//Pastes the Diagram's clipboard data (nodes/connectors) into the Diagram.
diagram.paste();
```



Grouping

Grouping commands are used to group/ungroup the selected elements on the Diagram.

The following code illustrates how to execute the Grouping commands.

JS

```
//Groups the selected elements.
diagram.group();
//Ungroups the selected group.
diagram.ungroup();
```

Z-Order Command

Z-Order commands enable you to visually arrange the selected objects such as nodes and connectors on the page.

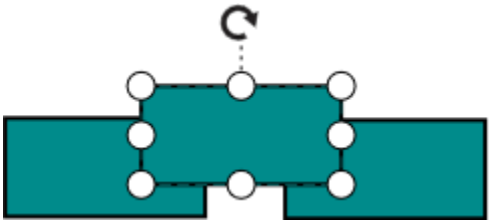
Copyright © 2001 - 2020 Syncfusion Inc.

bringToFront Command

The bringToFront command visually brings the selected element to front over all the other overlapped elements. The following code illustrates how to execute the bringToFront command.

JS

```
//Brings to front
diagram.bringToFront();
```

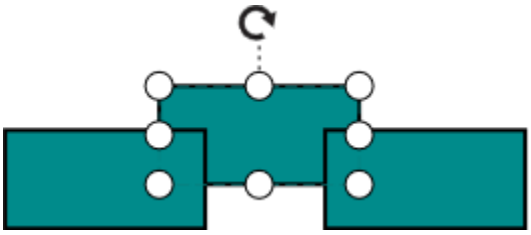


sendToBack Command

The sendToBack command visually moves the selected element behind all the other overlapped elements. The following code illustrates how to execute the sendToBack command.

JS

```
//Sends to back
diagram.sendToBack();
```

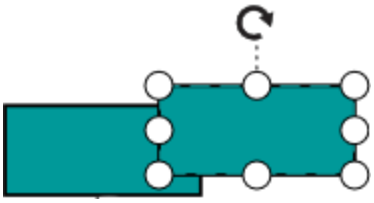


moveForward Command

The moveForward command visually moves the selected element over the nearest overlapping element. The following code illustrates how to execute the moveForward Command.

JS

```
//Moves forward
diagram.moveForward();
```



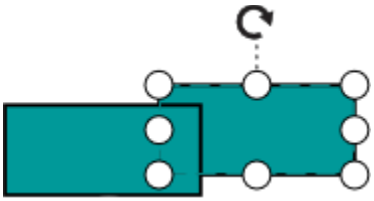
sendBackward Command

The sendBackward command visually moves the selected element behind the underlying element. The following code illustrates how to execute the sendBackward command.

JS

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Sends backward
diagram.sendBackward();
```



Zoom

zoomTo command is used to zoom-in and zoom-out the Diagram view.

The following code illustrates how to zoom-in/zoom out the Diagram.

JS

```
function Zoom() {
var diagram = $("#diagram").ejDiagram("instance");
var zoom = {
// Sets the zoomFactor
zoomFactor: 0.2,
// Sets the zoomCommand as zoomIn to zoom-in the Diagram
zoomCommand: ej.datavisualization.Diagram.ZoomCommand.ZoomIn,
// for zoomOut
//zoomCommand: ej.datavisualization.Diagram.ZoomCommand.ZoomOut
//Defines the focusPoint to zoom the Diagram with respect to any point
//When you do not set focus point, zooming is performed with reference to
the center of current Diagram view.
focusPoint: {
x: 100,
y: 100
}
};
diagram.zoomTo(zoom);
}
```

Nudge Command

nudge commands move the selected elements towards up, down, left or right by 1 pixel.

| Command | Parameter | Description |

|---|---|---|

| nudge | direction (string),

delta(integer) | Nudge command moves the selected elements towards the specified direction by the number of pixels specified by the parameter delta. When delta is not specified, it is considered as 1 pixel, by default. |

The accepted values of the argument "direction" are as follows.

- "up" - moves the selected elements towards up by the the specified delta value.
- "down" - moves the selected elements towards down by the specified delta value.
- "left" - moves the selected elements towards left by the specified delta value.

Copyright © 2001 - 2020 Syncfusion Inc.

- "right" - moves the selected elements towards right by the specified delta value.

The following code illustrates how to execute Nudge command.

JS

```
var diagram = $("#diagramContent").ejDiagram("instance");
//Nudges up
diagram.nudge("up", 5);
```

Nudge by using Arrow Keys

The corresponding arrow keys are used to move the selected elements towards up, down, left, or right direction by 1 pixel.

Nudge commands are particularly useful for accurate placement of elements.

For more information, refer to Keyboard Interaction.

BringIntoView

bringIntoView command brings the specified rectangular region into the view port of the Diagram

The following code illustrates how to execute the bringIntoView command.

JS

```
var diagram = $("#DiagramContent").ejDiagram("instance");
//Brings the specified rectangular region of the Diagram content to the
viewport of the page.
diagram.bringIntoView({
x: 700,
y: 500,
width: 100,
height: 100
});
```

BringToCenter

bringToCenter command brings the specified rectangular region of the Diagram content to the center of the view port.

The following code illustrates how to execute the bringToCenter command.

JS

```
var diagram = $("#DiagramContent").ejDiagram("instance");
//Brings the specified rectangular region of the Diagram content to the
center of the viewport.
diagram.bringToCenter({
x: 700,
y: 500,
width: 100,
height: 100
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

FitToPage command

fitToPage command helps to fit the Diagram content into the view with respect to either width, height, or at the whole.

Command	Parameter	Description
fitToPage	mode (string) Value accepted: ej.datavisualization.Diagram.FitMode region (string) Value accepted- ej.datavisualization.Diagram.Region margin (object)	FitToPage command fits the Diagram into the view. The area/bounds to be fit into view is specified through the parameters.mode – FitToMode.region – Region.margin – Space that is to be left in between the content and viewport.

The following code illustrates how to execute FitToPage command.

JS

```
//Fits to page - fit Diagram based on elements
diagram.fitToPage("page", "content", {
left: 25,
top: 25,
right: 25,
bottom: 25
});
```

FitToMode

Mode specifies whether the Diagram content has to be fit into view with respect to width, height, or entire bounds of the Diagram. To explore the mode, refer to FitToMode.

Region

Region specifies the region/bounds of the Diagram content that is to be fit into the view. For more information about Region, refer to Region.

Command Manager

Diagram provides support to map/bind command execution with desired combination of key gestures. Diagram provides some built-in commands. For more information about built-in commands, refer to Keyboard Interaction.

Command Manager provides support to define custom commands. The custom commands are executed, when the specified key gesture is recognized.

Custom command

To define a custom command, you need to specify following properties.

- execute: a method to be execute.
- canExecute: a method to define whether the command can be executed at the moment.

Copyright © 2001 - 2020 Syncfusion Inc.

- gesture: the combination of key gestures.

To explore the properties of custom commands, refer to Commands

The following code example illustrates how to define a custom command.

RAZOR

```
@Html.EJ().Diagram("OrganizationChart", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
//Method to define whether the command can be executed at the current moment
function canExecuteClone(args) {
//Defines that the clone command can be executed, if and only if the
selection list is not empty.
if (args.model.selectedItems.children.length) {
return true;
}
}
//Command handler
function executeClone(args) {
var diagram = $("#diagram").ejDiagram("instance");
//Logic to clone the selected element
diagram.copy();
diagram.paste();
}
</script>
```

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Commands to clone the selected item
Command clone = new Command() {
Execute = "executeClone", CanExecute = "canExecuteClone",
//Defines that the clone command has to be executed on the recognition of
Shift+C key press.
Gesture = new Gesture() { Key = Keys.C, KeyModifiers = KeyModifiers.Shift }
};
model.CommandManager.Commands.Add("clone", clone);
ViewData["diagramModel"] = model;
return View();
}
```

Modify the existing command

When any one of the default commands is not desired, they can be disabled. To change the functionality of a specific command, the command can be completely modified.

The following code example illustrates how to disable a command and how to modify the built-in commands.

RAZOR

```
@Html.EJ().Diagram("OrganizationChart", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script type="text/javascript">
//Method to define whether the command can be executed at the current moment
function canExecuteNudgeLeft(args) {
if (args.model.selectedItems.children.length) {
return true;
}
}
//Command handler
function executeNudgeLeft(args) {
var diagram = $("#diagram").ejDiagram("instance");
diagram.nudge("left");
}
</script>
```

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Command nudgeLeft = new Command() { Execute = "executeNudgeLeft", CanExecute
= "canExecuteNudgeLeft", Gesture = new Gesture() { Key = Keys.Left } };
//Assigns null value to an existing command and disables its execution
model.CommandManager.Commands.Add("nudgeUp", new Command());
model.CommandManager.Commands.Add("nudgeDown", new Command());
model.CommandManager.Commands.Add("nudgeRight", new Command());
//Modifies the existing command - nudgeLeft
model.CommandManager.Commands.Add("nudgeLeft", nudgeLeft);
ViewData["diagramModel"] = model;
return View();
}
```

Data Binding

- Diagram can be populated with the nodes and connectors based on the information provided from an external data source.
- Diagram exposes its specific data-related properties allowing you to specify the data source fields from where the node information has to be retrieved from.

To explore those properties, see Data source settings

- Diagram supports three different kinds of Data binding.
- Local Data
- Remote Data
- HTML Table Data

Local Data

Diagram can be populated based on the user defined JSON data (**Local Data**) by mapping the relevant data source fields.

To map the user defined JSON data with Diagram, you have to configure the fields of DataSourceSettings. The following code example illustrates how to bind local data with the Diagram.

Copyright © 2001 - 2020 Syncfusion Inc.

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
//Binds custom JSON with node
function nodeTemplate(diagram, node) {
// Sets the Name field of JSON data as label.
node.labels[0].text = node.Name;
}
</script>
```

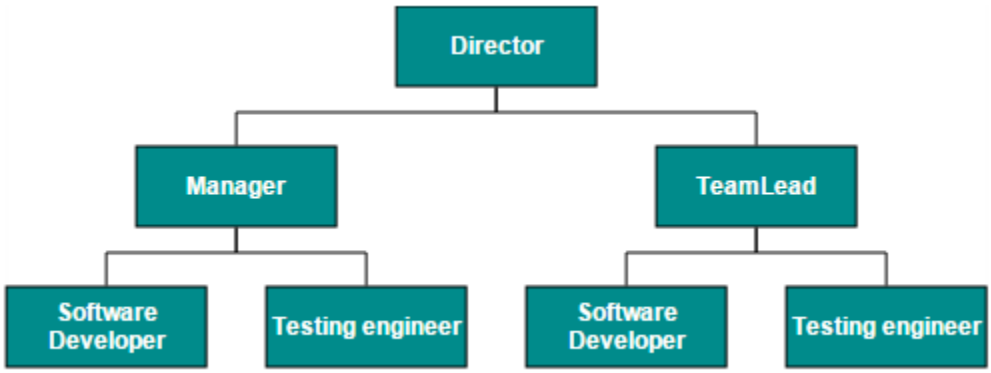
C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Uses layout to auto-arrange nodes on the Diagram page
model.Layout.Type = LayoutTypes.HierarchicalTree;
model.Layout.HorizontalSpacing=30;
model.Layout.VerticalSpacing=30;
//Sets the default properties for nodes and connectors
Label label = new Label() { Name = "label1", FontColor = "white", Bold =
true };
model.DefaultSettings.Node = new Node() { Width = 100, Height = 40,
FillColor = "darkcyan" };
model.DefaultSettings.Node.Labels.Add(label);
model.DefaultSettings.Connector = new Connector()
{
Segments = new Collection() { new Segment(Segments.Orthogonal) },
TargetDecorator = new Decorator() { Shape = DecoratorShapes.None },
};
//Configures data source for Diagram
//Defines the unique field of each JSON data
model.DataSourceSettings.Id = "Name";
//Defines the parent field which builds the relationship
model.DataSourceSettings.Parent = "ReportingPerson";
//Sets the local data source to the diagram.
model.DataSourceSettings.DataSource = GetDataSource();
//Initializes the node template.
model.NodeTemplate = "nodeTemplate";
ViewData["diagramModel"] = model;
return View();
}
public Array GetDataSource()
{
String allText =
System.IO.File.ReadAllText(Server.MapPath("~/App_Data/data.json"));
Dictionary<string, object> requestArgs = (Dictionary<string, object>)new
JavaScriptSerializer().DeserializeObject(allText);
requestArgs = (Dictionary<string, object>)requestArgs["root"];
return (Array)requestArgs.Values.ElementAt(0);
}
```

JS

Copyright © 2001 - 2020 Syncfusion Inc.

```
{root: {data: [
{ "Name": "Director" },
{ "Name": "Manager", "ReportingPerson": "Director" },
{ "Name": "TeamLead", "ReportingPerson": "Director" },
{ "Name": "Software Developer", "ReportingPerson": "TeamLead" },
{ "Name": "Testing engineer", "ReportingPerson": "TeamLead" },
{ "Name": "Software Developer", "ReportingPerson": "Manager" },
{ "Name": "Testing engineer", "ReportingPerson": "Manager" }
]}}
```



Remote Data

You can bind the Diagram with Remote Data by using dataManager.

- DataManager supports the following types of data-binding: JSON, Web Services, oData.
- It uses two different classes: ej.DataManager for processing and ej.Query for serving data. ej.DataManager communicates with data source and ej.Query generates data queries that are read by the dataManager.
- To learn more, refer to Data Manager.

To bind remote data to the Diagram, you have to configure the fields of DataSourceSettings. The following code illustrates how to bind remote data to the Diagram.

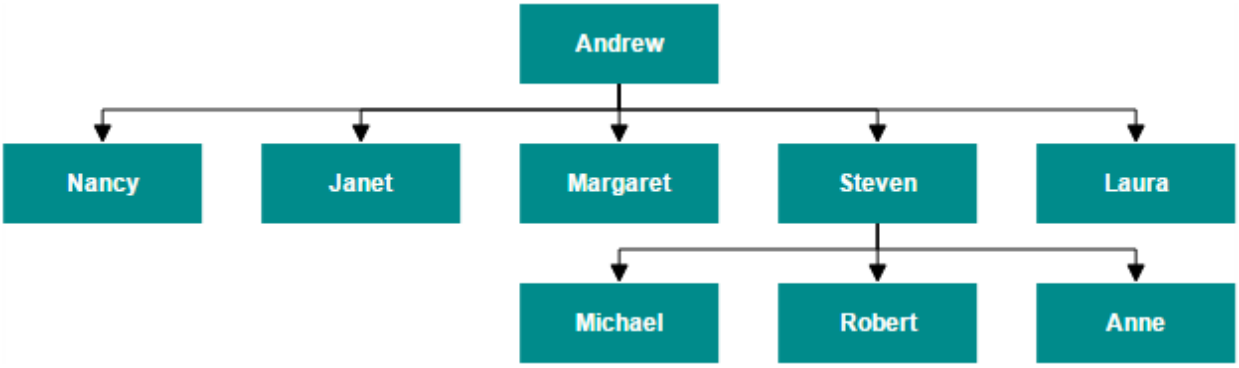
RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
//Binds custom JSON with node
function nodeTemplate(diagram, node) {
// Sets the Name field of JSON data as label.
node.labels[0].text = node.FirstName;
}
</script>
```

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
```

```
//Uses layout to auto-arrange nodes on the Diagram page
model.Layout.Type = LayoutTypes.HierarchicalTree;
model.Layout.HorizontalSpacing = 30;
model.Layout.VerticalSpacing = 30;
//Sets the default properties for nodes and connectors
Label label = new Label() { Name = "label1", FontColor = "white", Bold =
true };
model.DefaultSettings.Node = new Node() { Width = 100, Height = 40,
FillColor = "darkcyan" };
model.DefaultSettings.Node.Labels.Add(label);
model.DefaultSettings.Connector = new Connector()
{
Segments = new Collection() { new Segment(Segments.Orthogonal) },
TargetDecorator = new Decorator() { Shape = DecoratorShapes.None },
};
//Initializes the node template.
model.NodeTemplate = "nodeTemplate";
model.DataSourceSettings.DataSource =
"http://mvc.syncfusion.com/Services/Northwnd.svc/";
model.DataSourceSettings.Query =
"ej.Query().from('Employees').select('EmployeeID,ReportsTo,FirstName')";
model.DataSourceSettings.Id = "EmployeeID";
model.DataSourceSettings.Parent = "ReportsTo";
model.DataSourceSettings.TableName = "Employees";
}
```



HTML Table Data

The Diagram provides support to populate the Diagram from the **HTML table**. It is flexible to convert HTML table to Diagram by using **Data Manager**.

The following code illustrates how to convert HTML table to the Diagram.

C#

```
DiagramProperties Model = new DiagramProperties();
Model.Height = "600px";
Model.Width = "600px";
//Initializes the node template.
Model.NodeTemplate = "nodeTemplate";
Model.Layout.Type = LayoutTypes.HierarchicalTree;
Model.Layout.VerticalSpacing = 30;
Model.Layout.HorizontalSpacing = 30;
Model.DefaultSettings.Node = new Node()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
Width = 120,
Height = 40,
BorderColor = "transparent",
Labels = new Collection() { new Label() { Name = "label1", FontColor =
"#ffffff" } }
};
Model.DefaultSettings.Connector = new Connector()
{
Segments = new Collection() { new Segment(Segments.Orthogonal) },
TargetDecorator = new Decorator() { FillColor = "#4F4F4F", BorderColor =
"#4F4F4F" }
};
ViewData["Diagram"] = Model;
```

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
@using Syncfusion.JavaScript.DataVisualization.DiagramEnums
@using Syncfusion.JavaScript.DataVisualization.Models.Diagram
@using Syncfusion.JavaScript.DataVisualization.Models.Collections
@(Html.EJ().Diagram("Diagram").Width("100%").Height("600px")
@*Configures data source for Diagram*@
.DataSourceSettings(e =>
{
e.DataSource(dataSource => dataSource.Table("#binding"))
.Id("Id")
.Parent("ReportingPerson");
}))
<!-- HTML Table -->
<script id="binding" type="text/template" >
<table style="display: none">
<thead>
<tr>
<th>Id</th>
<th>Designation</th>
<th>Color</th>
<th>ReportingPerson</th>
</tr>
</thead>
<tbody>
<tr>
<td>parent</td>
<td>Managing Director</td>
<td>#822b86</td>
<td>null</td>
</tr>
<tr>
<td>1</td>
<td>Project manager</td>
<td>#3c418d</td>
<td>parent</td>
</tr>
<tr>
<td>2</td>
```

```
<td>Project manager</td>
<td>#108d8d</td>
<td>parent</td>
</tr>
<tr>
<td>3</td>
<td>Product Lead</td>
<td>#3c418d</td>
<td>1</td>
</tr>
<tr>
<td>4</td>

CRUD

- This feature allows the user to read the DataSource and perform add/edit/delete the data in datasource at runtime.

Read DataSource

- This feature allows you to define nodes and connectors collection in the DataSource and ConnectionDataSource respectively.
- We can set the data collection in the model's DataSourceSettings DataSource property. The nodes will be generated based on the data specified in the DataSource.
- We can set the connector collection in the model's DataSourceSettings ConnectionDataSource property.
- If we have a data (data will be set in the DataSource property) with parent relationship in the database and also defined the connector in the ConnectionDataSource simultaneously, then the connectors set in the ConnectionDataSource will be considered as a priority to render the connector.

C#

```
model.DataSourceSettings = new DataSourceSettings()
{
//set the data collection
DataSource = DiagramContext.HierarchicalData.ToList(),
//bind the column name to the Id property which generates the unique name
for the object
Id = "Name",
//Specify the custom property/columns which is available in the DataSource.
CustomFields = new List<string>()
{
"Description",
"Color"
},
ConnectionDataSource = new ConnectionDataSourceSettings()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
//set the connector collection
DataSource = DiagramContext.HierarchicalDetails.ToList(),
//bind the column name to the Id property which generates the unique name
for the object
Id = "Name",
SourceNode = "SourceNode",
TargetNode = "TargetNode",
//Specify the custom property/columns which is available in the
ConnectionDataSource.
CustomFields = new List<string>()
{
"Description",
"Color"
},
}
};
```

How to perform Editing at runtime

We need to specify the URL for create/update/destroy of nodes and connectors.

InsertData

- The following code example illustrates how to send the newly added/inserted data from client to server side.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
//Sends the newly added nodes/connectors from client side to the server side
through the URL which is specified in server side.
diagram.insertData();
```

C#

```
model.DataSourceSettings = new DataSourceSettings()
{
CrudAction = new CRUDAction()
{
//Specify the method name which is used to get the newly added data from
client side to the server side
Create = "/Diagram/InsertShape",
},
ConnectionDataSource = new ConnectionDataSourceSettings()
{
CrudAction = new CRUDAction()
{
//Specify the method name which is used to get the newly added data from
client side to the server side
Create = "/Diagram/InsertConnector",
}
}
};
[HttpPost]
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public void InsertShape(List<HierarchicalData> data)
{
foreach (HierarchicalData hierarchicalData in data)
{
DiagramContext.HierarchicalData.InsertOnSubmit(hierarchicalData);
DiagramContext.SubmitChanges();
}
}
[HttpPost]
public void InsertConnector(List<HierarchicalDetail> data)
{
foreach (HierarchicalDetail hierarchicalData in data)
{
DiagramContext.HierarchicalDetails.InsertOnSubmit(hierarchicalData);
DiagramContext.SubmitChanges();
}
}
```

UpdateData

- The following code example illustrates how to send the updated data from client to the server side.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
//Sends the updated nodes/connectors from client side to the server side
through the URL which is specified in server side.
diagram.updateData();
```

C#

```
model.DataSourceSettings = new DataSourceSettings()
{
CrudAction = new CRUDAction()
{
//Specify the method name which is used to get the updated data from client
side to the server side
Update = "/Diagram/UpdateShape",
},
ConnectionDataSource = new ConnectionDataSourceSettings()
{
CrudAction = new CRUDAction()
{
//Specify the method name which is used to get the updated data from client
side to the server side
Update = "/Diagram/UpdateConnector",
}
}
};
[HttpPost]
public void UpdateShape(List<HierarchicalData> data)
{
foreach (HierarchicalData hierarchicalData in data)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
HierarchicalData originalData = DiagramContext.HierarchicalData.Single(h =>
h.Name == hierarchicalData.Name);
originalData.Description = hierarchicalData.Description;
originalData.Color = hierarchicalData.Color;
DiagramContext.SubmitChanges();
}
}
[HttpPost]
public void UpdateConnector(List<HierarchicalDetail> data)
{
foreach (HierarchicalDetail hierarchicalData in data)
{
HierarchicalDetail originalData =
DiagramContext.HierarchicalDetails.Single(h => h.Name ==
hierarchicalData.Name);
originalData.SourceNode = hierarchicalData.SourceNode;
originalData.TargetNode = hierarchicalData.TargetNode;
DiagramContext.SubmitChanges();
}
}
```

DeleteData

The following code example illustrates how to send the deleted data from client to the server side.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
//Sends the deleted nodes/connectors from client side to the server side
through the URL which is specified in server side.
diagram.removeData();
```

C#

```
model.DataSourceSettings = new DataSourceSettings()
{
CrudAction = new CRUDAction()
{
//Specify the method name which is used to get the deleted data from client
side to the server side
Destroy = "/Diagram/DeleteShape",
},
ConnectionDataSource = new ConnectionDataSourceSettings()
{
CrudAction = new CRUDAction()
{
//Specify the method name which is used to get the updated data from client
side to the server side
Destroy = "/Diagram/DeleteConnector",
}
}
};
[HttpPost]
public void DeleteShape(List<HierarchicalData> data)
{
foreach (HierarchicalData hierarchicalData in data)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
HierarchicalData originalData = DiagramContext.HierarchicalData.Single(h =>
h.Name == hierarchicalData.Name);
DiagramContext.HierarchicalData.DeleteOnSubmit(originalData);
DiagramContext.SubmitChanges();
}
}
[HttpPost]
public void DeleteConnector(List<HierarchicalDetail> data)
{
foreach (HierarchicalDetail hierarchicalData in data)
{
HierarchicalDetail originalData =
DiagramContext.HierarchicalDetails.Single(h => h.Name ==
hierarchicalData.Name);
DiagramContext.HierarchicalDetails.DeleteOnSubmit(originalData);
DiagramContext.SubmitChanges();
}
}
```

Automatic Layout

Diagram provides support to auto-arrange the nodes in the Diagram area that is referred as **Layout**. It includes the following layout modes.

- Hierarchical Layout
- Organization Chart
- Radial Tree

Hierarchical Layout

The Hierarchical Tree Layout arranges nodes in a tree-like structure, where the nodes in the hierarchical layout may have multiple parents. There is no need to specify the layout root.

To arrange the nodes in hierarchical structure, you need to specify the layout Type as hierarchical tree. The following example shows how to arrange the nodes in a hierarchical structure.

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
//Binds custom JSON with node
function nodeTemplate(diagram, node) {
node.labels[0].text = node.Name;
}
</script>
```

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Uses layout to auto-arrange nodes on the Diagram page
model.Layout.Type = LayoutTypes.HierarchicalTree;
model.Layout.HorizontalSpacing=30;
```

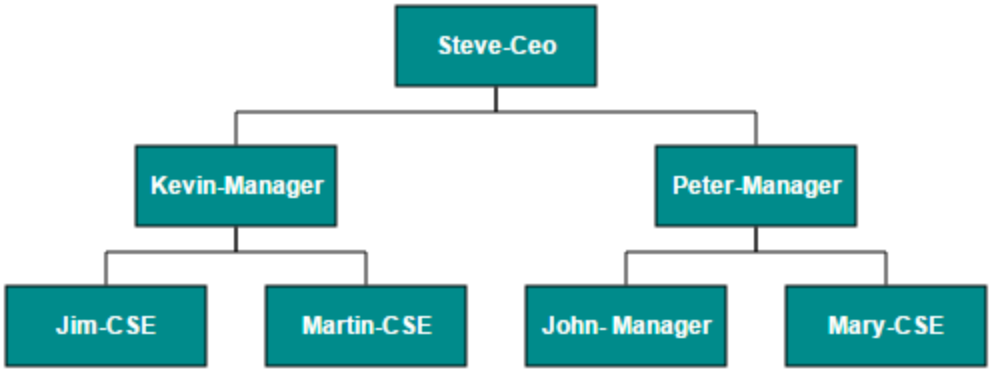
Copyright © 2001 - 2020 Syncfusion Inc.

```
model.Layout.VerticalSpacing=30;
//Sets the default properties for nodes and connectors
Label label = new Label() { Name = "label1", FontColor = "white" };
model.DefaultSettings.Node = new Node() { Width = 100, Height = 40,
FillColor = "darkcyan" };
model.DefaultSettings.Node.Labels.Add(label);
model.DefaultSettings.Connector = new Connector()
{
Segments = new Collection() { new Segment(Segments.Orthogonal) },
TargetDecorator = new Decorator() { Shape = DecoratorShapes.None },
};
//Configures data source for Diagram
//Defines the unique field
model.DataSourceSettings.Id = "Name";
//Defines the relationship
model.DataSourceSettings.Parent = "ReportingPerson";
//Specifies the dataSource
model.DataSourceSettings.DataSource = GetDataSource();
//Initializes the node template.
model.NodeTemplate = "nodeTemplate";
ViewData["diagramModel"] = model;
return View();
}
public Array GetDataSource()
{
String allText =
System.IO.File.ReadAllText(Server.MapPath("~/App_Data/data.json"));
Dictionary<string, object> requestArgs = (Dictionary<string, object>)new
JavaScriptSerializer().DeserializeObject(allText);
requestArgs = (Dictionary<string, object>)requestArgs["root"];
return (Array)requestArgs.Values.ElementAt(0);
}
```

JS

```
{root: {data: [
{Name: "Steve-CEO"},
{Name: "Kevin-Manager", ReportingPerson: "Steve-CEO"},
{Name: "Peter-Manager", ReportingPerson: "Steve-CEO"},
{Name: "John- Manager", ReportingPerson: "Peter-Manager"},
{Name: "Mary-CSE ", ReportingPerson: "Peter-Manager"},
{Name: "Jim-CSE ", ReportingPerson: "Kevin-Manager"},
{Name: "Martin-CSE", ReportingPerson: "Kevin-Manager"}
]}}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Note: You can ignore a particular Node from layout arrangement by setting its **ExcludeFromLayout** property as true.

Radial Tree Layout

The Radial Tree layout arranges nodes on a virtual concentric circles around a root node. Sub-trees formed by the branching of child nodes are located radially around the child nodes. This arrangement results in an ever-expanding concentric arrangement with radial proximity to the root node indicating the node level in the hierarchy. When no root node is set, the algorithm automatically considers one of the Diagram nodes as the root node.

To arrange nodes in a radial tree structure, you need to set the `Layout.Type` as `RadialTree`. The following code illustrates how to arrange the nodes in a radial tree structure.

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
//Binds custom JSON with node
function nodeTemplate(diagram, node) {
node.name = node.Id;
node.source = node.ImageUrl;
}
</script>
```

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Uses layout to auto-arrange nodes on the Diagram page
model.Layout.Type = LayoutTypes.RadialTree;
model.Layout.HorizontalSpacing=30;
model.Layout.VerticalSpacing=30;
//Sets the default properties for nodes
model.DefaultSettings.Node = new ImageNode() { Width = 40, Height = 40,
BorderColor = "transparent" };
//Configures data source for Diagram
model.DataSourceSettings.Id = "Id";
model.DataSourceSettings.Parent = "ReportingPerson";
model.DataSourceSettings.DataSource = GetOrgChartData();
//Initializes the node template.
```

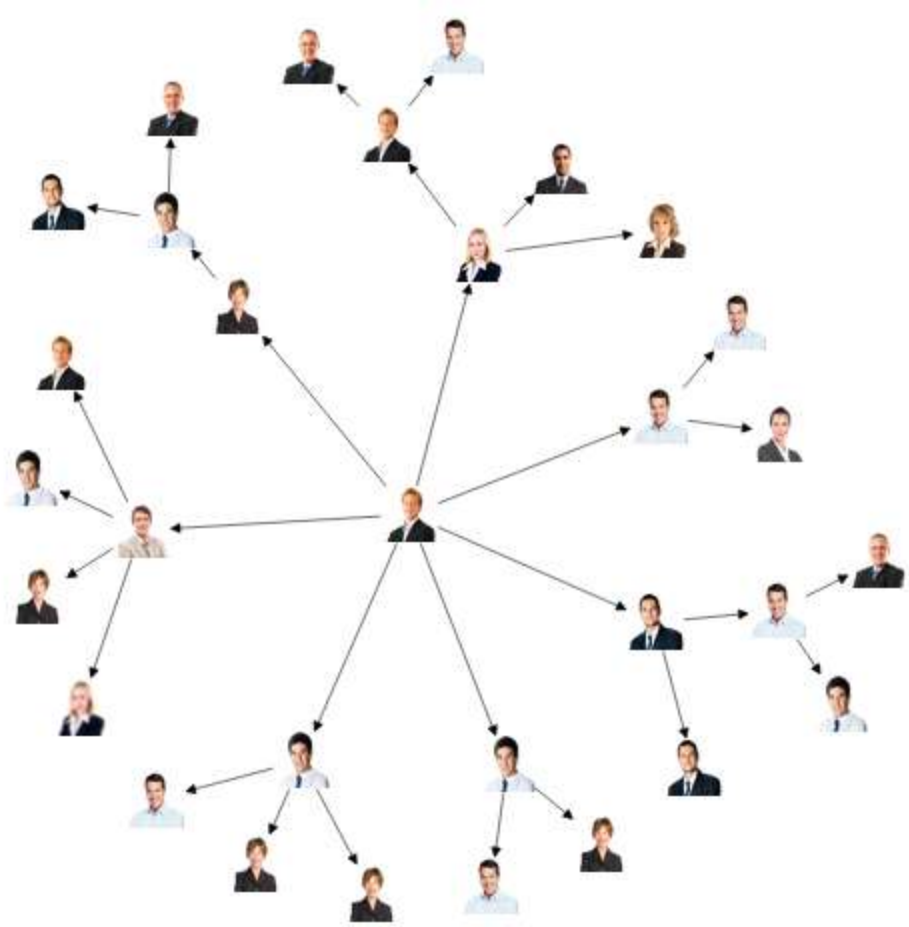
Copyright © 2001 - 2020 Syncfusion Inc.

```
model.NodeTemplate = "nodeTemplate";
ViewData["diagramModel"] = model;
return View();
}
public Array GetDataSource()
{
String allText =
System.IO.File.ReadAllText(Server.MapPath("~/App_Data/data.json"));
Dictionary<string, object> requestArgs = (Dictionary<string, object>)new
JavaScriptSerializer().DeserializeObject(allText);
requestArgs = (Dictionary<string, object>)requestArgs["root"];
return (Array)requestArgs.Values.ElementAt(0);
}
```

JS

```
{root: {data: [
{Id: "parent", ImageUrl: "images/Clayton.png"},
{Id: 1, ImageUrl: "images/image55.png", ReportingPerson: "parent"},
{Id: 2, ImageUrl: "images/Robin.PNG", ReportingPerson: "parent"},
{Id: 3, ImageUrl: "images/Robin.PNG", ReportingPerson: "parent"},
{Id: 4, ImageUrl: "images/Paul.png", ReportingPerson: "parent"},
{Id: 5, ImageUrl: "images/image53.png", ReportingPerson: "parent"},
{Id: 6, ImageUrl: "images/Maria.png", ReportingPerson: "parent"},
{Id: 7, ImageUrl: "images/Jenny.png", ReportingPerson: 3},
{Id: 8, ImageUrl: "images/Thomas.PNG", ReportingPerson: "parent"},
{Id: 9, ImageUrl: "images/Jenny.png", ReportingPerson: 2},
{Id: 10, ImageUrl: "images/Thomas.png", ReportingPerson: 2},
{Id: 11, ImageUrl: "images/Maria.PNG", ReportingPerson: 4},
{Id: 12, ImageUrl: "images/Thomas.PNG", ReportingPerson: 1},
{Id: 13, ImageUrl: "images/Clayton.png", ReportingPerson: 6},
{Id: 14, ImageUrl: "images/Jenny.png", ReportingPerson: 3},
{Id: 15, ImageUrl: "images/Thomas.png", ReportingPerson: 3},
{Id: 16, ImageUrl: "images/John.png", ReportingPerson: 6},
{Id: 17, ImageUrl: "images/Jenny.png", ReportingPerson: 4},
{Id: 18, ImageUrl: "images/Robin.png", ReportingPerson: 4},
{Id: 19, ImageUrl: "images/Clayton.png", ReportingPerson: 4},
{Id: 20, ImageUrl: "images/image57.png", ReportingPerson: 12},
{Id: 21, ImageUrl: "images/Robin.png", ReportingPerson: 5},
{Id: 22, ImageUrl: "images/image51.png", ReportingPerson: 6},
{Id: 23, ImageUrl: "images/image55.png", ReportingPerson: 19},
{Id: 24, ImageUrl: "images/Thomas.png", ReportingPerson: 8},
{Id: 25, ImageUrl: "images/image56.png", ReportingPerson: 8},
{Id: 26, ImageUrl: "images/image55.png", ReportingPerson: 1},
{Id: 27, ImageUrl: "images/image57.png", ReportingPerson: 13},
{Id: 28, ImageUrl: "images/Robin.PNG", ReportingPerson: 12},
{Id: 29, ImageUrl: "images/Thomas.PNG", ReportingPerson: 13},
{Id: 30, ImageUrl: "images/image57.png",ReportingPerson: 19}
]}}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Organizational Chart

An **Organizational Chart** is a Diagram that displays the structure of an organization and relationships. To create an organizational chart, `Layout.Type` should be set as `OrganizationalChart`.

The following code example illustrates how to create an organizational chart.

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
//Binds custom JSON with node
function nodeTemplate(diagram, node) {
node.labels[0].text = node.Role;
}
</script>
```

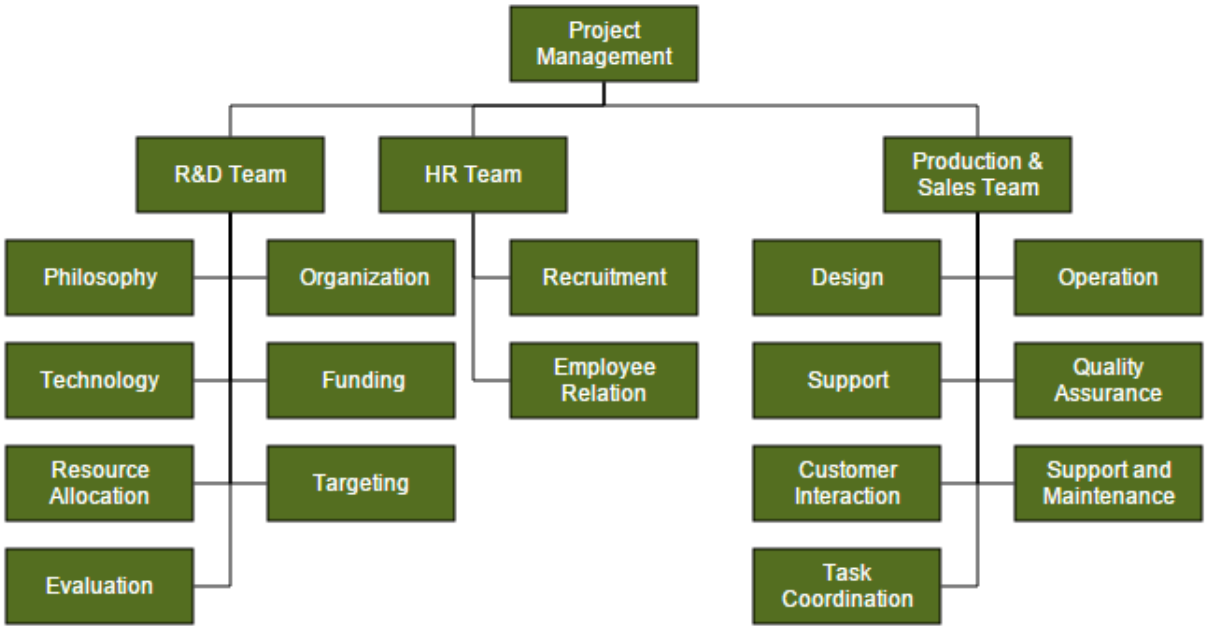
]}}
```



Organizational chart layout starts parsing from root and iterate through all its child elements. 'getLayoutInfo' method provides necessary information of a node's children and the way to arrange (direction, orientation, offsets, etc.) them. You can customize the arrangements by overriding this function as explained.

GetLayoutInfo

You can set Chart orientations, chart types, and offset to be left between parent and child nodes by overriding the method, model.layout.getLayoutInfo. The getLayoutInfo method is called to configure every subtree of the organizational chart. It takes the following arguments.

- diagram: Reference of diagram
- node: Parent node to that options are to be customized
- options: object to set the customizable properties

The following code example illustrates how to define the method getLayoutInfo.

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
var chartOrientations = ej.datavisualization.Diagram.ChartOrientations;
var chartTypes = ej.datavisualization.Diagram.ChartTypes;
//Defines getLayoutInfo
function getLayoutInfo(diagram, node, options) {
options.orientation = chartOrientations.Vertical;
//Configures the sub tree of the node vertically at right-side.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
options.type = chartTypes.Right;
options.offset = 10;
}
</script>
```

The following table illustrates the properties that "options" argument takes.

Property|Description|Default Value

options.children|Contains the list of child nodes. Children collection can be modified.|Array of child nodes

options.assistants|By default, the collection is empty. When any of the child nodes have to be set as "Assistant", you can remove from children collection and have to insert into assistants collection. |Empty array

options.orientation|Gets or sets the organizational chart orientation. |ChartOrientation.Vertical

options.type|Gets or sets the chart organizational chart type |For horizontal chart orientation:ChartType.Center For Vertical chart orientation:ChartType.Alternate

options.offset|Offset is the horizontal space to be left between parent and child nodes.|20 pixels.Applicable only for vertical chart orientations.

options.hasSubTree|Gets whether the node contains sub trees.|Boolean

options.level|Gets the depth of the node from layout root|Number

options.enableRouting|By default, Connections are routed based on the chart type and orientations.This property gets or sets whether default routing is to be enabled or disabled.|true

The following table illustrates the different chart orientations and chart types.

| Orientation | Type | Description | Example |

|---|---|---|---|

| Horizontal | Left | Arranges the child nodes horizontally at the left side of parent. |

|

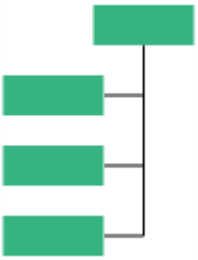
| | Right | Arranges the child nodes horizontally at the right side of parent. |

|

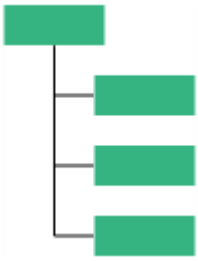
Copyright © 2001 - 2020 Syncfusion Inc.

| | Center | Arranges the children like standard tree layout orientation. |

|



| Vertical | Left | Vertically arranges the children at the left side of parent | |



| | Right | Vertically arranges the children at the right side of parent | |

| | Alternate | Vertically arranges the children at both left and right sides of parent |

|

The following code example illustrates how to set the vertical right arrangement to the leaf level trees.

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
var chartOrientations = ej.datavisualization.Diagram.ChartOrientations;
var chartTypes = ej.datavisualization.Diagram.ChartTypes;
//Creates the node template
function nodeTemplate(diagram, node) {
node.labels[0].text = node.Role;
}
function getLayoutInfo(diagram, node, options) {
if (!options.hasSubTree) {
options.type = chartTypes.Right;
options.orientation = chartOrientations.Vertical;
}
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Uses layout to auto-arrange nodes on the Diagram page
model.Layout.Type = LayoutTypes.OrganizationalChart;
model.Layout.HorizontalSpacing=30;
model.Layout.VerticalSpacing=30;
model.Layout.GetLayoutInfo = "getLayoutInfo";
//Sets the default properties for nodes
Label label = new Label() { Name = "label1", FontColor = "white" };
model.DefaultSettings.Node = new Node() { Width = 100, Height = 40,
FillColor = "#546e20" };
model.DefaultSettings.Node.Labels.Add(label);
//Sets the default properties for connectors
model.DefaultSettings.Connector = new Connector()
{
Segments = new Collection() { new Segment(Segments.Orthogonal) },
TargetDecorator = new Decorator() { Shape = DecoratorShapes.None },
};
//Configures data source for Diagram
model.DataSourceSettings.Id = "Id";
model.DataSourceSettings.Parent = "Manager";
model.DataSourceSettings.DataSource = GetOrgChartData();
//Initializes the node template.
model.NodeTemplate = "nodeTemplate";
ViewData["diagramModel"] = model;
return View();
}
public Array GetDataSource()
{
String allText =
System.IO.File.ReadAllText(Server.MapPath("~/App_Data/data.json"));
Dictionary<string, object> requestArgs = (Dictionary<string, object>)new
JavaScriptSerializer().DeserializeObject(allText);
requestArgs = (Dictionary<string, object>)requestArgs["root"];
return (Array)requestArgs.Values.ElementAt(0);
}
```

JS

```
{root: {data: [
{ Id: "parent", Role: "Board" },
{ Id: "1", Role: "General Manager", Manager: "parent" },
{ Id: "2", Role: "Human Resource Manager", Manager: "1" },
{ Id: "3", Role: "Trainers", Manager: "2" },
{ Id: "4", Role: "Recruiting Team", Manager: "2" },

```
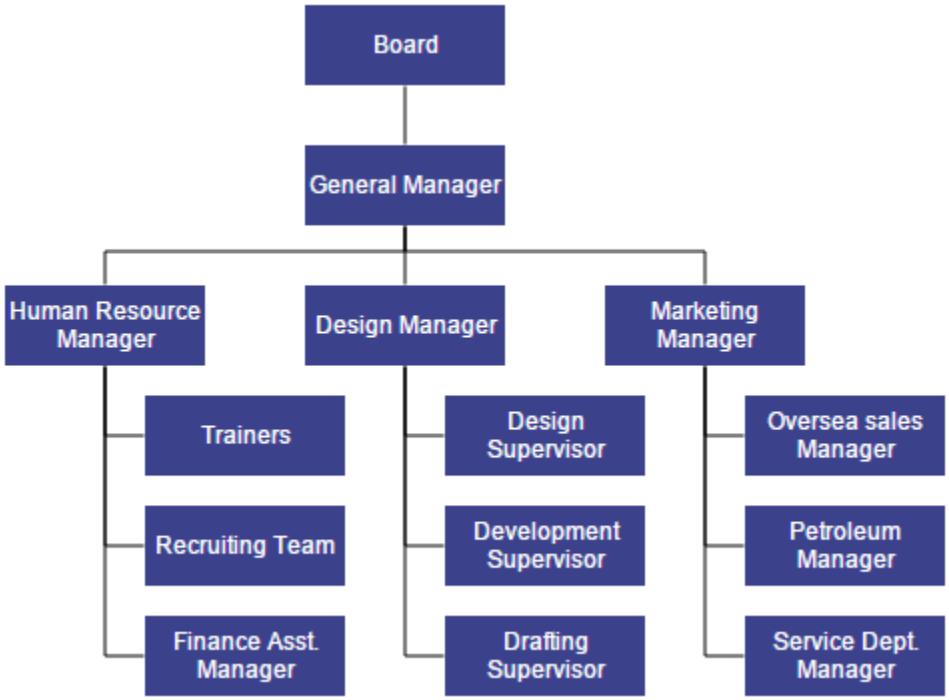
{ Id: "12", Role: "Petroleum Manager", Manager: "10" },
{ Id: "13", Role: "Service Dept. Manager", Manager: "10" }
]}}
```



Assistant

Assistants are child item that have a different relationship with the parent node. They are laid out in a dedicated part of the tree. You can specify a node as an assistant of its parent by adding it to assistants property of the argument "options".

The following code example illustrates how to add assistants to layout.

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
//Creates the node template
function nodeTemplate(diagram, node) {
node.labels[0].text = node.Role;
}
//Defines getLayoutInfo
function getLayoutInfo(diagram, node, options) {
if (node.labels[0].text == "General Manager") {
options.assistants.push(options.children[0]);
options.children.splice(0, 1);
}
options.orientation = "horizontal";
options.type = "center"
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Uses layout to auto-arrange nodes on the Diagram page
model.Layout.Type = LayoutTypes.OrganizationalChart;
model.Layout.HorizontalSpacing=30;
model.Layout.VerticalSpacing=30;
model.Layout.GetLayoutInfo = "getLayoutInfo";
//Sets the default properties for nodes
Label label = new Label() { Name = "label1", FontColor = "white" };
model.DefaultSettings.Node = new Node() { Width = 100, Height = 40,
FillColor = "#546e20" };
model.DefaultSettings.Node.Labels.Add(label);
//Sets the default properties for connectors
model.DefaultSettings.Connector = new Connector()
{
Segments = new Collection() { new Segment(Segments.Orthogonal) },
TargetDecorator = new Decorator() { Shape = DecoratorShapes.None },
};
//Configures data source for Diagram
model.DataSourceSettings.Id = "Id";
model.DataSourceSettings.Parent = "Team";
model.DataSourceSettings.DataSource = GetOrgChartData();
//Initializes the node template.
model.NodeTemplate = "nodeTemplate";
ViewData["diagramModel"] = model;
return View();
}
public Array GetDataSource()
{
String allText =
System.IO.File.ReadAllText(Server.MapPath("~/App_Data/data.json"));
Dictionary<string, object> requestArgs = (Dictionary<string, object>)new
JavaScriptSerializer().DeserializeObject(allText);
requestArgs = (Dictionary<string, object>)requestArgs["root"];
return (Array)requestArgs.Values.ElementAt(0);
}
```

JS

```
{root: {data: [
{ Id: 1, Role: "General Manager" },
{ Id: 2, Role: "Assistant Manager", Team: 1 },
{ Id: 3, Role: "Human Resource Manager", Team: 1 },
{ Id: 4, Role: "Design Manager", Team: 1 },
{ Id: 5, Role: "Operation Manager", Team: 1 },
{ Id: 6, Role: "Marketing Manager", Team: 1 }
]}}
```

Customize Layout

Orientation, spacings, and position of layout can be customized with a set of properties.

To explore layout properties, refer to Layout Properties.

Layout Orientation

Diagram provides support to customize the orientation of layout. You can set the desired orientation using Layout.Orientation. For more information about orientation, refer to Layout Orientations

The following code illustrates how to arrange the nodes in a "BottomToTop" orientation.

RAZOR

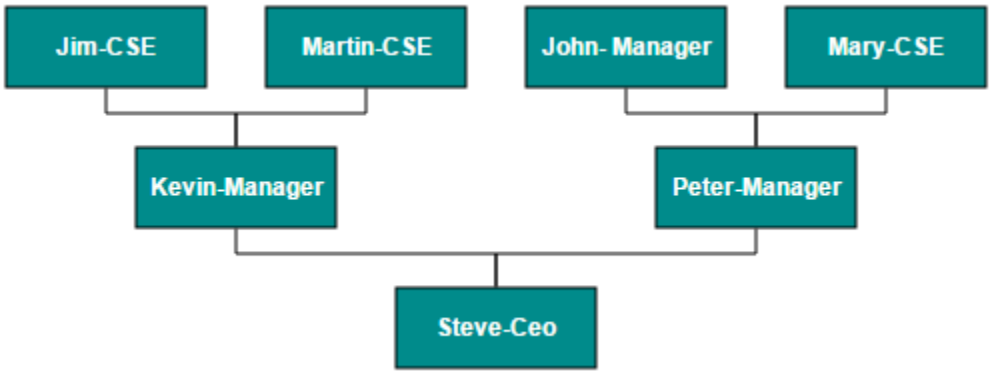
```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
//Creates the node template
function nodeTemplate(diagram, node) {
node.labels[0].text = node.Role;
}
//Defines getLayoutInfo
function getLayoutInfo(diagram, node, options) {
if (node.labels[0].text == "General Manager") {
options.assistants.push(options.children[0]);
options.children.splice(0, 1);
}
options.orientation = "horizontal";
options.type = "center";
}
</script>
```

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Sets the type of the layout
model.Layout.Type = LayoutTypes.HierarchicalTree;
//Sets the orientation
model.Layout.Orientation = LayoutOrientations.BottomToTop;
//Sets the space to be horizontally left between nodes
model.Layout.HorizontalSpacing = 20;
//Sets the space to be vertically left between nodes
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
model.Layout.VerticalSpacing = 20;
model.Layout.GetLayoutInfo = "getLayoutInfo";
//Sets the default properties for nodes and connectors
model.DefaultSettings.Node = new Node() {
Width = 100, Height = 40, FillColor = "#546e20",
Labels = new Collection() { new Label() { Name = "label1", FontColor =
"white" } }
};
model.DefaultSettings.Connector = new Connector()
{
Segments = new Collection() { new Segment(Segments.Orthogonal) },
TargetDecorator = new Decorator() { Shape = DecoratorShapes.None },
};
//Configures data source for Diagram
model.DataSourceSettings.Id = "Id";
model.DataSourceSettings.Parent = "Manager";
model.DataSourceSettings.DataSource = GetOrgChartData();
//Initializes the node template.
model.NodeTemplate = "nodeTemplate";
ViewData["diagramModel"] = model;
return View();
}
public Array GetDataSource()
{
String allText =
System.IO.File.ReadAllText(Server.MapPath("~/App_Data/data.json"));
Dictionary<string, object> requestArgs = (Dictionary<string, object>)new
JavaScriptSerializer().DeserializeObject(allText);
requestArgs = (Dictionary<string, object>)requestArgs["root"];
return (Array)requestArgs.Values.ElementAt(0);
}
```



Fixed Node

Layout provides support to arrange the nodes with reference to the position of a fixed node and the fixed node has to be set to the Layout.FixedNode.

This is helpful when you try to expand/collapse a node. It might be expected that the position of the double-clicked node should not be changed.

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
//Creates the node template
function nodeTemplate(diagram, node) {
node.labels[0].text = node.Role;
}
//Defines getLayoutInfo
function getLayoutInfo(diagram, node, options) {
options.orientation = "horizontal";
options.type = "center"
}
</script>
```

C#

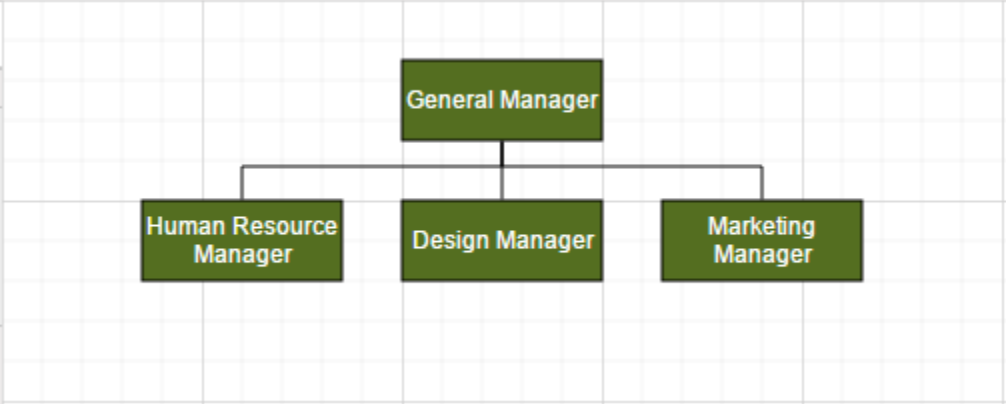
```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Defines default layout as organizational chart
model.Layout.Type = LayoutTypes.HierarchicalTree;
model.Layout.FixedNode = "parent";
model.Layout.GetLayoutInfo = "getLayoutInfo";
//Sets the default properties for nodes and connectors
model.DefaultSettings.Node = new Node() {
Width = 100, Height = 40, FillColor = "#546e20",
Labels = new Collection() { new Label() { Name = "label1", FontColor =
"white" } }
};
model.DefaultSettings.Connector = new Connector()
{
Segments = new Collection() { new Segment(Segments.Orthogonal) },
TargetDecorator = new Decorator() { Shape = DecoratorShapes.None },
};
//Configures data source for Diagram
model.DataSourceSettings.Id = "Id";
model.DataSourceSettings.Parent = "Manager";
model.DataSourceSettings.DataSource = GetOrgChartData();
//Initializes the node template.
model.NodeTemplate = "nodeTemplate";
ViewData["diagramModel"] = model;
return View();
}
public Array GetDataSource()
{
String allText =
System.IO.File.ReadAllText(Server.MapPath("~/App_Data/data.json"));
Dictionary<string, object> requestArgs = (Dictionary<string, object>)new
JavaScriptSerializer().DeserializeObject(allText);
requestArgs = (Dictionary<string, object>)requestArgs["root"];
return (Array)requestArgs.Values.ElementAt(0);
}
```

JS

```
{root: {data: [
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{ name: "parent", Role: "General Manager", offsetX: 250, offsetY: 50 },
{ name: "1", Role: "Human Resource Manager", Manager: "parent" },
{ name: "2", Role: "Design Manager", Manager: "parent"},
{ name: "3", Role: "Marketing Manager", Manager: "parent"}
]}}
```



Expand and collapse

Diagram allows to expand/collapse the sub trees of a layout. Node.IsExpanded allows you to expand/collapse its children. The following code example shows how to expand/collapse the children of a node.

RAZOR

```
@Html.EJ().Diagram("Diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
<script type="text/javascript">
function onDoubleClick(args) {
var diagram = $("#diagram").ejDiagram("instance");
var node = args.element;
// Sets the double clicked node as fixed node
$("#diagram").ejDiagram({ layout: { fixedNode: node.name } });
//Expands/collapses the children of node
diagram.updateNode(node.name, { isExpanded: !node.isExpanded });
}
</script>
```

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Defines default layout as organizational chart
model.Layout.Type = LayoutTypes.HierarchicalTree;
model.Layout.HorizontalSpacing=30;
model.Layout.VerticalSpacing=30;
model.Layout.GetLayoutInfo = "getLayoutInfo";
//Defines double click event
model.DoubleClick = "onDoubleClick";
//Sets the default properties for nodes and connectors
model.DefaultSettings.Node = new Node() {
Width = 100, Height = 40, FillColor = "#546e20",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Labels = new Collection() { new Label() { Name = "label1", FontColor =
"white" } }
};
model.DefaultSettings.Connector = new Connector()
{
Segments = new Collection() { new Segment(Segments.Orthogonal) },
TargetDecorator = new Decorator() { Shape = DecoratorShapes.None },
};
//Configures data source for Diagram
model.DataSourceSettings.Id = "Id";
model.DataSourceSettings.Parent = "Team";
model.DataSourceSettings.DataSource = GetOrgChartData();
ViewData["diagramModel"] = model;
return View();
}
```

In above example, while expanding/collapsing a node, it is set as fixed node in order to prevent it from repositioning.

Refresh layout

Diagram allows to refresh the layout at runtime. To refresh the layout, refer to Refresh layout.

Overview Control

Overview control allows you to see a preview or an overall view of the entire content of a Diagram. This helps you to look at the overall picture of a large Diagram and also to navigate, pan, or zoom, on a particular position of the page.

When you work on a very large Diagram, you may not know the part you are actually working on, or navigation from one part to another might be difficult. One solution for navigation is to zoom out the entire Diagram and find where you are. Then, you can zoom in a particular area you want to. This solution is not suitable when you need some frequent navigation.

Overview control solves these problems by showing you a preview, that is, an overall view of the entire Diagram. A rectangle indicates viewport of the Diagram. Navigation becomes easy by dragging this rectangle.

Create overview

The SourceID property of overview should be set with the corresponding Diagram ID for you need the overall view. The following code illustrates how to create overview.

HTML

```
//Initializes overview
<div>
@Html.EJ().Overview("Overview", ViewData["overview"] as
Syncfusion.JavaScript.DataVisualization.Models.OverviewProperties)
</div>
//Initializes Diagram
<div>
@Html.EJ().Diagram("Diagram1", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
DiagramProperties model = new DiagramProperties();
model.Height = "600px";
model.Width = "1000px";
ViewData["diagramModel"] = model;
OverviewProperties overview = new OverviewProperties();
overview.Height = "300px";
overview.Width = "233px";
overview.SourceID = "Diagram1";
ViewData["overview"] = overview;
```

Zoom and Pan

In overview, the view port of the Diagram is highlighted with a red colored rectangle. Diagram can be zoomed/panned by interacting with that. You can interact with overview as follows.

- Resize the rectangle - Zooms in/out the Diagram
- Drag the rectangle - Pans the Diagram
- Click at a position - Navigates to the clicked region
- Choose a particular region by clicking and dragging - Navigates to the specified region

The following image shows how the Diagram is zoomed/panned with overview.

Symbol Palette

The **SymbolPalette** displays a collection of palettes. The Palette shows a set of nodes and connectors. It allows you to drag and drop the nodes and connectors into the Diagram.

Create symbol palette

The DiagramId property of symbolpalette should be set with the corresponding Diagram ID to drag and drop the nodes and connectors into the Diagram. The following code illustrates how to create symbolpalette.

HTML

```
//Initializes overview
<div>
@Html.EJ().SymbolPalette("SymbolPalette", ViewData["SymbolPaletteModel"] as
Syncfusion.JavaScript.DataVisualization.Models.SymbolPaletteProperties)
@Html.EJ().Diagram("Diagram", ViewData["DiagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
</div>
```

C#

```
//Initializes the symbol palette
SymbolPaletteProperties symbolPalette = new SymbolPaletteProperties();
//Defines the palette collection
symbolPalette.Palettes = new Collection()
{
palette
};
//Specifies the symbol palette size
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
symbolPalette.Width = "100%";
symbolPalette.Height = "100%";
ViewData["SymbolPaletteModel"] = symbolpalette;
DiagramProperties model = new DiagramProperties();
model.Height = "550px";
model.Width = "800px";
ViewData["DiagramModel"] = model;
```

Add palettes to SymbolPalette

A palette allows to display a group of related symbols and it textually annotates the group with its header.

To initialize a palette, define a JSON object with the property `Name` that is displayed as the header text of palette. The `Expanded` property of palette allows to expand/collapse its palette items.

The following code example illustrates how to define a palette and how its added to symbol palette.

JAVASCRIPT

```
//Creates a node
BasicShape ellipse = new BasicShape()
{
//Specifies node size
Width = 50,
Height = 50,
//Specifies node offset
OffsetX = 50,
OffsetY = 50,
//Specifies node shape
Shape = BasicShapes.Ellipse
};
Palette palette = new Palette("Basic Shapes");
palette.Expanded = true;
//Adds the palette items to palette
palette.Items.Add(ellipse);
```

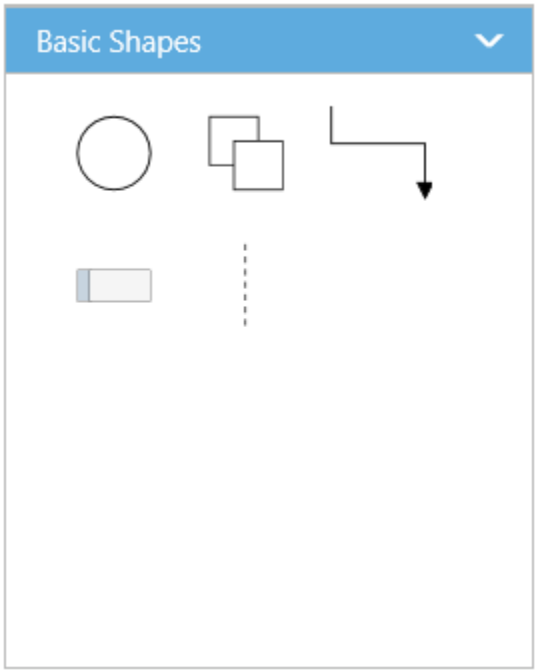
You can add any number of palettes to the `Palettes` collection of the symbol palette. The following example illustrates how to define symbol palette with a palette object that is defined in the previous step.

JAVASCRIPT

```
//Initializes the symbol palette
SymbolPaletteProperties symbolpalette = new SymbolPaletteProperties();
symbolpalette.Palettes = new Collection()
{
palette
};
ViewData["SymbolPaletteModel"] = symbolpalette;
DiagramProperties model = new DiagramProperties();
model.Height = "550px";
model.Width = "800px";
ViewData["DiagramModel"] = model;
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following image shows the symbol palette with multiple palette Items.



Customize the Palette Header

Palettes can be annotated with its header texts and you can change the height of palette header by using HeaderHeight property of symbol palette.

Also, you can embed any HTML element into a palette header by defining the ScriptTemplate id to palette's templateId property. Following code example illustrates how to customize palette headers.

HTML

```
<!--dependency scripts-->
<script id="svgTemplate" type="text/x-jsrender">
<!--define html element-->
<svg version="1.0" xmlns="http://www.w3.org/2000/svg" width="225px"
height="28px">
<g visibility="visible">
<image width="26px" height="26px" opacity="1"
xmlns:xlink="http://www.w3.org/1999/xlink" xlink:href="image.png"></image>
<text x="40" y="18" font-size="14">
<tspan>Basic Shapes</tspan>
</text>
</g>
</svg>
</script>
```

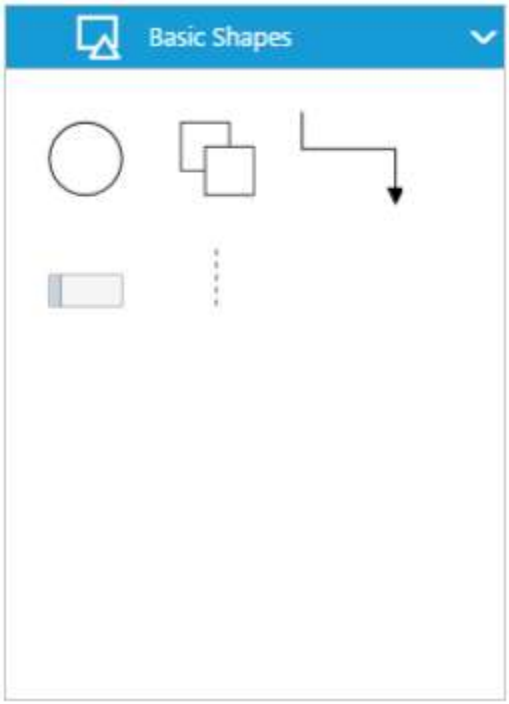
JAVASCRIPT

```
//Initializes the symbol palette
SymbolPaletteProperties symbolpalette = new SymbolPaletteProperties();
symbolpalette.Height = "550px";
symbolpalette.Width = "300px";
Palette palette = new Palette("Basic Shapes");
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Sets the id of the script template
palette.TemplateId = "svgTemplate";
palette.Expanded = true;
symbolpalette.HeaderHeight = 50;
symbolpalette.Palettes = new Collection() { palette };
ViewData["SymbolPaletteModel"] = symbolpalette;
```

The following image shows the customized palette header



Add symbols to palette

The symbol need to be defined and added to the Items collection of the palette. You can create a symbol as a node, group, connector, lane, or phase except swimlane.

The following code example illustrates how to define a palette with symbols that are defined in the previous section.

JS

```
//Initializes the symbol palette
SymbolPaletteProperties symbolpalette = new SymbolPaletteProperties();
symbolpalette.Height = "550px";
symbolpalette.Width = "300px";
//Creates a node
BasicShape ellipse = new BasicShape()
{
//Specifies node size
Width = 50,
Height = 50,
//Specifies node offset
OffsetX = 50,
OffsetY = 50,
//Specifies node shape
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Shape = BasicShapes.Ellipse
};
Palette palette = new Palette("Basic Shapes");
//Sets the id of the script template
palette.TemplateId = "svgTemplate";
palette.Expanded = true;
//Adds the palette items to palette
palette.Items.Add(ellipse);
symbolpalette.HeaderHeight = 50;
symbolpalette.Palettes = new Collection() { palette };
ViewData["SymbolPaletteModel"] = symbolpalette;
```

Customize the size of symbols

You can customize the size of the individual symbol. The PaletteItem property of node enables you to define the size of the symbols. The following code example illustrates how to change the size of a symbol.

JS

```
//Initializes the symbol palette
SymbolPaletteProperties symbolpalette = new SymbolPaletteProperties();
symbolpalette.Height = "550px";
symbolpalette.Width = "300px";
//Creates a node
BasicShape ellipse = new BasicShape()
{
//Specifies node size
Width = 50,
Height = 50,
//Specifies node shape
Shape = BasicShapes.Ellipse,
PaletteItem = new PaletteItem() { Width = 50, Height = 50, Margin = new
Margin() { Left = 20, Top = 20, Right = 20, Bottom = 20 } }
};
Palette palette = new Palette("Basic Shapes");
palette.Expanded = true;
//Adds the palette items to palette
palette.Items.Add(ellipse);
//Specifies the default size to render symbols
symbolpalette.PaletteItemWidth = 50;
symbolpalette.PaletteItemHeight = 50;
symbolpalette.Palettes = new Collection() { palette };
ViewData["SymbolPaletteModel"] = symbolpalette;
```

Symbol size will be set based on the following precedence.

Precedence

| Palette Item | Rendering Size |

|---|---|---|

| Width | PaletteItem.Width > model.PaletteItemWidth > Node.Width |

| Height | PaletteItem.height > model.PaletteItem.Height > Node.Height |

Copyright © 2001 - 2020 Syncfusion Inc.

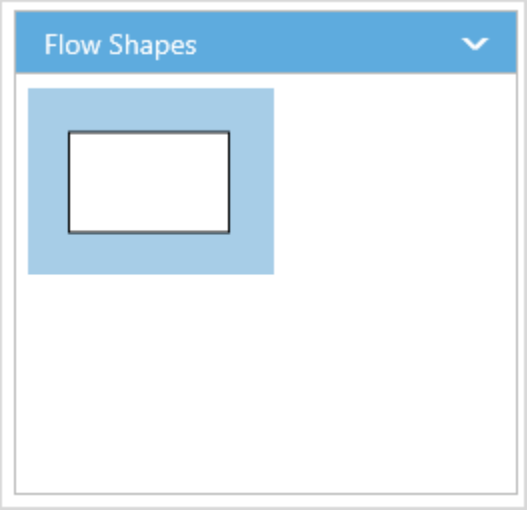
- Symbol size will be rendered in the palette based on Node.PaletteItem's Width and Height property.
- If PaletteItem's Width and Height property is not specified, symbol size will be rendered in the palette based on model's PaletteItemWidth and PaletteItemHeight property.
- If you don't specify above two, then symbol size will be rendered in the palette based on node's Width and Height property.

Stretch the symbols into the palette

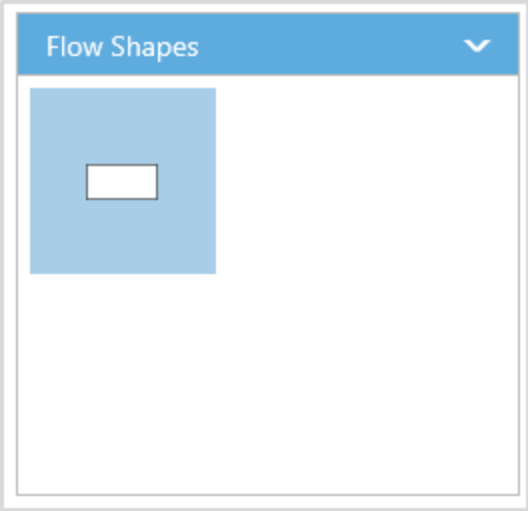
The EnableScale property of the paletteItem enables you to customize the size of the symbol regardless of the precedence. The following code example illustrates how to customize the symbol size.

JAVASCRIPT

```
//Initializes the symbol palette
SymbolPaletteProperties symbolpalette = new SymbolPaletteProperties();
symbolpalette.Height = "550px";
symbolpalette.Width = "300px";
//Creates a node
BasicShape rectangle = new BasicShape()
{
//Specifies node size
Width = 80,
Height = 40,
// Enables to fit the content into the specified palette item size
// When it is set as false, the element is rendered with actual node size
PaletteItem = new PaletteItem() { EnableScale = true }
};
Palette palette = new Palette("Basic Shapes");
palette.Expanded = true;
//Adds the palette items to palette
palette.Items.Add(rectangle);
//Specifies the default size to render symbols
symbolpalette.PaletteItemWidth = 50;
symbolpalette.PaletteItemHeight = 50;
symbolpalette.Palettes = new Collection() { palette };
ViewData["SymbolPaletteModel"] = symbolpalette;
```



Copyright © 2001 - 2020 Syncfusion Inc.



Symbol Previews

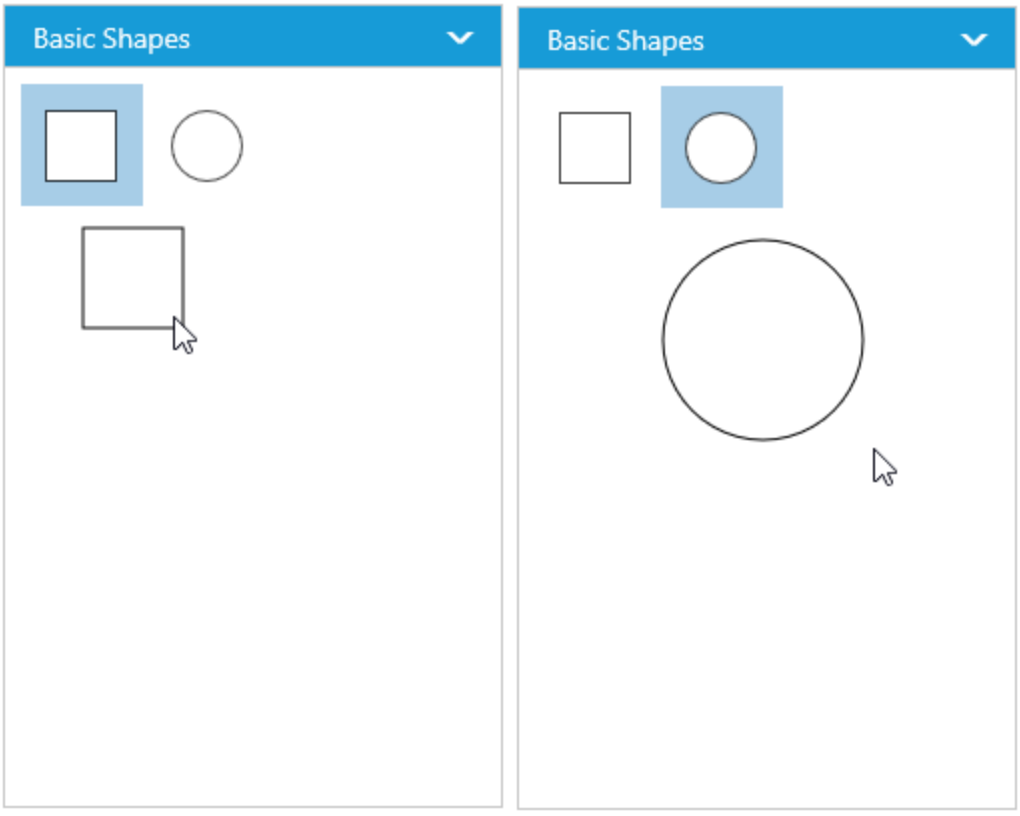
Image, simple snippet to customize the preview size

You can customize the preview size of the individual palette items. The PaletteItem property of node enables you to define the preview size of the symbol items. The following code example illustrates how to change the preview size of a palette item.

JAVASCRIPT

```
//Initializes the symbol palette
SymbolPaletteProperties symbolpalette = new SymbolPaletteProperties();
symbolpalette.Height = "550px";
symbolpalette.Width = "300px";
//Creates a node
BasicShape rectangle = new BasicShape()
{
//Specifies node size
Width = 50,
Height = 50,
//Specifies the individual palette item preview size
PaletteItem = new PaletteItem() { PreviewHeight = 50, PreviewWidth = 50 }
};
BasicShape ellipse = new BasicShape()
{
//Specifies node size
Width = 50,
Height = 50,
Shape = BasicShapes.Ellipse,
};
Palette palette = new Palette("Basic Shapes");
palette.Expanded = true;
//Adds the palette items to palette
palette.Items.Add(rectangle);
palette.Items.Add(ellipse);
symbolpalette.Palettes = new Collection() { palette };
ViewData["SymbolPaletteModel"] = symbolpalette;
```

Copyright © 2001 - 2020 Syncfusion Inc.

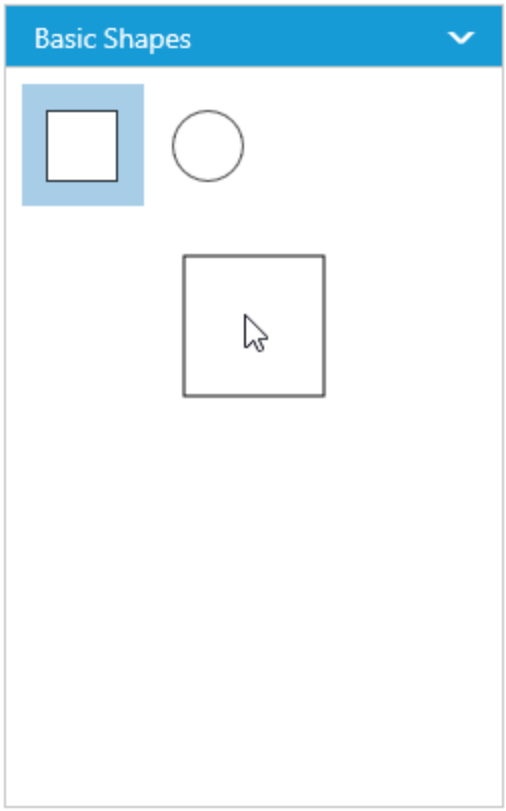


You can also customize the preview size of the all palette items. The PreviewWidth and PreviewHeight property of SymbolPalette enables you to define the preview size to all the symbol palette items. The following code example illustrates how to change the preview size of a symbol palette items.

JS

```
//Initializes the symbol palette
SymbolPaletteProperties symbolpalette = new SymbolPaletteProperties();
symbolpalette.Height = "550px";
symbolpalette.Width = "300px";
//Creates a node
BasicShape rectangle = new BasicShape()
{
//Specifies node size
Width = 50,
Height = 50,
};
Palette palette = new Palette("Basic Shapes");
palette.Expanded = true;
//Adds the palette items to palette
palette.Items.Add(rectangle);
symbolpalette.PreviewHeight = 100;
symbolpalette.PreviewWidth = 100;
symbolpalette.Palettes = new Collection() { palette };
ViewData["SymbolPaletteModel"] = symbolpalette;
```

Copyright © 2001 - 2020 Syncfusion Inc.

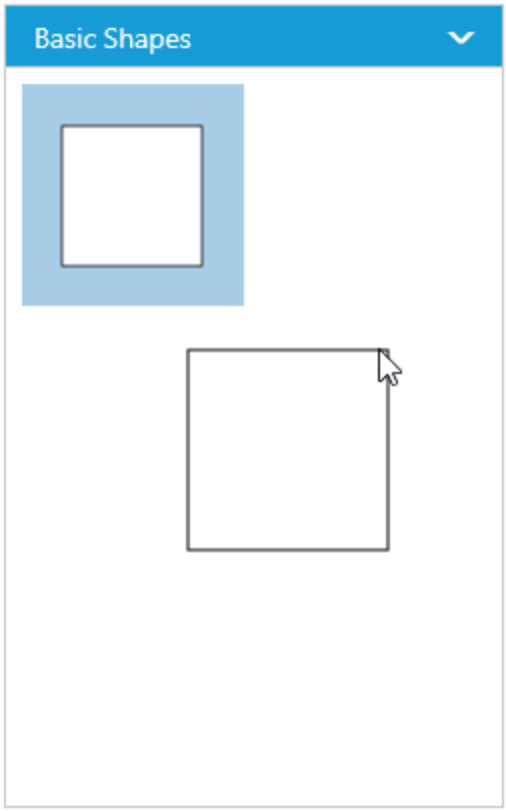


Symbol palette allows to sets the offset of the dragging helper relative to the mouse cursor.

JAVASCRIPT

```
//Initializes the symbol palette
SymbolPaletteProperties symbolpalette = new SymbolPaletteProperties();
symbolpalette.Height = "550px";
symbolpalette.Width = "300px";
//Creates a node
BasicShape rectangle = new BasicShape()
{
//Specifies node size
Width = 50,
Height = 50,
};
Palette palette = new Palette("Basic Shapes");
palette.Expanded = true;
//Adds the palette items to palette
palette.Items.Add(rectangle);
symbolpalette.PreviewOffset = new DiagramPoint() { X = 50, Y = 50 };
symbolpalette.Palettes = new Collection() { palette };
ViewData["SymbolPaletteModel"] = symbolpalette;
```

Copyright © 2001 - 2020 Syncfusion Inc.



Symbol preview size will be set based on the following precedence.

Precedence

| Palette Item | Preview Size |

|---|---|

| Width | PaletteItem.PreviewWidth > Model.PreviewWidth > Node.Width |

| Height | PaletteItem.PreviewHeight > Model.PreviewHeight > Node.Height |

- Symbol preview size will be set based on node.paletteItem's PreviewWidth and PreviewHeight property.
- If paletteItem's width and height property is not specified, symbol size will be set based on model's PreviewWidth and PreviewHeight property.
- If you don't specify above two, then symbol size will be rendered in the palette based on node's Width and Height property.

Show/hide the symbol Text

You can show/hide the symbol text by using the ShowPaletteItemText property of symbol palette.

JS

```
//Initializes the symbol palette
SymbolPaletteProperties symbolpalette = new SymbolPaletteProperties();
symbolpalette.Height = "550px";
symbolpalette.Width = "300px";
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Specifies whether palette item text should be visible or not
symbolpalette.ShowPaletteItemText = true;
ViewData["SymbolPaletteModel"] = symbolpalette;
```

To explore the properties of symbol palette, refer to Symbol Palette Properties.

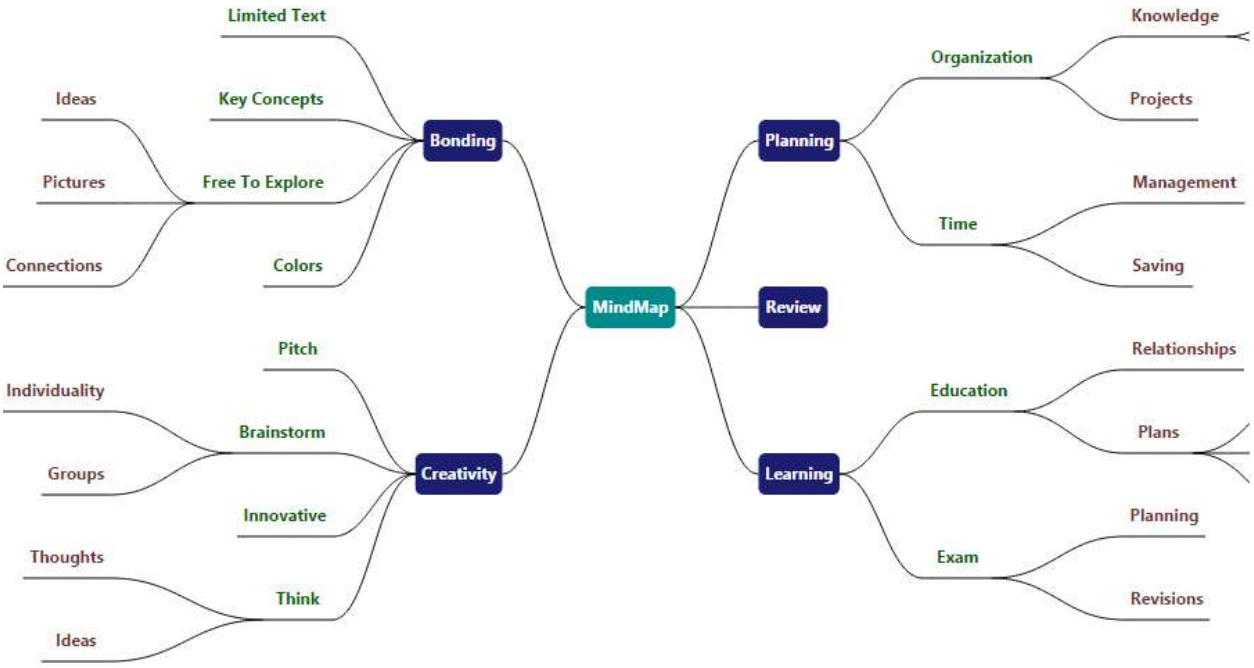
Exporting

Diagram provides support to export its content as image/svg files.

The client side method exportDiagram helps to export the Diagram. The following code illustrates how to export the Diagram as image.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
//Exports the Diagram as an image of JPEG format
diagram.exportDiagram();
```



Exporting options

Diagram provides support to export the desired region of the Diagram to desired formats.

FileName

FileName is the name of the file to be downloaded. By default, the file name is set as "Diagram".

Format

Format is to specify the type/format of the exported file. By default, Diagram is exported as .jpg format. You can export Diagram to the following formats.

- JPG
- PNG
- BMP
- SVG

Copyright © 2001 - 2020 Syncfusion Inc.

For more information about the exportable formats, refer to File Formats.

Margin

Margin specifies the amount of space that has to be left around the Diagram.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
var options = {
//Name of the file to be downloaded
fileName: "diagram",
//Margin to the exported file/data
margin: {
left: 30,
right: 30,
top: 30,
bottom: 30
}
};
diagram.exportDiagram(options);
```

Mode

Mode specifies whether the Diagram is to be exported as files or as data(ImageURL/SVG). The exporting options are as follows.

- Exports and downloads Diagram as image
- Exports Diagram as data of formats ImageURL/SVG

For more information about the exporting modes, refer to Exporting Modes.

The following code example illustrates how to export the Diagram as raw data.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
var options = {
fileName: "diagram",
//Specifies whether to export as files/data
mode: "data"
};
diagram.exportDiagram(options);
```

Note: In IE-9, Diagrams cannot be exported as downloadable files. Instead, Diagram provides the exported data (DataURL/SVG) that enables to export it from application.

Region

You can export any particular region of the Diagram and the region is categorized as follows.

- Region that fits all nodes and connectors that are added to model
- Region that fits all pages (single or multiple pages based on page settings)

For more information about region, refer to Regions.

The following code example illustrates how to export the region occupied by the Diagram elements.

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
var options = {
//Specifies the exporting region
mode: "content"
};
diagram.exportDiagram(options);
```

The following code example illustrates how to export any specific region of the Diagram.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
var options = {
fileName: "diagram",
//Specifies whether to export as files/data
mode: "download",
//Format of the exported file
format: "jpg",
// Defines the custom bounds that has to be exported
bounds: {
x: 1000,
y: 1000,
width: 500,
height: 500
},
};
diagram.exportDiagram(options);
```

Localization

- Localization is the process of providing controls in different cultures to help you set your own culture easily. Diagram provides localization support for Context Menu items.
- The Diagram model's Locale property is used to define the culture code.

The following code illustrates how to provide localization support for Context Menu items.

RAZOR

```
@*Initialize diagram control*@
<div>
@Html.EJ().Diagram("diagram", ViewData["diagramModel"] as
Syncfusion.JavaScript.DataVisualization.Models.DiagramProperties)
</div>
// Defines the context menu items with Spanish language
ej.datavisualization.Diagram.Locale["es-ES"] = {
cut: "Corte",
copy: "Copia",
paste: "Pasta",
undo: "Deshacer",
redo: "Rehacer",
selectAll: "Seleccionar todo",
grouping: "Agrupación",
group: "Grupo",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
ungroup: "Desagrupar",
order: "Fin",
bringToFront: "Traer a delante",
moveForward: "Movimiento adelante",
sendToBack: "Enviar a espalda",
sendBackward: "Enviar hacia atrás"
};
```

C#

```
DiagramProperties model = new DiagramProperties();
//Adds nodes and connectors to model
model.Nodes.Add(new Node()
{
Name = "rectangle1",
OffsetY = 100,
Labels = new Collection() {
new Label(){Text="Rectangle1"}
}
});
model.Nodes.Add(new Node()
{
Name = "rectangle2",
OffsetY = 300,
Labels = new Collection() {
new Label(){ Text="Rectangle2" }
}
});
model.Connectors.Add(new Connector()
{
Name = "connector1",
SourceNode = "rectangle1",
TargetNode = "rectangle2"
});
//Defines the default properties
model.DefaultSettings.Node = new Node()
{
Width = 100,
Height = 100,
OffsetX = 100,
BorderColor = "#1BA0E2",
FillColor = "darkcyan",
Labels = new Collection() { new Label() { FontColor = "white" } }
};
//Sets the culture
model.Locale = "es-ES";
ViewData["diagramModel"] = model;
```

Note: You have to define the textual descriptions of the context menu items for your custom cultures.

Copyright © 2001 - 2020 Syncfusion Inc.

Tools

Drawing Tools

Drawing tool allows you to draw any kind of node/connector during runtime by clicking and dragging on the Diagram page.

Shapes

To draw a shape, you need to set the JSON of that shape to the drawType property of the Diagram model and you have to activate the drawing tool by using the tool property. The following code example illustrates how to draw a rectangle at run time.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
//JSON to create a rectangle
diagram.model.drawType = {
type: ej.datavisualization.Diagram.Shapes.Basic,
shape: "rectangle",
//customize the appearance of the shape
fillColor: "#fcbc7c",
borderColor: "#f89b4c",
labels: [{
"text": "Rectangle"
}]
};
//To draw an object once, activate draw once
diagram.update({
tool: ej.datavisualization.Diagram.Tool.DrawOnce,
});
//To draw an object multiple times, activate continuous draw tool
diagram.update({
tool: ej.datavisualization.Diagram.Tool.ContinuesDraw,
});
```

The following code example illustrates how to draw a path.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
diagram.model.drawType = {
name: "Path",
fillColor: "#fbe172",
labels: [{
text: "Path"
}],
shape: "path",
```

```
pathData: "M13.560 67.524 L 21.941 41.731 L 0.000 25.790 L 27.120 25.790 L
35.501 0.000 L 43.882 25.790 L 71.000 25.790 L 49.061 41.731 L 57.441 67.524
L 35.501 51.583 z"
};
//To draw an object once, activate draw once
diagram.update({
tool: ej.datavisualization.Diagram.Tool.DrawOnce,
});
```

Connectors

To draw connectors, you have to set the JSON of the connector to drawType property. The drawing tool can be activated by using the tool property as shown. The following code example illustrates how to draw a straight line connector.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
//JSON to create a straight line connector
diagram.model.drawType = {
type: "connector",
segments: [{
type: "straight"
}]
};
//To draw an object once, activate draw once
diagram.update({
tool: ej.datavisualization.Diagram.Tool.DrawOnce
});
```

Text

Diagram allows you to create a textNode as soon as you click on the Diagram page. The following code illustrates how to draw a text.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
//JSON to draw a text
diagram.model.drawType = { type: "text" };
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
diagram.update({
tool: ej.datavisualization.Diagram.Tool.DrawOnce
});
```

Once you activate the TextTool, you can also able to perform label editing of a node/connector.

Polyline Tool

Diagram allows to create the polyline segments with straight lines and angled vertices at the control points by clicking and moving the mouse at run time on the diagram page.

JAVASCRIPT

```
var diagram = $("#diagram").ejDiagram("instance");
// set the default segment type as polyline
diagram.model.drawType = {
type: "connector",
segments: [{ type: "polyline" }]
};
var tool = diagram.tool();
//To draw an object once, activate draw once
diagram.update({ tool: tool | ej.datavisualization.Diagram.Tool.DrawOnce })
```

Once you activate the polyline tool, you can also able to draw the polyline connector on diagram page.

Tool Selection

There are some functionalities that can be achieved by clicking and dragging on the Diagram surface. They are as follows.

- Draw selection rectangle - MultipleSelect tool
- Pan the Diagram - Zoom pan
- Draw nodes/connectors - ContinuousDraw / DrawOnce

As all the three behaviors are completely different, You can achieve only one behavior at a time based on the tool that you choose.

When more than one of those tools are applied, a tool is activated based on the precedence given in the following table.

| Precedence | Tools | Description |

|---|---|---|

| 1st | ContinuesDraw | Allows you to draw the nodes or connectors continuously. Once it is activated, you cannot perform any other interaction in the Diagram. |

| 2nd | DrawOnce | Allows you to draw single node or connector. Once you complete the drawOnce action, SingleSelect and MultipleSelect tools are automatically enabled. |

| 3rd | ZoomPan | Allows you to pan the Diagram. When you enable both the SingleSelect and ZoomPan tools, you can perform the basic interaction as the cursor hovers node/connector. Panning is enabled when cursor hovers the Diagram. |

Copyright © 2001 - 2020 Syncfusion Inc.

| 4th | MultipleSelect | Allows you to select multiple nodes and connectors. When you enable both the MultipleSelect and ZoomPan tools, cursor hovers the Diagram. When panning is enabled, you cannot select multiple nodes. |

| 5th | SingleSelect | Allows you to select individual nodes or connectors. |

| 6th | None | Disables all tools |

You can set the desired tool to the tool property of the Diagram model. The following code illustrates how to enable single/multiple tools.

C#

```
// To Enable Single Tool
DiagramProperties model = new DiagramProperties();
model.Tool = Tool.SingleSelect;
ViewData["Diagram"] = model;
// Enables multiple tools
DiagramProperties model = new DiagramProperties();
model.Tool = Tool.SingleSelect | Tool.ZoomPan;
ViewData["Diagram"] = model;
```

Tooltip

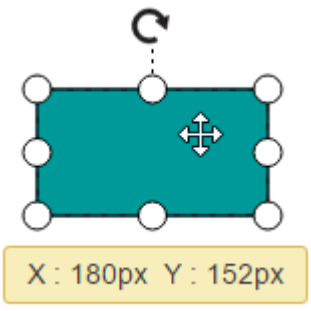
In Graphical User Interface (GUI), tooltip is a message that is displayed when mouse hovers over an element. Diagram provides tooltip support while dragging, resizing, rotating a node, and when mouse hovers any Diagram element.

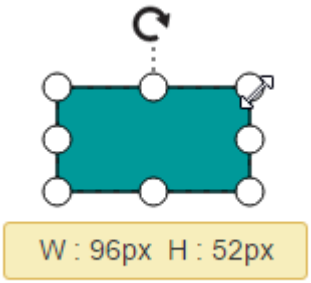
Default tooltip

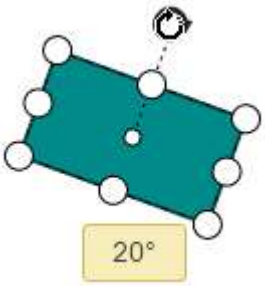
By default, Diagram displays a tooltip to provide the size, position, and angle related information while dragging, resizing, and rotation. The following images illustrate how the Diagram displays the node information during interaction.

| Drag | Resize | Rotate |

|---|---|---|







| | | |

Disable default tooltip

To disable the default tooltip, You need to set SelectedItems.Tooltip as null. The following code example illustrates how to disable default tooltip.

C#

```
// To Enables multiple tools
DiagramProperties Model = new DiagramProperties();
```

```
//Disable tooltip during interaction
Model.SelectedItems.Tooltip = null;
```

Common tooltip for all nodes and connectors

Diagram provides support to show tooltip when mouse hovers over any node/connector.

To show tooltip on mouse over, the Tooltip property of Diagram model needs to be set with the tooltip TemplateId and Alignment as shown in the following example.

HTML

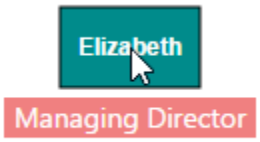
```
<!--Define tooltip template-->
<script type="text/x-jsrender" id="mouseovertooltip">
<div style="background-color: #F08080; color: white; white-space: nowrap;
height: 20px">
<span style="padding: 5px;"> {{:addInfo.Designation}} </span>
</div>
</script>
```

C#

```
public partial class DiagramController : Controller
{
public ActionResult DiagramFeatures()
{
//Initialize the Diagram Model
DiagramProperties Model = new DiagramProperties();
Model.Width = "100%";
Model.Height = "700px";
//Defines mouse over tooltip
Model.Tooltip = new Tooltip();
Model.Tooltip.TemplateId = "mouseovertooltip";
Model.Tooltip.Alignment.Horizontal = HorizontalAlignment.Center;
Model.Tooltip.Alignment.Vertical = VerticalAlignment.Center;
Label Label = new Label() { Text = "Elizabeth", FontColor = "white", Bold =
true };
Collection Labels = new Collection();
Labels.Add(Label);
//Defines nodes
Node Node = new Node()
{
Name = "elizabeth",
Width = 70,
Height = 40,
OffsetX = 100,
OffsetY = 100,
FillColor = "darkCyan",
Labels = Labels
};
Node.AddInfo = new Dictionary<string, object>();
Dictionary<string, object> AddInfo = new Dictionary<string, object>();
AddInfo.Add("Designation", "Managing Director");
Node.AddInfo = AddInfo;
Model.Nodes.Add(Node);
ViewData["diagramModel"] = Model;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
return View();
}
```



Disable tooltip at runtime

Tooltips on mouse over can be disabled by assigning tooltip property as null. The following code example illustrates how to disable the mouse over tooltip at runtime.

JS

```
$("#diagram").ejDiagram({
//Disables mouse over tooltip at runtime
tooltip: null
});
```

Tooltip for a specific node/connector

Tooltips can be customized for every node. Tooltip can be defined for individual node/connector by using the Tooltip property of that node/connector. In addition to that, you have to remove the **InheritTooltip** option from the Constraints of that node/connector. The following code example illustrates how to customize tooltips for individual elements.

C#

```
//Enables tooltip for any node/connector
DiagramProperties Model = new DiagramProperties();
Node Node = new Node();
Node.Name = "elizabeth";
//Remove InheritTooltip not to inherit the tooltip defined in model
Node.Constraints = NodeConstraints.Default &
~NodeConstraints.InheritTooltip;
//Defines mouse over tooltip for a node
Node.Tooltip.TemplateId = "nodetooltiptemplate";
Model.Nodes.Add(Node);
//Disables tooltip for any node/connector
Node.Tooltip = null;
Model.Nodes.Add(Node);
```

Tooltip alignments

Tooltip relative to object

Diagram provides support to show tooltip around the node/connector that is hovered by mouse. You can align the tooltip as you wish by using the Alignment and Margin properties of tooltip. The RelativeMode property of tooltip defines whether the tooltip has to be displayed around the object or at the mouse position. The following code example illustrates how to position the tooltip around object.

HTML

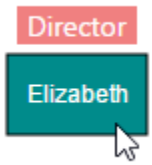
```
<!--Define tooltip template-->
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script type="text/x-jsrender" id="mouseovertooltip">
<div style="background-color: #F08080; color: white; padding: 5px;">
<span style="padding: 5px;"> {{:addInfo.Designation}} </span>
</div>
</script>
```

C#

```
//Initialize the Diagram Model
DiagramProperties Model = new DiagramProperties();
Model.Width = "100%";
Model.Height = "700px";
//Defines mouse over tooltip
Model.Tooltip = new Tooltip();
Model.Tooltip.TemplateId = "mouseovertooltip";
Model.Tooltip.Alignment.Horizontal = HorizontalAlignment.Center;
Model.Tooltip.Alignment.Vertical = VerticalAlignment.Center;
Label Label = new Label() { Text = "Elizabeth", FontColor = "white", Bold =
true };
Collection Labels = new Collection();
Labels.Add(Label);
BasicShape Node = new BasicShape();
//Defines nodes
Node.Name = "elizabeth";
Node.Width = 70; Node.Height = 40;
Node.OffsetX = 100; Node.OffsetY = 100;
//Removes inherit tooltip from constraints
Node.Constraints = NodeConstraints.Default &
~NodeConstraints.InheritTooltip;
//Defines tooltip for a node
Node.Tooltip = new Tooltip();
//Defines template id
Node.Tooltip.TemplateId = "mouseovertooltip";
//Sets to show tooltip around the element
Node.Tooltip.RelativeMode = RelativeMode.Object;
//Sets the alignment properties
//Defines horizontal alignment around node
Node.Tooltip.Alignment.Horizontal = HorizontalAlignment.Center;
//Defines vertical alignment around node
Node.Tooltip.Alignment.Vertical = VerticalAlignment.Top;
Node.AddInfo = new Dictionary<string, object>();
Dictionary<string, object> AddInfo = new Dictionary<string, object>();
AddInfo.Add("Designation", "Managing Director");
Node.AddInfo = AddInfo;
Model.Nodes.Add(Node);
```



Copyright © 2001 - 2020 Syncfusion Inc.

Tooltip relative to mouse position

To display the tooltip at mouse position, you need to set "Mouse" option to the RelativeMode property of tooltip. The following code example illustrates how to show tooltip at mouse position.

C#

```
//Initialize the Diagram Model
DiagramProperties Model = new DiagramProperties();
Model.Width = "100%";
Model.Height = "700px";
//Defines mouse over tooltip
Model.Tooltip = new Tooltip();
Model.Tooltip.TemplateId = "mouseovertooltip";
Model.Tooltip.Alignment.Horizontal = HorizontalAlignment.Center;
Model.Tooltip.Alignment.Vertical = VerticalAlignment.Center;
Label Label = new Label() { Text = "Elizabeth", FontColor = "white", Bold =
true };
Collection Labels = new Collection();
Labels.Add(Label);
BasicShape Node = new BasicShape();
//Defines nodes
Node.Name = "elizabeth";
Node.Width = 70; Node.Height = 40;
Node.OffsetX = 100; Node.OffsetY = 100;
//Removes inherit tooltip from constraints
Node.Constraints = NodeConstraints.Default &
~NodeConstraints.InheritTooltip;
//Disables tooltip for a node
//Defines template id
Node.Tooltip.TemplateId = "mouseovertooltip";
//Sets to show tooltip around the element
Node.Tooltip.RelativeMode = RelativeMode.Mouse;
//Sets margin - absolute distance between mouse position and tooltip
Node.Tooltip.Margin.Top = 10;
Node.Tooltip.Margin.Left = 10;
Node.AddInfo = new Dictionary<string, object>();
Dictionary<string, object> AddInfo = new Dictionary<string, object>();
AddInfo.Add("Designation", "Managing Director");
Node.AddInfo = AddInfo;
Model.Nodes.Add(Node);
```

Constraints

Constraints are used to enable/disable certain behaviors of the diagram, node and connector. Constraints are provided as flagged enumerations, so that multiple behaviors can be enabled/disabled with bitwise operators (&, |, ~, <<, etc.).

To know more about bitwise operators, refer to Bitwise Operations

Copyright © 2001 - 2020 Syncfusion Inc.

DiagramConstraints

Diagram constraints allow to enable or disable the following behaviors.

- Page Editing
- Line Bridging
- Zoom and Pan
- Undo Redo

For more information about Diagram constraints, refer to Diagram Constraints.

Example

The following example illustrates how to disable page editing.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Set Diagram in read-only mode
model.Constraints = DiagramConstraints.Default &~
DiagramConstraints.PageEditable;
ViewData["diagramModel"] = model;
return View();
}
```

NodeConstraints

NodeConstraints allows to enable or disable the following behaviors of node.

- Selection
- Deletion
- Drag
- Resize
- Rotate
- Connect
- Drop shadow
- Drag label
- Define tooltip

For more information about node constraints, refer to Node Constraints

Example

The following code illustrates how to disable rotation.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Disables rotation
BasicShape task1 = new BasicShape() {
Constraints = NodeConstraints.Default &~ NodeConstraints.Rotate
};
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
model.Nodes.Add(task1);
ViewData["diagramModel"] = model;
return View();
}
```

ConnectorConstraints

ConnectorConstraints allow to enable or disable certain behaviors of Connectors. They are as follows.

- Selection
- Deletion
- Drag
- Segment editing
- Define tooltip
- Bridging
- Label dragging

For more information about connector constraints, refer to Connector Constraints

Example

The following code illustrates how to disable selection.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Disables Selection
Connector connector1 = new Connector() {
Constraints = ConnectorConstraints.Default &~ ConnectorConstraints.Select
};
model.Connectors.Add(connector1);
ViewData["diagramModel"] = model;
return View();
}
```

PortConstraints

You can enable or disable certain behaviors of Port. They are as follows.

- Connect

For more information about port constraints, refer to Port Constraints

Example

The following code illustrates how to disable creating connections with a port.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
BasicShape node1 = new BasicShape(){
Name = "Node1",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Defines ports for task2
Ports = new Collection() {
new Port(){ Constraints = PortConstraints.None },
}
};
model.Nodes.Add(node1);
ViewData["diagramModel"] = model;
return View();
}
```

SelectorConstraints

Selector visually represents the selected elements with certain editable thumbs. The visibility of the thumbs can be controlled with selector constraints. The part of selector is categorized as follows.

- Resizer
- Rotator
- User handles

For more information about Selector constraints, refer to Selector Constraints

Example

The following code illustrates how to hide rotator.

C#

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
//Hides rotator
model.SelectedItems = new SelectedItems(){
Constraints = SelectorConstraints.All &~ SelectorConstraints.Rotator
};
ViewData["diagramModel"] = model;
return View();
}
```

SnapConstraints

Snap Constraints control the visibility of gridlines and enable/disable snapping. Snap constraints allow to set the following behaviors.

- Show only horizontal or vertical gridlines
- Show both horizontal and vertical gridlines
- Snap to either horizontal or vertical gridlines
- Snap to both horizontal and vertical gridlines

For more information about snap constraints, refer to Snap Constraints

Example

The following code illustrates how to show only horizontal gridlines.

C#

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
model.SnapSettings = new SnapSettings()
{
SnapConstraints = SnapConstraints.ShowHorizontalLines
};
ViewData["diagramModel"] = model;
return View();
}
```

Inherit behaviors

Some of the behaviors can be defined through both the specific object(node/connector) and Diagram. When the behaviors are contradictorily defined through both, the actual behavior is set through inherit options.

The following code example illustrates how to inherit the line bridging behavior from the Diagram model.

RAZOR

```
public ActionResult Index()
{
DiagramProperties model = new DiagramProperties();
Connector connector1 = new Connector() {
Name = "Connector",
SourcePoint = new DiagramPoint(100f, 100f),
TargetPoint = new DiagramPoint(200f, 200f),
//Sets to inherit bridging from model
Constraints = ConnectorConstraints.Default |
ConnectorConstraints.InheritBridging
};
model.Connectors.Add(connector1);
//Enables line bridging for all connectors
model.Constraints = DiagramConstraints.Default |
DiagramConstraints.Bridging;
ViewData["diagramModel"] = model;
return View();
}
```

Bitwise Operations

Bitwise Operations are used to manipulate the flagged enumerations [enum]. In this section, Bitwise Operations are illustrated by using node Constraints. The same is applicable while working with Node Constraints, Connector Constraints, or Port Constraints.

Add Operation

You can **add** or **enable** multiple values at a time by using **Bitwise** '\|' (OR) **operator**.

C#

```
node.Constraints = NodeConstraints.Select | NodeConstraints.Rotate;
```

In the above example, you can do both the selection and rotation.

Copyright © 2001 - 2020 Syncfusion Inc.

Remove Operation

You can **remove** or **disable** values by using **Bitwise** '&~' (XOR) **operator**.

C#

```
node.Constraints = node.Constraints & ~(NodeConstraints.Rotate);
```

In the above example, **Rotation** is disabled but other constraints are enabled.

Check Operation

You can check any value by using **Bitwise** '&' (AND) **operator**.

C#

```
if ((node.Constraints & (NodeConstraints.Rotate)) ==
(NodeConstraints.Rotate))
```

In the above example, you can check whether the rotate constraints are enabled in a Node. When Node constraints have rotate constraints, the expression returns a rotate constraint.

Scroll Settings

The Diagram can be scrolled by using the vertical and horizontal scrollbars. In addition to the scrollbars, you can use mouse wheel to scroll the Diagram.

Diagram's ScrollSettings enables you to read the current scroll status, view port size, current zoom, and zoom factor. It also allows you to scroll the Diagram programmatically.

Get current scroll status

Scroll settings allows you to read the scroll status, view port size, and current zoom factor with a set of properties. To explore those properties, see Scroll Settings

Define scroll status

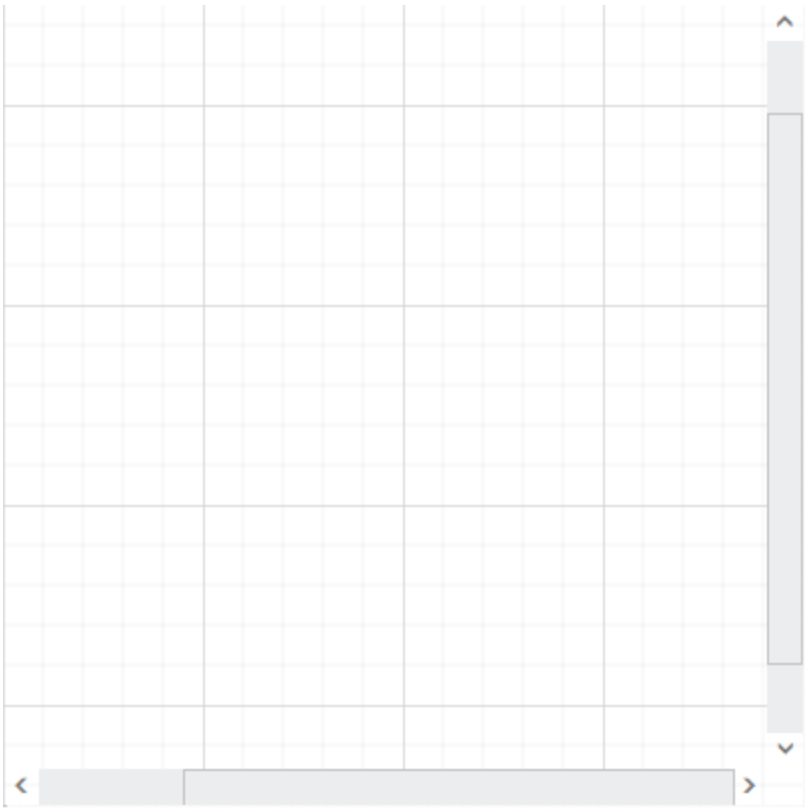
Diagram allows you to pan the Diagram before loading, so that any desired region of a large Diagram is made to view. You can programmatically pan the Diagram with the HorizontalOffset and VerticalOffset properties of scroll settings. The following code illustrates how to set pan the Diagram programmatically.

C#

```
// To Enables multiple tools
DiagramProperties Model = new DiagramProperties();
Model.Height = "400px";
Model.Width = "400px";
//Sets horizontal and vertical scroll offsets
Model.ScrollSettings.HorizontalOffset = 100;
Model.ScrollSettings.VerticalOffset = 50;
Model.ScrollSettings.ZoomFactor = 0.2;
//Sets page settings
Model.PageSettings.PageWidth = 500;
Model.PageSettings.PageHeight = 500;
```

In the example given below, the vertical scroll bar is scrolled down by 50px and horizontal scroll bar is scrolled to right by 100px.

Copyright © 2001 - 2020 Syncfusion Inc.



Update scroll status

You can programmatically change the scroll offsets at runtime by using the client side method update. The following code illustrates how to change the scroll offsets and zoom factor at runtime.

JS

```
var diagram = $("#diagram").ejDiagram("instance");
var scrollSettings = {
//Sets scroll status
horizontalOffset: 200,
verticalOffset: 200,
//Sets zoomFactor
zoomFactor: 0.5
}
//Updates scroll settings
diagram.update({ scrollSettings: scrollSettings });
```

AutoScroll

Autoscroll feature automatically scrolls the Diagram whenever the node or connector is moved beyond the boundary of the Diagram. So that, it is always visible during dragging, resizing, and multiple selection operations. Autoscroll is automatically triggered when any one of the following is done towards the edges of the Diagram.

- Node dragging, resizing
- Connection editing
- Rubber band selection
- Label dragging

Copyright © 2001 - 2020 Syncfusion Inc.

Autoscroll border

The Autoscroll border is used to specify the maximum distance between the object and Diagram edge to trigger Autoscroll. The default value is set as 15 for all sides (left, right, top, and bottom) and it can be changed by using the AutoScrollBorder property of page settings. The following code example illustrates how to set Autoscroll border.

C#

```
// To Enables multiple tools
DiagramProperties Model = new DiagramProperties();
Model.Height = "400px";
Model.Width = "400px";
// Specifies autoscroll border
Model.PageSettings.AutoScrollBorder.Left = 150;
Model.PageSettings.AutoScrollBorder.Top = 15;
Model.PageSettings.AutoScrollBorder.Right = 15;
Model.PageSettings.AutoScrollBorder.Bottom = 15;
```

Scroll limit

The scroll limit allows you to define the scrollable region of the Diagram. It includes the following options.

- Allows to scroll in all directions without any restriction.
- Allows to scroll within the Diagram content.
- Allows to scroll within the specified scrollable area.

ScrollLimit property of scroll settings helps to limit the scrolling. For the accepted values of the scrollLimit, refer to

Scroll Limit.

The following code example illustrates how to specify the scroll limit.

C#

```
// To Enables multiple tools
DiagramProperties Model = new DiagramProperties();
Model.Height = "400px";
Model.Width = "400px";
//Sets the scroll limit
Model.PageSettings.ScrollLimit = ScrollLimit.Infinity;
```

Scrollable Area

You can restrict scrolling beyond any particular rectangular area by using the ScrollableArea property of scroll settings. To restrict scrolling beyond any custom region, you have to set the ScrollLimit as "Limited". The following code example illustrates how to customize scrollable area.

C#

```
// To Enables multiple tools
DiagramProperties Model = new DiagramProperties();
Model.Height = "400px";
Model.Width = "400px";
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Sets scroll limit as limited
Model.PageSettings.ScrollLimit = ScrollLimit.Limited;
//Sets the limited scrollable area
Model.PageSettings.ScrollableArea.X = 0;
Model.PageSettings.ScrollableArea.Y = 0;
Model.PageSettings.ScrollableArea.Width = 500;
Model.PageSettings.ScrollableArea.Height = 500;
```

Context Menu

In graphical user interface (GUI), a context menu is a type of menu that appears when you perform right-click operation. Nested level of context menu items can be created.

Diagram provides some built-in context menu items and allows to define custom menu items.

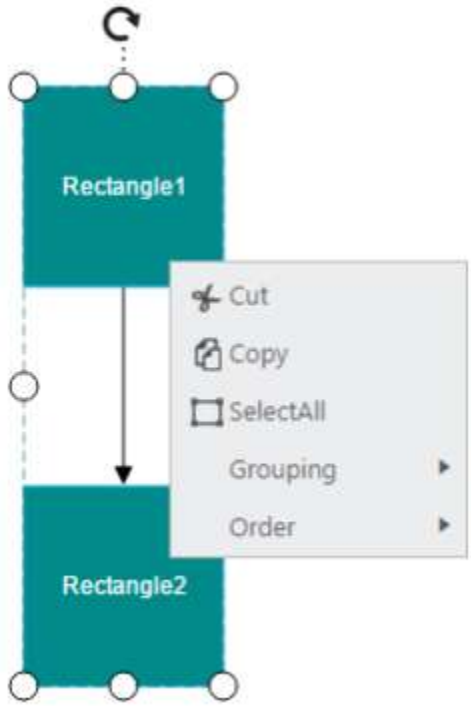
Default Context Menu

The EnableContextMenu property helps you to enable/disable the context menu. Diagram provides some default context menu items to ease the execution of some frequently used commands.

The following code illustrates how to enable the default context menu items.

C#

```
DiagramProperties model = new DiagramProperties();
//Disables the context menu
model.EnableContextMenu = false;
ViewData["Diagram"] = model;
```



Copyright © 2001 - 2020 Syncfusion Inc.

Customize Context Menu

Apart from the default context menu items, you can define some additional context menu items. Those additional items have to be defined and added to ContextMenu.Items. Sub menu items for context menu can set using ContextMenu.Items.SubItems

The following code example illustrate how to add custom context menu items.

C#

```
DiagramProperties model = new DiagramProperties();
model.Height = "600px";
model.Width = "600px";
//enable the context menu
model.EnableContextMenu = true;
model.ContextMenu = new DiagramContextMenu();
List<ContextMenuItem> SubItems = new List<ContextMenuItem>();
SubItems.Add(new ContextMenuItem() { Name = "zoomIn", Text = "ZoomIn", });
SubItems.Add(new ContextMenuItem() { Name = "zoomOut", Text = "ZoomOut", });
model.ContextMenu.Items.Add(new ContextMenuItem() { Name = "zoom", Text =
"Zoom", SubItems = SubItems });
ViewData["Diagram"] = model;
```

When you want to display only your custom context menu items, you can set true to the showCustomMenuItemsOnly property.

Icons of context menu items can be customized by overriding the default context menu item style.

The following code example illustrates how to customize the icon of context menu items.

CSS

```
#Zoom_image {
background-image: url("zoom.png");
}
#ZoomIn_image {
background-image: url("zoom-in.png");
}
#ZoomOut_image {
background-image: url("zoom-out.png");
}
```

Context Menu Events

You would be notified with events when you try to open the context menu items(contextMenuBeforeOpen) and when you click the menu items(contextMenuClick). The following code example illustrates how to define those events.

C#

```
DiagramProperties model = new DiagramProperties();
model.Height = "600px";
model.Width = "600px";
//enable the context menu
model.EnableContextMenu = true;
model.ContextMenu = new DiagramContextMenu();
List<ContextMenuItem> SubItems = new List<ContextMenuItem>();
SubItems.Add(new ContextMenuItem() { Name = "zoomIn", Text = "ZoomIn", });
SubItems.Add(new ContextMenuItem() { Name = "zoomOut", Text = "ZoomOut", });
model.ContextMenu.Items.Add(new ContextMenuItem() { Name = "zoom", Text =
"Zoom", SubItems = SubItems });
model.ContextMenuBeforeOpen = "contextMenuBeforeOpen";
model.ContextMenuClick = "contextMenuClick";
```

JS

```
function contextMenuBeforeOpen(args) {
//do your custom action here.
}
function contextMenuClick(args) {
switch (args.text) {
case "zoom":
//do your custom action here.
break;
}
}
```

How To

Bitwise Operations

Bitwise Operation

Bitwise Operations are used to manipulate the flagged enumerations [enum]. In this section, Bitwise Operations are illustrated by using Graph Constraints. The same is applicable while working with Node Constraints, Connector Constraints, or Port Constraints.

Add Operation

You can add or enable multiple values at a time by using Bitwise '|' (OR) operator.

C#

```
node.Constraints = NodeConstraints.Select | NodeConstraints.Rotate;
```

In the above example, you can do both selection and rotation.

Remove Operation

You can remove or disable values by using Bitwise '&~' (XOR) operator.

C#

```
node.Constraints = node.Constraints &~ NodeConstraints.Rotate;
```

In the above example, Rotation is disabled, but other constraints are enabled.

Copyright © 2001 - 2020 Syncfusion Inc.

Check Operation

You can check any value by using Bitwise '&' (AND) operator.

C#

```
if ((node.constraints & (NodeConstraints.Rotate)) ==
(NodeConstraints.Rotate));
```

In the above example, you can check whether the rotate constraints are enabled in a Node. When Node constraints have rotate constraints, the expression returns a rotate constraint.

Dialog

Overview

The Dialog control displays a Dialog window within a web page. The Dialog enables a message to be displayed, such as supplementary content like images and text, and an interactive content like forms.

Key Features

- Model dialog support: Displays the content in a modal dialog, disabling interaction with other items on the page
- AJAX Load: Load AJAX content in dialog content panel.
- Drag support: Drag the Dialog within the page.
- Customized dialog position: By default, the dialog is shown in the center of the container. If given a position, the dialog is displayed at the particular position.
- Keyboard navigation: Users can interact with the dialog by using the keyboard.

Getting Started

This section helps to understand the getting started of the Dialog widget with the step-by-step instructions.

Create a Dialog

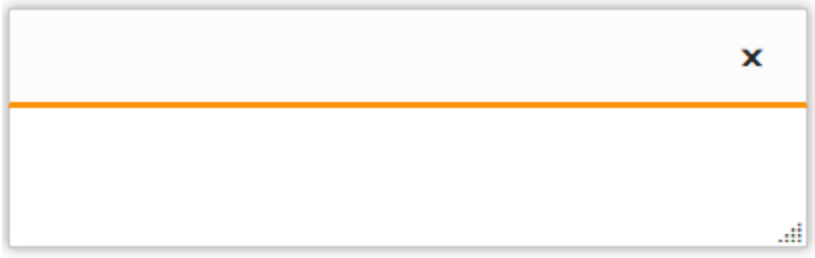
Create a MVC Project and add the necessary DLL and scripts with the help of the given MVC Getting Started documentation.

Add the following code snippet to the corresponding view page to render the Dialog.

RAZOR

```
@{
Html.EJ()
.Dialog("dialog")
.Render();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

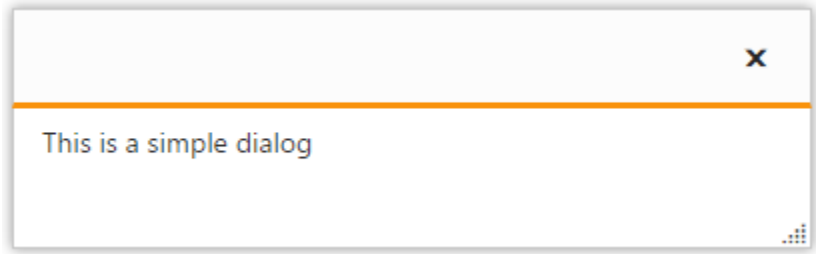


Set content

Add the contents for the dialog using ContentTemplate property as below.

RAZOR

```
@{
Html.EJ()
.Dialog("dialog")
.ContentTemplate(@<p>This is a simple dialog</p>)
.Render();
}
```

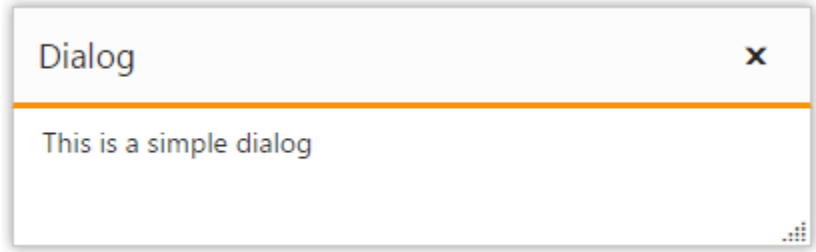


Set Title

The Dialog widget's title can be set as follows.

RAZOR

```
@{
Html.EJ()
.Dialog("dialog")
.Title("Dialog")
.ContentTemplate(@<p>This is a simple dialog</p>)
.Render();
}
```



Copyright © 2001 - 2020 Syncfusion Inc.

Open Dialog dynamically

In most cases, the Dialog widgets are needed only in dynamic actions like showing some messages on clicking a button, to provide alert, etc. So the Dialog widget provides “open” and “close” methods to open/close the dialogs dynamically.

The Dialog widget can be hidden on initialize using ShowOnInit property which should be set to false.

Button.

Refer the below example. The dialog will be opened on clicking the Button widget.

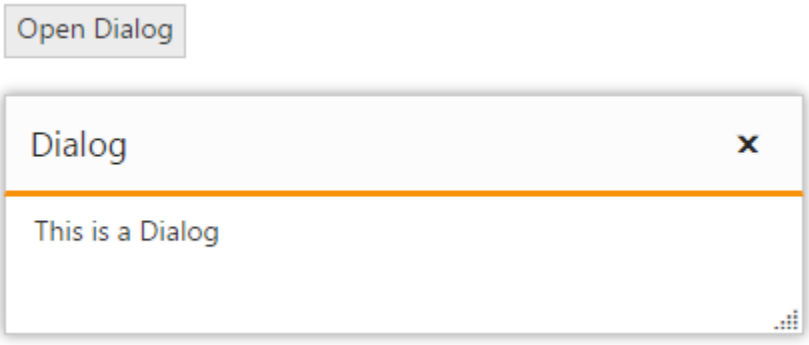
RAZOR

```
@*button widget*@
@{
Html.EJ()
.Button("button")
.Text("Open Dialog")
.Type(ButtonType.Button)
.ClientSideEvents(evt => evt.Click("openDialog"))
.Render();
}
@{
Html.EJ()
.Dialog("dialog")
.Title("Dialog")
.ShowOnInit(false)
.ContentTemplate(@<p>This is a Dialog</p>)
.Render();
}
```

Add the below script to the view page

JS

```
<script>
function openDialog() {
$("#dialog").ejDialog("open");
}
</script>
```



Copyright © 2001 - 2020 Syncfusion Inc.

Load content

By default, the content inside the ContentTemplate property element is considered as the content for the Dialog widget.

Also, we can render the Dialog widget content through the following ways.

1. Request through AJAX
2. Request iframe content
3. Request image content

This settings can be specified through ContentType property.

N> Create a view page (AjaxContent.cshtml) which contains the content of the dialog.

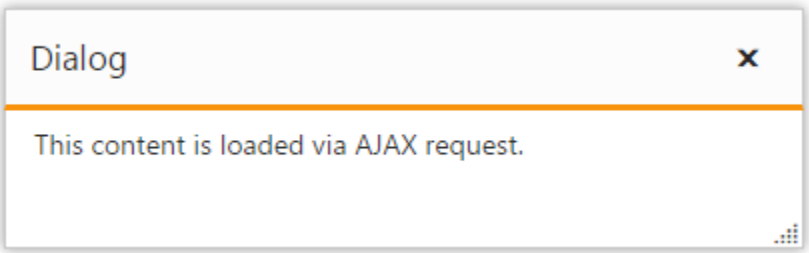
RAZOR

```
@{
Html.EJ()
.Dialog("dialog")
.Title("Dialog")
.ContentType("ajax")
.ContentUrl("AjaxContent")
.Render();
}
```

AjaxContent.cshtml

RAZOR

```
<div id="content"> This content is loaded via AJAX request. </div>
```



We can handle the AJAX request's success and failures through the events "ClientSideOnAjaxSuccess" and "ClientSideOnAjaxError" events respectively.

You can modify the previous example as below to handle the success and failure events.

RAZOR

```
@{
Html.EJ()
.Dialog("dialog")
.Title("Dialog")
.ContentType("ajax")
.ContentUrl("AjaxContent")
.ClientSideEvents(evt => evt.AjaxSuccess("onSuccess").AjaxError("onError"))
.Render();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
```

Add the below script to the view page

JS

```
<script>
function onSuccess(args) {
//handle success event
}
function onError(args) {
//handle success event
}
</script>
```

Note: The same way we can render the iframe and image content for the Dialog widget by specifying the ContentType as “iframe” and “image” respectively and also by specifying the proper location in the ContentUrl property. If you wish to dynamically change the dialog content, you can set the ContentUrl and the ContentType property through setModel on any action.

Action Buttons

The Dialog widget provides the following action buttons.

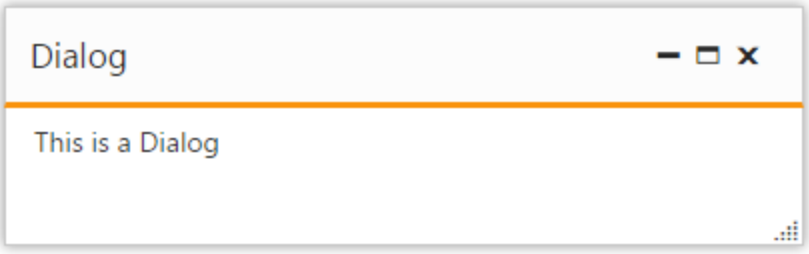
1. Close
2. Maximize
3. Minimize
4. Pin/Unpin
5. Collapse/Expand

You can display only the necessary buttons in the Dialog widget by configuring the ActionButtons property.

RAZOR

```
@{
List<string> actionButtons = new List<string>();
actionButtons.Add("close");
actionButtons.Add("maximize");
actionButtons.Add("minimize");
}
@{
Html.EJ()
.Dialog("dialog")
.Title("Dialog")
.ActionButtons(actionButtons)
.ContentTemplate(@<p>This is a Dialog</p>)
.Render();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Customizing Action Buttons

We can customize the action buttons in dialog widget.

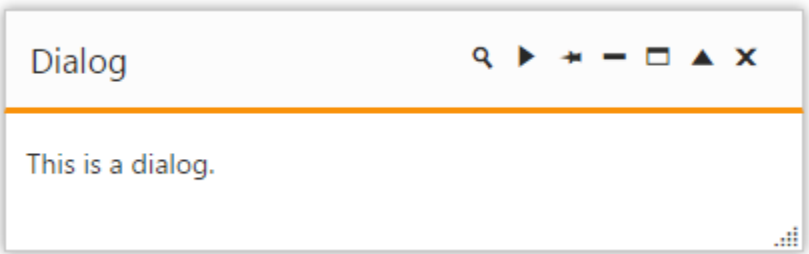
You can add new action button in the dialog widget by configuring the actionButtonClick event.

RAZOR

```
@{
List<string> actionButtons = new List<string>();
actionButtons.Add("close");
actionButtons.Add("maximize");
actionButtons.Add("minimize");
actionButtons.Add("collapsible");
actionButtons.Add("pin");
actionButtons.Add("mediaplay");
actionButtons.Add("search");
}
@{
Html.EJ()
.Dialog("dialog")
.Title("Dialog")
.ActionButtons(actionButtons)
.ClientSideEvents(event =>event.ActionButtonClick("playMedia"))
.ContentTemplate(@<p>This is a Dialog</p>)
.Render();
}
```

JAVASCRIPT

```
function playMedia(args)
{
console.log(args.buttonID);
}
```



Animation

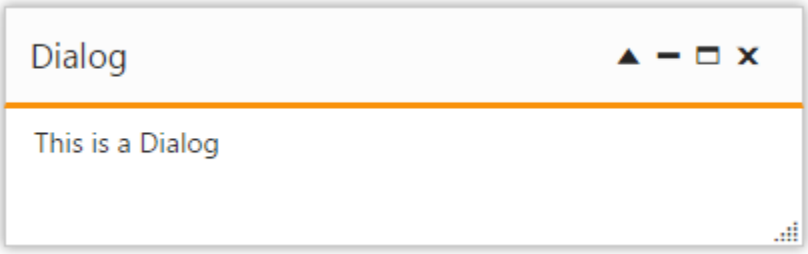
The Dialog widget can be animated while opening and closing the dialog.

Copyright © 2001 - 2020 Syncfusion Inc.

We can specify the effect and the duration for the animation. There are two types of effects (slide and fade). We can configure these settings separately for open and close dialog actions.

RAZOR

```
@{
List<string> actionButtons = new List<string>();
actionButtons.Add("close");
actionButtons.Add("maximize");
actionButtons.Add("minimize");
actionButtons.Add("collapsible");
}
@{
Html.EJ()
.Dialog("dialog")
.Title("Dialog")
.ActionButtons(actionButtons)
.Animation(animate => animate.Show(show =>
show.Duration(500).Effect("slide")).Hide(hide =>
hide.Duration(500).Effect("fade")))
.ContentTemplate(@<p>This is a Dialog</p>)
.Render();
}
```



Keyboard interaction

You can use Keyboard shortcut keys as an alternative for mouse actions to interact with the Dialog widget. The keyboard interaction will be enabled by default in the Dialog widget. It can be disabled by setting AllowKeyboardNavigation to false. Please refer the below table for details about short cut keys and its corresponding usage.

Shortcut Key	Usage
Up	Moves the dialog at upward direction.
Down	Moves the dialog at downward direction.
Left	Moves the dialog at left direction.
Right	Moves the dialog at right direction.
Ctrl Up	Reduces the dialog height.
Ctrl Down	Increases the dialog height.
Ctrl Left	Reduces the dialog width.

Copyright © 2001 - 2020 Syncfusion Inc.

Ctrl Right	Increases the dialog width.
Esc	Closes the dialog N> It will work only if closeOnEscape is set to true.

How To?

Create Multiple Dialogs

Essential Studio for ASP.NET library supports multiple Dialog widgets in the same web page with different contents and different functionalities.

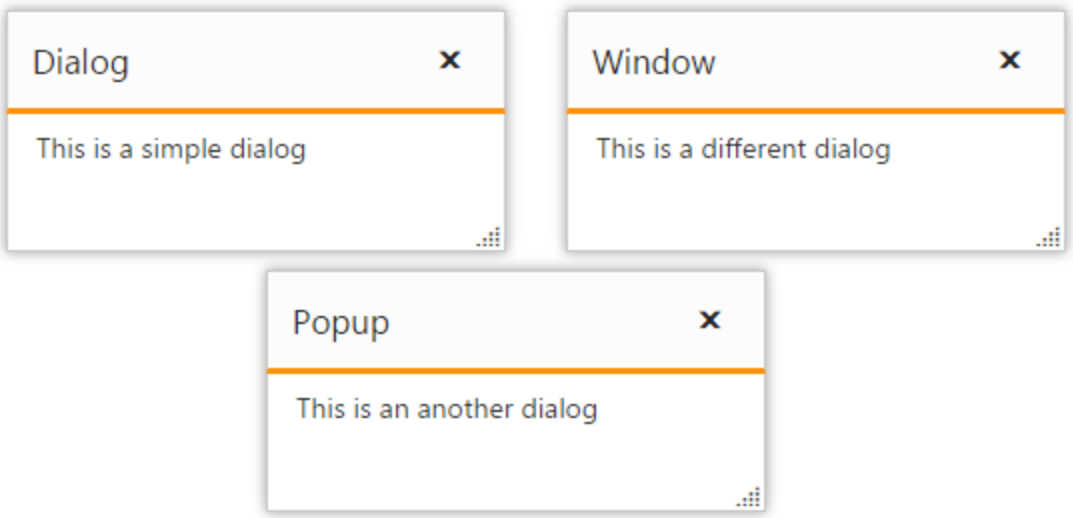
Initialize the Dialog widgets by configuring as below.

RAZOR

```
@{
Html.EJ()
.Dialog("firstDialog")
.Title("Dialog")
.Width(250)
.Position(position => position.XValue("20px").YValue("20px"))
.ContentTemplate(@<p>This is a simple dialog</p>)
.Render();
}
@{
Html.EJ()
.Dialog("secondDialog")
.Title("Window")
.Width(250)
.Position(position => position.XValue("300px").YValue("20px"))
.ContentTemplate(@<p>This is a different dialog</p>)
.Render();
}
@{
Html.EJ()
.Dialog("thirdDialog")
.Title("Popup")
.Width(250)
.Position(position => position.XValue("150px").YValue("150px"))
.ContentTemplate(@<p>This is an another dialog</p>)
.Render();
}
```

Note: If the position of the dialog is not set as above, all the three dialogs will be overlapped with each other.

Copyright © 2001 - 2020 Syncfusion Inc.



Create Nested Dialog

A Dialog widget can be nested within another Dialog widget.

Create a div element to render the child Dialog widget and use it as a content of parent Dialog widget.

RAZOR

```
@{
Html.EJ()
.Button("outerButton")
.Text("Open Dialog")
.Type(ButtonType.Button)
.ClientSideEvents(clientEvent => clientEvent.Click("openDialog"))
.Render();
}
@{
Html.EJ()
.Dialog("outerDialog")
.Title("Dialog")
.Width(500)
.Height(400)
.ShowOnInit(false)
.ContentTemplate(@<div>
@Html.EJ().Button("innerButton").Text("Open Nested
Dialog").ClientSideEvents(clientEvent =>
clientEvent.Click("openNestedDialog"))
</div>)
.Render();
}
@{
Html.EJ()
.Dialog("secondDialog")
.Title("Window")
.Width(400)
.Height(300)
.ShowOnInit(false)
.ContentTemplate(@<p>This is a nested dialog</p>)
.Render();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Add the below script to the view page

JS

```
<script>
function openDialog() {
$("#outerDialog").ejDialog("open");
}
function openNestedDialog() {
$("#secondDialog").ejDialog("open");
}
</script>
```

Create a Confirmation Dialog with Footer section

Essential JS library supports Alert Dialog widgets.

Using ShowFooter property to render Alert Dialog with Footers in Dialog widget.

Create a Dialog Widget with enabling Footer property.

RAZOR

```
<div class="control">
@Html.EJ().Button("btnOpen").Size(ButtonSize.Medium).Type(ButtonType.Button)
.Height("30").Width("150").ClientSideEvents(evt=>evt.Click("onOpen")).Text("
Click to open dialog")
@{Html.EJ().Dialog("basicDialog").Containment(".control").Title("Software
Installation Agreement").ContentTemplate(
@<div class="cnt">
Do you really leave the session?
</div>).Target(".control").ShowFooter(true).FooterTemplateId("sample").Clien
tSideEvents(evt => evt.Close("onDialogClose")).Render();
}
</div>
```

Add the following script to close and open the Dialog widget.

JAVASCRIPT

```
$("#btnOpen").hide();
function onDialogClose(args) {
$("#btnOpen").show();
}
function onOpen() {
$("#btnOpen").hide();
$("#basicDialog").ejDialog("open");
});
```

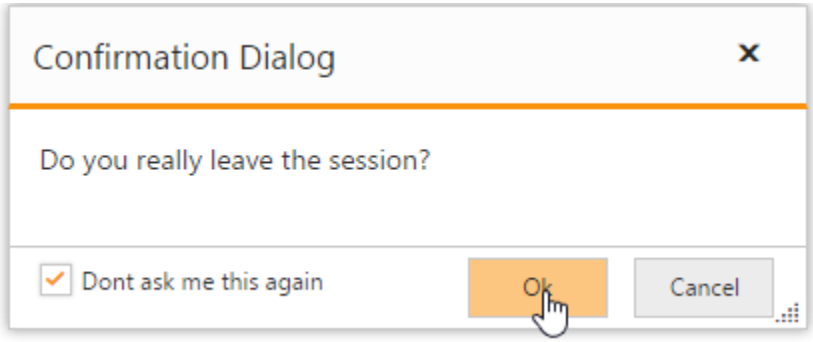
Initialize Footer in Dialog widgets by adding the script section as below.

JAVASCRIPT

```
<script id="sample" type="text/x-jsrender">
<div class="footerspan" style="float:right">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().Button("btn1").Size(ButtonSize.Mini).Height("30").Width("70").Tex
t("Ok")
@Html.EJ().Button("btn2").Size(ButtonSize.Mini).Height("30").Width("70").Tex
t("Cancel")
</div>
<div class="condition" style="float:left; margin-left:15px">
@Html.EJ().CheckBox("check1").Text("Don't ask me this again")
</div>
</script>
```



Render Dialog from Code behind

Dialog can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of Dialog properties in the controller.

C#

```
//Namespace to get the JavaScript (Dialog) component properties
using Syncfusion.JavaScript;
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class DialogController : Controller
{
public ActionResult DialogFeatures()
{
//Initializing the Dialog model
DialogProperties DialogObj = new DialogProperties();
//Initializing the content and other properties
DialogObj.ShowOnInit = true;
DialogObj.Title = "My Dialog";
DialogObj.ContentTemplate = new MvcTemplate<object>
{
RazorViewTemplate = (data) =>
{
return "This is Dialog content";
}
};
DialogObj.Width = "550";
DialogObj.IsResponsive = true;
//Passing Dialog properties using the ViewData
ViewData["DialogModel"] = DialogObj;
return View();
```

```
}
}
}
```

Binding the Dialog properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().Dialog("basicDialog",
(Syncfusion.JavaScript.Models.DialogProperties)ViewData["DialogModel"]).Rend
er();   // render the Dialog in view
}
```

DigitalGauge

DigitalGauge

Digital Gauge for Essential Studio encompasses the visualization of the segmented display of both the 7-segment numeric values and the 14-segment alphanumeric characters. It can display the following five kinds of character types:

- Seven Segment

- Fourteen Segment

- Sixteen Segment

- EightCrossEightDotMatrix

- EightCrossEightSquareMatrix

Copyright © 2001 - 2020 Syncfusion Inc.

Digital Gauge

There are several other properties available in Digital Gauge which enable you to perform various customizations such as changing the space between the characters, segment width, segment length, spacing between the segments, and other customizations.

Key Features

- Character Types – Provide support for five different character types.
- Background Image - Provide support to add images as the background for the Digital Gauge.
- Custom Font - Provide support to enable the custom font for text within the Digital Gauge.

Getting Started

- The ASP.NET MVC **Digital Gauge** provides support to display the **DigitalGauge** within your web page and allows you to customize it. This section encompasses the details on how to configure DigitalGauge. Here you will learn how to provide data for a **DigitalGauge** and display the data in the required way.
- In addition, you will learn how to customize the default **DigitalGauge** appearance according to your requirements. As a result, you will get a DigitalGauge that shows it as Digital thermometer.
- You can use this **DigitalGauge** in advertisements, decorative purposes, displaying share details in share market, game score boards, token systems, etc.

Digital Thermometer

Create a Digital Gauge

ASP.NET MVC Digital Gauge widget basically renders with flexible APIs. You can easily create the Digital Gauge widget by using the following steps.

1. First create an MVC Project and add necessary Dll's and scripts with the help of the given MVC-Getting Started Documentation.
2. Add the following code example to the corresponding view page to render Digital Gauge.

ASPX-CS

```
@(Html.EJ().DigitalGauge("digitalGauge"))
```

3. Add the following code example in the controller page.

CSHARP

```
public ActionResult Default()
{
return View();
}
```

Run the above code example and you will get a default Digital Gauge as follows.

Digital Gauge

Set Height and Width values

Basic attributes of each canvas elements are height and width. You can set the height and width of the gauge.

ASPX-CS

```
@(Html.EJ().DigitalGauge("digitalGauge")
.Height(145)
.Width(260)
)
```

Run the above code example and you will see a default gauge with the specified height and width values.

Digital Gauge with Height and Width

Set Items Property

Items have different properties to customize the Digital Gauge.

Copyright © 2001 - 2020 Syncfusion Inc.

Add Segment and Character Properties

- In the Welcome Board, the text color must be attentive in nature. You can give some segment properties such as segment spacing, segment width, segment color, segment length and segment opacity.
- Character type is to define the Digital representation of the character. The five types of character representation available are,
    1. EightCrossEightDotMatrix
    2. SevenSegment
    3. FourteenSegment
    4. SixteenSegment
    5. EightCrossEightSquareMatrix.

ASPX-CS

```
@(Html.EJ().DigitalGauge("digitalGauge")
.Height(145)
.Width(260)
.Items(item=>
{
item.SegmentSettings(seg=>seg.Length(20).Width(2))
.Value("102")
. CharacterSettings(character=>{character.Spacing(12)
.Type(CharacterType.SevenSegment);}).Add();
}))
```

Run the above code example and you will see the following output.

Digital Gauge Segment Properties

Add Background Image

- Add a

  element to set the background for the **Digital Gauge**.

- Add a style tag in the View page to add the background image for the Digital Gauge.
- Add the required properties to show the background image such as position, margin, display, etc.,

ASPX-CS

```
<div id="frameDiv">
@(Html.EJ().DigitalGauge("digitalGauge")
.Height(145)
.Width(260)
.Items(item=>
{
```

```
item.SegmentSettings(seg=>seg.Length(20).Width(2))                .Value("102")
. CharacterSettings(character=>{character.Spacing(12)
.Type(CharacterType.SevenSegment);}).Add();
}))
</div>
<style>
#frameDiv {
align : center;
position : relative;
margin : 0px auto;
display :table;
background-image :url("script/frame.png");
background-repeat :no-repeat;
}
</style>
```

Run the above code example and you will see the following output.

Digital Gauge Background Image

Add Location

The Location property is used to position the digital letters inside the canvas element.

ASPX-CS

```
@(Html.EJ().DigitalGauge("DigitalGauge1").Height(145).Width(260).Items(item=
>
{
item.SegmentSettings(seg=>seg.Length(20).Width(2))
.Value("102").CharacterSettings(character=>{character.Spacing(12).Type(Chara
cterType.SevenSegment);})
.Position(loc=>loc.X(15).Y(40)).Add();
}))
```

Run the above code example and you will see the following output.

Digital Gauge with Segment Location

Add Items Collection

You can further add the Items Collection to display the temperature value like Digital Thermometer.

ASPX-CS

```
@(Html.EJ().DigitalGauge("digitalGauge").Height(145).Width(260).Items(item=>
{
item.SegmentSettings(seg=>seg.Length(20).Width(2))
.Value("102").CharacterSettings(character=>{character.Spacing(12).Type(Chara
cterType.SevenSegment);})
.Position(loc=>loc.X(15).Y(40)).Add();
item.SegmentSettings(seg=>seg.Length(5).Width(2))
.Value("0").CharacterSettings(character=>{character.Spacing(12).Type(Charact
erType.SevenSegment);})
.Position(loc => loc.X(85).Y(28)).Add();
item.SegmentSettings(seg=>seg.Length(20).Width(2))
.Value("F").CharacterSettings(character=>{character.Spacing(12).Type(Charact
erType.SevenSegment);})
.Position(loc => loc.X(170).Y(40)).Add();
item.SegmentSettings(seg=>seg.Length(9).Width(1).Color("#F5b43f"))
.Value("38").CharacterSettings(character=>{character.Spacing(12).Type(Charac
terType.SevenSegment);})
.Position(loc => loc.X(70).Y(90)).Add();
item.SegmentSettings(seg=>seg.Length(3).Width(1).Color("#F5b43f"))
.Value("0").CharacterSettings(character=>{character.Spacing(12).Type(Charact
erType.SevenSegment);})
.Position(loc => loc.X(90).Y(80)).Add();
item.SegmentSettings(seg=>seg.Length(9).Width(1).Color("#F5b43f"))
.Value("c").CharacterSettings(character=>{character.Spacing(12).Type(Charact
erType.SevenSegment);})
.Position(loc => loc.X(120).Y(90)).Add();
}))
```

Run the above code example and you will see the following output.

Digital Gauge with Item Collection

Basic Settings

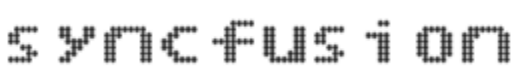
Height and Width Customization

The basic customization for any control is to set the dimension. Here dimension refers to two major attributes such as **height** and **width**. The height and width assigned in the control will render the canvas element in the given size. The code example to set height and width is as follow.

ASPX-CS

```
@(Html.EJ().DigitalGauge("DigitalGauge1")
@*For setting height of the canvas element. *@
.Height(200)
// For setting width of the canvas element.
.Width(500)
// For setting text
.Value("syncfusion"))
```

Execute the above code examples to render the **DigitalGauge** as follows.



Digital Gauge control with height and width values

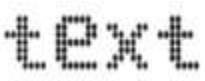
Responsive Layout

- For any display devices, the control will be rendered based on the space available in that device. For this purpose, **resizing** property is given to the **Digital Gauge** control. The **Digital Gauge** renders with a given value.
- When the browser resize the canvas element checks the dimension with its parent element. If there are any changes in parent dimension, **Gauge** control will changes the dimension based on its parent element change. This feature is enabled by using the property IsResponsive.

ASPX-CS

```
@* For Digital Gauge rendering *@
@(Html.EJ().DigitalGauge("DigitalGauge1")
// For enabling responsive.
.IsResponsive(true))
```

Execute the above code examples to render the DigitalGauge as follows.



Digital Gauge control with Responsible layout

Themes

Themes give the good appearance to the control. There are two types of Themes available for **DigitalGauge** as follows

- flatlight
- flatdark

ASPX-CS

```
@* For Digital Gauge rendering *@
@(Html.EJ().DigitalGauge("DigitalGauge1")
// For setting theme for digital gauge.
.Themes(Themes.FlatDark)
// For setting text
.Value("LOS ANGELS 40 KM"))
```

Execute the above code examples to render the DigitalGauge as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Digital Gauge control with flatdark theme

Setting Text for Digital Gauge

Digital Gauge is mainly used to display the text in the digital format. We can define the value for the text with the help of value property. It is string data type. The Code example for setting the text is as follows.

ASPX-CS

```
@* For Digital Gauge rendering  *@
@(Html.EJ().DigitalGauge("DigitalGauge1")
// For setting text
.Value("GO SLOW"))
```

Execute the above code examples to render the DigitalGauge as follows.

Digital Gauge control with text as "GO SLOW"

Frames

Inner and Outer Customization

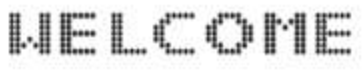
Frames are space that enclose the **Digital Gauge**. The inner width of the Frame is the distance between the canvas element and the frame. The outer width is the distance from the frame. The code example to set frame's innerWidth and outerWidth is as follow.

ASPX-CS

```
@*For Digital Gauge rendering *@
@(Html.EJ().DigitalGauge("DigitalGauge1")
// For setting text
.Value("WELCOME").Frame(fr=>fr
// For setting frame inner width
.InnerWidth(6)
// For setting outer width
.OuterWidth(10)))
```

Execute the above code examples to render the **DigitalGauge** as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Digital Gauge control with frame inner and outer width

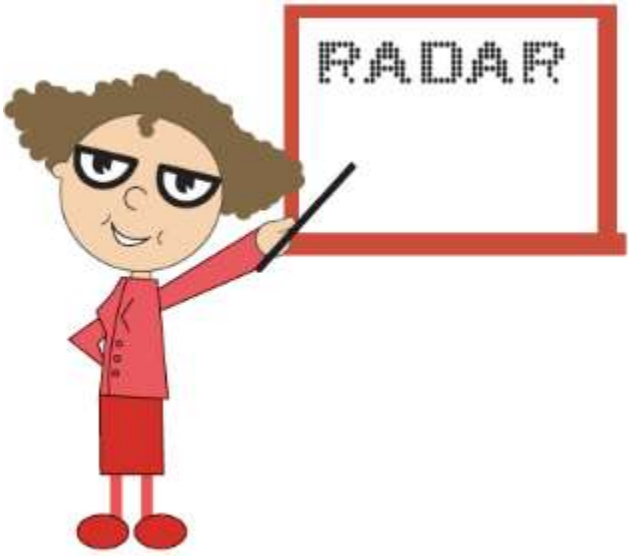
Setting Background Image

For a better appearance, you can set the background image for the **Digital Gauge** using the property backgroundImageUrl.

ASPX-CS

```
@*For Digital Gauge rendering *@
@(Html.EJ().DigitalGauge("DigitalGauge1")
// For setting text
.Frame(fr=>fr
// For setting frame background image
.BackgroundImageUrl("../Content/images/gauge/board3.jpg"))
.Items(it=> { it.Value("RADAR")
// For setting segment color
.SegmentSettings(cs=> cs.Color("Black"))
.Position(position=>position.X(80).Y(10)).Add();}))
```

Execute the above code examples to render the **DigitalGauge** as follows.



Digital Gauge control with frame background image

Digital Elements

Text Customization

- The attribute value refers the text displayed in the **Digital Gauge**. This text is applicable only for that item instead of all items. Text color is changed by using the property textColor.
- It is possible to align the text inside the **Digital Gauge** control by using the property textAlign. Two possible values for text align are as follows

Copyright © 2001 - 2020 Syncfusion Inc.

1. left
2. right

ASPX-CS

```
@* For Digital Gauge rendering *@
@(Html.EJ().DigitalGauge("DigitalGauge1").Items(it=>{it
// For Setting the text value
.Value("STOP")
// For aligning the text
.TextAlign(TextAlign.Right).Add();
}))
```

Execute the above code examples to render the **DigitalGauge** as follows.

Digital Gauge control with text customization

Segment Settings

Appearance

- **Digital Gauge** consists of several digital segments. Segment is customized with some properties. Color of the segment is set by using color property. Color is either given as string or hexadecimal value.
- You can add gradient effects to the segments with the help of gradient attribute. The opacity of the segment is also adjustable. The space between two segments are adjusted with spacing property.

ASPX-CS

```
@* For Digital Gauge rendering *@
@(Html.EJ().DigitalGauge("DigitalGauge1")
.Width(800)
.Value("GO AHEAD")
.Items(it=>
{ it.SegmentSettings(ss =>
// For setting segment opacity
ss.Opacity(0.1)
// For setting segment spacing
.Spacing(4)
// For setting segment color
.Color("Green")).Add();   }))
```

Execute the above code examples to render the **DigitalGauge** as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Digital Gauge control with segment settings

Dimension Modification

- **Digital Gauge** consists of several digital segments. Segment is customized with some properties. Color of the segment is set by using color property. Color is either given as string or hexadecimal value.
- You can add gradient effects to the segments with the help of gradient attribute. The opacity of the segment is also adjustable. The space between two segments are adjusted with spacing property.

ASPX-CS

```
@* For Digital Gauge rendering *@
@(Html.EJ().DigitalGauge("DigitalGauge1")
.Width(800)
.Value("WELCOME")
.Items(it=>
{ it.SegmentSettings(ss =>
// For setting segment opacity
ss.Length(3)
// For setting segment color
.Width(3)).Add();
}))
```

Execute the above code examples to render the **DigitalGauge** as follows.

Digital Gauge control with segment dimension

Character Settings

Appearance

The opacity of the character is adjustable with the help of opacity property. The space between two characters are adjusted with spacing property as like in the segment settings.

ASPX-CS

```
@* For Digital Gauge rendering *@
@(Html.EJ().DigitalGauge("DigitalGauge1")
.Width(800)
.Value("Syncfusion")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Items(it=>
{ it.CharacterSettings(cs => cs
// For setting character opacity
.Opacity(0.3)
// For setting character spacing
.Spacing(3)).Add();
}))
```

Execute the above code examples to render the **DigitalGauge** as follows.

Digital Gauge control with character setting

Count and Type

- The number of text to be displayed can be limited by the attribute called count. In **Digital Gauge** five different types of characters are supported. They are as follows,
    1. EightCrossEightDotMatrix
    2. SevenSegment
    3. FourteenSegment
    4. SixteenSegment
    5. EightCrossEightSquareMatrix.

ASPX-CS

```
@(Html.EJ().DigitalGauge("DigitalGauge1")
.Width(800)
.Value("123456789")
.Items(it=>
{ it.CharacterSettings(cs => cs
// For setting character count
.Count(10)
// For setting character spacing
.Spacing(10)
// For setting character type
.Type(CharacterType.SevenSegment))
.SegmentSettings(ss=>
// For setting segment length
ss.Length(8)
// For setting segment width
.Width(1)).Add();
}))
```

Execute the above code examples to render the **DigitalGauge** as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Digital Gauge control with character type as seven segment

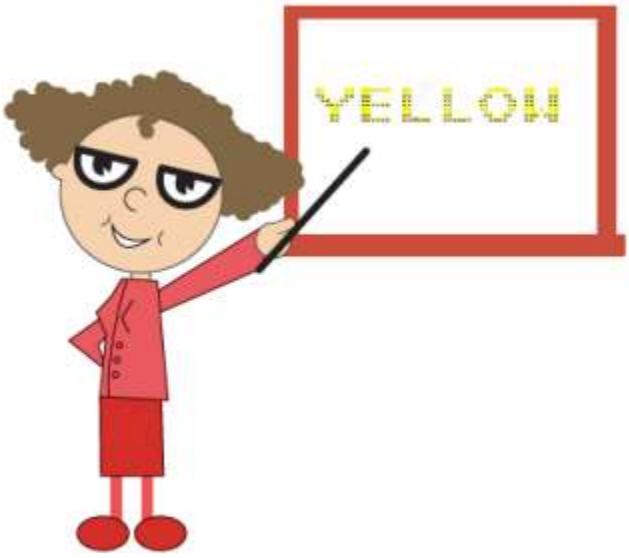
Text Positioning

The text in the **DigitalGauge** is positioned with position object. This object contains two attributes such as x and y. The x variable positions the text in the horizontal axis and the y variable positions the text in the vertical axis.

ASPX-CS

```
@* For Digital Gauge rendering *@
@(Html.EJ().DigitalGauge("DigitalGauge1")
// For setting Width and Height
.Width(800).Height(300)
.Frame(fr=>fr
// For setting frame background image
.BackgroundImageUrl("../Content/images/gauge/Board1.jpg"))
.Items(it=> { it.Value("YELLOW")
// For setting segment color
.SegmentSettings(cs=>cs.Color("Yellow"))
.Position(position=>position
// For setting horizontal position
.X(80)
// For setting Vertical position
.Y(10)).Add();}))
```

Execute the above code examples to render the **DigitalGauge** as follows.



Digital Gauge control with position text based on the background image

Copyright © 2001 - 2020 Syncfusion Inc.

Shadow Effects

- You can add the shadow effects for text using following properties.
- You can enable/disable the blurring effect for the shadows of the text using shadow blur property.
- You can specify the color of the text shadow using shadow color property.
- You can set the x-offset value for the shadow of the text, indicating the location where it needs to be displayed.
- You can set the y-offset value for the shadow of the text, indicating the location where it needs to be displayed.

ASPX-CS

```
@* For Digital Gauge rendering*@
@(Html.EJ().DigitalGauge("DigitalGauge1")
// For setting Width and Height
.Width(800)
.Items(it=> { it.Value("WELCOME")
// For setting Shadow blur
.ShadowBlur(20)
// For setting Shadow color  .ShadowColor("Yellow")
// For setting Shadow horizontal offset     .ShadowOffsetX(15)
// For setting Shadow vertical offset .ShadowOffsetY(15)
// For setting segment length and width
.SegmentSettings(cs=>
cs.Length(3) .Width(3)).Add();}))
```

Execute the above code examples to render the **DigitalGauge** as follows.

Digital Gauge control with shadow option

Font Customization

You can customize the **font** of the text as per your requirement. To customize the font, you have to set enableCustomFont. Following font customization options are available.

Font-family- used to set the font-family of the text.

Font-style- used to set the font-style of the text.

Font-size- used to set the font-size of the text.

ASPX-CS

```
@* For Digital Gauge rendering *@
@(Html.EJ().DigitalGauge("DigitalGauge1")
.Width(800)
.Value("Syncfusion")
.Items(it=>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{ it.CharacterSettings(cs => cs
// For setting character opacity
.EnableCustomFont(true)
// For setting character spacing
.Font(ft=>ft.FontFamily("Arial").FontStyle(FontStyle.Bold).Size("18px"))
).Add();
}))
```

Multiple Items

The text in the **Digital Gauge** is positioned with position object. This object contains two attributes such as x and y. The x variable positions the text in the horizontal axis and y variable positions the text in the vertical axis.

ASPX-CS

```
@(Html.EJ().DigitalGauge("DigitalGauge1")
// For setting Width and Height
.Width(1300).Height(300)
.Frame(fr=>fr.BackgroundImageUrl("../Content/images/gauge/Board1.jpg"))
.Items(it =>
{
// For setting Item1
it.Value("YELLOW").SegmentSettings(cs =>
cs.Color("Yellow")).Position(position=>position.X(80).Y(0)).Add();
// For setting Item2
it.Value("RED").SegmentSettings(cs =>
cs.Color("Red")).Position(position => position.X(80).Y(20)).Add();
// For setting Item3
it.Value("GREEN").SegmentSettings(cs =>
cs.Color("Green")).Position(pos => pos.X(80).Y(40)).Add();
}))
```

Execute the above code example to render the **DigitalGauge** as follows.

Digital Gauge control with multiple items

Copyright © 2001 - 2020 Syncfusion Inc.

Exporting the Digital Gauge

Digital Gauge has an exporting feature where **Gauge** control is converted into image format and then exported to client-side. The method API exportImage exports the Digital Gauge. It has two arguments such as **filename** and **file format**. For exporting, you can refer the following code example.

ASPX-CS

```
// For Digital Gauge rendering
@(Html.EJ().DigitalGauge("DigitalGauge1")
// For setting text
.Value("Syncfusion"))
<script>
$("#DigitalGauge1").ejDigitalGauge("exportImage", "Digital", "PNG");
<script/>
```

Execute the above code examples to render the **DigitalGauge** as follows.

Digital Gauge control with Export functionality

MVVM

AngularJS

Digital Gauge contains AngularJS support. It is possible to add object as well as array object in the **Digital Gauge**. The two way binding support is given to the value for displaying the text.

Rendering the Digital Gauge

HTML

```
**ej-DigitalGauge** is the control tag, where ej is tag prefix and
**DigitalGauge** is the control name.**Digital Gauge** is rendered with the
following code example.
<div ng-app="syncApp">
<div ng-controller="DigitalGauge">
<ej-DigitalGauge id="digitalCore" e-height="500" e-load="loadGaugeTheme">
</ej-DigitalGauge>
</div>
</div>
<script type="text/javascript">
<!—binding the value to the scope variables in application controller-->
```

```
angular.module('syncApp', ['ejangular'])
.controller('DigitalGauge', function ($scope) {
$scope.value = "text";
});
</script>
```

Execute the above code to render the following output.

Default Digital Gauge in AngularJS

Adding the Digital Gauge Items

Digital Gauge is rendered with the following code example. You can extend the Object in the array collection such as, position, characterSetting, segmentSetting, etc. with hyphen in the same tag.

Example: e-position-x.

HTML

```
<!--To Render the Digital gauge-->
<ej-DigitalGauge id="digitalCore">
<!--Adding Item collection to the digital gauge-->
<e-items>
<e-item e-segmentSettings-width="1" e-segmentSettings-spacing="0"
e-value="Syncfusion" e-characterSetting-opacity="0.8"
e-position-x="52" e-position-y="52">
</e-item>
</e-items>
</ej-DigitalGauge>
```

Finally while running the above codes, the following output will be rendered.

Digital Gauge Rendered in AngularJS

Two Way Binding

Digital Gauge supports the two way biding for the property value as mentioned earlier. Following code example explains how to achieve the two way binding to the **Digital Gauge**.

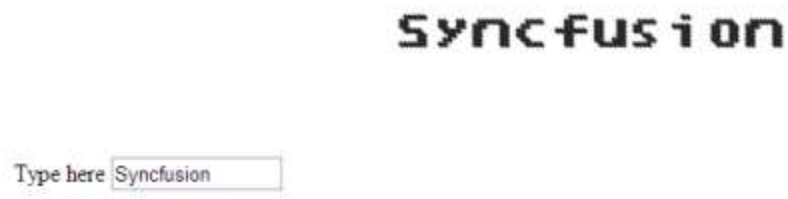
HTML

```
<div ng-app="syncApp">
<div ng-controller="DigitalGauge">
<ej-DigitalGauge id="digitalCore" e-height="200" e-load="loadGaugeTheme">
<e-items>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<e-item e-segmentSettings-width="1" e-segmentSettings-spacing="0"
e-characterSetting-opacity="0.8" e-position-x="52"
e-value="value" e-position-y="52">
</e-item>
</e-items>
</ej-DigitalGauge>
Type here <input type="text" id="txtValue" ng-model="nvalue"
Style="width:110px"/>
</div>
</div>
<script type="text/javascript">
<!—binding the value to the scope variables in application controller-->
angular.module('syncApp', ['ejangular'])
.controller('DigitalGauge', function ($scope) {
$scope.value = "Syncfusion";
});
</script>
```

Execute the above code to render the following output.



Digital Gauge with two way binding in AngularJS

KnockoutJS Binding

- KnockoutJS support allows you to bind the HTML elements against any of the available data models.Two types of KnockoutJS binding is supported as of AngularJS,
    1. one-way binding
    2. two-way binding
- **One way binding** refers to the process of applying observable values to all the available properties of the **Digital Gauge** control, but the changes made in it does not reflect and trigger in turn to the observable collection. This kind of binding applies to all the properties of the Digital Gauge control.
- **Two-way binding** supports both the processes – it applies the observable values to the **Digital Gauge** properties as well as the changes made in it is also reflected back and triggered within the observable collections. Only **Value** of the schedule properties support two-way binding.

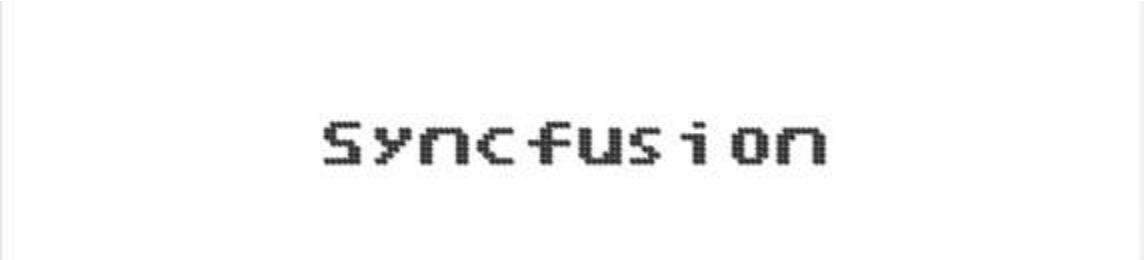
ASPX-CS

```
<div id="digitalCore"
data-bind="ejDigitalGauge:
{
value: sampleValue,
}">
</div>
<script type="text/javascript">
$(function ()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
window.viewModel =
{
sampleValue: ko.observable("syncfusion"),
};
$(function ()
{
ko.applyBindings(viewModel);
});
});
</script>
```

Execute the above code to render the following output.



Digital Gauge with KnockoutJS binding

Methods

destroy()

To destroy the digital gauge

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1"))
```

JS

```
var gauge = $("#Gauge1").data("ejDigitalGauge");
gauge.destroy();
```

exportImage(fileName, fileType)

To export Digital Gauge as Image

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1"))
```

JS

```
var gauge = $("#Gauge1").data("ejDigitalGauge");
gauge.exportImage();
```

getPosition(itemIndex)

Gets the location of an item that is displayed on the gauge.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().DigitalGauge("Gauge1"))
```

JS

```
var gauge = $("#Gauge1").data("ejDigitalGauge");
gauge.getPosition();
```

getValue(itemIndex)

ClientSideMethod getValue Gets the value of an item that is displayed on the gauge

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1"))
```

JS

```
var gauge = $("#Gauge1").data("ejDigitalGauge");
gauge.getValue();
```

refresh()

Refresh the digital gauge widget

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1"))
```

JS

```
var gauge = $("#Gauge1").data("ejDigitalGauge");
gauge.refresh();
```

setPosition(itemIndex, value)

ClientSideMethod Set Position Sets the location of an item to be displayed in the gauge

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1"))
```

JS

```
var gauge = $("#Gauge1").data("ejDigitalGauge");
gauge.setPosition();
```

setValue(itemIndex, value)

ClientSideMethod SetValue Sets the value of an item to be displayed in the gauge.

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1"))
```

JS

Copyright © 2001 - 2020 Syncfusion Inc.

```
var gauge = $("#Gauge1").data("ejDigitalGauge");
gauge.setValue();
```

Events

Init

Triggers when the gauge is initialized.

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1")
.Init("init")
)
```

JS

```
function init(){
// Do Something
}
```

ItemRendering

Triggers when the gauge item rendering.

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1")
.ItemRendering("itemRendering")
)
```

JS

```
function itemRendering(){
// Do Something
}
```

Load

Triggers when the gauge is start to load.

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1")
.Load("load")
)
```

JS

```
function load(){
// Do Something
}
```

RenderComplete

Triggers when the gauge render is completed.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1")
.RenderComplete("renderComplete")
)
```

JS

```
function renderComplete(){
// Do Something
}
```

Click

Click event triggers on clicking the gauges.

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1")
.Click("click")
)
```

JS

```
function click(){
// Do Something
}
```

DoubleClick

The DoubleClick event is triggered when double clicking the gauges.

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1")
.DoubleClick("doubleClick")
)
```

JS

```
function doubleClick(){
// Do Something
}
```

RightClick

The RightClick event is triggered when right clicking the gauges.

ASPX-CS

```
@(Html.EJ().DigitalGauge("Gauge1")
.RightClick("rightClick")
)
```

JS

Copyright © 2001 - 2020 Syncfusion Inc.

```
function rightClick(){
// Do Something
}
```

DropDownList

DropDownList

The DropDownList control displays a single column list of items which enables you to select single or multiple items from the list. By default, there will be no selection made in the control and the user have to navigate through the items using mouse or keyboard actions to select an item.

Key Features

- **DataSources** - Binds the DropDownList control with a list, database table or remote data service. Supports various client-side and remote data sources such as JSON, RESTful services, OData services, WCF services and much more.
- **Sorting** - Sorts in both ascending and descending orders.
- **Grouping** - Categorizes the list Items.
- **Searching** - Provides both incremental and Filter Search.
- **Virtual scrolling** - Fetches the data from remote on demand.
- **PopupList Resize** - Resizes the popup list in the needed dimensions dynamically.
- **Template** - Designs own layout of list items.
- **Cascading** - Cascades the data sources with multiple DropDownList.
- **State persistence** - Persistent state of properties on page refresh.
- **Responsive** - Suits responsive layouts.
- **Validation** - Built-in jQuery validation.
- **Localization** - Supports localization to different cultures.
- **Selection** - Supports single or multi selection with the DropDownList and display the text in two modes, delimiter and visual mode.
- **Accessibility** - Supports keyboard and ARIA accessibility.

Getting Started

Creating your first DropDownList in MVC application

1. Create an MVC Project and add necessary assemblies, scripts and CSS files given in MVC-Getting Started Documentation.
2. Add DropDownList control using the helper from EJ namespace.

HTML

```
@Html.EJ().DropDownList("DropDownList1")
```

3. Execute the code and get a empty DropDownList control as below

Copyright © 2001 - 2020 Syncfusion Inc.

Populating data

The DropDownList can be bounded to any local list data and remote data services. You can use DataManager component to serve data from the data services based on the query provided.You can bind data locally from controller also. To render the DropDownList items, map the DropDownListFields with corresponding Fields

HTML

```
@Html.EJ().DropDownList("customersList").Datasource((IEnumerable<Customers>)
ViewBag.datasource).DropDownListFields(df =>
df.ID("id").Text("text").Value("text"))
```

C#

```
List<Customers> customer = new List<Customers>();
public ActionResult Index()
{
customer.Add(new Customers { id = "1", text = "ALFKI" });
customer.Add(new Customers { id = "2", text = "ANATR" });
customer.Add(new Customers { id = "3", text = "ANTON" });
customer.Add(new Customers { id = "4", text = "AROUT" });
customer.Add(new Customers { id = "5", text = "BERGS" });
customer.Add(new Customers { id = "6", text = "BLAUS" });
ViewBag.datasource = customer;
return View();
}
public class Customers
{
public string id { get; set; }
public string text { get; set; }
}
```

Execute the code and to get a DropDownList control with data bound from controller

Setting Dimensions

DropDownList dimensions can be set using Width and Height Properties.

HTML

```
@Html.EJ().DropDownList("customersList").Datasource((IEnumerable<Customers>)
ViewBag.datasource).DropDownListFields(df =>
df.ID("id").Text("text").Value("text")).Width("300px").Height("50px")
```

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
List<Customers> customer = new List<Customers>();
public ActionResult Index()
{
customer.Add(new Customers { id = "1", text = "ALFKI" });
customer.Add(new Customers { id = "2", text = "ANATR" });
customer.Add(new Customers { id = "3", text = "ANTON" });
customer.Add(new Customers { id = "4", text = "AROUT" });
customer.Add(new Customers { id = "5", text = "BERGS" });
customer.Add(new Customers { id = "6", text = "BLAUS" });
ViewBag.datasource = customer;
return View();
}
public class Customers
{
public string id { get; set; }
public string text { get; set; }
}
```

Setting dimensions to Popup list

PopupWidth and PopupHeight can be used to create a fixed size popup list.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).Height("50px").Width("500px").PopupHeight("2
00px").PopupWidth("300px")
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "List Item 1" });
DropdownData.Add(new Data { Value = "item2", Text = "List Item 2" });
DropdownData.Add(new Data { Value = "item3", Text = "List Item 3" });
DropdownData.Add(new Data { Value = "item4", Text = "List Item 4" });
DropdownData.Add(new Data { Value = "item5", Text = "List Item 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Setting and Getting Value

You can select single or multiple values from DropDownList control. To assign a value initially to the DropDownList, you can use Value property.

HTML

```
@model MVCApplication.Controllers.HomeController
@using (Html.BeginForm("DropdownlistFeatures", "Dropdownlist",
FormMethod.Post, null))
{
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).Height("50px").Width("500px").PopupHeight("2
00px").PopupWidth("300px").Value("item3")
<input type="submit" value="Get Value" />
}
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "List Item 1" });
DropdownData.Add(new Data { Value = "item2", Text = "List Item 2" });
DropdownData.Add(new Data { Value = "item3", Text = "List Item 3" });
DropdownData.Add(new Data { Value = "item4", Text = "List Item 4" });
DropdownData.Add(new Data { Value = "item5", Text = "List Item 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
[HttpPost]
public ActionResult DropdownlistFeatures(string DropDownList1)
{
//DropDownList1 is ID of DropDownList used in this example. You can get the
selected items value in controller using the ID
string DropDownValue = DropDownList1;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

DropDownList Dependencies

The external script dependencies of the DropDownList control are,

- jQuery 1.7.1 and later versions.
- jQuery.easing - to support the animation effects.

The internal script dependency ej.web.all.js is a bundle of all Syncfusion ASP.NET MVC controls. If you use ej.web.all.js in your application, you can leave this section or else you can try to render

Copyright © 2001 - 2020 Syncfusion Inc.

DropDownList in your application using ej.dropdownlist.min.js file. You can refer the following frameworks and controls in your project.

FileÂ	Description / Usage
ej.core.min.js	Must be referred always before using all the JS controls.
ej.data.min.js	Used to handle data operation and should be used while binding data to JS controls.
ej.dropdownlist.min.js	The dropdownlistâ€™s main file
ej.scroller.min.js	Should be referred when using scrolling in DropDownList.
ej.draggable.min.js	Should be referred when using popup resize functionality in DropDownList.

Rendering Mode

DropDownList control can be created using UL-LI element.

By default DropDownList control is rendered using DropDownList helper to which you can pass popup items using Datasource and DropDownListFields property.

Target Rendering

You can bind the predefined set of UL-LI elements to generate the list of popup items. These items can be customized by adding any images, div elements, radio buttons, text boxes etc.

Create a div with UL-LI elements and assign that div id into TargetID property for rendering the DropDownList control.

HTML

```
@Html.EJ().DropDownList("DropDownList1").TargetID("mail")
<div id="mail">
<ul>
<li>
<div class="mailtools categorize"></div>
Categorize and Move</li>
<li>
<div class="mailtools done"></div>
Done</li>
<li>
<div class="mailtools flag"></div>
Flag & Move</li>
<li>
<div class="mailtools forward"></div>
Forward</li>
<li>
<div class="mailtools movetofolder"></div>
Move to Folder</li>
<li>
<div class="mailtools newmail"></div>
New E-mail</li>
<li>
<div class="mailtools meeting"></div>
New Meeting</li>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<li>
<div class="mailtools reply"></div>
Reply & Delete</li>
</ul>
</div>
```

CSS

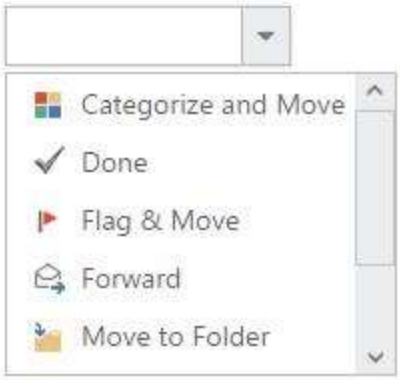
```
.mailtools {
display: block;
background-image: url('iconsapps.png');
height: 25px;
width: 25px;
background-position: center center;
background-repeat: no-repeat;
}
.mailtools.done {
background-position: 0 0;
}
.mailtools.movetofolder {
background-position: 0 -22px;
}
.mailtools.categorize {
background-position: 0 -46px;
}
.mailtools.flag {
background-position: 0 -70px;
}
.mailtools.forward {
background-position: 0 -94px;
}
.mailtools.newmail {
background-position: 0 -116px;
}
.mailtools.reply {
background-position: 0 -140px;
}
.mailtools.meeting {
background-position: 0 -164px;
}
```

JS

```
$(function() {
$('#dropdown1').ejDropDownList({
targetID: "mail"
});
});
```

Note: Images for this sample are available in (installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\samples\web\themes\images

Copyright © 2001 - 2020 Syncfusion Inc.



Note: Any EJ control can be embedded in the target element but the default action of that control should be prevented in order to create custom actions. To show a sample, integration with TreeView control is demonstrated here

Data Binding

To populate data in the DropDownList control, define DataSource property with associated fields. You can bind any list data and other remote services in the DropDownList.

Fields

The following properties provides you a way to bind either local or remote data to the DropDownList control.

Properties	Description
DataSource	The data source contains the list of data for generating the popup listÂ items.
Query	It specifies the query to retrieve the data from the online server.
Fields	It specifies the mapping fields for the data items of the DropDownList control.
ID	It specifies the ID of the tag.
Text	It specifies the text content of the tag.
Value	It specifies the value of the tag.
Category	It is used to categorize the items based on a specific field. The value mapped to this field must be able to group the popup items.
ImageUrl	It defines the image location.
ImageAttributes	It defines the image attributes such as height, width, styles, etc.
SpriteCssClass	It defines the sprite CSS for the image tag to add a prefix icon to all popup items.
HtmlAttributes	It defines the HTML attributes such as class and styles for an item.
Selected	This field defines the tag value to be selected initially. Corresponding field mapped has Boolean values to select the list items on control creation. The data with valueÂ trueÂ in this field is selected automatically when the control is initialized with checkbox.

Copyright © 2001 - 2020 Syncfusion Inc.

TableName	It defines the table name for the tag value or displays text while rendering remote data.

Local Data

Define a List data and initialize the control with DataSource property. Specify the column names in the Fields property.

Note: The columns are bounded automatically when the fields are specified with the default names like id, text, etc...

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Employee>)V
iewData["LocalDataSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Country").Category("Role").ImageUrl("Image").ImageAtt
ributes("ImageAttr"))
```

CSS

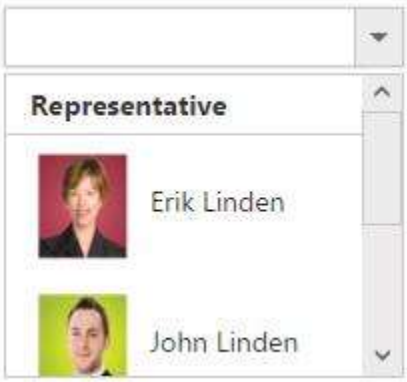
```
.ImageId {
margin: 0;
padding: 3px 10px 3px 3px;
border: 0 none;
width: 60px;
height: 60px;
float: none;
}
```

C#

```
public ActionResult Index()
{
List<Employee> Data = new List<Employee>();
Data.Add(new Employee
{
Text = "Erik Linden",
Role = "Executive",
Country = "England",
Image = "../Content/Employees/3.png",
ImageAttr = "class='ImageId'"
});
Data.Add(new Employee
{
Text = "John Linden",
Role = "Representative",
Country = "Norway",
Image = "../Content/Employees/6.png",
ImageAttr = "class='ImageId'"
});
Data.Add(new Employee
{
Text = "Louis",
Role = "Representative",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Country = "Australia",
Image = "../Content/Employees/7.png",
ImageAttr = "class='ImageId'"
});
Data.Add(new Employee
{
Text = "Lawrence",
Role = "Executive",
Country = "India",
Image = "../Content/Employees/8.png",
ImageAttr = "class='ImageId'"
});
ViewData["LocalDataSource"] = Data;
return View();
}
public class Employee
{
public string Text { get; set; }
public string Role { get; set; }
public string Country { get; set; }
public string Image { get; set; }
public string ImageAttr { get; set; }
}
```



Note: Images for this sample are available in (installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\samples\web\themes\images

SQL Data Binding

Fetch the Data from SQL data source and initialize the control with DataSource property. Specify the column names in the Fields property.

HTML

```
@Html.EJ().DropDownList("selectEmployee").Datasource((IEnumerable<Object>)Vi
ewBag.Data).DropDownListFields(df =>
df.ID("Id").Text("Name").Value("Designation")).Width("150px")
```

C#

```
public ActionResult DropdownlistFeatures()
{
List<Employee> data = new List<Employee>();
```

```
SqlConnection con = new SqlConnection(@"Data
Source=(LocalDB)\MSSQLLocalDB;AttachDbFilename=|DataDirectory|\SampleDB.mdf;
Integrated Security=True");
using (con)
{
con.Open();
SqlDataReader myReader = null;
SqlCommand myCommand = new SqlCommand("select * From [Table]",
con);
myReader = myCommand.ExecuteReader();
if (myReader.Read())
{
data.Add(new Employee(myReader["Name"].ToString(),
myReader["Designation"].ToString()));
}
con.Close();
ViewBag.Data = data;
}
return View();
}
public class Employee
{
public string Name { get; set; }
public string Designation { get; set; }
public Employee(string name, string deg)
{
this.Name = name;
this.Designation = deg;
}
}
```

LINQ Data Binding

Language-Integrated Query (LINQ) is not only about retrieving data. It is also a powerful tool for transforming data. By using a LINQ query, you can use a source sequence as input and modify it in many ways to create a new output sequence.

Defines model class

C#

```
public class Employee
{
public string name { set; get; }
public string employeeID { set; get; }
public string designation { set; get; }
public Employee() { }
public Employee(string name, string id, string designation)
{
name = name;
employeeID = id;
designation = designation;
}
}
```

In code behind, fetch the data from Employee class and assigned to the DropDownList as follows

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
public ActionResult DropdownlistFeatures()
{
List<Employee> data = new List<Employee>() { };
data.Add(new Employee("Nancy", "E11011", "Technical Writer"));
data.Add(new Employee("Angel", "E11012", "Professor"));
data.Add(new Employee("Daniah", "E11013", "Dancer"));
data.Add(new Employee("Jenifer", "E11014", "Beautician"));
data.Add(new Employee("Prince", "E11015", "Developer"));
var db = from result in data
select result;
ViewBag.dataSource = db.ToList();
return View();
}
```

HTML

```
@Html.EJ().DropDownList("selectCar").Datasource((IEnumerable<Employee>)ViewB
ag.datasource).DropDownListFields(df =>
df.ID("employeeID").Text("name").Value("designation")).WatermarkText("Select
a Student").Width("100%")
```

XmlDataSource

XmlDataSource is used to work with XML documents. The following steps explain the details about the data binding from XmlDataSource

Step 1: Create an XML Data source as follows

XML

```
<?xml version="1.0" encoding="utf-8" ?>
<Students>
<Student>
<Name>Abhishek</Name>
<Location>Dhanbad</Location>
</Student>
<Student>
<Name>Aman</Name>
<Location>Samastipur</Location>
</Student>
<Student>
<Name>Vicky</Name>
<Location>Munger</Location>
</Student>
<Student>
<Name>Chandan</Name>
<Location>Bhagalpur</Location>
</Student>
<Student>
<Name>Ravi</Name>
<Location>Dhanbad</Location>
</Student>
</Students>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Step 2: Read data from the XML file

C#

```
using System.Xml;
using DataBinding.Models;
public ActionResult DropdownlistFeatures()
{
List<Product> data = new List<Product>();
using (XmlReader reader =
XmlReader.Create("D:/Sample/MVC/DataBinding/DataBinding/App_Data/XMLData.xml
"))
{
while (reader.Read())
{
if (reader.IsStartElement())
{
switch (reader.Name.ToString())
{
case "Name":
data.Add(new Product { name = reader.ReadString() });
break;
}
}
}
}
ViewBag.data = data;
return View();
}
```

Step 3: Assign the data to the DropDownList's DataSource property. Specify the column names in the fields property.

RAZOR

```
@using DataBinding.Models
@Html.EJ().DropDownList("selectCar").Datasource((IEnumerable<Product>)ViewBa
g.data).DropDownListFields(df =>
df.Text("name").Value("name")).WatermarkText("Select a
Student").Width("100%")
```

EntityDataSource

Bind data to the DropDownList through Entity Framework. Please follow the below steps.

1. Create an entity data model

Please refer the link for more information

2. Refer the entity data model to your project and bind the data to the DropDownList

In code behind, create an object for the Entity mode (NORTHWNDEntities) and fetch the data from the Employees class and stored it to the List.

Assign the data to the DropDownList's DataSource property. Specify the column names in the fields property.

C#

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult DropdownlistFeatures()
{
NORTHWNDEntities sample = new NORTHWNDEntities();
var dataset = sample.Employees
.Select(x => new Employee
{
EmployeeID = x.EmployeeID,
FirstName = x.FirstName
}).ToList();
ViewBag.DataSource = dataset;
}
public class Employee
{
public int EmployeeID { get; set; }
public string FirstName { get; set; }
}
```

RAZOR

```
@Html.EJ().DropDownList("selectEmployee").Datasource((IEnumerable<Object>)Vi
ewBag. DataSource).DropDownListFields(df => df.Text("FirstName
").Value("EmployeeID ")).Width("150px")
```

AccessDataSource

The data can also be bound to the DropDownList using OLEDB database as depicted below.

RAZOR

```
Html.EJ().DropDownList("selectEmployee").Datasource((IEnumerable<Object>)Vie
wBag. DataSource).DropDownListFields(df =>
df.ID("Id").Text("Name").Value("Designation")).Width("150px")
```

The server-side code to retrieve and bind the data to DropDownList are as follows. Also, define a class with all the required fields as depicted in the below code example.

C#

```
public ActionResult DropdownlistFeatures()
{
OleDbConnection conn = new
OleDbConnection(@"Provider=Microsoft.Jet.OLEDB.4.0;Data
Source=|DataDirectory|\Database.mdb");
conn.Open();
OleDbCommand cmd = new OleDbCommand(" SELECT * from [Employees]", conn);
OleDbDataReader reader = null;
List<EmployeeDetails> data = new List<EmployeeDetails>();
reader = cmd.ExecuteReader();
while (reader.Read())
{
data.Add(new EmployeeDetails(reader["Name"].ToString(),
reader["Designation"].ToString()));
}
conn.Close();
ViewBag. DataSource = data;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public class EmployeeDetails
{
public string Name { get; set; }
public string Designation { get; set; }
public EmployeeDetails(string name, string deg)
{
this.Name = name;
this.Designation = deg;
}
}
```

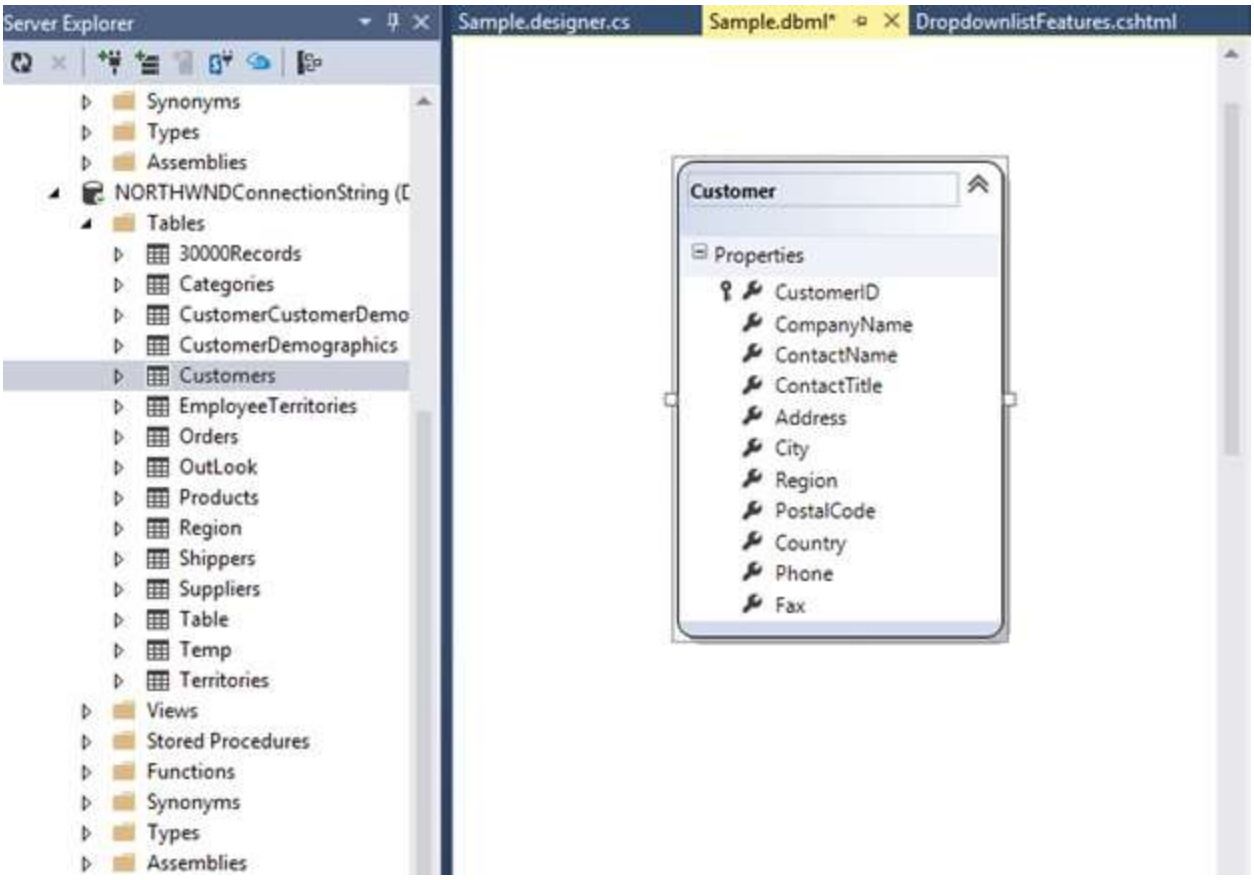
LINQ to SQL Data Binding

The LINQ to SQL can be used as the data source of the DropDownList in which the data model of a relational database is mapped to an object model and allow us to use the LINQ technology to access SQL database.

To create LINQ to SQL classes

- Right-click the App_Code folder and then click Add New Item.
- Under Installed templates, select LINQ to SQL Classes template, type a name for the .dbml file, and then click Add.
- The Object Relational Designer window is displayed.
- In Server Explorer, drag the database table into the Object Relational Designer window.
- The table and its columns are represented as an entity in the designer window.

Copyright © 2001 - 2020 Syncfusion Inc.



In code behind, fetch the data from classes and stored it to the ViewBag as follows

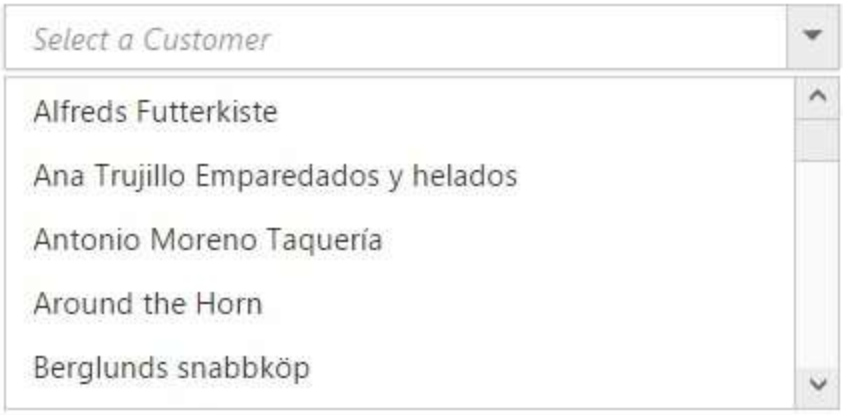
C#

```
ViewBag.dataSource = new SampleDataContext().Customers.ToList();
```

HTML

```
@Html.EJ().DropDownList("customers").Datasource((IEnumerable<Customer>)ViewB
ag.dataSource).DropDownListFields(df =>
df.Text("CompanyName").Value("CustomerID")).WatermarkText("Select a
Customer").Width("100%")
```

Copyright © 2001 - 2020 Syncfusion Inc.



Remote data

To bind remote data to the DropDownList, you can assign a service data as an instance of DataManager to the Datasource property.

OData

OData is a standardized protocol for creating and consuming data. You can provide the OData service URL directly to the Datasource URL property.

HTML

```
@Html.EJ().DropDownList("DropDownList1").Datasource(dataSource =>
dataSource.URL("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders")).Dr
opDownListFields(df=>df.Text("ShipCountry").Value("OrderID"))
```

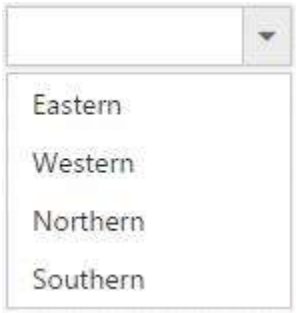
OData Version 4

For OData Version 4 support ODataV4Adaptor should be used. By using URL property of Datasource, you can bind OData Version 4 Service link and specify Adaptor value as enum AdaptorType.ODataV4Adaptor.

For further details about OData service please refer the link.

HTML

```
@Html.EJ().DropDownList("DropDownList1").Datasource(dataSource
=>dataSource.URL("http://services.odata.org/V4/Northwind/Northwind.svc/Regio
ns/").Adaptor(AdaptorType.ODataV4Adaptor)).DropDownListFields(df =>
df.Text("RegionDescription").Value("RegionID"))
```



Note: Events associated with remote data bind is listed here.

Copyright © 2001 - 2020 Syncfusion Inc.

WebAPI

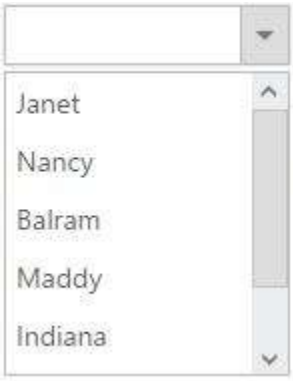
Using WebApiAdaptor, you can bind WebApi service's data to DropDownList. The data from WebApi service must be returned as an object that has property "Items" with its value as data source and another property "Count" with its value as dataSource's total records count.

HTML

```
@Html.EJ().DropDownList("DropDownList1").Datasource(dataSource =>
dataSource.URL("/api/Orders").Adaptor(AdaptorType.WebApiAdaptor)).DropDownLi
stFields(df => df.Text("Name").Value("EmployeeID"))
```

C#

```
public class OrdersController : ApiController
{
NorthwindDataContext db = new NorthwindDataContext();
// GET API/<controller>
public PageResult<EmployeePhoto> Get(ODataQueryOptions opts)
{
List<EmployeePhoto> photos = db.EmployeePhotos.ToList();
return new PageResult<EmployeePhoto>(photos as IEnumerable<EmployeePhoto>,
null, photos.Count);
}
}
```



Virtual Scrolling

To improve the performance when displaying large data set, you can use "AllowVirtualScrolling" and VirtualScrollMode property. This retrieves only a fixed amount of list items and loads remaining data on scrolling. The items will be fetched via AJAX request.

This supports two modes of virtualization. They are,

- Normal Mode
- Continuous Mode

Information: 1. Sorting and Grouping is not supported with Virtual Scrolling

Information: 2. "VirtualScrollMode" property accepts Syncfusion.JavaScript.VirtualScrollMode enum value.

Copyright © 2001 - 2020 Syncfusion Inc.

Normal Mode

It loads the data on scrolling the list of items. This can be achieved by setting Syncfusion.JavaScript.VirtualScrollMode.Normal value to the VirtualScrollMode property.

HTML

```
@Html.EJ().DropDownList("DropDownList1").Datasource(dataSource =>
dataSource.URL("http://mvc.syncfusion.com/services/Northwnd.svc/Orders")).Dr
opDownListFields(df =>
df.Text("ShipName").Value("ShipCountry")).AllowVirtualScrolling(true).Virtua
lScrollMode(VirtualScrollMode.Normal).ItemsCount(7)
```

Continuous Mode

It loads the set of items when the scroller reaches at the end. This behaves like infinity scrolling. So when scroll reaches the end, it will fetch the remaining set of items and bind with your DropDownList. This can be achieved by setting Syncfusion.JavaScript.Continuous value to the "VirtualScrollMode" property.

Note: In both modes, set of items will be fetched based on the count specified in the ItemsCount property and next set of items will be loaded on scrolling.

HTML

```
@Html.EJ().DropDownList("DropDownList1").Datasource(dataSource =>
dataSource.URL("http://mvc.syncfusion.com/services/Northwnd.svc/Orders")).Dr
opDownListFields(df =>
df.Text("ShipName").Value("ShipCountry")).AllowVirtualScrolling(true).Virtua
lScrollMode(VirtualScrollMode.Continuous).ItemsCount(7)
```

Checkbox

DropDownList displays checkboxes to the left of each item when you set ShowCheckbox property to true. It allows you to select more than one item at a time from DropDownList. Popup list stays open until the user finishes selection. When you click on an item’s text or checkbox then the checkbox checked status get change.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ShowCheckbox(true)
```

C#

```
public ActionResult Index()
{
List<Data> DropDownData = new List<Data>();
DropDownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropDownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropDownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropDownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropDownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropDownData;
return View();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

if you want to showcase the DropDownList with default checked items on data binding, specify Selected field with Boolean values.

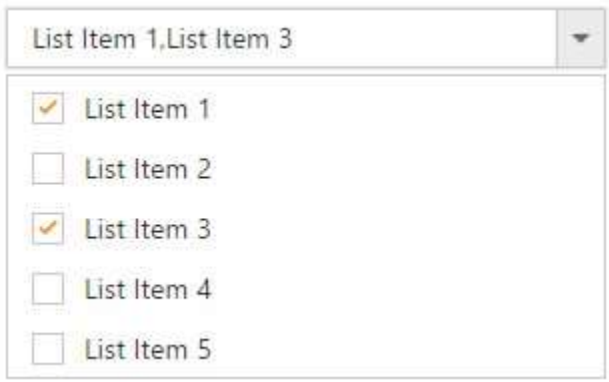
HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value").Selected("Selected")).ShowCheckbox(true).Widt
h("300px")
```

C#

```
public ActionResult Index()
{
List<Data> DropDownData = new List<Data>();
DropDownData.Add(new Data { Value = "item1", Text = "ListItem 1",
Selected=true });
DropDownData.Add(new Data { Value = "item2", Text = "ListItem 2",
Selected=false });
DropDownData.Add(new Data { Value = "item3", Text = "ListItem 3",
Selected=true });
DropDownData.Add(new Data { Value = "item4", Text = "ListItem 4",
Selected=false });
DropDownData.Add(new Data { Value = "item5", Text = "ListItem 5",
Selected=false });
ViewData["DropDownSource"] = DropDownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
public bool Selected { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Selection Modes

The MultiSelectMode property enables you to make multiple selections in the following two ways:

- Delimiter
- Visual Mode

Information: "MultiSelectMode" property accepts **Syncfusion.JavaScript.MultiSelectModeTypes** enum value.

Delimiter

Each checked item's text is appended to the textbox with delimiter "," by default. This is enabled by assigning **Syncfusion.JavaScript.MultiSelectModeTypes.Delimiter** (enum) value to MultiSelectMode property. You can customize the delimiter option by using DelimiterChar property.

HTML

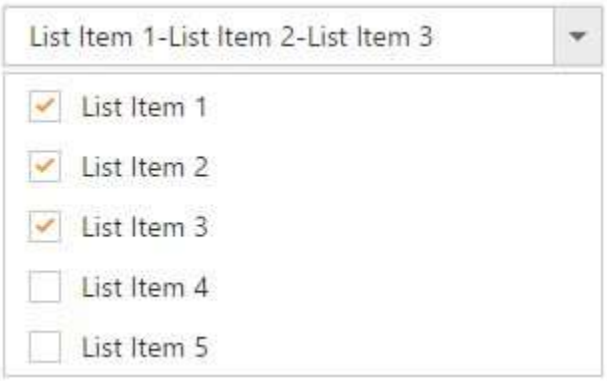
```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ShowCheckbox(true).MultiSelectMode(MultiSele
ctModeTypes.Delimiter).DelimiterChar("-").Width("300px")
```

C#

```
public ActionResult Index()
{
List<Data> DropDownData = new List<Data>();
DropDownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropDownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropDownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropDownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropDownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropDownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
```



Visual Mode

When you enable this option in DropDownList control, each checked item's text is appended to the text box in a box model layout. This is enabled by assigning **Syncfusion.JavaScript.MultiSelectModeTypes.VisualMode** (enum) value to MultiSelectMode property.

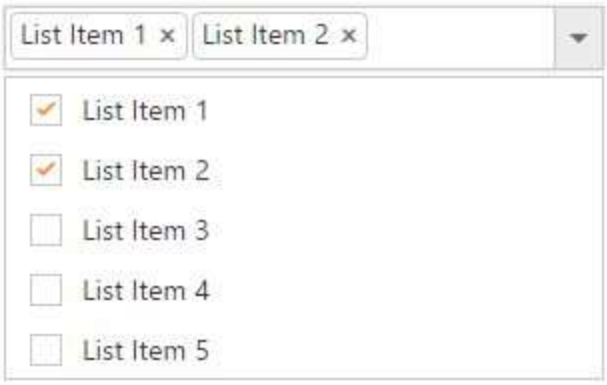
HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ShowCheckbox(true).Width("300px").MultiSelec
tMode(MultiSelectModeTypes.VisualMode)
```

C#

```
public ActionResult Index()
{
List<Data> DropDownData = new List<Data>();
DropDownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropDownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropDownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropDownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropDownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropDownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Select multiple values from controller

To pass selected values from controller, pass selected items using ViewBag, and assign this to the Value property of DropDownList. Refer to the following code.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).Value(ViewBag.Selected).ShowCheckbox(true)
```

C#

```
public ActionResult Index()
{
List<Data> DropDownData = new List<Data>();
DropDownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropDownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropDownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropDownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropDownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropDownData;
ViewBag.Selected = "item1,item2";
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

To pass multiple selected items from View to Controller, use ajax post to send selected items through change event of DropDownList. Refer to the following code

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ClientSideEvents(e=>e.Change("Changed")).Sho
wCheckbox(true).Value(ViewBag.Selected)
```

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
function Changed(args) {
$.ajax({
type: "POST",
url: '@Url.Action("Update")',
data: '{value: ' + JSON.stringify(args.model.value) + '}',
dataType: "json",
contentType: "application/json; charset=utf-8",
success: function (e) {
console.log(e.result);
},
error: function () {
alert("Error while sending data");
}
});
}
```

C#

```
public ActionResult Index()
{
List<Data> DropDownData = new List<Data>();
DropDownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropDownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropDownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropDownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropDownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropDownData;
ViewBag.Selected = "item1,item2";
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
[HttpPost]
public ActionResult Update(string Value)
{
var selected = Value;
return Json(new { result = Value, JsonRequestBehavior.AllowGet });
}
```

Refer HowTo section to add check all option in popup list

Functionalities

Selection

By default only one item can be selected from the popup list. For multiple selection, you have to enable checkboxes. The selected item consist of active class (“e-active”) to differentiate it from other items.

The following API’s, select the items in the DropDownList via text or value or indices.

Properties	Description

value	To select an item initially, you can pass the itemâ€™s value via value property. Multiple items can select via value property, the given values should be separated by delimiter character.
text	To select an item initially, you can pass the itemâ€™s text via text property. Multiple items can select via text property, the given values should be separated by delimiter character.
selectedIndex	Select a single item by passing an index value to the selectedIndex property.
selectedIndices	Select more than one items by passing index values to the selectedIndices property when multi selection enabled.

Note: Index starts from 0 here.

To use “selectedIndices” property, you should enable wither ShowCheckbox or MultiSelectMode property.

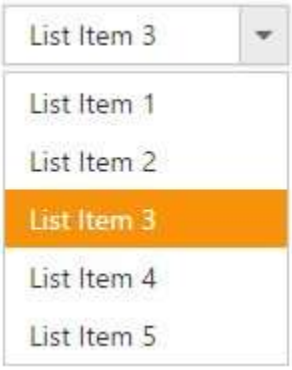
The following methods, select the items in the DropDownList.

Methods	Description
selectItemByIndices	This method is used to select the list of items in the DropDownList through the Index of the items.
selectItemByText	This method is used to select an item in the DropDownList by using the given text value.
selectItemByValue	This method is used to select an item in the DropDownList by using the given value.

The following methods, used to retrieve the items from the DropDownList.

Methods	Description
getListData	This method is used to retrieve the items that are bound with the DropDownList.
getSelectedItem	This method is used to get the selected items in the DropDownList.
getSelectedValue	This method is used to retrieve the items value that are selected in the DropDownList.

Copyright © 2001 - 2020 Syncfusion Inc.



Information: When multiSelectMode is enabled in a DropDownList and selected items having same text but its value is different means, the items can be selected. Please refer the online link

Using value or text

To select an item initially you can pass the item's value via Value property or SelectItemByValue API. To achieve this DropDownList control must be initiated with the associate value.

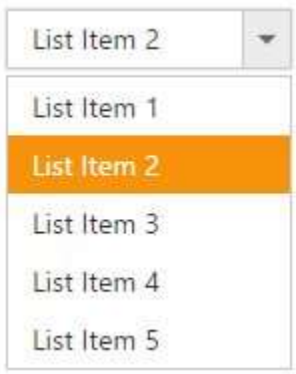
HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).Value("item3")
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Note: To retrieve the selected item's value in controller page, you can use DropDownList control name in the controller post action.

HTML

```
@model MVCApplication.Controllers.HomeController
@using (Html.BeginForm("DropdownlistFeatures", "Dropdownlist",
FormMethod.Post, null))
{
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).Height("50px").Width("500px").PopupHeight("2
00px").PopupWidth("300px")
<input type="submit" value="Get Value" />
}
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
[HttpPost]
public ActionResult DropdownlistFeatures(string DropDownList1)
{
//DropDownList1 is ID of DropDownList used in this example. You can get the
selected items value in controller using the ID
string DropDownValue = DropDownList1;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Using indices

You can select a single or more than one item by passing index values to the properties SelectedIndex or SelectedIndices respectively. Index starts from 0 here.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList").Datasource((IEnumerable<Data>)ViewDa
ta["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).SelectedIndex(1)
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Information: To use "SelectedIndices" property, you should enable either ShowCheckbox or MultiSelectMode property First.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList").Datasource((IEnumerable<Data>)ViewDa
ta["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ShowCheckbox(true).SelectedIndices(new
List<int> { 1,2 })
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Unselect items

Similarly, you can unselect a single or multiple items by using unselectItemByValue or unselectItemByIndices or unselectItemByText methods. This will remove the selection state of the corresponding data item from the popup list and textbox.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList").Datasource((IEnumerable<Data>)ViewDa
ta["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ShowCheckbox(true).SelectedIndices(new
List<int> { 1, 2, 3 })
<input type="button" value="Unselect" onclick="unselect()" />
```

JS

```
var obj;
$(function() {
obj = $('#dropdown1').data("ejDropDownList");
console.log("Selected Item's Text - " + obj.option("text"));
console.log("selected Item's Value - " + obj.option("value"));
});
function unselect() {
obj.unselectItemByValue("item2");
obj.unselectItemByIndices(2);
obj.unselectItemByText("ListItem 4");
}
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Grouping

The DropDownList items can be categorized by using a specific field in the popup list. This is enabled by using Category field on data source binding. By default grouping is disabled in DropDownList.

The below given example explains the behavior of grouping with List data binding.

HTML

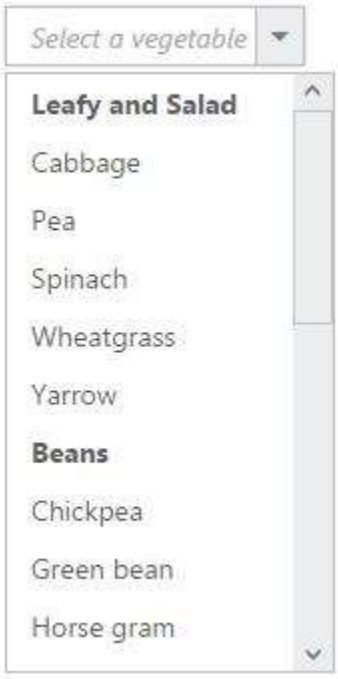
```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList").Datasource((IEnumerable<VegetableLis
t>)ViewData["VegData"]).DropDownListFields(Df =>
Df.Text("Name").Category("Category")).Width("150px").PopupHeight("300px").Wa
termarkText("Select a vegetable")
```

C#

```
public ActionResult Index()
{
List<VegetableList> Vegetables = new List<VegetableList>();
Vegetables.Add(new VegetableList { Name = "Cabbage", Category = "Leafy and
Salad" });
Vegetables.Add(new VegetableList { Name = "Pea", Category = "Leafy and
Salad" });
Vegetables.Add(new VegetableList { Name = "Spinach", Category = "Leafy and
Salad" });
Vegetables.Add(new VegetableList { Name = "Wheat grass", Category = "Leafy
and Salad" });
Vegetables.Add(new VegetableList { Name = "Yarrow", Category = "Leafy and
Salad" });
Vegetables.Add(new VegetableList { Name = "Chickpea", Category = "Beans" });
Vegetables.Add(new VegetableList { Name = "Green bean", Category = "Beans"
});
Vegetables.Add(new VegetableList { Name = "Horse gram", Category = "Beans"
});
Vegetables.Add(new VegetableList { Name = "Peanut", Category = "Beans" });
Vegetables.Add(new VegetableList { Name = "Pigeon pea", Category = "Beans"
});
Vegetables.Add(new VegetableList { Name = "Garlic", Category = "Bulb and
Stem" });
Vegetables.Add(new VegetableList { Name = "Garlic Chives", Category = "Bulb
and Stem" });
Vegetables.Add(new VegetableList { Name = "Lotus root", Category = "Bulb and
Stem" });
Vegetables.Add(new VegetableList { Name = "Nopal", Category = "Bulb and
Stem" });
Vegetables.Add(new VegetableList { Name = "Onion", Category = "Bulb and
Stem" });
Vegetables.Add(new VegetableList { Name = "Shallot", Category = "Bulb and
Stem" });
Vegetables.Add(new VegetableList { Name = "Beetroot", Category = "Root and
Tuberous" });
Vegetables.Add(new VegetableList { Name = "Carrot", Category = "Root and
Tuberous" });
Vegetables.Add(new VegetableList { Name = "Ginger", Category = "Root and
Tuberous" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Vegetables.Add(new VegetableList { Name = "Potato", Category = "Root and
Tuberous" });
Vegetables.Add(new VegetableList { Name = "Radish", Category = "Root and
Tuberous"});
Vegetables.Add(new VegetableList { Name = "Turmeric", Category = "Root and
Tuberous" });
ViewData["VegData"] = Vegetables;
return View();
}
public class VegetableList
{
public string Name { get; set; }
public string Category { get; set; }
}
```



Note: Grouping has restrictions in the following scenarios,

1. It is not supported on using HTML "select" element with predefined set of options
2. When using UL-LI elements you need to use “e-category” class in LI element to specify it as the grouping header. The following code will explain this behavior,
3. The sorting behavior varies when grouping is enabled in the DropDownList, based on browser as we have used browser based stable sorting method when there is multiple level of sorting.
4. To overcome this behavior on sorting order with browser, we suggest you to set ej.support.stableSort as false from the script when the page is loaded or in document ready function.

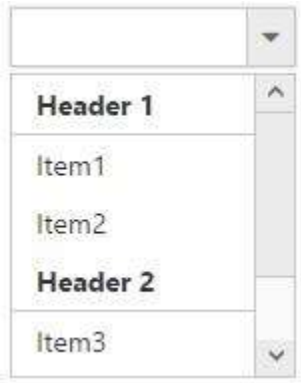
JAVASCRIPT

```
<script type="text/javascript">
$(document).ready(function () {
ej.support.stableSort = false;
```

```
});
</script>
```

HTML

```
@Html.EJ().DropDownList("DropDownList").TargetID("grouping").Width("150px").
PopupHeight("300px").WatermarkText("Select a vegetable")
<div id="grouping">
<ul>
<span class="e-category">Header 1</span>
<li>Item 1</li>
<li>Item 2</li>
<span class="e-category">Header 2</span>
<li>Item 3</li>
<li>Item 4</li>
<li>Item 5</li>
</ul>
</div>
```



Information: Virtual scrolling is not supported with Grouping.

Sorting

Sorting is enabled in order to display the items alphabetically in either ascending or descending order. By default the items is displayed in the initialized order, use EnableSorting property to automatically sort strings based on text field value. You can assign either SortOrder.Ascending or SortOrder.Descending enum values to the SortOrder property to sort out the list items. By default ascending order is followed when SortOrder property is not specified.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList").Datasource((IEnumerable<Data>)ViewDa
ta["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).EnableSorting(true).SortOrder(SortOrder.Desc
ending)
```

C#

```
public ActionResult Index()
{
List<Data> DropDownData = new List<Data>();
```

```
DropDownData.Add(new Data { Value = "item1", Text = "List Item 1" });
DropDownData.Add(new Data { Value = "item5", Text = "List Item 5" });
DropDownData.Add(new Data { Value = "item4", Text = "List Item 4" });
DropDownData.Add(new Data { Value = "item2", Text = "List Item 2" });
DropDownData.Add(new Data { Value = "item3", Text = "List Item 3" });
ViewData["DropDownSource"] = DropDownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Information: Virtual scrolling is not supported with Sorting.

Cascading

This works for series of DropDownList in which items are filtered based on the previous DropDownList's selection. Cascading is performed based on the value field and this field should be bounded with a foreign key. To perform cascading, specify the child DropDownList's id in CascadeTo property and use delimiter (",") to specify more than one child DropDownList.

Configuring the data items for cascading to the series of DropDownList is demonstrated below

HTML

```
@model MVCApplication.Controllers.HomeController
<div style="width: 400px;">
<div style="float: left;">
<span>Select Group</span>
@Html.EJ().DropDownList("GroupDropDown").Datasource((IEnumerable<Groups>)Vie
wData["Groups"]).DropDownListFields(Df =>
Df.Text("Text").ID("ParentId").Value("ParentId")).CascadeTo("CountryDropDown
")
</div>
<div style="float: right;">
<span>Select Country</span>
@Html.EJ().DropDownList("CountryDropDown").Datasource((IEnumerable<Country>)
ViewData["CountriesData"]).Enabled(false).DropDownListFields(df=>df.Text("Te
xt"))
</div>
</div>
```

C#

```
public ActionResult Index()
{
List<Groups> GroupList = new List<Groups>();
GroupList.Add(new Groups{ ParentId = "a", Text = "Group A" });
GroupList.Add(new Groups{ ParentId = "b", Text = "Group B" });
GroupList.Add(new Groups{ ParentId = "c", Text = "Group C" });
GroupList.Add(new Groups{ ParentId = "d", Text = "Group D" });
GroupList.Add(new Groups { ParentId = "e", Text = "Group E" });
List<Country> CountryList = new List<Country>();
CountryList.Add(new Country{ ParentId = "a", Text = "Algeria" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
CountryList.Add(new Country{ ParentId = "a", Text = "Armenia" });
CountryList.Add(new Country{ ParentId = "a", Text = "Bangladesh" });
CountryList.Add(new Country{ ParentId = "a", Text = "Cuba" });
CountryList.Add(new Country{ ParentId = "b", Text = "Denmark" });
CountryList.Add(new Country{ ParentId = "b", Text = "Egypt" });
CountryList.Add(new Country{ ParentId = "c", Text = "Finland" });
CountryList.Add(new Country{ ParentId = "c", Text = "India" });
CountryList.Add(new Country{ ParentId = "c", Text = "Malaysia" });
CountryList.Add(new Country{ ParentId = "d", Text = "New Zealand" });
CountryList.Add(new Country{ ParentId = "d", Text = "Norway" });
CountryList.Add(new Country{ ParentId = "d", Text = "Poland" });
CountryList.Add(new Country{ ParentId = "e", Text = "Romania" });
CountryList.Add(new Country{ ParentId = "e", Text = "Singapore" });
CountryList.Add(new Country{ ParentId = "e", Text = "Thailand" });
CountryList.Add(new Country{ ParentId = "e", Text = "Ukraine" });
ViewData["Groups"] = GroupList;
ViewData["CountriesData"] = CountryList;
return View();
}
public class Groups
{
public string ParentId { get; set; }
public string Text { get; set; }
}
public class Country
{
public string ParentId { get; set; }
public string Text { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Binding the data source to the cascading DropDownList using cascade event

Bind the data source to the cascading DropDownList dynamically using ClientSideEvent Cascade as demonstrated below,

HTML

```
@model MVCApplication.Controllers.HomeController
<div style="width: 530px;">
<div style="float: left;">
<span>Select Group</span>
@Html.EJ().DropDownList("GroupDropDown").Datasource((IEnumerable<Groups>)Vie
wData["Groups"]).DropDownListFields(Df =>
Df.Text("Text").ID("ParentId").Value("ParentId")).CascadeTo("CountryDropDown
, PlayersDropDown")
</div>
<div style="float: left; padding-left: 50px;">
<span>Select Country</span>
@Html.EJ().DropDownList("CountryDropDown").Datasource((IEnumerable<Country>)
ViewData["CountriesData"]).Enabled(false).DropDownListFields(df =>
df.Text("Text"))
</div>
<div style="float: right;">
<span>Select Players</span>
@Html.EJ().DropDownList("PlayersDropDown").Datasource((IEnumerable<Players>)
ViewData["PlayersData"]).Enabled(false).DropDownListFields(df =>
df.Text("Text"))
</div>
</div>
```

C#

```
public ActionResult Index()
{
List<Groups> GroupList = new List<Groups>();
GroupList.Add(new Groups{ ParentId = "a", Text = "Group A" });
GroupList.Add(new Groups{ ParentId = "b", Text = "Group B" });
List<Country> CountryList = new List<Country>();
CountryList.Add(new Country{ ParentId = "a", Text = "Algeria" });
CountryList.Add(new Country{ ParentId = "a", Text = "Armenia" });
CountryList.Add(new Country{ ParentId = "b", Text = "Denmark" });
CountryList.Add(new Country{ ParentId = "b", Text = "Egypt" });
List<Players> PlayerList = new List<Players>();
PlayerList.Add(new Players { ParentId = "a", Text = "Adams" });
PlayerList.Add(new Players { ParentId = "a", Text = "Clarke" });
PlayerList.Add(new Players { ParentId = "b", Text = "Brett" });
PlayerList.Add(new Players { ParentId = "b", Text = "James" });
ViewData["Groups"] = GroupList;
ViewData["CountriesData"] = CountryList;
ViewData["PlayersData"] = PlayerList;
return View();
}
public class Groups
{
public string ParentId { get; set; }
public string Text { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public class Country
{
public string ParentId { get; set; }
public string Text { get; set; }
}
public class Players
{
public string ParentId { get; set; }
public string Text { get; set; }
}
```

Multi-Level Cascading

The below scenario can be explained with three DropDownList for the multi-level cascading.

C#

```
public partial class DropdownlistController: Controller
{
List<groups> group = new List<groups>();
List<Countries> country = new List<Countries>();
List<Capital> capital = new List<Capital>();
public ActionResult DropdownlistFeatures()
{
group.Add(new groups { parentId = "a", text = "Group A" });
group.Add(new groups { parentId = "b", text = "Group B" });
group.Add(new groups { parentId = "c", text = "Group C" });
group.Add(new groups { parentId = "d", text = "Group D" });
group.Add(new groups { parentId = "e", text = "Group E" });
ViewBag.datasource = group;
country.Add(new Countries { value = 11, parentId = "a", text = "Algeria" });
country.Add(new Countries { value = 12, parentId = "a", text = "Armenia" });
country.Add(new Countries { value = 13, parentId = "a", text = "Bangladesh"
});
country.Add(new Countries { value = 14, parentId = "a", text = "Cuba" });
country.Add(new Countries { value = 15, parentId = "b", text = "Denmark" });
country.Add(new Countries { value = 16, parentId = "b", text = "Egypt"});
country.Add(new Countries { value = 17, parentId = "c", text = "Finland"});
country.Add(new Countries { value = 18, parentId = "c", text = "India" });
country.Add(new Countries { value = 19, parentId = "c", text = "Malaysia"});
country.Add(new Countries { value = 20, parentId = "d", text = "New
Zealand"});
country.Add(new Countries { value = 21, parentId = "d", text = "Norway" });
country.Add(new Countries { value = 22, parentId = "d", text = "Romania" });
country.Add(new Countries { value = 23, parentId = "e", text =
"Singapore"});
country.Add(new Countries { value = 24, parentId = "e", text = "Thailand"
});
```

```
country.Add(new Countries { value = 25, parentId = "e", text = "Ukraine"});
ViewBag.datasource1 = country;
capital.Add(new Capital { value = 11, text = "Algiers" });
capital.Add(new Capital { value = 12, text = "Cairo" });
capital.Add(new Capital { value = 13, text = "Copenhagen" });
capital.Add(new Capital { value = 14, text = "Washington" });
capital.Add(new Capital { value = 15, text = "Denmark" });
capital.Add(new Capital { value = 16, text = "Yerevan" });
capital.Add(new Capital { value = 17, text = "Copenhagen" });
capital.Add(new Capital { value = 18, text = "New Delhi" });
capital.Add(new Capital { value = 19, text = "Havana" });
capital.Add(new Capital { value = 20, text = "Brasilia" });
capital.Add(new Capital { value = 21, text = "Lima" });
capital.Add(new Capital { value = 22, text = "Canberra" });
capital.Add(new Capital { value = 23, text = "Wellington" });
capital.Add(new Capital { value = 24, text = "Alfred Faure" });
capital.Add(new Capital { value = 25, text = "King Edward Point" });
ViewBag.capital = capital;
return View();
}
}
public class groups
{
public string text { get; set; }
public string parentId { get; set; }
}
public class Countries
{
public string text { get; set; }
public int value { get; set; }
public string parentId { get; set; }
}
public class Capital
{
public string text { get; set; }
public int value { get; set; }
}
```

HTML

```
<div class="control" style="float: left;">
<span class="txt">Select Group</span>
@Html.EJ().DropDownList("groupsList").Datasource((IEnumerable<groups>)ViewBa
g.datasource).DropDownListFields(f =>
f.Value("parentId").Text("text")).CascadeTo("countryList")
</div>
<div class="control" style="float: left;">
<span class="txt">Select Country</span>
@Html.EJ().DropDownList("countryList").Datasource((IEnumerable<Countries>)Vi
ewBag.datasource1).DropDownListFields(f =>
f.Value("value").Text("text")).CascadeTo("capitalList").Enabled(false)
</div>
<div class="control" style="float: left;">
<span class="txt">Select Country</span>
@Html.EJ().DropDownList("capitalList").Datasource((IEnumerable<Capital>)View
Bag.capital).Enabled(false)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</div>
```

First two DropDownList cascaded based on the parentId, and then from second to third, cascading performed based on the value field.

Validations

DropDownList value can be validated in following ways,

1. Using jQuery Validator
2. Client side Validation
3. Server side validation

Using jQuery Validator

You can validate the DropDownList value on form submission using jQuery Validations, by applying “ValidationRules” and “ValidationMessage” to the DropDownList.

Note: jquery.validate.min script file should be referred for validation, for more details, refer here.

Validation Rules

The validation rules help you to verify the selected text by adding validation attributes to the input element. This can be set by using ValidationRules property.

Validation Messages

You can set your own custom error message by using ValidationMessage property. To display the error message, specify the corresponding annotation attribute followed by the message to display.

Note: jQuery predefined error messages to that annotation attribute will be shown when this property is not defined. The below given example explain this behavior of ‘required’ attribute,

When the DropDownList control is rendered, it creates an input hidden element which is used to store the selected items value. Hence, the validation is performed based on the value stored in this hidden element.

Required field and min value validation is demonstrated in the below given example.

HTML

```
@model MVCApplication.Controllers.HomeController
<form id="form1">
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ValidationMessage(message =>
message.AddMessage("required", "* Required").AddMessage("min","Select >
30")).ValidationRules(vr => vr.AddRule("required", true).AddRule("min",30))
<br /><input type="submit" value="Submit" />
</form>
```

JAVASCRIPT

```
$.validator.setDefaults({
ignore: [],
errorClass: 'e-validation-error', // to get the error message on jQuery
validation
errorPlacement: function (error, element) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$(error).insertAfter(element.closest(".e-widget"));
}
// any other default options and/or rules
});
//If necessary, we can create custom rules as below. here method defined for
min
$.validator.addMethod("min",
function (value, element, params) {
if (!/Invalid|NaN/.test(value)) {
return parseInt(value) > params;
}
}, 'Must be greater than 30.');
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "10", Text = "10" });
DropdownData.Add(new Data { Value = "20", Text = "20" });
DropdownData.Add(new Data { Value = "30", Text = "30" });
DropdownData.Add(new Data { Value = "40", Text = "40" });
DropdownData.Add(new Data { Value = "50", Text = "50" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Client Side Validation

When you are developing the MVC application in Visual Studio then the client-side becomes enabled by default, but you can easily enable or disable the writing of the following app setting code snippet in the web.config file.

XML

```
<appSettings>
<add key="ClientValidationEnabled" value="true" />
<add key="UnobtrusiveJavaScriptEnabled" value="true" />
</appSettings>
```

After setting the value as **true,** refer to the jQuery validation script file in the **_Layout page** as shown in the following code example.

HTML

```
<script src="@Url.Content("~/Scripts/jquery.validate.js")"></script>
```

The jQuery validation plug-in takes advantage of the Data Annotation attributes defined in the model. Let's create a Sample model that has a single property with Data annotation attributes.

C#

```
using System.ComponentModel.DataAnnotations;
public class DropDownListModel
{
[Required(ErrorMessage = "DropDownList value is Required")]
public List<DropDownValue> DropData { get; set; }
}
public class DropDownValue
{
public string Text { get; set; }
public string Value { get; set; }
}
```

After that you need to create the controller's action methods. These render views on the UI and bind a model with the view. So let's create a controller as follows.

The view is created as in the following code snippet:

RAZOR

```
@model MvcApplication.Models.DropDownListModel
@using (Html.BeginForm())
{
@Html.ValidationSummary(true)
@Html.EJ().DropDownListFor(Model => Model.
DropData,(Syncfusion.JavaScript.Models.DropDownListProperties)ViewData["prop
erties"])
<br />
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("Post").Type(ButtonType
.Submit)
}
```

C#

```
using MvcApplication.Models;
using Syncfusion.JavaScript.Models;
public ActionResult DropdownlistFeatures()
{
BindingData();
return View();
}
public void BindingData()
{
List<DropDownValue> data = new List<DropDownValue>() { };
data.Add(new DropDownValue() { Value = "item1", Text = "List Item 1" });
data.Add(new DropDownValue() { Value = "item2", Text = "List Item 2" });
data.Add(new DropDownValue() { Value = "item3", Text = "List Item 3" });
data.Add(new DropDownValue() { Value = "item4", Text = "List Item 4" });
data.Add(new DropDownValue() { Value = "item5", Text = "List Item 5" });
DropDownListProperties obj = new DropDownListProperties();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
obj.DataSource = data;
DropDownListFields fields = new DropDownListFields();
fields.Text = "Text";
fields.Value = "Value";
obj.DropDownListFields = fields;
ViewData["properties"] = obj;
}
[HttpPost]
public ActionResult DropdownlistFeatures(DropDownListModel model)
{
BindingData();
return View(model);
}
```

Server side Validation

The ASP.NET MVC Framework validates any data passed to the controller action that is executing.

For DropDownList, we have to create a sample using Data Annotation API to validate the model data for it.

1. Create a model named DropDownListModel (DropDownListModel.*cs*) under the *Models* folder and applies Data Annotation attributes on the properties of the DropDownListModel class that is the Text property of the DropDownList.
2. Now, create an action method in the controller that returns a view with a model after the post request.

C#

```
using System.ComponentModel.DataAnnotations;
public class DropDownListModel
{
public List<DropDownValue> DropData { get; set; }
}
public class DropDownValue
{
public string Text { get; set; }
public string Value { get; set; }
}
```

C#

```
using MvcApplication.Models;
using Syncfusion.JavaScript.Models;
public ActionResult DropdownlistFeatures()
{
BindingData();
return View();
}
public void BindingData()
{
List<DropDownValue> data = new List<DropDownValue>() { };
data.Add(new DropDownValue() { Value = "item1", Text = "List Item 1" });
data.Add(new DropDownValue() { Value = "item2", Text = "List Item 2" });
data.Add(new DropDownValue() { Value = "item3", Text = "List Item 3" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
data.Add(new DropDownValue() { Value = "item4", Text = "List Item 4" });
data.Add(new DropDownValue() { Value = "item5", Text = "List Item 5" });
DropDownListProperties obj = new DropDownListProperties();
obj.DataSource = data;
DropDownListFields fields = new DropDownListFields();
fields.Text = "Text";
fields.Value = "Value";
obj.DropDownListFields = fields;
ViewData["properties"] = obj;
}
[HttpPost]
public ActionResult DropdownlistFeatures(DropDownListModel model)
{
if(ModelState.IsValid)
BindingData();
return View(model);
}
```

3. After that, created a view to get value and show an error message if the value of the DropDownList is not given.

RAZOR

```
@using (Html.BeginForm())
{
@Html.ValidationSummary(true)
@Html.EJ().DropDownListFor(Model =>
Model.DropData,(Syncfusion.JavaScript.Models.DropDownListProperties)ViewData
["properties"])
<br />
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("Post").Type(ButtonType
.Submit)
}
```

Template Support

By default you can add any text or image to the DropDownList list item. To customize the items layout or to create your own visualized elements you can use this template support.

Header Template

You can create the popup header by using HeaderTemplate property. You can add any HTML content in header template.

Note: Please refer the How-To section for the check all option in Header

Template Field

Create a set of div containers with common syntax or elements and assign it to the Template property. You can add any HTML mark-up element inside the DropDownList list using this property.

In the demo, a List data is created with Text, Image, Role and Country which is initialized with DataSource property. Content template is created by using the corresponding fields and assigned in template property. The content template is customized with images and custom CSS styles to visualize the items in popup.

Copyright © 2001 - 2020 Syncfusion Inc.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Employee1>)
ViewData["LocalDataSource"]).HeaderTemplate("<div
class='eheader'><span>PHOTO</span>
<span>DETAILS</span></div>").Template("<div><Image class='ImageId'
src='../Content/Employees/${Image}.png' alt='employee'/> <div class='ename'>
${Text} </div><div class='role'> ${Role} </div><div class='cont'> ${Country}
</div></div>")
```

CSS

```
.ImageId {
margin: 0;
padding: 3px 10px 3px 3px;
border: 0 none;
width: 60px;
height: 60px;
float: none;
}
```

C#

```
public ActionResult Index()
{
List<Employee1> Data = new List<Employee1>();
Data.Add(new Employee1
{
Text = "Erik Linden",
Role = "Representative",
Country = "England",
Image = "3",
ImageAttr = "class='ImageId'"
});
Data.Add(new Employee1
{
Text = "John Linden",
Role = "Representative",
Country = "Norway",
Image = "6",
ImageAttr = "class='ImageId'"
});
Data.Add(new Employee1
{
Text = "Louis",
Role = "Representative",
Country = "Australia",
Image = "7",
ImageAttr = "class='ImageId'"
});
Data.Add(new Employee1
{
Text = "Lawrence",
Role = "Representative",
Country = "India",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Image = "8",
ImageAttr = "class='ImageId'"
});
ViewData["LocalDataSource"] = Data;
return View();
}
public class Employee
{
public string Text { get; set; }
public string Role { get; set; }
public string Country { get; set; }
public string Image { get; set; }
public string ImageAttr { get; set; }
}
```

Note: Images for this sample are available in (installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\samples\web\themes\images

Customization

Adding watermark text

It provides the short description of the expected value in dropdown and will display the text until any item is selected. You can set this text using WatermarkText property.

HTML

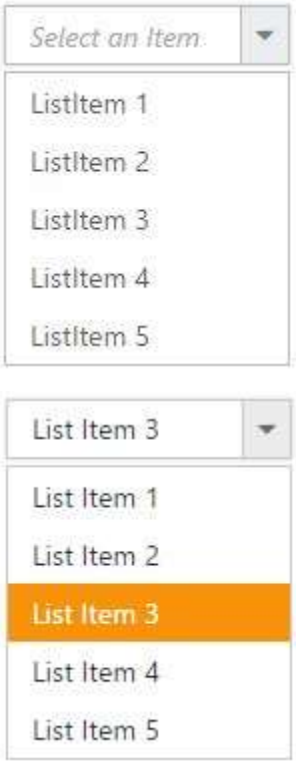
```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).WatermarkText("Select an Item")
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropdownData;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```



Applying Rounded Corner

You can use ShowRoundedCorner property to add rounded borders to the input and popup elements. By default, rounded corner property is disabled in DropDownList.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ShowRoundedCorner(true)
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Information: The browser support details for rounded corner is given here.

Enable/Disable the control

The Enabled property is used to indicate whether the control can respond to the user interaction or not. You can disable it by assigning false to this property. When the control is disabled state, you cannot interact with the control.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).Enabled(false)
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Applying HTML Attributes

Additional HTML attributes can be applied to the control by using HtmlAttributes property. The attributes such as name, required, read-only and disabled are directly applied to the input element of DropDownList, and other attributes such as style, class will be applied to the outer wrapper element of DropDownList.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).HtmlAttributes((IDictionary<string,object>)V
iewData["HtmlAttrData"])
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropdownData;
object StyleObj = new object();
StyleObj = "border:1px solid red;";
Dictionary<string, object> AttrVal = new Dictionary<string, object>
{
{"style" , StyleObj}
};
ViewData["HtmlAttrData"] = AttrVal;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Setting dimensions

Control Sizing

Fixed Size DropDownList control

You can customize the control dimensions using Width and Height properties. Fixed size values can be specified in pixel or percentage values. By default the DropDownList wrapper will be assigned with "143px" Width and "30px" Height.

Copyright © 2001 - 2020 Syncfusion Inc.

Fixed size popup list

You can customize the popup list dimensions using PopupWidth and PopupHeight properties. Fixed size values can be specified in pixel or percentage values. By default popup width is auto and popup height is "152px".

Auto Sizing

DropDownList is adaptive to mobile and web layout such that it is adjustable with screen resolution. The textbox will be rendered based on its parent containers dimensions on assigning 100% values to the width property. Default value for PopupWidth is auto, so when you assign 100% to PopupWidth then it will be rendered based on specified range.

Limit the number of items

You can use ItemsCount property to fetch only the specific number of items from the data source. To fetch the remaining items you can enable virtual scrolling support which loads the data on scrolling the data items in popup list.

Note: By default popup list is shown on DropDownList button click but you can display the list initially by enabling the ShowPopupOnLoad property.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ShowPopupOnLoad(true).ItemsCount(3)
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Popup resizing

To show a resize handle in the popup list, use EnablePopupResize property. You can customize the resize functionality by setting dimensions to the following properties.

MinPopupWidth	Default value is 0, once set you cannot resize below to the specified width
MaxPopupWidth	Default value is null, once set you cannot extend beyond to the specified width
MinPopupHeight	Default value is 0, once set you cannot resize below to the specified height
MaxPopupHeight	Default value is null, once set you cannot extend beyond to the specified height

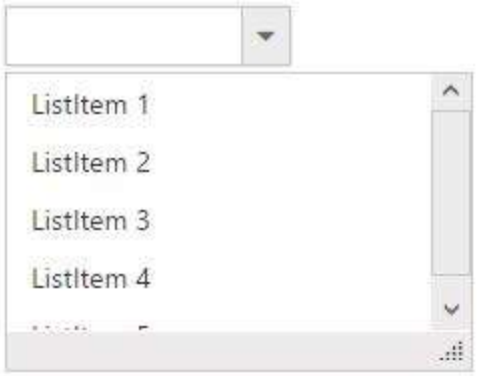
HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).EnablePopupResize(true).MaxPopupHeight("550p
x").MaxPopupWidth("550px").MinPopupHeight("150px").MinPopupWidth("150px")
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropdownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropdownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropdownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropdownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Search

Items are searched based on the keyed in values to the textbox. There are two types of searches,

- Incremental Search
- Filter Search

Incremental Search

Selects the item in the popup list based on the keyed in value. If the time taken to type exceeds 1000 milliseconds then filtered items will be reset based on the current input value. By default this mode of search is enabled. Incremental search can be case sensitive or case insensitive. To make case sensitive, you can use CaseSensitiveSearch property.

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList").Datasource((IEnumerable<Data>)ViewDa
ta["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).EnableIncrementalSearch(true).CaseSensitiveS
earch(true)
```

C#

```
public ActionResult Index()
{
List<Data> DropDownData = new List<Data>();
DropDownData.Add(new Data { Value = "emp1", Text = "Adams", Selected = true
});
DropDownData.Add(new Data { Value = "emp2", Text = "James", Selected = false
});
DropDownData.Add(new Data { Value = "emp3", Text = "Maria", Selected = true
});
DropDownData.Add(new Data { Value = "emp4", Text = "Jessica", Selected =
false });
DropDownData.Add(new Data { Value = "emp5", Text = "Jenneth", Selected =
false });
ViewData["DropDownSource"] = DropDownData;
return View();
}
public class Data
{
public string Value { get; set; }
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public string Text { get; set; }
}
```

Filter search

You can quickly locate specific item within a large data source by filtering matches with a search box. A text box appears in the popup list for searching when EnableFilterSearch property is enabled. By default, filtering returns the matched items list based on text in search textbox.

You can configure the search filter by using FilterType property that takes SearchFilterType enum values. There is two types of filter options,

- Starts With
- Contains

Note: Items are filtered based on “SearchFilterType.Contains” filter type by default.

HTML

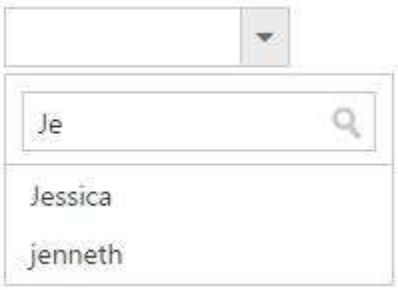
```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList").Datasource((IEnumerable<Data>)ViewDa
ta["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).EnableFilterSearch(true).FilterType(SearchFi
lterType.StartsWith)
```

C#

```
public ActionResult Index()
{
List<Data> DropDownData = new List<Data>();
DropDownData.Add(new Data { Value = "emp1", Text = "Adams", Selected = true
});
DropDownData.Add(new Data { Value = "emp2", Text = "James", Selected = false
});
DropDownData.Add(new Data { Value = "emp3", Text = "Maria", Selected = true
});
DropDownData.Add(new Data { Value = "emp4", Text = "Jessica", Selected =
false });
DropDownData.Add(new Data { Value = "emp5", Text = "Jenneth", Selected =
false });
ViewData["DropDownSource"] = DropDownData;
return View();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```



Information: When VirtualScrolling enabled with searching, then filter will be applied only on the DropDownList items available at the moment.

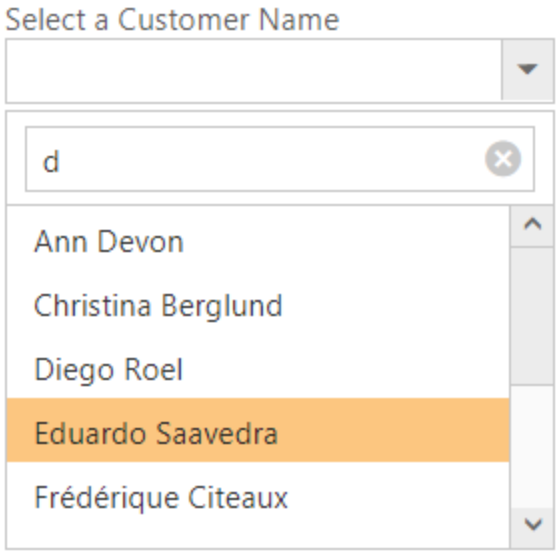
Server Filtering

Server filtering for displaying only a fixed amount of dataset from the whole dataset. In general, DropDownList displays just the data returned from the server. This feature is convenient for you to apply when the user does not want to see the whole dataset in the popup wrapper.

EnableServerFiltering If set to true, the filtering operations performed in the remote service and returns the result.

HTML

```
<div class="ctrllabel">Select a Customer Name</div>
@(Html.EJ().DropDownList("ContactName")
.Datasource(ds =>
ds.URL("http://js.syncfusion.com/demos/ejServices/Wcf/Northwind.svc/Customer
s").CrossDomain(true))
.DropDownListFields(f => f.Text("ContactName").Value("ContactName"))
.Width("100%")
.EnableFilterSearch(true)
.EnableServerFiltering(true)
.WatermarkText("Select a Customer Name")
)
```



This sample raises the query on Customer service. Returns ContactName records for customers with ContactName containing the string “d”.

State Persistence

DropDownList stores its model is local storage by defining the property EnablePersistence).

You can sustain the below given functionalities in DropDownList by enabling persistence property,

- Selected items value in the textbox
- Item’s selection state in the popup list

Control model will be stored in local storage / cookies of browser before page refreshes and reinitialized with the restored model after refresh.

The following properties are not included while maintaining DropDownList’s state in local storage to keep localStorage compact.

- Fields
- Data source
- Query

HTML

```
@model MVCApplication.Controllers.HomeController
<form id="form1">
```

```
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ShowCheckbox(true).Width("300px").EnablePers
istence(true)
<input type="submit" value="Get Value" />
</form>
```

C#

```
public ActionResult Index()
{
List<Data> DropDownData = new List<Data>();
DropDownData.Add(new Data { Value = "item1", Text = "ListItem 1" });
DropDownData.Add(new Data { Value = "item2", Text = "ListItem 2" });
DropDownData.Add(new Data { Value = "item3", Text = "ListItem 3" });
DropDownData.Add(new Data { Value = "item4", Text = "ListItem 4" });
DropDownData.Add(new Data { Value = "item5", Text = "ListItem 5" });
ViewData["DropDownSource"] = DropDownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

Accessing currently stored state

Persisted state can be accessed through local storage using corresponding key name. Key name formation would be in below order. It is combination of plugin name and control id.

JS

```
// DropDownList state as string
var dropdownlistStateString = window.localStorage.ejDropDownList_dropDown;
//DropDownList state as object
var dropdownlistStateObject =
JSON.parse(window.localStorage.ejDropDownList_dropDown);
```

Note: In the above example, ‘ejDropDownList’ is plugin name and _dropDown is control id.

Strongly Typed HTML Helper

The DropDownList control supports strongly typed HTML helpers which uses lambda expression to refer models or view models passed to a view template. These helpers allow you to define the value of the DropDownListFor from the model. The following steps explain how to use the strongly typed helpers to create DropDownListFor.

Add a class named ”DropDownListModel" in the Models folder and replace the code with the following code:

C#

```
public class DropDownListModel
{
[Display(Name = "Drop Down")]
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public List<DropDownValue> DropData { get; set; }
}
public class DropDownValue
{
public string Text { get; set; }
public string Value { get; set; }
}
```

In the controller, pass the model to the View.

C#

```
using MvcApplication.Models;
using Syncfusion.JavaScript.Models;
public ActionResult DropdownlistFeatures()
{
DropDownListModel model = new DropDownListModel();
BindingData();
return View(model);
}
public void BindingData()
{
List<DropDownValue> data = new List<DropDownValue>() { };
data.Add(new DropDownValue() { Value = "item1", Text = "List Item 1" });
data.Add(new DropDownValue() { Value = "item2", Text = "List Item 2" });
data.Add(new DropDownValue() { Value = "item3", Text = "List Item 3" });
data.Add(new DropDownValue() { Value = "item4", Text = "List Item 4" });
data.Add(new DropDownValue() { Value = "item5", Text = "List Item 5" });
DropDownListProperties obj = new DropDownListProperties();
obj.DataSource = data;
DropDownListFields fields = new DropDownListFields();
fields.Text = "Text";
fields.Value = "Value";
obj.DropDownListFields = fields;
ViewData["properties"] = obj;
}
```

In View, invoke the strongly typed DropDownListFor helper with the lambda expression to set the default value.

RAZOR

```
@model MvcApplication.Models. DropDownListModel
@Html.EJ().DropDownListFor(Model =>
Model.DropData,(Syncfusion.JavaScript.Models.DropDownListProperties)ViewData
["properties"])
```

Cascading operation can be performed in DropDownListFor.

Defines the Employee class as follows

C#

```
public class DropDownListModel
{
public List<Employee> DropData { get; set; }
public List<DeptDetails> getDept { get; set; }
}
public class Employee
{
public string Name { get; set; }
public string Department { get; set; }
}
public class DeptDetails
{
public string Department { get; set; }
public string Subject { get; set; }
}
```

In controller, defines Data source and properties for the both DropDownLists. The model will be passed to the view page. Here “DropDownListModel” class will be passed to the view.

C#

```
public ActionResult DropdownlistFeatures()
{
List<Employee> data = new List<Employee>() { };
data.Add(new Employee() { Name = "Nancy", Department = "Computer Science"
});
data.Add(new Employee() { Name = "Angel", Department = "Mechanics" });
data.Add(new Employee() { Name = "Prince", Department = "Electronics
Communication" });
data.Add(new Employee() { Name = "John", Department = "Information
Technology" });
data.Add(new Employee() { Name = "Daniha", Department = "Marine" });
DropDownListModel model = new DropDownListModel();
DropDownListProperties obj = new DropDownListProperties();
DropDownListFields fields = new DropDownListFields();
obj.DataSource = data;
obj.CascadeTo = "getDept";
fields.Text = "Name";
fields.Value = "Department";
obj.DropDownListFields = fields;
ViewData["properties"] = obj;
List<DeptDetails> dept = new List<DeptDetails>() { };
dept.Add(new DeptDetails() { Department = "Computer Science", Subject =
"Software Engineering" });
dept.Add(new DeptDetails() { Department = "Computer Science", Subject =
"Software Testing" });
dept.Add(new DeptDetails() { Department = "Computer Science", Subject = "Web
Technology" });
dept.Add(new DeptDetails() { Department = "Computer Science", Subject =
"Data Ware Housing" });
dept.Add(new DeptDetails() { Department = "Mechanics", Subject = "Thermal
Engineering" });
dept.Add(new DeptDetails() { Department = "Mechanics", Subject = "Materials
Engineering, Composites." });
dept.Add(new DeptDetails() { Department = "Mechanics", Subject = "Statics
and dynamics" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
dept.Add(new DeptDetails() { Department = "Mechanics", Subject = "Strength
of materials and solid mechanics" });
dept.Add(new DeptDetails() { Department = "Electronics Communication",
Subject = "Signals & Systems" });
dept.Add(new DeptDetails() { Department = "Electronics Communication",
Subject = "Electromagnetic Engineering" });
dept.Add(new DeptDetails() { Department = "Electronics Communication",
Subject = "Electronics Communication" });
dept.Add(new DeptDetails() { Department = "Information Technology", Subject
= "Analog Electronic Circuits" });
dept.Add(new DeptDetails() { Department = "Marine", Subject = "Effects of
waves" });
dept.Add(new DeptDetails() { Department = "Marine", Subject = "Towing and
mooring" });
dept.Add(new DeptDetails() { Department = "Marine", Subject = "Ocean
structures" });
DropDownListProperties deptProperties = new DropDownListProperties();
DropDownListFields objFields = new DropDownListFields();
deptProperties.DataSource = dept;
deptProperties.Enabled = false;
objFields.Text = "Subject";
objFields.Value = "Department";
deptProperties.DropDownListFields = objFields;
ViewData["Department"] = deptProperties;
return View(model);
}
```

C#

```
@Html.EJ().DropDownListFor(Model => Model.DropData,
(Syncfusion.JavaScript.Models.DropDownListProperties)ViewData["properties"])
@Html.EJ().DropDownListFor(Model => Model.getDept,
(Syncfusion.JavaScript.Models.DropDownListProperties)ViewData["Department"])
```

Localization

The DropDownList provides option to localize its strings, it is used to adapting the DropDownList to a particular local language. By default, the DropDownList will use the US English (en-US) as its language.

Note: The culture name has to be specified in a standard format such as [Language Code]-[County/Region Code].

To localize the dropdownlist's strings with your own localization, copy the default language informations and localize the strings in the values column. For example, to localize the DropDownList in German language ("de-DE").

JAVASCRIPT

```
ej.DropDownList.Locale["de-DE"] = {
emptyResultText: "Keine Vorschläge" //replace with your text
};
```

Set the locale property of the DropDownList to the new language.

HTML

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().DropDownList("selectCar").Datasource((IEnumerable<Product>)ViewBa
g.data).DropDownListFields(df =>
df.Text("name").Value("name")).WatermarkText("Select a
Student").Width("100%").Locale("de-
DE").EnableFilterSearch(true).EnableIncrementalSearch(true)
```

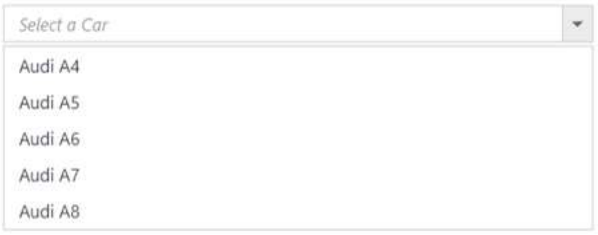
Load On Demand

Load on demand feature allows the DropDownList items load on request from the service/database, during only on click the DropDown icon or DropDownList. This functionality helps to improve performance on control initial rendering time. Because data items load on request.

The loadOnDemand property is used to enable or disable the load on demand functionality of the DropDownList.

ASPX-CS

```
@Html.EJ().DropDownList("selectCar").TargetID("carsList").Width("30%").Water
markText("Select a Car").LoadOnDemand(true)
<div id="carsList">
<ul>
<li>Audi A4</li>
<li>Audi A5</li>
<li>Audi A6</li>
<li>Audi A7</li>
<li>Audi A8</li>
</ul>
</div>
```



Accessibility

Keyboard Navigation

You can use the keyboard short cut keys as an alternative to the mouse and interact with DropDownList control.

Keyboard shortcut keys are,

Key	Single selection	Multi-selection
Access key + j	Sets focus to the input	Sets focus to the input
Up	Selects the previous item when the popup is opened/closed	Selects the previous item when the popup is opened/closed and clears all other selection
Down	Selects the next item when the popup is opened/closed	Selects the next item when the popup is opened/closed and clears all other selection
Page up	Selects the item in next page (i.e.,) scrolls down to next set of items when the popup is opened/closed	Selects the item in next page (i.e.,) scrolls down to next set of items when the popup is opened/closed and clear all existing selection
Page down	Selects the item in previous page (i.e.,) scrolls up to previous set of items when the popup is opened/closed	Selects the item in previous page (i.e.,) scrolls up to previous set of items when the popup is opened/closed and clear all existing selection
Left arrow	Selects the previous item when the popup is opened/closed. But in RTL mode selects next item	Selects the previous item when the popup is opened/closed and clears all other selection but in RTL mode selects the next item
Right arrow	Selects the next item when the popup is opened/closed. But in RTL mode selects previous item	Selects the next item when the popup is opened/closed and clears all other selection but in RTL mode selects the previous item
Backspace	No actions	Deletes the selected items from last when visual mode is enabled. (i.e.,) on first backspace key press, the last item will be selected and second backspace press will remove the corresponding item.
Tab	Close the popup if it is opened and focuses to next DOM element	Close the popup if it is opened and focuses to next DOM element
End	Selects the last list item	Select the last item and clear all selection
Home	Selects the first list item	Select the first item and clear all selection
Esc	Close the popup if itâ€™s opened	Close the popup if itâ€™s opened

Copyright © 2001 - 2020 Syncfusion Inc.

Space bar	Close the popup is itâ€™s opened	Check and uncheck the items which is focused.
Delete	No actions	Deletes the focused item in textbox when visual mode is enabled
Shift + up	Selects the previous item when the popup is opened/closed	Selects the immediate preceding item from current selected item
Shift + down	Selects the next item when the popup is opened/closed	Selects the immediate successive item from current selected item
Shift + home	Select the first list item	Select all items between focused item to first item
Shift + end	Selects the last list item	Select all items between focused item to last item
Shift + page up	Selects the item in previous page (i.e.,) scrolls down to previous set of items when the popup is opened/closed	Select all item between focused item to previous page or previous set of items when the popup is opened/closed
Shift + page down	Selects the item in next page (i.e.,) scrolls up to next set of items when the popup is opened/closed	Select all item between focused item to next page or next set of items when the popup is opened/closed
Ctrl + up	Selects the previous item when the popup is opened/closed	Maintain current selections and hovers to the previous item when the popup is opened/closed
Ctrl + down	Selects the next item when the popup is opened/closed	Maintain current selection and hovers to the next item when the popup is opened/closed
Alt + down	Opens the popup if itâ€™s closed	Open the popup if itâ€™s closed
Alt + up	Closes the popup if itâ€™s opened	Close the popup if itâ€™s opened
Enter	Closes the popup if itâ€™s opened	Selects the focused item when ctrl key pressed otherwise closes the popup if itâ€™s opened
Shift + Tab	Focuses the previous DOM element	Focuses the previous DOM element
Ctrl + shift + up	Selects the previous item when the popup is opened/closed	Maintains the existing items selection and selects the previous item from current selection.

Copyright © 2001 - 2020 Syncfusion Inc.

Ctrl + shift + down	Selects the next item when the popup is opened/closed	Maintain the existing items selection and selects next item from current selection.

Note:

i) *For Ctrl and Shift operations with multi-selection, the current focused item should be selected.*

ii) 
No round robin method is used on navigating through the list items in pop up, so that navigation stops when reaching the start/end of the popup list.

How To

Add check all option in popup list?

You can use HeaderTemplate property to add any HTML element. Code snippet to add check all option is given below,

HTML

```
@model MVCApplication.Controllers.HomeController
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).HeaderTemplate("<div class='temp'><input
id='check' type='checkbox' />
</div>").ShowCheckbox(true).Width("300").ClientSideEvents(clientEvent=>clien
tEvent.Create("create"))
```

CSS

```
.temp {
height: 30px;
display: block;
padding-left: 13px;
padding-top: 5px;
border-bottom: 1px solid #c8c8c8;
}
.e-chkbox-wrap .e-text {
font-size: 14px;
padding-left: 10px;
}
```

JS

Copyright © 2001 - 2020 Syncfusion Inc.

```
function create(args) {
$("#check").ejCheckBox({ text: "Check All", change: "Change" });
}
function Change(args) {
window.flag = true;
var obj = $("#DropDownList1").ejDropDownList("instance");
if (args.isChecked) obj.checkAll();
else obj.uncheckAll();
window.flag = false;
}
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "item1", Text = "List Item 1" });
DropdownData.Add(new Data { Value = "item2", Text = "List Item 2" });
DropdownData.Add(new Data { Value = "item3", Text = "List Item 3" });
DropdownData.Add(new Data { Value = "item4", Text = "List Item 4" });
DropdownData.Add(new Data { Value = "item5", Text = "List Item 5" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
public string Value { get; set; }
public string Text { get; set; }
}
```

The following screenshot exhibits the output of the above code,

Render the DropDownList in Partial View using normal mode

Create a Partial View and define as follows

RAZOR

```
@using DropdownList.Models
@Html.EJ().DropDownList("DropDown").Datasource((List<DropDownValue>)ViewData
["DataSrc"]).DropDownListFields(df=>df.Text("Text").Value("Value"))
@Html.EJ().ScriptManager()
```

Note: While rendering a control in the partial view, we need to specify @Html.EJ().ScriptManager() in the partial view page after the initializing the control.

Render the partial view into parental view

RAZOR

```
@Html.Partial("PartialView1")
```

Define DataSource and other required properties for rendering a simple DropDownList

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
public ActionResult MainView()
{
List<DropDownValue> data = new List<DropDownValue>() { };
data.Add(new DropDownValue() { Value = "item1", Text = "List Item 1" });
data.Add(new DropDownValue() { Value = "item2", Text = "List Item 2" });
data.Add(new DropDownValue() { Value = "item3", Text = "List Item 3" });
data.Add(new DropDownValue() { Value = "item4", Text = "List Item 4" });
data.Add(new DropDownValue() { Value = "item5", Text = "List Item 5" });
ViewData["DataSrc"] = data;
return View();
}
```

Render the DropDownList in Partial View using Unobtrusive mode

When you enable the **unobtrusive** in your application, refer to the **ej.unobtrusive.min.js** file in the application.

You have to set the value of **UnobtrusiveJavaScriptEnabled** to **true** in Root directory **web.config** file as shown in the following code example.

XML

```
<appSettings>
<add key="UnobtrusiveJavaScriptEnabled" value="true" />
</appSettings>
```

After setting the value as **true,** refer to the unobtrusive script file in the **_Layout page** as shown in the following code example.

RAZOR

```
<head>
<script src="@Url.Content("~/Scripts/ej/ej.unobtrusive.min.js")"></script>
</head>
```

Create a Partial View and define as follows

RAZOR

```
@using DropdownList.Models
@Html.EJ().DropDownList("DropDown").Datasource((List<DropDownValue>)ViewData
["DataSrc"]).DropDownListFields(df=>df.Text("Text").Value("Value"))
```

Render the partial view into parental view.

RAZOR

```
@Html.Partial("PartialView1")
```

Define DataSource and other required properties for rendering a simple DropDownList

C#

```
public ActionResult MainView()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
List<DropDownValue> data = new List<DropDownValue>() { };
data.Add(new DropDownValue() { Value = "item1", Text = "List Item 1" });
data.Add(new DropDownValue() { Value = "item2", Text = "List Item 2" });
data.Add(new DropDownValue() { Value = "item3", Text = "List Item 3" });
data.Add(new DropDownValue() { Value = "item4", Text = "List Item 4" });
data.Add(new DropDownValue() { Value = "item5", Text = "List Item 5" });
ViewData["DataSrc"] = data;
return View();
}
```

Dynamically bind the data to ejDropDownList on AJAX call

Render the DropDownList with the empty DataSource, In client event called “click” of Button control, the AJAX post is called.

C#

```
@Html.EJ().DropDownList("bikeList").DropDownListFields(df =>
df.ID("id").Text("text")).ClientSideEvents(e => e.Create("onCreate"))<br />
@Html.EJ().Button("button").Text("click").ClientSideEvents(e =>
e.Click("onClick"))
```

HTML

```
public class DropDownController : Controller
{
// GET: DropDown
public ActionResult Index()
{
return View();
}
public ActionResult Add()
{
return RedirectToAction("Index", "DropDown");
}
}
```

Once the AJAX call is success, bind the data to the dropdown list on AJAX call by using the property “dataSource”.

JAVASCRIPT

```
function onClick() {
$.ajax({
url: '/DropDown/Add',
type: 'POST'
}).success(function (result) {
BikeList = [
{ id: "bk1", text: "Apache RTR" }, { id: "bk2", text: "CBR 150-R" }, { id:
"bk3", text: "CBZ Xtreme" },
{ id: "bk4", text: "Discover" }, { id: "bk5", text: "Dazzler" }, { id:
"bk6", text: "Flame" },
{ id: "bk7", text: "Fazer" }, { id: "bk8", text: "FZ-S" }, { id: "bk9",
text: "Pulsar" },
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{ id: "bk10", text: "Shine" }, { id: "bk11", text: "R15" }, { id: "bk12",
text: "Unicorn" }
];
var data1 = $("#bikeList").data("ejDropDownList");
data1.option("dataSource", BikeList);
})
}
```

Remove validation error message on item selection

You can remove the validation error message of DropDownList on selecting an item through change event using the below code.

RAZOR

```
@model MVCApplication.Controllers.HomeController
<form id="form1">
@Html.EJ().DropDownList("DropDownList1").Datasource((IEnumerable<Data>)ViewD
ata["DropDownSource"]).ClientSideEvents(e =>
e.Change("change")).DropDownListFields(Df =>
Df.Text("Text").Value("Value")).ValidationMessage(message =>
message.AddMessage("required", "* Required")).ValidationRules(vr =>
vr.AddRule("required", true))
<br /><input type="submit" value="Submit" />
</form>
```

JAVASCRIPT

```
$.validator.setDefaults({
ignore: [],
errorClass: 'e-validation-error', // to get the error message on jQuery
validation
errorPlacement: function (error, element) {
$(error).insertAfter(element.closest(".e-widget"));
}
// any other default options and/or rules
});
function change(args){
this.element.valid();  //validation of dropdownlist through change event.
}
```

C#

```
public ActionResult Index()
{
List<Data> DropdownData = new List<Data>();
DropdownData.Add(new Data { Value = "10", Text = "10" });
DropdownData.Add(new Data { Value = "20", Text = "20" });
DropdownData.Add(new Data { Value = "30", Text = "30" });
DropdownData.Add(new Data { Value = "40", Text = "40" });
DropdownData.Add(new Data { Value = "50", Text = "50" });
ViewData["DropDownSource"] = DropdownData;
return View();
}
public class Data
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public string Value { get; set; }
public string Text { get; set; }
}
```

Render DropDownList from code behind

DropDownList can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of DropDownList using DropDownList properties from code behind.

RAZOR

```
@{Html.EJ().DropDownList("Customer", Model).Render(); }
```

C#

```
public ActionResult Index()
{
DropDownListProperties DDLObj = new DropDownListProperties();
DDLObj.DataSource =
"http://js.syncfusion.com/ejServices/wcf/NorthWind.svc/";
DDLObj.Query = "ej.Query().from('Suppliers').select('SupplierID',
'ContactName').take(10)";
DDLObj.DropDownListFields.Text = "ContactName";
DDLObj.DropDownListFields.Value = "SupplierID";
return View(DDLObj);
}
```

FileExplorer

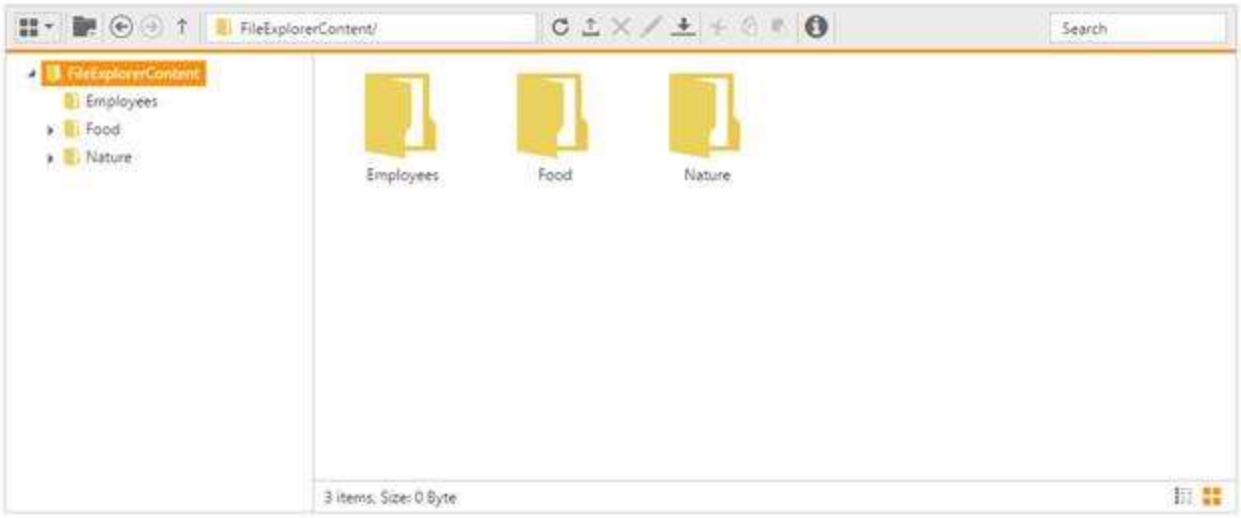
Overview

The EJ MVC FileExplorer component provides all the functionalities that is available in EJ FileExplorer, since it is a server side wrapper of EJ FileExplorer widget. It is an interface for managing the file system through any web application. It allows the user to perform the most common file operations such as browse files, open, create, rename, copy, paste or move, delete and file searching.

For a live demo of FileExplorer check the online sample from here.

Note: The FileExplorer control was officially added with the Essential Studio ASP.NET MVC package from the v13.1 release only.

Copyright © 2001 - 2020 Syncfusion Inc.



Key features

- Windows explorer like functionalities and appearances
- Handy file operations (copy, paste, move and delete)
- File download and upload
- File type restriction
- Easy UI customization
- Different layouts (grid, tile and large icons view)
- Context menu support
- Built-in image viewer support
- Keyboard navigation
- Right to Left alignment (RTL) support
- Localization support
- File access rules

Getting Started

The following section is briefly explain the things to get started with FileExplorer control.

A new MVC Application and required assemblies with dependent files

To get start with Essential ASP.NET MVC FileExplorer, create a new MVC Application and add the required assemblies in references and then refer the below specified dependent CSS file as well as scripts

To create a MVC Project and add necessary assemblies you can use the help of the given MVC-Getting Started Documentation.

Adding the references

To include the control in the application the following references need to be added:

- CSS references
- Script references

CSS file

- ej.web.all.min.css includes all widgets styles (To know more about theme refer Theming in Essential JavaScript Component

Note: Essential JS widgets having the support for 13 built-in themes, to know more please check here

Script references

The external script dependencies of the FileExplorer widget are,

- jQuery 1.7.1 or later versions.
- jsrender – for grid view template.

And the internal script dependencies of the FileExplorer widget are:

File	Description/Usage
ej.core.min.js	Must be referred always before using all the JS controls.
ej.data.min.js	Used to handle data operation and should be used while binding data to JS controls.
ej.touch.min.js	Used to handle touch operations
ej. draggable.min.js	Used to handle the drag and drop functionality
ej.scroller.min.js	Used to show the scrollbar in the layout area
ej.button.min.js	Used to display the buttons in the toolbar
ej.checkbox.min.js	Used to display the checkbox in files items
ej.splitbutton.min.js	Used to display the split buttons in the toolbar
ej.treeview.min.js	Used to display the â€œTreeViewâ€• in the navigation pane
ej.uploadbox.min.js	Used to perform the upload functionalityÂ
ej.waitingpopup.min.js	Used to showcase the waiting popup
ej.dialog.min.js	Used to create the alert windowsÂ
ej.splitter.min.js	Used as the body section to separate the navigation and layout area
ej.toolbar.min.js	Used to showcase the hearer section
ej.menu.min.js	Used to showcase the context menu
ej.grid.min.js	Used to showcase the grid layout view

Copyright © 2001 - 2020 Syncfusion Inc.

ej.fileexplorer.min.js	FileExplorer plugin
ej.globalize.min.js	Used to working with different localization culture formats

You can use the “**ej.web.all.min.js**” file, which encapsulates all the EJ MVC controls and frameworks in one single file

Note: To add required assembly references, scripts and CSS files automatically into your application, please refer following link http://help.syncfusion.com/aspnetmvc/getting-started#through-syncfusion-nuget-packages-2. Also, it configures the “web.config” file automatically.

FileExplorer using helper

In the view page, add FileExplorer helper as shown below.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
)
```

In above code block, “Path” denotes the URL of filesystem that are to be explored in "FileExplorer" and “AjaxAction” specifies the URL of server side AJAX handling method that handles the file operations of FileExplorer control. So “Path” and “AjaxAction” are the mandatory configuration at here.

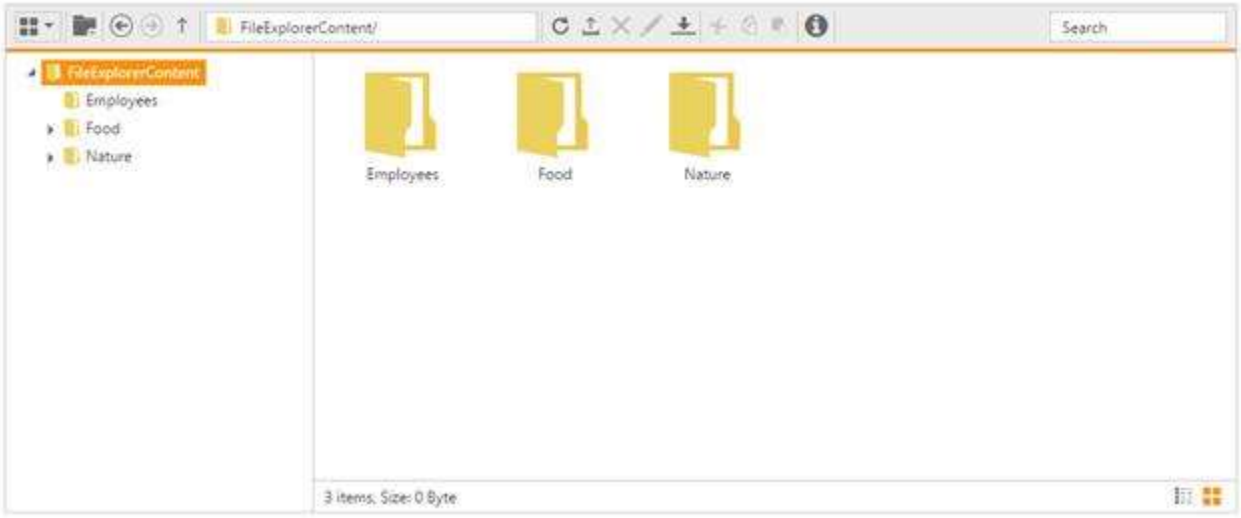
Add the following code example to the corresponding controller page.

C#

```
public ActionResult FileActionDefault(FileExplorerParams args)
{
FileExplorerOperations operation = new FileExplorerOperations();
switch (args.ActionType)
{
case "Read":
return Json(operation.Read(args.Path, args.ExtensionsAllow));
case "CreateFolder":
return Json(operation.CreateFolder(args.Path, args.Name));
case "Paste":
return Json(operation.Paste(args.LocationFrom, args.LocationTo, args.Names,
args.Action, args.CommonFiles));
case "Remove":
return Json(operation.Remove(args.Names, args.Path));
case "Rename":
return Json(operation.Rename(args.Path, args.Name, args.NewName,
args.CommonFiles));
case "GetDetails":
return Json(operation.GetDetails(args.Path, args.Names));
case "Download":
operation.Download(args.Path, args.Names);
break;
case "Upload":
operation.Upload(args.FileUpload, args.Path);
break;
case "Search":
```

```
return Json(operation.Search(args.Path, args.ExtensionsAllow,
args.SearchString, args.CaseSensitive));
}
return Json("");
}
```

Once you have completed the above steps, you will get an output like below.



Note: In the section, you can know the details about file handling operations, which are performed at server side of “FileExplorer”.

Note: If you are using 13.3.0.7rd or later version of script files and assemblies, above specified code blocks are helpful to render “FileExplorer” control. Also in future, we will provide the support based on this. If you are using the older version of Essential Studio (Before 13.3.0.7), refer following section to render “FileExplorer” control.

Behavior Settings

Here are the some properties to customize the behavior of FileExplorer.

File type restriction

FileExplorer control showcase all the files from the filesystem, here you can customize the file types that what you want to show by using “FileTypes” property. It filter the files based on the file extensions.

By default it having the value " \.\ ", so it allows all the file types. In case of image browser you can allow the image files only by setting “*.png,* .gif, *.jpg,* .jpeg”, so it doesn’t allow the other type of files.

In the view page, add FileExplorer helper and specify the file type restriction as shown below.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.FileTypes("*.png, *.gif, *.jpg, *.jpeg, *.docx")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Customize the AJAX request settings

As you already know FileExplorer is a client – server based control and each action performed in the client sends an AJAX request to the server to perform the server side operations. While the AJAX request, the AJAX configurations can be customized through "AjaxSettings" property.

The beforeAjaxRequest event will be triggered before the AJAX request is performed. You can modify the ajax request in this event.

You can see the following requests passed during the **client – server** actions:

- Read
- Create folder
- Remove
- Rename
- Paste
- Get details
- Upload
- Download
- Get Image
- Search

The actions "Read, CreateFolder, Remove, Rename, Paste, GetDetails, Search" are supported all the jQuery AJAX configurations. The remaining actions "Upload, Download, GetImage" are accepted the URL only.

If you want to customize read action alone, the AJAX "**Url**" and "**DataType**" are changed for the "Read" action.

In the view page, add FileExplorer helper and specify the AJAX settings for Read request as shown below.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("http://js.syncfusion.com/demos/ejServices/Content/FileBrowser/")
.AjaxAction("http://js.syncfusion.com/demos/ejServices/api/FileExplorer/File
Operations")
.AjaxSettings(settings =>
settings.Read(read =>
read.Url("http://js.syncfusion.com/demos/ejServices/api/FileExplorer/FileOpe
rationsCors")
.DataType("jsonp")
))
)
```

User Interface

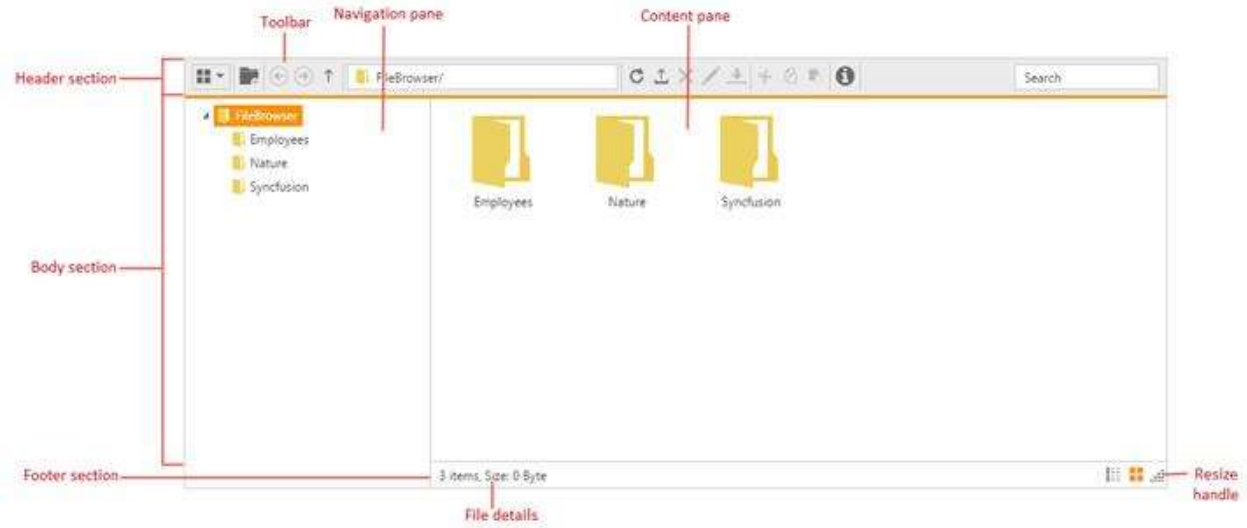
FileExplorer UI combined of several sections like header, body and footer. Each section having the corresponding components to perform the FileExplorer related operations.

- The **header section** contains the toolbar which having the list of tools to perform the file and navigation related operations.
- The **body section** is the main area which explores the filesystem contents. It separated into

Copyright © 2001 - 2020 Syncfusion Inc.

- **Navigation pane** which contains the tree view to showcase the folder hierarchy
- **Content pane** which show cases the files from the file system. The files in the content pane can be viewable in the following modes
- Grid
- Tile
- Large Icons
- The **footer section** contains the status bar which showcases the file details.

The following screenshot shows the diagrammatic detail of FileExplorer UI:



From above screenshot, you can see FileExplorer has several subcomponents for different functionalities. The upcoming sections explains the brief details of each components and their customizations.

File Actions

The FileExplorer provides the support for file and folder related operations and these can be done through the toolbar items as well as through the context menu items.

File action through Toolbar

The toolbar element is placed in the header section, and it having the list of tools to perform the file, navigation and search related operations.

For more details about file action through toolbar, please refer here.

File action through Context menu

The FileExplorer having the support for context menu which opens while right click on any file or folder. The context menu having the set of items which is used to perform the corresponding operations in a handy picture way. For example the user can delete the file through the context menu by right click on it.

In FileExplorer, in the following places the context menu appears.

- While right click on “TreeView” nodes (from navigation pane)
- While right click on file / folder
- While right click on layout (content pane)

Copyright © 2001 - 2020 Syncfusion Inc.

For more details about file action through context menu, please refer here.

Access Control

The FileExplorer provides method to assign permissions or access rights to specific users and group of users. It allows you to define access permissions for folders and files using a set of access rules to user(s).

The FileAccessInfo allows you to specify a Root **Path** and **Role**, and lists the permission (allow or deny) associated with this **Rules**. You can specify permissions to Copy, Download, Edit, Edit Contents, Path, Read, Role, and Upload a file/folder. The rule priority is determined by its index within an access rules collection.

Syntax

C#

```
// For File rule
new AccessRule { Path = "Documents/*.*", Role = "Document Manager", Read =
Permission.Allow, Edit = Permission.Allow, Copy = Permission.Allow, Download
= Permission.Allow },
// For Folder rule
new AccessRule { Path = "Documents/*", Role = "Document Manager", Read =
Permission.Allow, Edit = Permission.Allow, Copy = Permission.Allow,
EditContents = Permission.Allow, Upload = Permission.Allow },
```

The below table list out the FileAccessInfo properties:

Properties	Description
Role	Specifies the which role is applied
Rules	Specifies the collections of rules for folder and files
RootPath	Specifies the root path of the folderâ€™s which want to be secure

The below table below list out the AccessRule properties which is available for file and folder access rules.

Properties	Applicable for File	Applicable for Folder	Description
Copy	Yes	Yes	Specifies the permission to copy a file/folder
Download	Yes	No	Specifies the permission to download a file
Edit	Yes	Yes	Specifies the permission to edit a file/folder
EditContents	No	Yes	Specifies the permission to edit its content for folder
Path	Yes	Yes	Specifies the path to apply the rules which are defined
Read	Yes	Yes	Specifies the permission to read a file/folder content

Copyright © 2001 - 2020 Syncfusion Inc.

Role	Yes	Yes	Specifies the role to which the rule is applied
Upload	No	Yes	Specifies the permission to upload files to a folder

To specify the rule to be allow/deny, use the Permission enumeration values:

Permission	Description
Allow	Specify the rule to be allowed
Deny	Specify the rule to be denied

You can associate any number of access rules with specific security roles, it allows grouping related permissions together. To associate an access rule with a security role, assign the role's name to the AccessRule's Role property.

FileAccessOperations

The **FileAccessOperations** class allows user to perform the most common file operations such as read, create, rename, copy, paste or move, delete and file searching. The class helps to handle the file access operations in server end. You implement a new custom class for handling file operations in server end by inheriting this class.

By default, we send following parameters in data field of corresponding AJAX request to handle the server side operation. The request parameter and response data are explained in following table.

Operation	Default Request Parameter	Response data	Details
Read	string path, string filter, IEnumerable<object> selectedItems	It should be in JSON format with key name as files and cwd. The JSON fields contains the following field names 'name, isFile, hasChild, permission'. For example: {"cwd":{"name":"FileContent","type":"Directory","size":0,"dateModified":"3/30/2016 9:19:27 PM","hasChild":true,"isFile":false,"filterPath":null,"permission":{"Copy":false,"Download":false,"Edit":false,"EditContents":false,"Read":true,"Upload":false}}, "files":[{"name":"Documents","type":"Directory","size":0,"dateModified":"3/30/2016 9:20:10 PM","hasChild":false,"isFile":false,"filterPath":null,"permission":{"Copy":true,"Download":false,"Edit":false,"EditContents":true,"Read":true,"Upload":true}}, {"name":"Nature","type":"Directory","size":0,"dateModified":"3/30/2016 9:19:27 PM","hasChild":false,"isFile":false,"filterPath":null,"permission":{"Copy":false,"Download":false,"Edit":false,"EditContents":false,"Read":false,"Upload":false}}], "details":null, "error":null}	It used to get all immediate files and sub-folders of the given path and

			it returns the matched type of files only, which are specified in 'filter' parameter. (here cwd represents details of the given path and files represents details of the child files and folders of the

			given path)
CreateFolder	string path, string name, IEnumerable<object> selectedItems	It is in JSON format with key name as files. The 'name' and 'permission' fields are necessary on return JSON data. For example: {"cwd":null, "files":[{"name":"New Folder", "type":"Directory","size":0,"dateModified":"4/6/2016 2:55:22 PM","hasChild":true,"isFile":false,"filterPath":null,"permission":{"Copy":true, "Download":false,"Edit":true,"EditContents":true,"Read":true,"Upload":true} }], "details":null, "error":null}	It used to create a new folder in given path with specified name.(here files represents details of the newly added folderâ€™s)
Paste	string sourceDir, string backupDir, string[] names, string option, IEnumerable<CommonFileDetails> commonFiles, IEnumerable<o	It returns the pasted file details or null. For example: {"cwd":null, "files":[{"name":"bird(1).jpg","type":"File","size":102182,"dateModified":"3/23/2016 6:05:32 PM","hasChild":false,"isFile":true,"filterPath":null,"permission":{"Copy":true, "Download":true,"Edit":true,"EditContents":true,"Read":true,"Upload":true}}], "details":null, "error":null}	This method helps to copy or move files from

	bject> selectedItems, IEnumerable<object> targetFolder		one location to another location.(here files represents details of the pasted items)
Remove	string[] names, string path, IEnumerable<object> selectedItems	It returns the removed file details or null. For example: {"cwd":null, "files":[{"name":"New folder", "type":"Directory","size":0,"dateModified":"4/6/2016 3:05:17 PM","hasChild":true,"isFile":false,"filterPath":null,"permission":{"Copy":true, "Download":false,"Edit":true,"EditContents":true,"Read":true,"Upload":true} }], "details":null, "error":null}	It helps to remove the specified items from given path.(here files represents details of the removed

			item)
Rename	string path, string oldName, string newName, IEnumerable<CommonFileDetails> commonFiles, IEnumerable<object> selectedItems	It returns the renamed file details or null. For example: {"cwd":null, "files":[{"name":"my folder", "type":"Directory","size":0,"dateModified":"4/6/2016 3:05:17 PM","hasChild":true,"isFile":false,"filterPath":null,"permission":{"Copy":true, "Download":false,"Edit":true,"EditContents":true,"Read":true,"Upload":true} }], "details":null, "error":null}	This method helps to rename the file/folder, which is available in given path.(here files represents details of the renamed items)
GetDetails	string path, string[] names, IEnumerable<object> selectedItems	It is in JSON data with key name as details. For example: {"cwd":null, "files":null, "details":[{"Name":"green.jpg","Location":"C:\\Users\\XXX\\AppData\\Local\\\Syncfusion\\EssentialStudio\\14.1.0.40\\MVC\\Samples\\web\\FileContent \\Documents\\green.jpg","Type":".jpg","Size":89894,"Created":"3/30/2016 9:19:25 PM","Modified":"3/23/2016 6:05:32 PM","Permission":{"Copy":true,"Download":true,"Edit":true,"EditContents":true,"Read":true,"Upload":true}}], "error":null}	This method used to get the details of the specified

			file or directory. (here details represents details of the given path which is need to be showcased to user)
Download	string path, string[] names, IEnumerable<object> selectedItems	Void	This method helps to download the specified files in the given path.

Upload	IEnumerable<System.Web.HttpPostedFileBase> files, string path, IEnumerable<object> selectedItems	Void	This method helps to upload the specified files to given path.
Search	string path, string filter, string searchString, bool caseSensitive, IEnumerable<object> selectedItems	It returns JSON data with key name as files and JSON fields need to be with following field names 'name, isFile, hasChild, permission'. For example: {"cwd":{"name":"FileContent","type":"Directory","size":0,"dateModified":"3/30/2016 9:19:27 PM","hasChild":true,"isFile":false,"filterPath":null,"permission":{"Copy":false,"Download":false,"Edit":false,"EditContents":false,"Read":true,"Upload":false}}, "files":[{"name":"bird.jpg","type":"File","size":102182,"dateModified":"1/9/2016 6:48:42 AM","hasChild":false,"isFile":true,"filterPath":null,"permission":{"Copy":false,"Download":false,"Edit":false,"EditContents":true,"Read":true,"Upload":false}}, {"name":"sea.jpg","type":"File","size":97145,"dateModified":"1/9/2016 6:48:42 AM","hasChild":false,"isFile":true,"filterPath":null,"permission":{"Copy":false,"Download":false,"Edit":false,"EditContents":false,"Read":true,"Upload":true}}], "details":null, "error":null}	It used to search all the matched files and sub-folders in the given folder path also it filters the specified files using it

			type s.

Note: If needed, customer can also add additional data along with existing properties using **FileExplorerDirectoryContent** class

Example

We can make a FileExplorer with access rule by doing following steps,

1. Add the following code example to the corresponding View page to render the FileExplorer.

CSHARP

```
@Html.EJ().FileExplorer("fileExplorer").Path("~/FileContent/").AjaxAction(@Url.Content("FileAccessDefault"))
```

2. Add the following code example to the corresponding controller page. The FileAccessDefault method triggers from AJAX request with specific ActionType value as parameter.

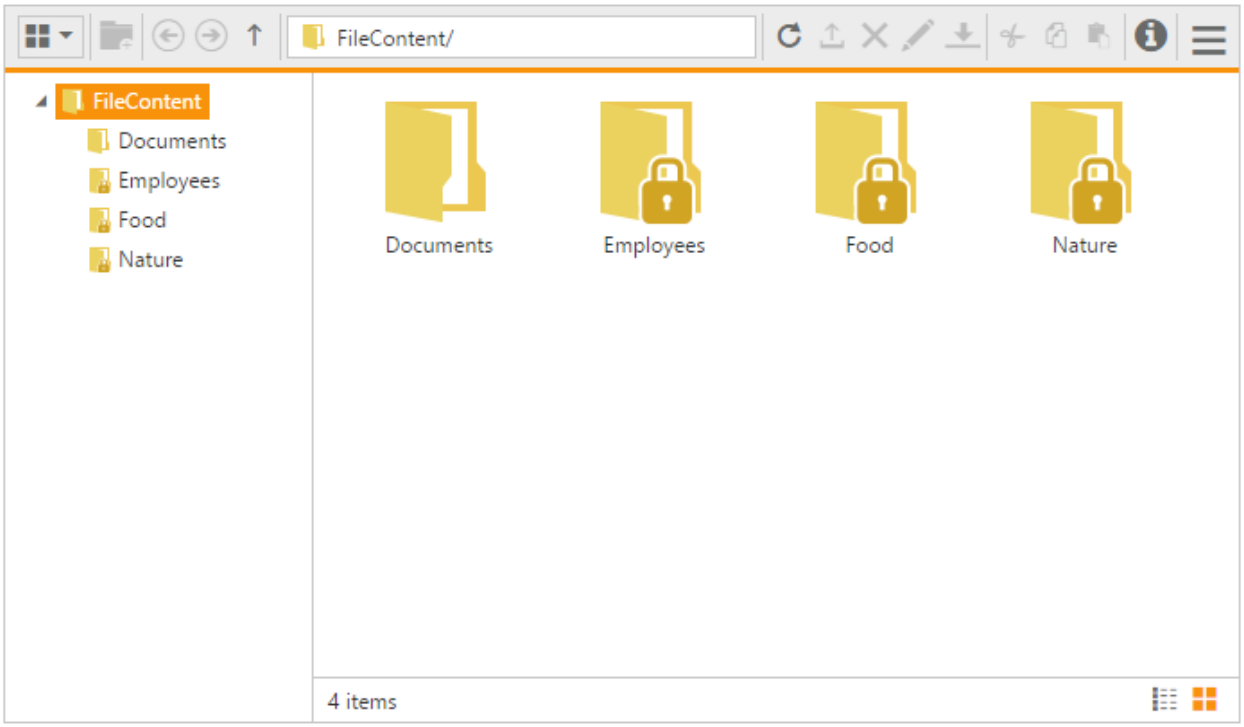
CSHARP

```
public ActionResult FileAccessDefault(FileExplorerParams args)
{
FileAccessOperations operation = new FileAccessOperations(GetRules());
switch (args.ActionType)
{
case "Read":
return Json(operation.Read(args.Path, args.ExtensionsAllow));
case "CreateFolder":
return Json(operation.CreateFolder(args.Path, args.Name));
case "Paste":
return Json(operation.Paste(args.LocationFrom, args.LocationTo, args.Names,
args.Action, args.CommonFiles));
case "Remove":
return Json(operation.Remove(args.Names, args.Path));
case "Rename":
return Json(operation.Rename(args.Path, args.Name, args.NewName,
args.CommonFiles));
case "GetDetails":
return Json(operation.GetDetails(args.Path, args.Names));
case "Download":
operation.Download(args.Path, args.Names);
break;
case "Upload":
operation.Upload(args.FileUpload, args.Path);
break;
case "Search":
return Json(operation.Search(args.Path, args.ExtensionsAllow,
args.SearchString, args.CaseSensitive));
}
return Json("");
}
public FileAccessInfo GetRules()
{
FileAccessInfo rules = new FileAccessInfo();
```

```
List<AccessRule> accessRules = new List<AccessRule> {
// For Default User
new AccessRule { Path = "*.*", Role = "Default User", Read =
Permission.Deny, Edit = Permission.Deny, Copy = Permission.Deny, Download =
Permission.Deny },
new AccessRule { Path = "*", Role = "Default User", Read = Permission.Deny,
Edit = Permission.Deny, Copy = Permission.Deny, EditContents =
Permission.Deny, Upload = Permission.Deny },
new AccessRule { Path = "", Role = "Default User", Read = Permission.Allow,
Edit = Permission.Deny, Copy = Permission.Deny, EditContents =
Permission.Deny, Upload = Permission.Deny },
// For Administrator
new AccessRule { Path = "*.*", Role = "Administrator", Read =
Permission.Allow, Edit = Permission.Allow, Copy = Permission.Allow, Download
= Permission.Allow },
new AccessRule { Path = "*", Role = "Administrator", Read =
Permission.Allow, Edit = Permission.Allow, Copy = Permission.Allow,
EditContents = Permission.Allow, Upload = Permission.Allow },
new AccessRule { Path = "", Role = "Administrator", Read = Permission.Allow,
Edit = Permission.Deny, Copy = Permission.Allow, EditContents =
Permission.Allow, Upload = Permission.Allow },
// For Document Manager
new AccessRule { Path = "*.*", Role = "Document Manager", Read =
Permission.Deny, Edit = Permission.Deny, Copy = Permission.Deny, Download =
Permission.Deny },
new AccessRule { Path = "Documents/*.*", Role = "Document Manager", Read =
Permission.Allow, Edit = Permission.Allow, Copy = Permission.Allow, Download
= Permission.Allow },
new AccessRule { Path = "*", Role = "Document Manager", Read =
Permission.Deny, Edit = Permission.Deny, Copy = Permission.Deny,
EditContents = Permission.Deny, Upload = Permission.Deny },
new AccessRule { Path = "", Role = "Document Manager", Read =
Permission.Allow, Edit = Permission.Deny, Copy = Permission.Deny,
EditContents = Permission.Deny, Upload = Permission.Deny },
new AccessRule { Path = "Documents", Role = "Document Manager", Read =
Permission.Allow, Edit = Permission.Deny, Copy = Permission.Allow,
EditContents = Permission.Allow, Upload = Permission.Allow },
new AccessRule { Path = "Documents/*", Role = "Document Manager", Read =
Permission.Allow, Edit = Permission.Allow, Copy = Permission.Allow,
EditContents = Permission.Allow, Upload = Permission.Allow },
};
rules.Rules = accessRules;
rules.Role = User.Identity.Name; // Specify the current user role
rules.RootPath = "~/FileContent/";
return rules;
}
```

The following screenshot displays the output of the above code.

Copyright © 2001 - 2020 Syncfusion Inc.



FileExplorer with Access Rule

Toolbar

The toolbar element having the number of tools, and each tool can be configurable.

Toolbar items

The toolbar having the list of items to perform various operations and grouped into some categorizes.

From below you can see the available toolbar items and its categorization:

RAZOR

```
@*all tools grouped under following categories*@
@{
List<String> layout = new List<string>() {
"Layout"
};
List<String> creation = new List<string>() {
"NewFolder"
};
List<String> navigation = new List<string>() {
"Back",
"Forward",
"Upward"
};
List<String> addressBar = new List<string>() {
"Addressbar"
};
List<String> editing = new List<string>() {
"Refresh",
"Upload",
"Delete",
"Rename",
```

```
"Download"
};
List<String> copyPaste = new List<string>() {
"Cut",
"Copy",
"Paste"
};
List<String> getProperties = new List<string>() {
"Details"
};
List<String> searchBar = new List<string>() {
"Searchbar"
};
List<String> sortBy = new List<string>() {
"SortBy"
};
}
@*all tools categories are placed in the toolbar by the below order*@
@{
List<String> toolsList = new List<string>() {
"layout",
"creation",
"navigation",
"addressBar",
"editing",
"copyPaste",
"getProperties",
"searchBar",
"sortBy"
};
}
```

The following table explains the functionality of each toolbar item:

Tool name	Description
Layout	In FileExplorer, files have been displayed in 3 types of views “Grid”, “Tile” and “Large Icons”. Using this tool, you can change the view type from one to another.
NewFolder	It creates a new folder on the current directory. While click on the NewFolder item, the dialog displays to get the folder name. Based on the user input, FileExplorer creates new folder on the current directory.Also createFolder event will be triggered when new folder is created successfully in the file system.
Back	It navigates to the previous directory from the user history. When the backward history is not available when it is disabled state.
Forward	It navigates to the next directory from the user history. When the forward history is not available when it is disable state.
Upward	It navigates to the parent directory of the current folder.

Copyright © 2001 - 2020 Syncfusion Inc.

Address bar	The “address bar” is the textbox which displays the path of the current directory, as a series of its parent directory separated by slash (“/”). And the address bar is an editable area, so you can enter any directory’s path to a quick navigation.
Refresh	It refreshes the current directory.
Upload	It uploads a file or list of files into the current directory. And you can customize the upload configurations, for details check here.
Delete	It delete the current selected file or folder. The delete icon is enable state if you select any file or folder. If you selected the multiple files, it deletes all the selected items.
Rename	This is used to rename the current selected file or folder. The rename icon is enable state if you select any file or folder. Even if you selected multiple files, it renames the last selected file only.
Download	It downloads the selected files. The download icon is enable state if you select any file or folder. The beforeDownload event will be triggered before the files are downloaded. If you select multiple files, it downloads all the files in a zip format.
Cut	It makes the copy of the selected files or folders into the clipboard. When the user paste the files in any location, the files are removed from the source location.The cut event will be triggered when files or folders are removed from the source.
Copy	It makes the copy of the selected files or folders into the clipboard. When the user paste the files, the copy of the files are pasted in the target location.The copy event will be triggered when file or folder is copied.
Paste	It pastes the files from the clipboard into the currently selected folder. Note: Only when the files are copied into the clipboard it is enabled.The paste event will be triggered when file or folder is pasted.
Details	It displays the details of the current selected file or folder.
Search bar	The Search bar is the textbox which is used to search the files from the current directory. It list the files based on the user search.

Copyright © 2001 - 2020 Syncfusion Inc.

	The search behavior of the “search bar” can be customize, for details check here.
Sort by	It's used to sorting the files from the current directory.The sorting can be done based on the columns available from grid,in both ascending and descending order.

Toolbar Visibility

The visibility of the toolbar can be customized through the “ShowToolbar” property. By disabling this property you can remove the toolbar from FileExplorer. Also you can remove the particular toolbar item by using removeToolbarItem method.

In the view page, add FileExplorer helper and specify “ShowToolbar” as false

RAZOR

```
@*hides the toolbar*@
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.ShowToolbar(false)
)
```

Toolbar Configuration

As you can see the available toolbar items from here. From the list of available items, you can configure and group your required toolbar items only through the “Tools” property. And also you can arrange the toolbar items by the “ToolsList” property.

In the view page, create the tools list and add FileExplorer helper as shown below

RAZOR

```
@{
List<String> toolsList = new List<string>() {
"creation",
"navigation",
"addressBar",
"copyPaste",
"searchBar"
};
List<String> creation = new List<string>() {
"NewFolder"
};
List<String> navigation = new List<string>() {
"Back",
"Forward",
"Upward"
};
List<String> addressBar = new List<string>() {
"Addressbar"
};
List<String> copyPaste = new List<string>() {
"Cut",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
"Copy",
"Paste"
};
List<String> searchBar = new List<string>() {
"Searchbar"
};
}
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.Tools(tools =>
tools.Creation(creation)
.AddressBar(addressBar)
.Navigation(navigation)
.CopyPaste(copyPaste)
.SearchBar(searchBar)
)
.ToolsList(toolsList)
)
```

Search bar

The Search bar can be customize through the "FilterSettings" property. By default the search doesn't consider the case sensitivity, and the search works based on "FilterType".

The FileExplorer allows the following filter types in the search functionality.

- "FilterOperator.StartsWith" – Supports to search text with starts with
- "FilterOperator.Contains" – Supports to search text with contains with
- "FilterOperator.EndsWith" – Supports to search text with ends with

In the view page, you can configure the filter type with enabling case sensitivity like below:

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.FilterSettings(settings =>
//it changes the search filter type as "startsWith"
settings.FilterType(FilterOperator.StartsWith)
//it enables the case sensitive search
.CaseSensitiveSearch(true)
)
)
```

Custom Tool in Toolbar

From the toolbar items you can see the list of built-in tools to perform the operations. Along with this built-in tools, you can add your custom tool with the custom functionality.

You can find an online demo sample of FileExplorer with custom tool from here.

In the view page, add FileExplorer helper and specify custom tool as shown below

RAZOR

Copyright © 2001 - 2020 Syncfusion Inc.

```
@{
// denotes the order of the tools categories
List<String> toolsList = new List<string>() {
"creation",
"navigation",
"addressBar",
"copyPaste",
"searchBar",
"customTool"
};
}
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.ToolsList(toolsList)
//defines the tool items for customTool category
.Tools(tool =>
tool.CustomTool(custom =>
custom.Name("Help")
.Tooltip("Help")
.Css("e-fileExplorer-toolbar-icon Help")
.Action("dialogOpen").Add()
))
)
<script>
//click handler of custom tool
function dialogOpen() {
alert("custom tool item clicked");
}
</script>
@*Define the CSS that needs to apply for the custom tool.*@
<style class="cssStyles">
.e-fileExplorer-toolbar-icon {
height: 22px;
width: 22px;
font-family: 'ej-webfont';
font-size: 18px;
margin-top: 2px;
text-align: center;
}
.e-fileExplorer-toolbar-icon.Help:before {
content: "\e72b";
}
</style>
```

Enable / Disable the Toolbar Item

Each toolbar item can be enabled or disabled through the below client-side public methods.

- enableToolbarItem
- disableToolbarItem

These methods accepts the tool name as the parameter. It also allows the parameter as tool item index or the jQuery object of the tool item.

Copyright © 2001 - 2020 Syncfusion Inc.

JAVASCRIPT

```
$(function () {
var fileExpObj = $("#fileExplorer").data("ejFileExplorer");
// this disables the NewFolder item
fileExpObj.disableToolbarItem("NewFolder");
// this disables the Layout item (since index of Layout is 0)
fileExpObj.disableToolbarItem(0);
// this enables the NewFolder item
fileExpObj.enableToolbarItem("NewFolder");
});
```

Enable / Disable the custom added tool in Toolbar Item

If you want to enable / disable the custom added tool in toolbar, you need to pass the corresponding li elements of custom added tool in enableToolbarItem / disableToolbarItem method of FileExplorer. Since we have consider this custom tool as a object type.

JAVASCRIPT

```
var fileExpObj = $("#fileExplorer").data("ejFileExplorer");
//tool is a cssClass of FileExplorer
// this disables the custom tool item
var li = $(".tool").find(".Help").closest('li');
fileExpObj.disableToolbarItem(li);
// this enables the custom tool item
fileExpObj.enableToolbarItem(li);
```

Customizing the Upload Functionality

FileExplorer helps you to upload the file using "Upload" component. File upload can be done through the toolbar item or context menu item. The "UploadSettings" property is used to configure the upload functionalities.

This property has the below sub properties with the default values:

RAZOR

```
UploadSettings(settings =>
settings.AllowMultipleFile(true)
.FileSize(31457280)
.AutoUpload(false)
)
```

AllowMultipleFile: This property used to control the behavior of multiple files upload and this was enabled by default so you can upload multiple files at a time. If you disable this "AllowMultipleFile" property then you can upload only one file at a time.

MaxFileSize: The property limits the maximum file size to upload. It accepts the value in bytes.

If you want to upload more than 4 MB files in FileExplorer, you should specify the **maxRequestLength** attribute in webconfig file and specify the **MaxFileSize** property to upload it. Please check the below code block.

RAZOR

Copyright © 2001 - 2020 Syncfusion Inc.

```
<httpRuntime targetFramework="4.6"
maxRequestLength="2147483647"executionTimeout="1600"
requestLengthDiskThreshold="2147483647" />
<system.webServer>
<security>
<requestFiltering>
<requestLimits maxAllowedContentLength="3221225472" />
</requestFiltering>
</security>
…
</system.webServer>
```

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/Content/images/FileExplorer/")
.AjaxAction(@Url.Content("/FileExplorer/FileActionDefault"))
.UploadSettings(settings =>
settings.MaxFileSize(3221225472)
)
)
```

To know more details, please check the below reference link and sample.

Reference Link

Sample

AutoUpload: when you enable this property, the upload action performed automatically after select the files. When you disable this property, it shows a confirmation dialog with the selected file details and perform the upload action on press the “upload” button.

During upload process following events will be triggered, beforeUploadSend, beforeUploadDialogOpen, beforeUpload, uploadError, uploadSuccess and uploadComplete. You can customize the upload settings with these events.

In the view page, add FileExplorer helper and specify the upload settings as shown below

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.UploadSettings(settings =>
// it disables the multi file upload functionality
settings.AllowMultipleFile(false)
// it enables the auto upload functionality
.AutoUpload(true)
)
)
```

Context Menu

The context-menu has list of items which helps to perform FileExplorer operations, and it appears based on the target such as file or folder.

Copyright © 2001 - 2020 Syncfusion Inc.

Context menu items

The below table shows the context menu items corresponding to the location where it is opened:

Context menu location	Context menu items	Screenshot
While right click on tree view nodes (from navigation pane)	*New folder* Upload *Delete* Rename *Cut* Copy *Paste* Get info	
While right click on File / Folder	*Open* Download *Upload* Delete *Rename* Cut *Copy* Paste *Get info* Open folder location	
While right click on layout (content pane)	*Refresh* Paste *Sort by* New folder *UploadÂ* Get infoÂ	

The below table explains the behavior of each context menu item:

Open	It opens the selected folder. When an image file selected it opens the preview of the image. For the remaining files this option becomes disabled.
Download	It downloads the selected file. When a file or number of files selected at that time only download option enabled. If multiple files selected then it downloads all the files in a zip format.
Cut	It makes the copy of the selected files or folders into the clipboard. When the user paste the files in any location, the files are removed from the source location.

Copyright © 2001 - 2020 Syncfusion Inc.

Copy	It makes the copy of the selected files or folders into the clipboard. When the user paste the files, the copy of the files only pasted in the target location.
Paste	It paste the files from the clipboard into the current selected folder. Note that when the files are copied into the clipboard at that time only it enabled.
Delete	It deletes the current selected file or folder. When you select any file or folder at that time only this option gets enabled. If multiple files selected then it deletes all the selected items.
Rename	This is used to rename the current selected file or folder. When you select any file or folder at that time only this option gets enabled. Even multiple files selected it renames the single file only.
New Folder	It creates a new folder on the current directory. While click on the â€œNewFolderâ€• item a dialog appears to get the folder name. Based on the user input, a new folder create on the current directory.
Upload	It uploads a file or list of files into the current directory.
Get info	It displays the details of the current selected file or folder.
Sort By	It's used to sorting the files and folders from the current directory.The sorting can be done based on the columns available from grid,in both ascending and descending order.
Open folder location	It helps to open a file location from the filtered list.

Context menu Visibility

The presence of the context menu can be controlled by the “ShowContextMenu” property. This was enabled by default, and by disabling this property you can prevent our built-in context menu.

In the view page, add FileExplorer helper and specify the context menu visibility as false.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.ShowContextMenu(false)
)
```

Enable / Disable the Context menu Item

The context menu items can be enabled or disabled through the client side public methods. It enables or disables the item from all the context menu where it is present.

Copyright © 2001 - 2020 Syncfusion Inc.

For example, if you disable the “Upload” item, it disables in all places wherever it appears such as open the context menu on “TreeView”, open on file/folder, and open on layout.

- enableMenuItem
- disableMenuItem

These methods only accepts the context menu item name as the parameter.

JAVASCRIPT

```
$(function () {
var fileExpObj = $("#fileExplorer").data("ejFileExplorer");
// this disables the New Folder item
fileExpObj.disableMenuItem("New folder");
// this disables the Download item
fileExpObj.disableMenuItem("Download");
});
```

Context Menu Customization

You can customize the ContextMenu of FileExplorer control by using ContextMenuSettings property.

You can add your own context menu items and its action along with default context menu items of FileExplorer control. You can also remove the default context menu items in FileExplorer control.

To add/remove/re-arrange context menu items, you need to use ContextMenuSettings.items property and to bind required actions for newly added menu items and add sub menu items, use ContextMenuSettings.CustomMenuFields property.

Add the following code example to the corresponding controller page.

C#

```
public ActionResult FileActionContextMenu(FileExplorerParams args)
{
FileExplorerOperations operation = new FileExplorerOperations();
switch (args.ActionType)
{
case "Read":
return Json(operation.Read(args.Path, args.ExtensionsAllow));
case "CreateFolder":
return Json(operation.CreateFolder(args.Path, args.Name));
case "Paste":
return Json(operation.Paste(args.LocationFrom, args.LocationTo, args.Names,
args.Action, args.CommonFiles));
case "Remove":
return Json(operation.Remove(args.Names, args.Path));
case "Rename":
return Json(operation.Rename(args.Path, args.Name, args.NewName,
args.CommonFiles));
case "GetDetails":
return Json(operation.GetDetails(args.Path, args.Names));
case "Download":
operation.Download(args.Path, args.Names);
break;
case "Upload":
operation.Upload(args.FileUpload, args.Path);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
break;
case "Search":
return Json(operation.Search(args.Path, args.ExtensionsAllow,
args.SearchString, args.CaseSensitive));
}
return Json("");
}
```

In the view page, add FileExplorer helper and specify the **ContextMenuSettings** property.

RAZOR

```
@* removed the "NewFolder" item from NavigationPane ContextMenu *@
@{List<String> navigationBar = new List<string>() { "Upload", "|", "Delete",
"Rename", "|", "Cut", "Copy", "Paste", "|", "Getinfo" }; }
@* added the custom ContextMenu item (View) to Current working directory
ContextMenu *@
@{List<String> cwd = new List<string>() { "Refresh", "Paste", "|", "SortBy",
"View", "|", "NewFolder", "Upload", "|", "Getinfo" };}
@* removed "Upload" item from Selected files/ folder's ContextMenu *@
@{List<String> files = new List<string>() { "Open", "Download", "|",
"Delete", "Rename", "|", "Cut", "Copy", "Paste", "|",
"OpenFolderLocation", "Getinfo" }; }
@Html.EJ().FileExplorer("fileExplorer").Path("~/FileExplorerContent/").Conte
xtMenuSettings(
settings => settings.Items(
item => item.Navbar(navigationBar).Cwd(cwd).Files(files)
).CustomMenuFields(fields =>
{
fields.Add().Id("View").Text("View by").SpriteCssClass("custom-
grid").Child(child =>
{
child.Add().Id("tile").Text("Tile view").Action("onLayout");
child.Add().Id("grid").Text("Grid view").Action("onLayout");
child.Add().Id("largeIcons").Text("Large icons view").Action("onLayout");
});
})
).AjaxAction(@Url.Content("FileActionContextMenu")).ClientSideEvents(
e => e.MenuOpen("onMenuOpen").LayoutChange("onLayoutChange")
).Width("100%").IsResponsive(true).MinWidth("150px")
```

Icons of context menu items can be customized by overriding the default context menu item style. The following code example illustrates how to customize the icon of context menu items.

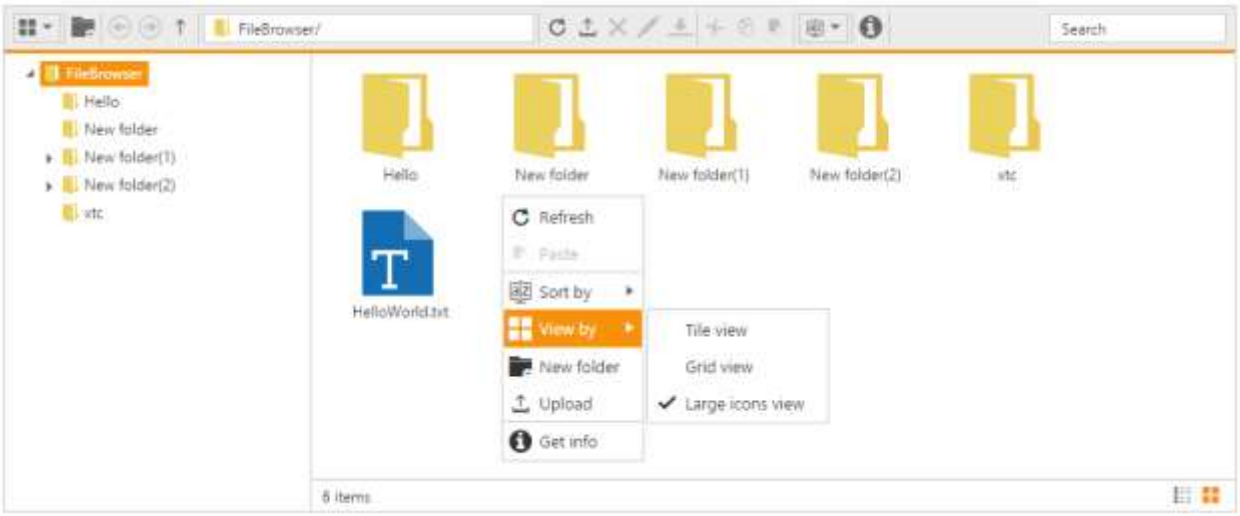
CSS

```
<style>
.fe-context-menu .custom-grid:before {
content: "\e7b9";
}
.fe-context-menu .custom-largeIcons:before {
content: "\e7bb";
}
.fe-context-menu .custom-tile:before {
content: "\e7be";
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</style>
```

The following screenshot displays the customization of context menu in FileExplorer control.



Context Menu Events

You would be notified with events when you try to open the context menu items (**MenuBeforeOpen**), after context menu items is opened (**MenuOpen**) and when you click the menu items (**MenuClick**). The following code example illustrates how to define those events.

RAZOR

```
@Html.EJ().FileExplorer("fileExplorer").Path("~/FileExplorerContent/").AjaxAction(@Url.Content("FileActionContextMenu")).ClientSideEvents(e => e.MenuBeforeOpen("menuBeforeOpen").MenuOpen("menuOpen").MenuClick("menuClick"))
```

JS

```
function menuBeforeOpen(args) {
//you add/remove the context menu items in run time
//do your custom action here.
args.dataSource.pop();
}
function menuOpen(args) {
//you can also identify which context menu is opened by
if (args.contextMenu == "cwd") {
//do your custom action here.
}
}
function menuClick(args) {
switch (args.text) {
case "largeIcons":
//do your custom action here.
break;
}
}
```

Customization

Dimension Customization

The dimension of the FileExplorer can be customized through “Height” and “Width” property. The dimension can be set in percentage (ex; width: “100 %”), so that the control inherits the width from the parent element.

In the view page, add FileExplorer helper with custom height and width

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.Height("300px")
.Width("900px")
)
```

Customizing the Navigation pane

The navigation pane contains the tree view element which displays all the folders from the filesystem in a hierarchical manner. This is useful to a quick navigation of any folder in the filesystem.

The visibility of the navigation pane can be controlled by the “ShowNavigationPane” property. By disabling this property, you can hide the navigation pane from FileExplorer.

In the view page, add FileExplorer helper and specify the navigation pane as false

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.ShowNavigationPane(false)
)
```

Customizing the Content pane

The content pane is the main part of the Fie explorer UI which displays all the files and folders from the filesystem. The content pane supports the following two types of layout views:

- Grid
- Tile
- Large Icons

The **grid view** displays the files and folders in a grid layout with the details in separate columns. By default the grid view having the four columns which displays the file name, type, date modified and size of the file. For more details about grid view customization, refer here.

The **tile view** display the files and folders like a small size icons in left side and file details in right. It allows the thumbnails for the image files so that you can view the tiny preview of all image files.

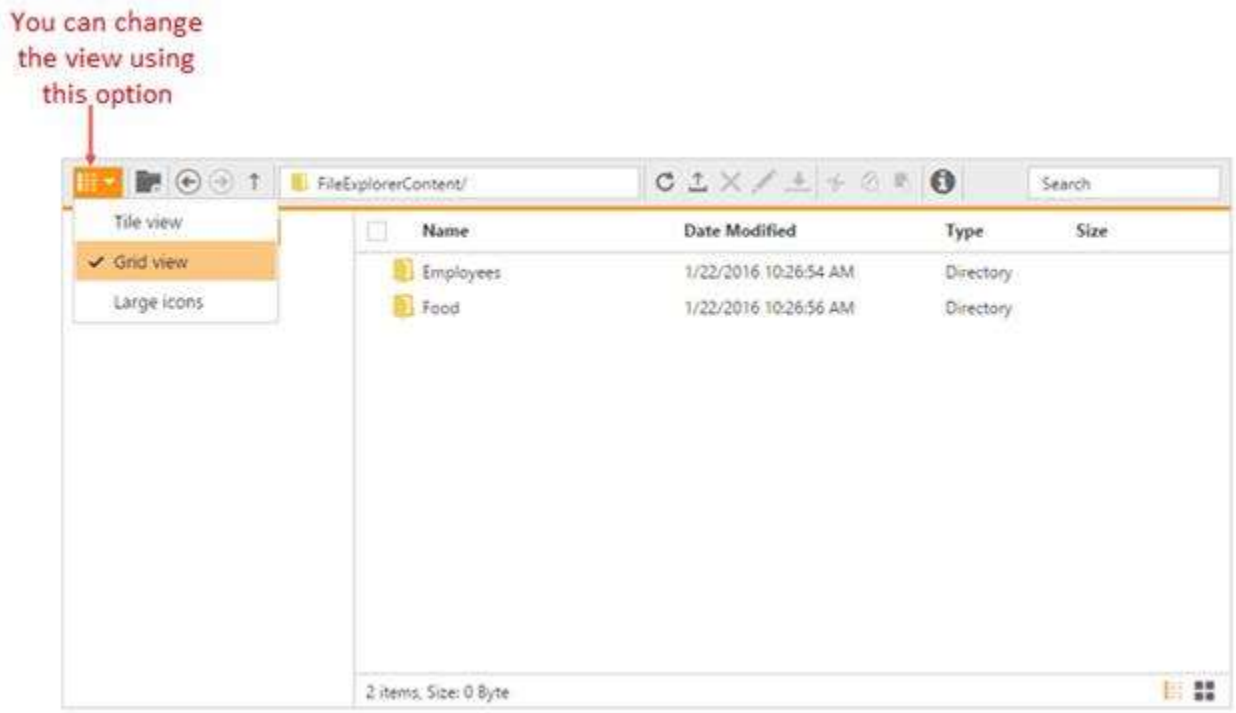
The **large icons view** display the files and folders like a large size icons with name. It allows the thumbnails for the image files so that you can view the tiny preview of all image files.

Changing the Layout views

Copyright © 2001 - 2020 Syncfusion Inc.

You can change the layout of current view by the switcher which displays at right-bottom of footer in the FileExplorer. By clicking the grid and large icons view buttons you can change the layout of current view.

You can change the layout using toolbar option. While clicking this tool, popup opens with different layout types. Here you can choose any options.



Also the layout views can be changed through the "Layout" property. The layoutChange event will be triggered whenever the layout view type is changed.

In the view page, add FileExplorer helper and specify the layout type as shown below

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
// while rendering it displays as tile view
.Layout(LayoutType.Tile)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Customizing the Grid view

By default sorting is enabled in grid view of FileExplorer, it helps you to sort each columns in ascending or descending order by pressing the corresponding column header. The sorting functionality can be disabled by setting "AllowSorting" property to false.

The behavior of the columns can be customized through the "Columns" property.

In the view page, add FileExplorer helper with custom grid settings

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
// under gridSettings you can customize the grid view functionalities
.GridSettings(settings =>
// disables the sorting functionality in grid view
settings.AllowSorting(true)
// it displays 3 columns only, like this you can display your desired
columns at here
.Column(column =>
{
column.Add()
.Field("name")
.HeaderText("Name")
.Width("150");
column.Add()
.Field("dateModified")
.HeaderText("Date Modified")
.Width("150");
column.Add()
.Field("size")
.HeaderText("Size")
.Width("90")
.TextAlign(TextAlign.Right)
.HeaderTextAlign(TextAlign.Left);
}
)
)
)
```

Footer Customization

The footer displays the details of the current selected files and folders, and the footer contains the switcher to change the layout view. The visibility of the footer can be customized by the "ShowFooter" property.

In the view page, add FileExplorer helper and hides the footer as shown below.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
// it hides the footer element
.ShowFooter(false)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Multiple Selection

The FileExplorer allows the user to select multiple files by enabling the "AllowMultiSelection" property. The multiple selection can be done by pressing the "**Ctrl"** key or "**Shift"** key. You can select all the files in the directory by pressing "**Ctrl + A**". The multiple selection is useful on copy pasting multiple files, deleting multiple files and downloading multiple files. In another way, multiple files can be selected by mouse down and drag over the desired files. In addition to that, additional files can be selected with the preselected file by holding the ctrl/shift key and drag the mouse over the files. Also, holding the ctrl/shift key and dragging over selected files will unselect the selected files.

The select event will be triggered when the items of FileExplorer control is selected.

Also unselect event will be triggered when the items of FileExplorer control is unselected.

Note: For selecting files by mouse down and drag set AllowMultiSelection property as true.

In the view page, add FileExplorer helper and specify the multi selection as true

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.AllowMultiSelection(true)
)
@*AllowMultiSelection property is true by default*@
```

Checkbox option

You can enable or disable the checkbox using "ShowCheckbox" API of FileExplorer

In the view page, add FileExplorer helper and disable the checkbox as shown below

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.ShowCheckbox(false)
)
```

Resizing

The FileExplorer has the resize support through the resize handle which appears at right-bottom corner of footer. By clicking the resize handle the user can resize the FileExplorer through the UI. While resizing the dimension of the FileExplorer is automatically adjusted.

The resize behavior can be enabled through the "EnableResize" property.

In the view page, add FileExplorer helper with resizable option as shown below

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
// it enables the resize functionality
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
// and a resize handle added in the Footer element
.EnableResize(true)
)
```

Responsiveness

By enabling the "IsResponsive" property, you can make the FileExplorer as responsive. While resizing the FileExplorer component, the inner content and toolbar items are automatically adjusted to equalize the size. The toolbar items are displayed within Dropdown on enabling the responsive. Otherwise it floated to the next line to equalize the space.

In the view page, add FileExplorer helper with responsive option

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
// it enables the resize functionality
// and a resize handle added in the Footer element
.EnableResize(true)
// it enables the control responsiveness
.IsResponsive(true)
)
```

Restriction on Resize

You can restrict the dimension of the FileExplorer by setting the "MinHeight", "MaxHeight", "MinWidth" and "MaxWidth" properties while resizing the FileExplorer.

In the view page, add FileExplorer helper and set resize option within particular region.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.EnableResize(true)
.IsResponsive(true)
// restricts the dimensions for height and width
.MinHeight("200px")
.MaxHeight("400px")
.MinWidth("300px")
.MaxWidth("1200px")
)
```

Drag and Drop Support

The FileExplorer allows files to be moved from one folder to another by using drag and drop. It also supports uploading a file by dragging it from Windows Explorer to a folder in the FileExplorer control.

You can enable or disable this support by using "**AllowDragAndDrop**" API of FileExplorer.

The dragStart, drag, dragStop and drop events occur in the mentioned order when a drag and drop operation is performed.

In the view page, add "FileExplorer" helper and specify the drag and drop option as specified below.

Copyright © 2001 - 2020 Syncfusion Inc.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Layout(LayoutType.Tile)
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileAction"))
.AllowDragAndDrop(true)
)
```

Thumbnail Image Compression Support

The “FileExplorer” allows thumbnail images to be compressed on the server side and loaded into the “FileExplorer” layout to improve performance when working with large size images.

You can enable this option using “**EnableThumbnailCompress**” API of FileExplorer. For enabling this API, showThumbnail must be set to true in order to render thumbnail preview of images in Tile and LargeIcons layout.

The beforeGetImage event is triggered before loading a requested image from the server and getImage event is triggered after the requested image is loaded.

Refer following code block that will be helpful to you.

In the view page, add “FileExplorer” helper and specify the thumbnail image compress option as specified below.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Layout(LayoutType.Tile)
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionThumbnailCompress"))
.EnableThumbnailCompress(true)
)
```

In the controller page, specify the “GetImage” handling operation as shown below. This handling function is necessary to compress and load the images in “FileExplorer”, while “EnableThumbnailCompress” option has been enabled.

C#

```
public ActionResult FileActionThumbnailCompress(FileExplorerParams args)
{
FileExplorerOperations operation  = new FileExplorerOperations();
switch (args.ActionType)
{
case "Read":
return Json(operation.Read(args.Path, args.ExtensionsAllow));
case "CreateFolder":
return Json(operation.CreateFolder(args.Path, args.Name));
case "Paste":
return Json(operation.Paste(args.LocationFrom, args.LocationTo, args.Names,
args.Action, args.CommonFiles));
case "Remove":
return Json(operation.Remove(args.Names, args.Path));
case "Rename":
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
return Json(operation.Rename(args.Path, args.Name, args.NewName,
args.CommonFiles));
case "GetDetails":
return Json(operation.GetDetails(args.Path, args.Names));
case "Download":
operation.Download(args.Path, args.Names);
break;
case "Upload":
operation.Upload(args.FileUpload, args.Path);
break;
case "Search":
return Json(operation.Search(args.Path, args.ExtensionsAllow,
args.SearchString, args.CaseSensitive));
case "GetImage":
//Helps to reduce thumbnail image size before loading it into FileExplorer
operation.GetImage(args.Path, args.CanCompress);
break;
}
return Json("");
}
```

Access shared folder using FileExplorer

Using “FileExplorer”, you can manage the files that are available in a shared folder of another system which is connected through LAN. Refer following steps, here you will see the details about accessing the shared folder with FileExplorer.

First you have to specify the shared folder path in any of following formats.

1. “\\Server\SharedFolder”
2. “\\Server”
3. “//Server/SharedFolder”
4. “//Server”

In the view page, add “FileExplorer” helper and specify the shared path as following format.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Layout(LayoutType.Tile)
.Path(@"\\Server\SharedFolder")
.AjaxAction(@Url.Content("FileActionDefault")))
```

In the controller page, specify the file handling operation as shown below. This handling functions are necessary to perform file operations in FileExplorer.

C#

```
public ActionResult FileActionDefault(FileExplorerParams args)
{
FileExplorerOperations operation = new FileExplorerOperations();
switch (args.ActionType)
{
case "Read":
return Json(operation.Read(args.Path, args.ExtensionsAllow));
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
case "CreateFolder":
return Json(operation.CreateFolder(args.Path, args.Name));
case "Paste":
return Json(operation.Paste(args.LocationFrom, args.LocationTo, args.Names,
args.Action, args.CommonFiles));
case "Remove":
return Json(operation.Remove(args.Names, args.Path));
case "Rename":
return Json(operation.Rename(args.Path, args.Name, args.NewName,
args.CommonFiles));
case "GetDetails":
return Json(operation.GetDetails(args.Path, args.Names));
case "Download":
operation.Download(args.Path, args.Names);
break;
case "Upload":
operation.Upload(args.FileUpload, args.Path);
break;
case "Search":
return Json(operation.Search(args.Path, args.ExtensionsAllow,
args.SearchString, args.CaseSensitive));
}
return Json("");
}
```

Authentication problem in shared folder

If shared folder is restricted with authentication, that time you are not able to access this folder using our FileExplorer. Here you will get an exception like "**System.UnauthorizedAccessException, Please add your windows credential details to open '\\server\'**". In order to solve this problem, you have to add the shared folder credential details in the windows credential manager that is available in your service hosted machine.

Localization

The FileExplorer control provides the translations for all static texts and messages. By default the FileExplorer uses the US English (en-US) language, and it having the built-in values of all texts with the corresponding key.

The below table lists out the keys with corresponding texts in English culture.

JAVASCRIPT

```
ej.FileExplorer.Locale["en-US"] = {
```

```

Change the Culture

The language of the FileExplorer can be changed by the "Locale" property. This property allows the culture code of the country as input. The culture code has to specify in the standard format as **[Language Code]-[County/Region Code]**.

For example the culture code for German is "**de-DE**".

You can customize built-in text and messages based on your culture. The below example shows the usage of FileExplorer with German (de-DE) culture.

RAZOR

Keyboard Navigation

The FileExplorer control can be fully accessible with the help of keyboard shortcuts and it can be allowed by specifying allowKeyboardNavigation as true. The below table shows the list of keyboard shortcuts to access the FileExplorer control.

Note: Set focus on FileExplorer component to access the keyboard shortcuts.

Key	Description
Ctrl + Shift + 1	Focuses the Toolbar
Ctrl + Shift + 2	Focuses the Tree view
Ctrl + Shift + 3	Focuses the Splitter
Ctrl + Shift + 4	Focuses the Grid view
Ctrl + Shift + 5	Focuses the Tile view
Ctrl + Shift + 6	Focuses the Large icons view
Ctrl + Shift + 7	Focuses the Status bar
Right	Focusing next item
Left	Focusing previous item

Copyright © 2001 - 2020 Syncfusion Inc.

Enter	Selection the focused item
Esc	Closes the opened dialog
F2	Renames the selected item
Ctrl + A	Selects the all items
Alt + N	Creates "New folder" dialog
Ctrl + U	Opens Upload dialog
F5	Refresh the content
Alt + Enter	Get the details of selected item
Ctrl + X	To cut the selected items
Ctrl + C	To copy the selected items
Ctrl + V	Pastes the copied items
Delete	Deletes the selected items
Shift + F10	Opens the Context Menu

Virtual Scrolling

Virtual Scrolling is introduced to provide support for loading files and folders on demand in order to improve performance in FileExplorer when large amount of files are present.

Virtual Scrolling can be enabled by using VirtualItemCount API. It specifies the total files to be loaded initially, and on each scroll the next set of files are loaded. For eg- If VirtualItemCount value is given as ”20”, then 20 items are loaded initially and on each scroll the next/previous 20 items are loaded. If the value of VirtualItemCount is 0, virtual scrolling will be disabled.

Note: Default value of `VirtualItemCount` is 0.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.VirtualItemCount(40)
)
```

How To

File handling operations

In controller page, we have specified some built-in classes at "**FileActionDefault**" action method. It helps to perform the server side operation of FileExplorer and you can find the details about these classes at below.

When you have made AJAX request on client-side, “FileActionDefault” method is triggered in controller part. Here received AJAX data will be stored in “FileExplorerParams” parameter. This “FileActionDefault” method finds out the specific operations using the “ActionType” property and calls the corresponding built-in methods of “FileExplorerOperations” class.

BasicFileOperations class

“BasicFileOperations” is an abstract class and it is useful for handling file operations in server end. By inheriting this class, easily you can implement a new custom class for handling file operations in server end. Refer class reference of “BasicFileOperations”

FileExplorerOperations class

This class is useful for handling file operations in server end. This class inherits the “BasicFileOperations” class and its abstract methods has been implemented here for managing files in **underlying machine’s physical file system**. Refer class reference of “FileExplorerOperations”

FileExplorerParams class

“FileExplorerParams” class is used to receive the AJAX data in server side. In server side, we have a common method to handle all the AJAX requests, which is raised from client part of FileExplorer. This method contains “FileExplorerParams” object as a parameter and it is used to store the AJAX request data that will be useful for handling file operations. Refer class reference of “FileExplorerParams”

Note: Here “ActionType” specifies following operations such as “Read”, “CreateFolder”, “Paste”, “Remove”, “Rename”, “GetDetails”, “Download”, “Upload”, “Search”. Following section contains the details about each operation.

Customizing AJAX handling functions

In FileExplorer, server side functionalities are necessary to handle the AJAX request of FileExplorer. Here “Syncfusion.EJ” assembly contains built-in “BasicFileOperations” abstract class and implementation of “FileExplorerOperations” class for providing the content to FileExplorer and handling AJAX requests. If is it necessary, you can customize the server side functionalities of FileExplorer as per your requirement.

Override the existing Syncfusion.JavaScript.FileExplorerOperations class

Using “FileExplorerOperations” class, you can manage the underlying machine's physical file system with the help of FileExplorer control. Here you can override the necessary methods that is available in “**FileExplorerOperations**” by sub classing the existing “**FileExplorerOperations**” class.

Below code example shows how to override “**GetDetails**” method, which is available in **“FileExplorerOperations**”

C#

```
public class FileExplorerCustomOperations : FileExplorerOperations
{
FileExplorerOperations operation = new FileExplorerOperations();
CustomFileExplorerResponse customDetails = new CustomFileExplorerResponse();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public override object GetDetails(string path, string[] names,
IEnumerable<object> selectedItems = null)
{
FileExplorerResponse response = (FileExplorerResponse)
operation.GetDetails(path, names);
FileDetails fDetails = response.details.ElementAt(0) ;
CustomFileDetails cfDetails =new CustomFileDetails() ;
CustomFileDetails[] responseDetails = new CustomFileDetails[1];
cfDetails.Name= fDetails.Name;
cfDetails.Location= fDetails.Location;
cfDetails.Size= fDetails.Size;
cfDetails.Created= fDetails.Created;
cfDetails.IsFile = (fDetails.Type == "File Folder"? "false" : "true");
responseDetails[0] = cfDetails;
customDetails.details = responseDetails;
return customDetails;
}
}
public class CustomFileDetails
{
public string Name { get; set; }
public string Location { get; set; }
public long Size { get; set; }
public string Created { get; set; }
public string IsFile { get; set; }
}
public class CustomFileExplorerResponse
{
public IEnumerable<FileExplorerDirectoryContent> files { get; set; }
public IEnumerable<CustomFileDetails> details { get; set; }
public object error { get; set; }
}
```

Implement a new custom class to handle AJAX request and provide content for FileExplorer

When overriding the particular methods were not enough, you can create a new custom class using "BasicFileOperations" abstract class. It helps to provide different file sources to be used the content for FileExplorer control, such as database system, physical system or online storage system such as Azure.

Notes to Implementers

When you implement a derived class of "BasicFileOperations", you must provide implementations for following methods and its details has been given in this section

- Read
- CreateFolder
- Remove
- Rename
- Paste
- Upload
- Download
- GetDetails
- GetImage
- Search

Copyright © 2001 - 2020 Syncfusion Inc.

Abstract methods in BasicFileOperations class

Operation and Request Parameter	**Response data**	**Details**
Operation: Read **Request Parameter** **Name**: path **Type :** String **Description:**Specifies the path of selected folder **Name**: filter **Type :** String **Description:** Specifies the file types that need to be filter **Name**: selectedItems **Type :** IEnumerable<object> **Description:** It contains the details about selected folder	Response data should be in JSON format with key name as "**files** " and JSON fields should be with following field names *â€œname, isFile, hasChildâ€*. *For example:* {"**files**":[{"**name":"bird.jpg**","type":"File","size":102182,"dateModified":"1/9/2016 6:48:42 AM","**hasChild":false,"isFile":true**,"filterPath":null},{"**name":"sea.jpg**","type":"File","size":97145,"dateModified":"1/9/2016 6:48:42 AM","**hasChild":false,"isFile":true**,"filterPath":null}],"details":null,"error":null} Note: If needed, customer can also add additional data along with existing properties of â€œFileExplorerDirectoryContentâ€• class.	It used to get all immediate files and sub-folders of the given path and it returns the matched type of files only, which are specified in â€œfilterâ€• parameter.
Operation: CreateFolder **Request Parameter** **Name**: path **Type :** String **Description:**Specifies the path of selected folder **Name**: name **Type :** String **Description:**specifies the name of new folder **Name**: selectedItems **Type :** IEnumerable<object> **Description:**It contains the details about selected folder	Response data should be in JSON format with key name as "**files**".In that returning JSON, â€œ**name**â€• field is necessary. *For example:* {"files":[{"**name":"New folder**","type":"Directory","size":0,"dateModified":"2/25/2016 7:31:02 AM","hasChild":true,"isFile":false,"filterPath":null}],"details":null,"error":null}	It used to create a new folder in given path with specified name

Copyright © 2001 - 2020 Syncfusion Inc.

Operation: Remove **Request Parameter** **Name:**names **Type :** String[] **Description:**specifies the selected item names, which is going to be removed **Name**: path **Type :** String **Description:**specifies the parent folder path of selected items **Name**: selectedItems **Type :** IEnumerable<object> **Description:**It contains the details about selected items, which is going to be removed	Here you may return the removed file details or empty.	It helps to remove the specified items from given path.
Operation: Rename **Request Parameter** **Name**: path **Type :** String **Description:**specifies the parent folder path of renaming item **Name**: oldName **Type :** String **Description:**specifies the existing file name **Name**: newName **Type :** String **Description:**specifies the new file name **Name**: selectedItems **Type :** IEnumerable<object> **Description:**It contains	Here you may return the renamed file details or empty.	This method helps to rename the file/folder, which is available in given path.

the details about selected items, which is going to be renamed **Name**: commonFiles **Type :** IEnumerable **Description:**It contains the details about already existing files, which contains same name and type as given in new file with same parent folder.		
Operation: Paste **Request Parameter** **Name**: sourceDir **Type :** String **Description:**specifies the path of source directory **Name**: backupDir **Type :** String **Description:**specifies the path of destination directory **Name**: names **Type :** String[] **Description:**Specifies the name of file/ folders, which are going to be pasted in destination folder. **Name**: option **Type :** String **Description:**specifies the operation type â€œmoveâ€• or â€œcopyâ€•. **Name**: selectedItems **Type :** IEnumerable<object> **Description:**It contains the details about	Here you may return the pasted file details or empty.	This method helps to copy or move files from one location to another location.

selected items, which is going to be pasted **Name**: commonFiles **Type :** IEnumerable **Description:**It contains the details about already existing files in destination folder, which contains the files in same name and type as same as newly copied files. **Name**: targetFolder **Type :** IEnumerable<object> **Description:**It contains the details about target folder, where the files are going to be pasted.		
Operation: Upload **Request Parameter** **Name**: files **Type :** IEnumerable<System.Web.HttpPostedFileBase> **Description:**Specifies the file details that is going to be uploaded **Name**: path **Type :** String **Description:**specifies the path of destination directory, where the files need to be uploaded **Name**: selectedItems **Type :** IEnumerable<object> **Description:**It contains the details about selected items, which is going to be uploaded.	Return type of this method is â€œvoidâ€•	This method helps to upload the specified files to given directory

Copyright © 2001 - 2020 Syncfusion Inc.

Operation: Download **Request Parameter** **Name**: path **Type :** String **Description:**Specifies the parent directory path of selected files, which is going to be download **Name**: names **Type :** String [] **Description:**specifies the name of files that is need to be downloaded **Name**: selectedItems **Type :** IEnumerable<object> **Description:**It contains the details about files, which is going to be downloaded.	Return type of this method is â€œvoidâ€•	This method helps to download the specified files.
Operation: GetDetails **Request Parameter** **Name**: path **Type :** String **Description:**Specifies the parent directory path of selected file **Name**: names **Type :** String [] **Description:**Specifies the name of files in order to get itâ€™s details **Name**: selectedItems **Type :** IEnumerable<object> **Description:**It contains the basic details about selected files	Response data should be in JSON format like below {details : [{CreationTime:"4/28/2015 9:44:32 AM", Extension:".png", Format:"Archive", FullName:"F:\All samples\FileExplorer_Custom\FileExplorerContent\human.png", LastAccessTime:"4/28/2015 9:44:32 AM", LastWriteTime:"3/31/2015 3:16:35 PM", Length:11059, Name:"human.png"}]} Note: Here you may add additional date fields along with existing JSON data using â€œFileDetailsâ€• class.	This method used to get the details of the specified file or directory.

Operation: GetImage **Request Parameter** **Name**: path **Type :** String **Description:**specifies the path of image file **Name**: selectedItems **Type :** IEnumerable<object> **Description:**It contains the details about selected image	Return type of this method is void.	This method helps to get an image using â€œHttpResponseâ€• option
Operation: Search **Request Parameter** **Name**: path **Type :** String **Description:**specifies the directory path **Name**: filter **Type :** String **Description:**Specifies the file types that need to be filter **Name**: searchString **Type :** String **Description:**specifies the search string **Name**: caseSensitive **Type :** String **Description:**specifies the case sensitive option **Name**: selectedItems **Type :** IEnumerable<object> **Description:**It contains the details about selected folder	It should return data in JSON format with key name as "**files**" and JSON fields need to be with following field names. *â€œname, isFile, hasChild,filterPathâ€.* *For example:* {"**files**":[{"**name":"bird.jpg**","type":"File","size":102182,"dateModified":"1/9/2016 6:48:42 AM","**hasChild":false,"isFile":true**,"filterPath":null},{"**name":"sea.jpg**","type":"File","size":97145,"dateModified":"1/9/2016 6:48:42 AM","**hasChild":false,"isFile":true**,"filterPath":null }],"details":null,"error":null}	It used to search all the matched files and sub-folders in the given folder path also it filters the specified files using it types.

Copyright © 2001 - 2020 Syncfusion Inc.

Here you need to implement new class by sub classing the existing "**BasicFileOperations**" abstract class.

C#

```
public class NewClass : BasicFileOperations
{
public override object CreateFolder(string path, string name,
IEnumerable<object> selectedItems = null)
{
throw new NotImplementedException();
}
public override void Download(string path, string[] names,
IEnumerable<object> selectedItems = null)
{
throw new NotImplementedException();
}
public override object GetDetails(string path, string[] names,
IEnumerable<object> selectedItems = null)
{
throw new NotImplementedException();
}
public override void GetImage(string path, IEnumerable<object> selectedItems
= null)
{
throw new NotImplementedException();
}
public override object Paste(string sourceDir, string targetDir, string[]
names, string option, IEnumerable<CommonFileDetails> commonFiles,
IEnumerable<object> selectedItems = null, IEnumerable<object> targetFolder =
null)
{
throw new NotImplementedException();
}
public override object Read(string path, string filter, IEnumerable<object>
selectedItems = null)
{
throw new NotImplementedException();
}
public override object Remove(string[] names, string path,
IEnumerable<object> selectedItems = null)
{
throw new NotImplementedException();
}
public override object Rename(string path, string oldName, string newName,
IEnumerable<CommonFileDetails> commonFiles, IEnumerable<object>
selectedItems = null)
{
throw new NotImplementedException();
}
public override object Search(string path, string filter, string
searchString, bool caseSensitive, IEnumerable<object> selectedItems = null)
{
throw new NotImplementedException();
}
public override void Upload(IEnumerable<HttpPostedFileBase> files, string
path, IEnumerable<object> selectedItems = null)
{
```

```
throw new NotImplementedException();
}
}
```

Also we have option to configure the AJAX request in client side, please refer link: https://help.syncfusion.com/js/fileexplorer/behavior-settings#customize-the-ajax-request-settings

Managing files that is available in SQL database

You can manage the files that are available in database using our FileExplorer control. Here you may use this custom "**SQLFileExplorerOperations**" class for handling file management related operations using SQL database. This class is used to simplify the process on server side. It contains some built-in methods that are used to handle file operations (like read, copy, move, delete, etc.) using SQL database. This class is created by inheriting the abstract class "BasicFileOperations". If is it necessary, you may override the methods in "**SQLFileExplorerOperations**" class.

- To make connection with SQL database (FileManager.mdf) services, please specify connection string in "Web.config" file as specified in the following code example.

C#

```
<add name="FileExplorerConnection" connectionString="Data
Source=(LocalDB)\v11.0;AttachDbFilename=|DataDirectory|\FileManager.mdf;Inte
grated Security=True;Trusted_Connection=true" />
```

- In controller part, you need to create an object of "SQLFileExplorerOperations" class as shown in the following code example.

C#

```
//Here "FileExplorerConnection" is a connection string name, which is
defined in Web.config file.
//"Product" is a table name, which is defined in SQL database
SQLFileExplorerOperations sqlObj = new
SQLFileExplorerOperations("FileExplorerConnection", "Product");
```

After creating the object for "SQLFileExplorerOperations" class in controller part, you have to call the corresponding built-in file operation handling methods available in "SQLFileExplorerOperations" class based on the file operation type.

We have prepared the following sample based on this, FileExplorer Sample

File Access permission for the files that is available in SQL database

The FileExplorer provides method to assign permissions or access rights to specific users and group of users. It allows you to define access permissions for folders and files using a set of access rules to user(s).

- As per the above details, In controller part, you need to create an object of "SQLFileExplorerOperations" class and additionally you need to pass the access rules as a constructor parameter.

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
//Here "FileExplorerConnection" is a connection string name, which is
defined in Web.config file.
//"Product" is a table name, which is defined in SQL database
// SQLGetRules() which a function which returns the access rules
SQLFileAccessOperations sqlObj = new
SQLFileAccessOperations("FileExplorerConnection", "Product", SQLGetRules());
```

For this, we have prepared the sample and you can get it from the below link

sample

Note: Here we have fetched the file permissions from the SQL table for the files located in SQL database.

To know more details about file access permission, please refer this link

Cross-origin resource sharing support for FileExplorer

Cross-origin request

The “FileExplorer” can browse and manage files on remote servers, which is located in other domains. If a server is located on a different domain, on a different port or using different protocol (HTTP / HTTPS) such requests are considered to be “**cross-origin requests**”. These type requests are prohibited by IE9 and its earlier browsers.

Enabling cross-origin request in IE8 and IE9

By default, Internet Explorer 9 and earlier prohibits cross-origin requests for Internet Zone, also it ignores "Access-Control-Allow" headers. To enable cross-origin in IE8 and IE9, we have specified two type of options. As per the requirements, you can use any option that is mentioned below.

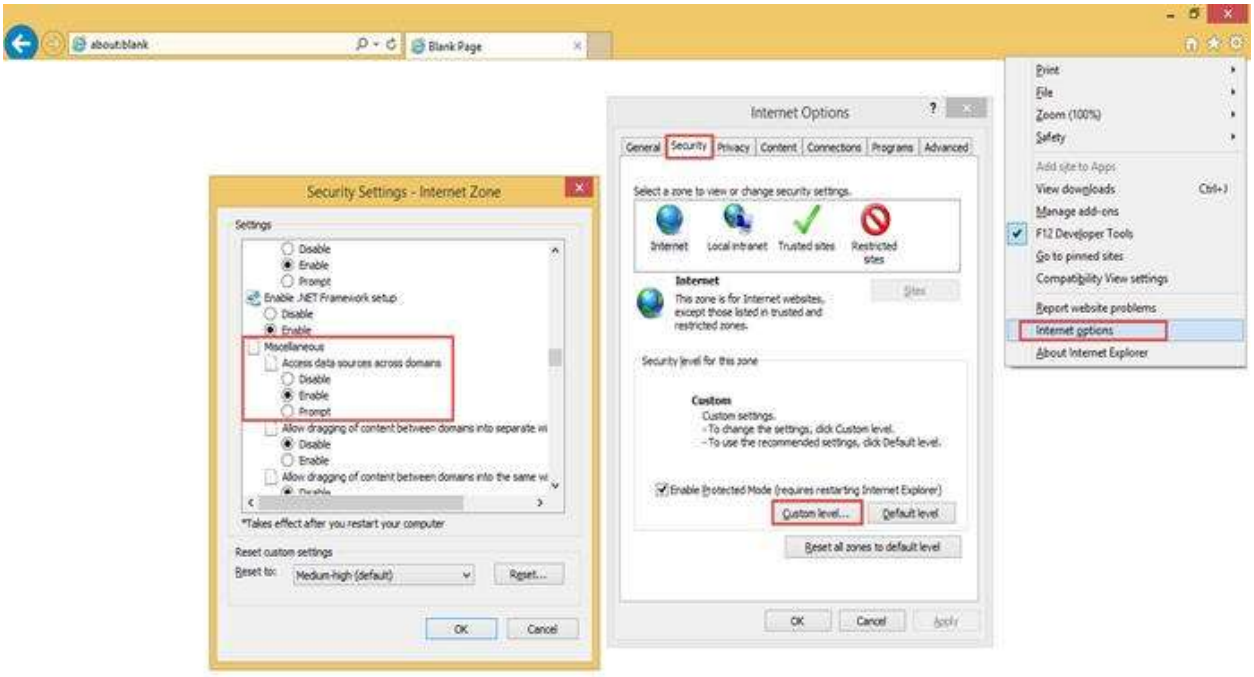
Option 1: Enabling cross-origin in IE through browser settings

To enable cross-origin access using settings of IE browser, go to Tools->Internet Options->Security tab, click on “Custom Level” button. Find the Miscellaneous and select “Enable” option, which is available under “Access data sources across domains” settings.

If your server is located in Intranet Zone, In IE Browser, confirmation dialog will be popped during first cross-domain request as “*This page is accessing information that is not under its control. This poses a security risk. Do you want to continue*?”

To suppress this warning, you need to specify the "*Access data sources across domains*" setting to “allow”.

Copyright © 2001 - 2020 Syncfusion Inc.



Option 2: Using JSONP for cross-origin request

Using JSONP data type, you can perform cross origin-request. To enable cross-origin request, in your "FileExplorer", you have to specify "**AjaxDataType"**as "**jsonp**". And we have provided "**doJSONPAction**" method to handle "jsonp" type AJAX request on server side. Please refer below code snippet to specify "**AjaxDataType"**as "**jsonp**".

Code example [CSHTML]:

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("http://js.syncfusion.com/demos/ejServices/Content/FileBrowser/")
.AjaxAction("http://js.syncfusion.com/demos/ejServices/api/FileExplorer/File
Operations")
.AjaxDataType("jsonp")
)
```

If we specify "AjaxDataType" as "jsonp", data will be received in string format while calling "doJSONPAction" method of Web API Controller, here you need to deserialize the received "localData" data into "FileExplorerParams" object. After performing corresponding operations, you have to specify the response data in serialized format with wrapped callback function. Please refer below code snippet to handle "jsonp" operations on server.

Code example [C#]:

C#

```
[HttpGet]
[ActionName("doJSONPAction")]
public object doJSONPAction(string callback, string localData)
{
```

```
object Data = null;
var serializer = new JavaScriptSerializer();
FileExplorerParams args =
(FileExplorerParams)serializer.Deserialize(localData,
typeof(FileExplorerParams));
try
{
switch (args.ActionType)
{
case "Read":
Data = FileExplorerOperations.ReadData(args.Path, args.ExtensionsAllow);
break;
case "Search":
Data = FileExplorerOperations.Search(args.Path, args.ExtensionsAllow,
args.SearchString, args.CaseSensitive);
break;
case "CreateFolder":
Data = FileExplorerOperations.NewFolder(args.Path, args.Name);
break;
case "Paste":
Data = FileExplorerOperations.Paste(args.LocationFrom, args.LocationTo,
args.Names, args.Action, args.CommonFiles);
break;
case "Remove":
Data = FileExplorerOperations.Remove(args.Names, args.Path);
break;
case "Rename":
Data = FileExplorerOperations.Rename(args.Path, args.Name, args.NewName,
args.CommonFiles);
break;
case "GetDetails":
Data = FileExplorerOperations.GetDetails(args.Path, args.Names);
break;
}
HttpContext.Current.Response.Write(string.Format("{0}({1});", callback,
serializer.Serialize(Data)));
return "";
}
catch (Exception e)
{
FileExplorerResponse Response = new FileExplorerResponse();
Response.error = e.GetType().FullName + ", " + e.Message;
HttpContext.Current.Response.Write(string.Format("{0}({1});", callback,
serializer.Serialize(Response)));
return "";
}
}
[HttpPost]
[ActionName("doJSONPAction")]
public void doJSONPAction()
{
if (HttpContext.Current.Request.Files.Count > 0)
FileExplorerOperations.Upload(HttpContext.Current.Request.Files,
HttpContext.Current.Request.QueryString.GetValues("Path")[0]);
}
[HttpGet]
[ActionName("doJSONPAction")]
```

```
public void doJSONPAction(string ActionType, string Path, string
SelectedItems)
{
if (ActionType == "Download")
FileExplorerOperations.Download(Path,
HttpContext.Current.Request.QueryString.GetValues("Names"));
else if (ActionType == "GetImage")
FileExplorerOperations.GetImage(Path);
}
```

In IE8 and IE9 Browser, These options helps to render our “FileExplorer” control with cross-origin resource support.

Access static physical path using FileExplorer control

Using “FileExplorer”, also you can manage the files that are available in local file system by referring its physical path. Please refer below example to achieve this.

In the view page, add “FileExplorer” helper and specify the physical path as below shown format.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("C:/Samples/web/FileExplorerContent")
.AjaxAction(@Url.Content("FileActionDefault"))
)
```

In the controller page, specify the “GetImage” handling operation as shown below. This handling function is necessary to render the images in FileExplorer, while physical path has been mentioned.

C#

```
public ActionResult FileActionDefault(FileExplorerParams args)
{
FileExplorerOperations operation = new FileExplorerOperations();
switch (args.ActionType)
{
case "Read":
return Json(operation.Read(args.Path, args.ExtensionsAllow));
case "CreateFolder":
return Json(operation.CreateFolder(args.Path, args.Name));
case "Paste":
return Json(operation.Paste(args.LocationFrom, args.LocationTo, args.Names,
args.Action, args.CommonFiles));
case "Remove":
return Json(operation.Remove(args.Names, args.Path));
case "Rename":
return Json(operation.Rename(args.Path, args.Name, args.NewName,
args.CommonFiles));
case "GetDetails":
return Json(operation.GetDetails(args.Path, args.Names));
case "Download":
operation.Download(args.Path, args.Names);
break;
case "Upload":
operation.Upload(args.FileUpload, args.Path);
break;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
case "Search":
return Json(operation.Search(args.Path, args.ExtensionsAllow,
args.SearchString, args.CaseSensitive));
case "GetImage":
operation.GetImage(args.Path);
break;
}
return Json("");
}
```

Adding Custom column in grid view of FileExplorer

You can add custom column in grid view of “FileExplorer”. To achieve this requirement, in controller page you have to add the custom column with existing AJAX response by overriding the “Read” method, which is available in “FileExplorerOperations” class. Please refer following code example.

C#

```
public partial class FileExplorerController : Controller
{
public ActionResult Default()
{
return View();
}
public ActionResult FileActionDefault(FileExplorerParams args)
{
FileExplorerCustomOperations customOperation = new
FileExplorerCustomOperations();
FileExplorerOperations operation = new FileExplorerOperations();
switch (args.ActionType)
{
case "Read":
return Json(customOperation.Read(args.Path, args.ExtensionsAllow));
case "CreateFolder":
return Json(operation.CreateFolder(args.Path, args.Name));
case "Paste":
return Json(operation.Paste(args.LocationFrom, args.LocationTo, args.Names,
args.Action, args.CommonFiles));
case "Remove":
return Json(operation.Remove(args.Names, args.Path));
case "Rename":
return Json(operation.Rename(args.Path, args.Name, args.NewName,
args.CommonFiles));
case "GetDetails":
return Json(operation.GetDetails(args.Path, args.Names));
case "Download":
operation.Download(args.Path, args.Names);
break;
case "Upload":
operation.Upload(args.FileUpload, args.Path);
break;
case "Search":
return Json(operation.Search(args.Path, args.ExtensionsAllow,
args.SearchString, args.CaseSensitive));
case "GetImage":
operation.GetImage(args.Path);
break;
```

```
}
return Json("");
}
}
public class FileExplorerCustomOperations : FileExplorerOperations
{
public override object Read(string path, string filter, IEnumerable<object>
selectedItems = null)
{
CustomFileExplorerResponse ReadResponse = new CustomFileExplorerResponse();
try
{
var directory = new DirectoryInfo(GetPhysicalPath(ToAbsolute(path)));
filter = filter.Replace(" ", "");
var extensions = (filter ?? "*").Split(",|;".ToCharArray(),
System.StringSplitOptions.RemoveEmptyEntries);
var files = extensions.SelectMany(directory.GetFiles)
.Select(file => new CustomFileExplorerDirectoryContent
{
name = file.Name,
isFile = true,
size = file.Length,
type = "File",
dateModified = file.LastWriteTime.ToString(),
hasChild = false,
//assign the value in extension property
extension = file.Extension
});
var directories = directory.GetDirectories().Select(subDirectory => new
CustomFileExplorerDirectoryContent
{
name = subDirectory.Name,
size = 0,
isFile = false,
type = "Directory",
dateModified = subDirectory.LastWriteTime.ToString(),
hasChild = subDirectory.GetDirectories().Length > 0 ? true : false,
extension = ""
});
object fileDetails = files.Concat(directories);
ReadResponse.files =
(IEnumerable<CustomFileExplorerDirectoryContent>)fileDetails;
return ReadResponse;
}
catch (Exception e)
{
ReadResponse.error = e.GetType().FullName + ", " + e.Message;
return ReadResponse;
}
}
}
public class CustomFileExplorerDirectoryContent
{
public string name { get; set; }
public string type { get; set; }
public long size { get; set; }
public string dateModified { get; set; }
```

```
public bool hasChild { get; set; }
public bool isFile { get; set; }
//add custom property
public string extension { get; set; }
}
//customize the FileExplorer response
public class CustomFileExplorerResponse
{
public IEnumerable<CustomFileExplorerDirectoryContent> files { get; set; }
public IEnumerable<FileDetails> details { get; set; }
public object error { get; set; }
}
```

In the view page, add the custom column in grid using "GridSettings" API of "FileExplorer".

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.AjaxAction(@Url.Content("FileActionDefault"))
.GridSettings(grid =>
grid.Column(column=>
{
column.Add().Field("name").HeaderText("Name").Width("30%");
column.Add().Field("type").HeaderText("Type");
//adding new column
column.Add().Field("extension").HeaderText("Extension");
column.Add().Field("size").HeaderText("Size");
column.Add().Field("dateModified").HeaderText("Date Modified");
}
)
)
)
```

Create FileExplorer in older version

In older versions (Before 13.3.0.7), you can easily create the FileExplorer widget by using the following steps.

1. Add the following code example to the corresponding view page to render the FileExplorer.

RAZOR

```
@Html.EJ().FileExplorer("fileExplorer").Path("~/FileExplorerContent/").AjaxA
ction(@Url.Content("FileActionDefault"))
```

In above code block, "Path" denotes the filesystem path that are to be explored and "AjaxAction" specifies the URL of server side AJAX handling method that handles file operations of FileExplorer control. So "Path" and "AjaxAction" are the mandatory configuration at here.

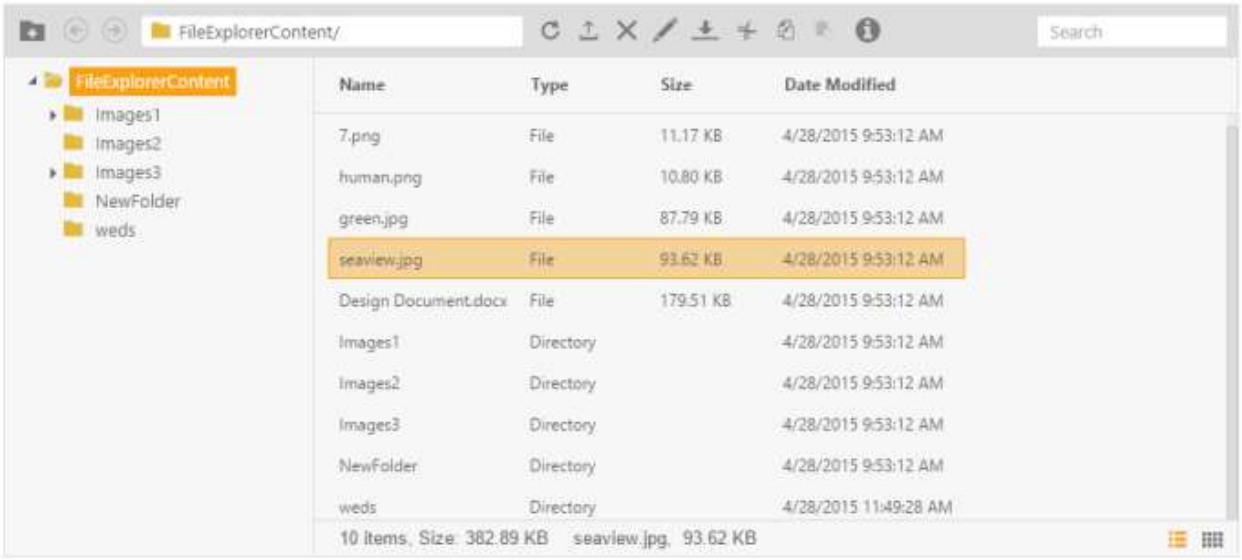
2. Add the following code example to the corresponding controller page

C#

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult FileActionDefault(FileExplorerParams args)
{
switch (args.ActionType)
{
case "Read":
return Json(FileExplorerOperations.Read(args.Path, args.ExtensionsAllow));
case "CreateFolder":
return Json(FileExplorerOperations.CreateFolder(args.Path, args.Name));
case "Paste":
FileExplorerOperations.Paste(args.LocationFrom, args.LocationTo,
args.Name.Split(','), args.Action, args.CommonFiles);
break;
case "Delete":
FileExplorerOperations.Delete(args.Name.Split(','), args.Path);
break;
case "Rename":
FileExplorerOperations.Rename(args.Path, args.PreviousName, args.NewName,
args.Type, args.CommonFiles);
break;
case "GetDetails":
return Json(FileExplorerOperations.GetDetails(args.Path, args.Name,
args.Type));
case "Download":
FileExplorerOperations.Download(args.Path);
break;
case "Upload":
FileExplorerOperations.Upload(args.FileUpload, args.Path);
break;
}
return Json("");
}
```

Once you have completed the above steps, you will get an output like below.



Copyright © 2001 - 2020 Syncfusion Inc.

FileExplorerOperations is a predefined class, which is used to perform File Explorer-based operations like read, createFolder, download, upload, rename, paste, getImage. It minimizes the work load on server-side.

By default, we send following parameters in data field of corresponding AJAX request. This helps to handle server side operation. Some Server side action method will only return the response data. This response data and request parameter are explained in following table.

Operation	Default Request Parameter	Response data	Details
Read	String ActionType,String Path,String ExtensionsAllow	Should return data in array of JSON format and JSON fields need to be in following field names. "**name, size, type, dateModified, hasChild**" *For example:*[{name: "7.png", type: "File", size: 11439, dateModified: "3/31/2015 3:16:38 PM", hasChild: false},{name: "human.png", type: "File", size: 11059, dateModified: "3/31/2015 3:16:35 PM", hasChild: false}]	Read the data from the given path
CreateFolder	String ActionType,String Path,String Name	Should return new folder name in string	Create the new folder to given path
Paste	String ActionType, String LocationFrom, String LocationTo, String Name,String Type, String Action	Void	Paste the content from source to target place
Delete	String ActionType, String Name,String Path	Void	Delete the data from the given path
Rename	String ActionType, String Path,String PreviousName, String NewName, String Type	Void	Rename the file or folder from the given path

GetDetails	String ActionType, String Path, String Name,String Type	Response data should be in JSON format like below {CreationTime:"4/28/2015 9:44:32 AM", Extension:".png", Format:"Archive", FullName:"F:\All samples\FileExplorer_Custom\FileExplorerContent\human.png", LastAccessTime:"4/28/2015 9:44:32 AM", LastWriteTime:"3/31/2015 3:16:35 PM", Length:11059, Name:"human.png"} Here you may add additional date fields with this JSON	To get the details of the data from the given path
Download	String ActionType,String Path	Void	To download the data from the given path
Upload	String ActionType, IEnumerable<HttpPostedFileBase> FileUpload, String Path	Void	To upload the data from the given path

Customize the Root Folder name in FileExplorer

You can set the alias name to the root folder of FileExplorer by using `rootFolderName` API. It is used to replace the actual root folder name in the FileExplorer UI. Refer to the below code to set the alias name for the root folder of FileExplorer.

RAZOR

```
@(Html.EJ().FileExplorer("fileExplorer")
.Path("~/FileExplorerContent/")
.RootFolderName ("This PC")
.AjaxAction(@Url.Content("FileActionDefault"))
)
```

Use the FTP connection using FileExplorer

You can access your FTP service using our FileExplorer component and can manage your files easily.

FTP Login

First you will need the FTP account login information. You can connect with the primary username and password or an FTP account. The FTP server is open to the public, using anonymous access. But most of the FTP servers are password protected.

Copyright © 2001 - 2020 Syncfusion Inc.

Username: username or user@example.com

Password: The password that was created for the user you are using.

FTP with FileExplorer server

In this FTP application, we have provided “FTPFileOperationController” file, which contains “FileActionDefault” action method. When you make AJAX request to this controller part, “FileActionDefault” method will be called after based on ActionType” parameter value, then it calls the corresponding built-in FTP file handling methods such as ‘Read’, ‘Search’, ‘Download’, ‘Upload’, ‘Remove’, ‘Rename’ which are available in our “FTPFileExplorerOperations” class.

Steps to create FileExplorer application to access FTP server

Step 1: Create a new ASP.NET MVC project using Visual Studio.

Step 2: Include **“FTPFileExplorerOperations”** file in that application. This file contains built-in file handling methods which helps to connect our FileExplorer with FTP service.

https://www.syncfusion.com/downloads/support/directtrac/general/ze/FTPFileExplorerOperations901960089.zip

Step 3: Add **“FileExplorerController.cs”** file in the controller part of FTP project.

This file, contains action handler methods. Based on the request parameters, it helps to call the built-in file handling methods of **FTPFileExplorerOperations** and perform corresponding actions.

C#

```
public ActionResult FileActionDefault(FileExplorerParams args)
{
FTPFileExplorerOperations operation= new FTPFileExplorerOperations();
// FTP Operations
switch (args.ActionType)
{
case "Read":
return Json(operation.Read(args.Path, args.ExtensionsAllow));
case "CreateFolder":
return Json(operation.CreateFolder(args.Path, args.Name));
case "Paste":
return Json(operation.Paste(args.LocationFrom, args.LocationTo, args.Names,
args.Action, args.CommonFiles));
case "Remove":
return Json(operation.Remove(args.Names, args.Path));
case "Rename":
return Json(operation.Rename(args.Path, args.Name, args.NewName,
args.CommonFiles));
case "GetDetails":
return Json(operation.GetDetails(args.Path, args.Names));
case "Download":
operation.Download(args.Path, args.Names);
break;
case "GetImage":
operation.GetImage(args.Path, args.Names);
break;
case "Upload":
operation.Upload(args.FileUpload, args.Path);
break;
case "Search":
```

```
return Json(operation.Search(args.Path, args.ExtensionsAllow,
args.SearchString, args.CaseSensitive));
}
return Json("");
}
```

Step 4: Add FTP Storage path that is viewed by FileExplorer.

You will create FTP URL like “ftp://localhost/FileBrowser/” (Port number may vary).

After that, you need to specify the FTP folder path and AJAX action handler name as shown in below code block.

RAZOR

```
@Html.EJ().FileExplorer("fileexplorer").Path("ftp://localhost/FileBrowser/")
.AjaxAction(@Url.Content("/FileExplorer/FileActionDefault"))
```

We have prepared a demo based on above steps, please refer this.

https://www.syncfusion.com/downloads/support/directtrac/general/ze/FTPMVC1739148525.zip

Gantt

Overview

The Essential JavaScript Gantt control is designed to visualize and edit the project schedule, and track the project progress. It helps to organize and schedule the projects and also you can update the project schedule through interactions like editing, dragging and resizing.

Key Features

- Sorting
- Editing
- Filtering
- Task relationship
- Stripline
- Baseline
- Timeline customization
- Work break down structure
- Taskbar customization
- Task label customization
- Localization
- Resources
- Resource allocation view
- Critical path
- Selection
- Task scheduling modes
- Work breakdown structure
- Exporting
- Row drag and drop
- Sequencing tasks

Copyright © 2001 - 2020 Syncfusion Inc.

- Searching
- Holidays
- Work and effort driven tasks

Getting Started

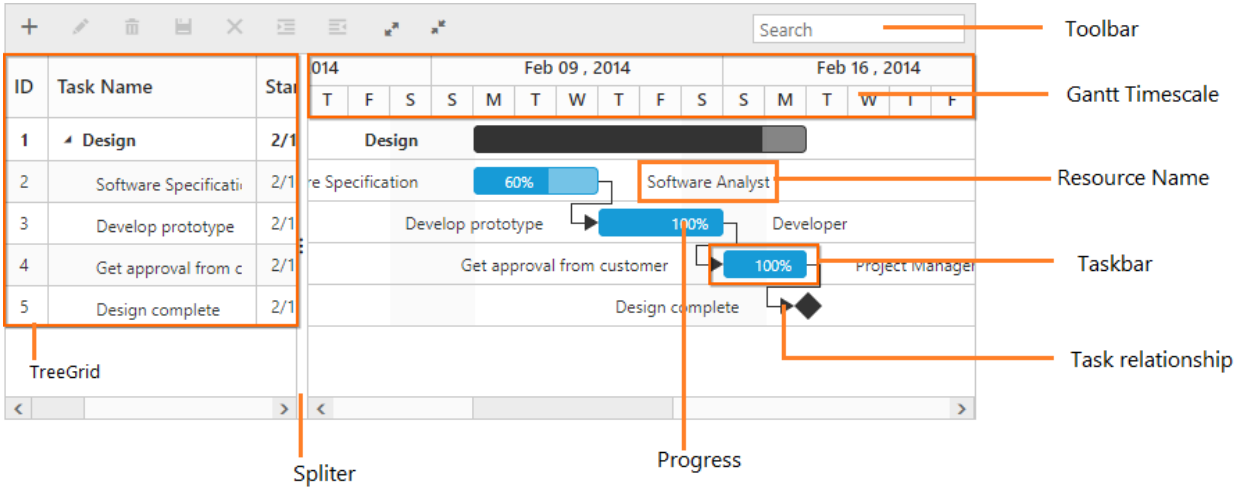
This section explains briefly about how to create a Gantt chart in your application with ASP.NET MVC.

Create your first Gantt in MVC

This section explains briefly about the control structure and how to create a Gantt chart.

Control Structure

Gantt chart is used to edit and visualize project schedule and also to track progress of a task. The following screen shot illustrates the elements of a Gantt chart.



Elements of a Gantt chart

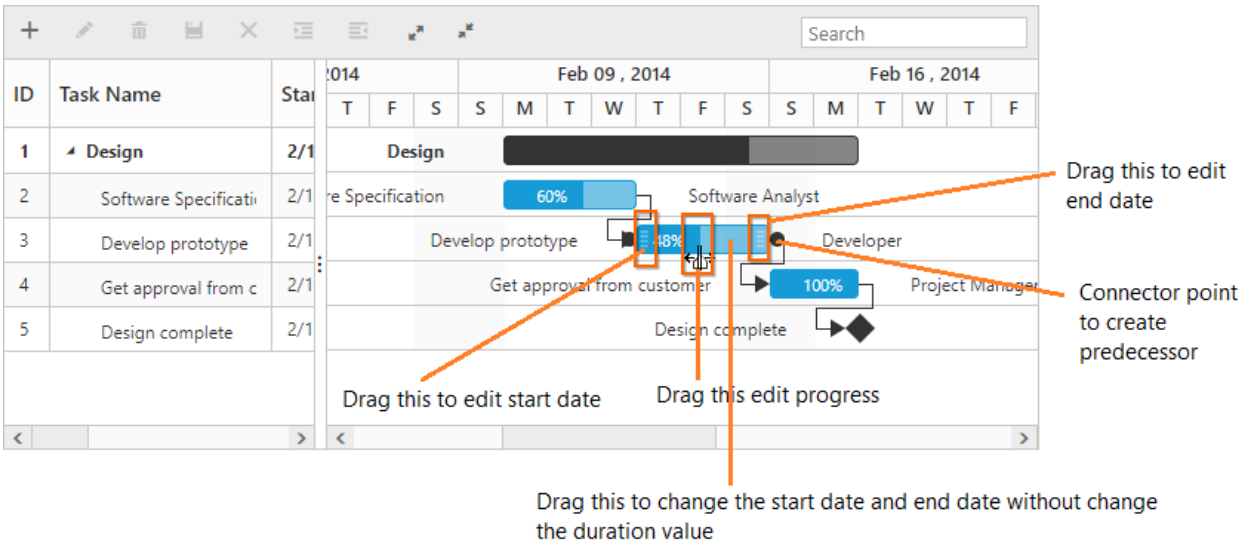
- Toolbar – It is a collection of toolbar buttons to add, edit, delete a task. You can outdent and indent a task using outdent and indent buttons. Following screen shot illustrates the function of each toolbar button,

Toolbar of Gantt chart

- Search Textbox – It is used to search tasks, which contains the search string.
- Resource Names – It displays the names of the resources assigned to that task.
- Task bar – It is a graphical representation of the duration of task.
- Task Progress – It displays the percentage of the task completed.
- Header – It represents time scale based on which a task bar is drawn.
- Tree Grid – It displays the tasks and its sub tasks in hierarchical table.
- Task Relationship – It determines when to start or finish a task.

Copyright © 2001 - 2020 Syncfusion Inc.

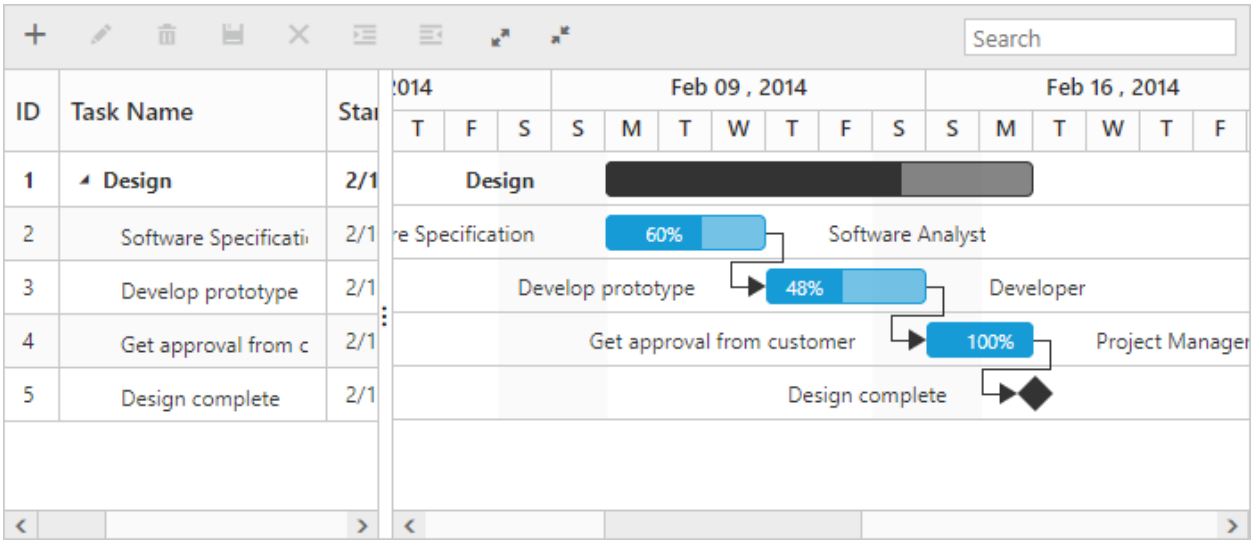
- Interactive Editing – You can edit the duration of a task by dragging or resizing the task bar. Following screen shot illustrates this.



Editing options Gantt chart

Create your Gantt chart

In this tutorial, you will learn how to create a simple Gantt chart, add tasks and subtasks, and set relationship between tasks for design phase of software project. The following screen shot displays the output after completing this tutorial.



Simple Gantt chart

1. First, create a new MVC Razor project; please refer MVC-Getting Started documentation to create new project and add necessary DLL's and script files.
2. Create a data source in Controllers/HomeController.cs file, We can bind datasource to Gantt using Datasource property.

Copyright © 2001 - 2020 Syncfusion Inc.

3. Add the following code example in the Index.cshtml file to create a Gantt control in the View page.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
.TaskIdMapping("TaskID")//Provide name of the property which contains task
id in the data source
.TaskNameMapping("TaskName")//Provide name of the property which contains
task name
.StartDateMapping("StartDate")//Provide name of the property which contains
start date of the task
.DurationMapping("Duration")//Provide name of the property which contains
duration of the task
.ProgressMapping("Progress")//Provide name of the property which contains
progress of the task
.ScheduleStartDate("02/01/2014")//Provide schedule header start date
.ScheduleEndDate("03/14/2014")//Provide schedule header end date
.ChildMapping("SubTasks")//Provide name of the property which contains
subtask of the task
.TreeColumnIndex(1)
.SizeSettings(ss=>ss.Width("700").Height("300"))
.Datasource(ViewBag.datasource) //Provides data source for Gantt
)
@(Html.EJ().ScriptManager())
```

C#

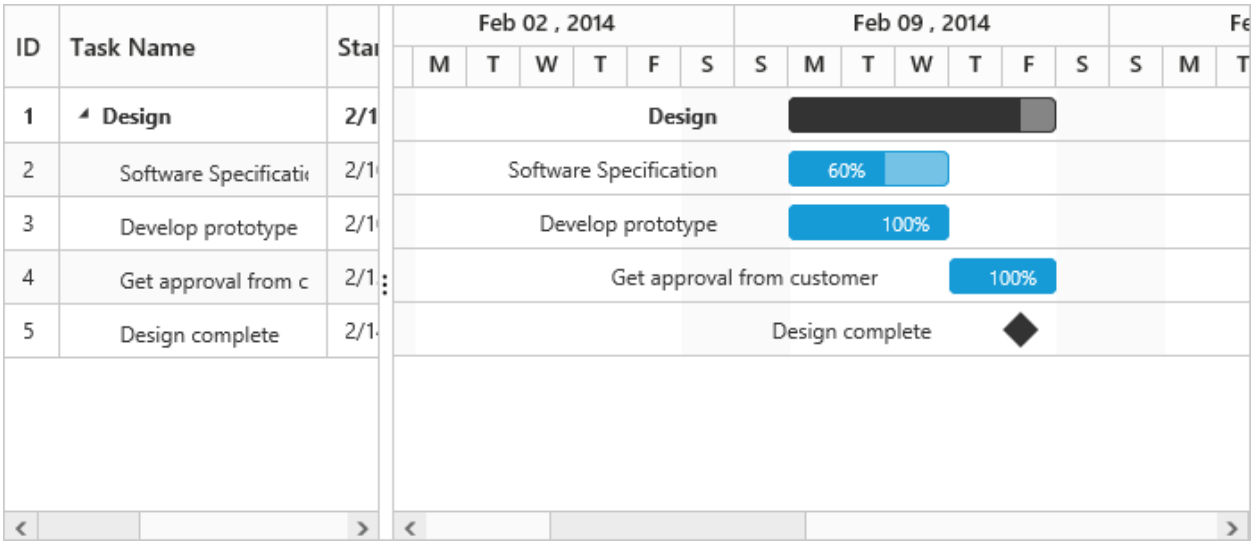
```
public class DefaultData
{
public string StartDate { get; set; }
public string EndDate { get; set; }
public int TaskID { get; set; }
public string TaskName { get; set; }
public int Duration { get; set; }
public int Progress { get; set; }
public List<DefaultData> SubTasks { get; set; }
public string Predecessors { get; set; }
public List<int> ResourceID { get; set; }
}
public class GanttDefaultData
{
public static List<DefaultData> GetData()
{
List<DefaultData> tasks = new List<DefaultData>();
tasks.Add(new DefaultData()
{
TaskID = 1,
TaskName = "Design",
StartDate = "02/10/2014",
EndDate = "02/14/2014",
Duration = 6,
});
tasks[0].SubTasks = new List<DefaultData>();
tasks[0].SubTasks.Add(new DefaultData()
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
TaskID = 2,
TaskName = "Software Specification",
StartDate = "02/10/2014",
EndDate = "02/12/2014",
Duration = 3,
Progress = 60,
ResourceID = new List<int>() { 2 }
});
tasks[0].SubTasks.Add(new DefaultData()
{
TaskID = 3,
TaskName = "Develop prototype",
StartDate = "02/10/2014",
EndDate = "02/12/2014",
Duration = 3,
Progress = 100,
Predecessors = "2FS",
ResourceID = new List<int>() { 3 }
});
tasks[0].SubTasks.Add(new DefaultData()
{
TaskID = 4,
TaskName = "Get approval from customer",
StartDate = "02/13/2014",
EndDate = "02/14/2014",
Duration = 2,
Progress = 100,
Predecessors = "3FS",
ResourceID = new List<int>() { 1 }
});
tasks[0].SubTasks.Add(new DefaultData()
{
TaskID = 5,
TaskName = "Design complete",
StartDate = "02/14/2014",
EndDate = "02/14/2014",
Duration = 0,
Predecessors = "4FS"
});
return tasks;
}
}
public ActionResult SimpleGantt()
{
var DataSource = GanttDefaultData.GetData();
ViewBag.datasource = DataSource;
return View();
}
```

The following screen shot displays the Gantt.

Copyright © 2001 - 2020 Syncfusion Inc.



Gantt chart

Enable Toolbar

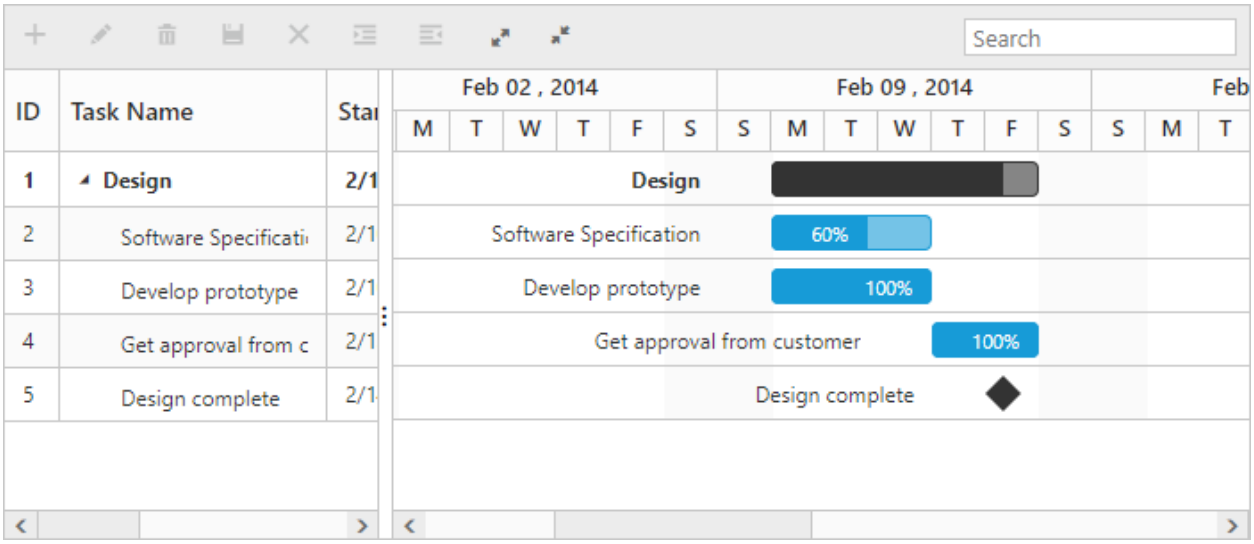
Gantt control contains the toolbar options to Add, Edit, Delete, Search, Indent, Outdent, Expand and Collapse all records. You can enable toolbar using ToolbarSettings.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
.ToolbarSettings(ts =>
{
ts.ShowToolbar(true);
ts.ToolbarItems(new List<GanttToolBarItems>()
{
GanttToolBarItems.Add,
GanttToolBarItems.Edit,
GanttToolBarItems.Delete,
GanttToolBarItems.Update,
GanttToolBarItems.Cancel,
GanttToolBarItems.Indent,
GanttToolBarItems.Outdent,
GanttToolBarItems.ExpandAll,
GanttToolBarItems.CollapseAll,
GanttToolBarItems.Search
});
})
)
@(Html.EJ().ScriptManager())
```

The following screen shot displays a Tool bar in Gantt.

Copyright © 2001 - 2020 Syncfusion Inc.



Toolbar in Gantt chart

Note: Add, Edit, Delete options are enabled when enabling the AllowEditing, AllowAdding, AllowDeleting in the EditSettings.

Enable sorting

Gantt control has the sorting functionality for arranging the tasks in ascending or descending based on the particular column.

Multicolumn sorting

Enable the multicolumn sorting in Gantt by setting AllowMultiSorting to true. You can sort multiple columns in Gantt by selecting the desired column header while holding the CTRL key.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.AllowSorting(true)
.AllowMultiSorting(true)
)
@(Html.EJ().ScriptManager())
```

Enable Editing

You can enable editing using EditSettings and AllowGanttChartEditing.

Cell Editing

Modify the task details through the grid cell editing by setting the EditMode as CellEditing.

Normal Editing

Modify the task details through the edit dialog by setting the EditMode as Normal.

Taskbar Editing

Modify the task details through user interaction like resizing and dragging the taskbar.

Predecessor Editing

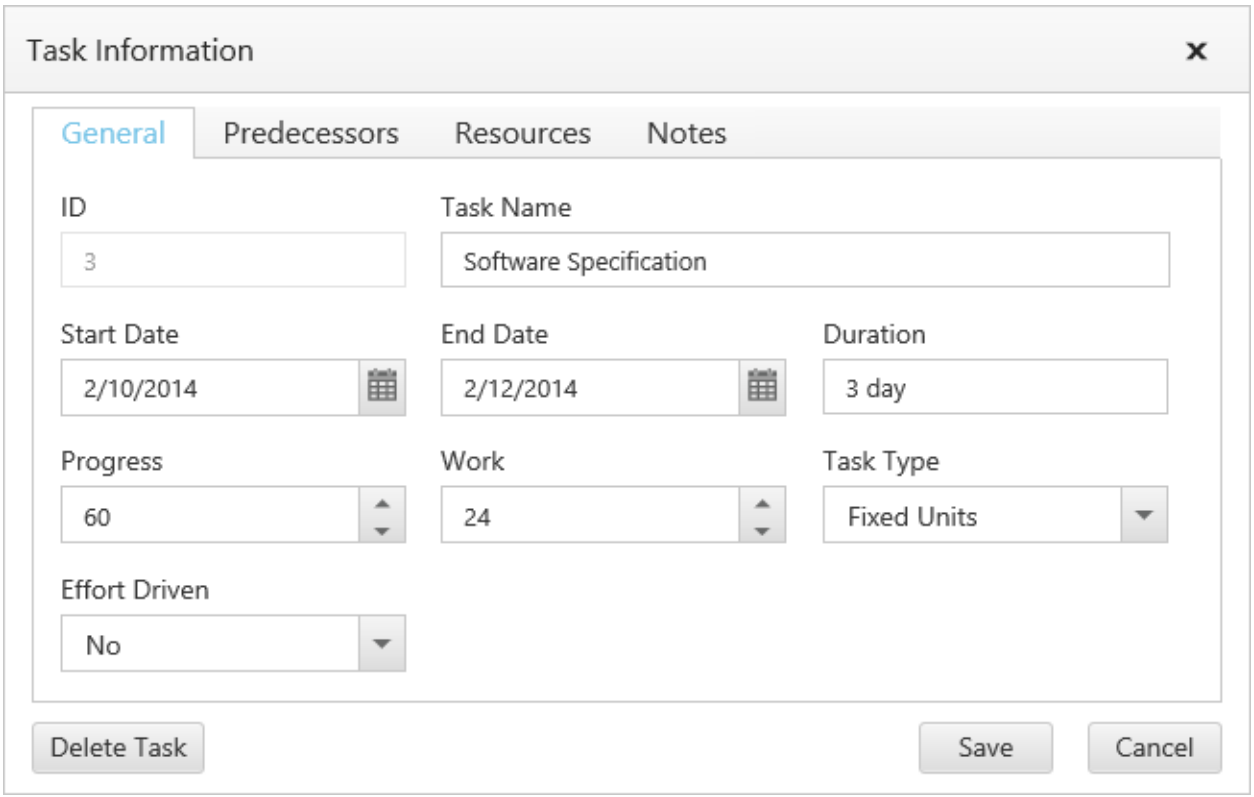
Modify the predecessor details of a task by using mouse interactions by setting AllowGanttChartEditing as true and setting the value for PredecessorMapping property.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.AllowGanttChartEditing(true)
.PredecessorMapping("Predecessor") // Predecessor editing
.EditSettings(edit =>
{
edit.AllowEditing(true);
edit.AllowAdding(true);
edit.AllowDeleting(true);
edit.EditMode("cellEditing");
edit.AllowIndent(true);
})
)
@(Html.EJ().ScriptManager())
```

The following screen shot displays the Gantt control with dialog editing option.



Enable Context Menu

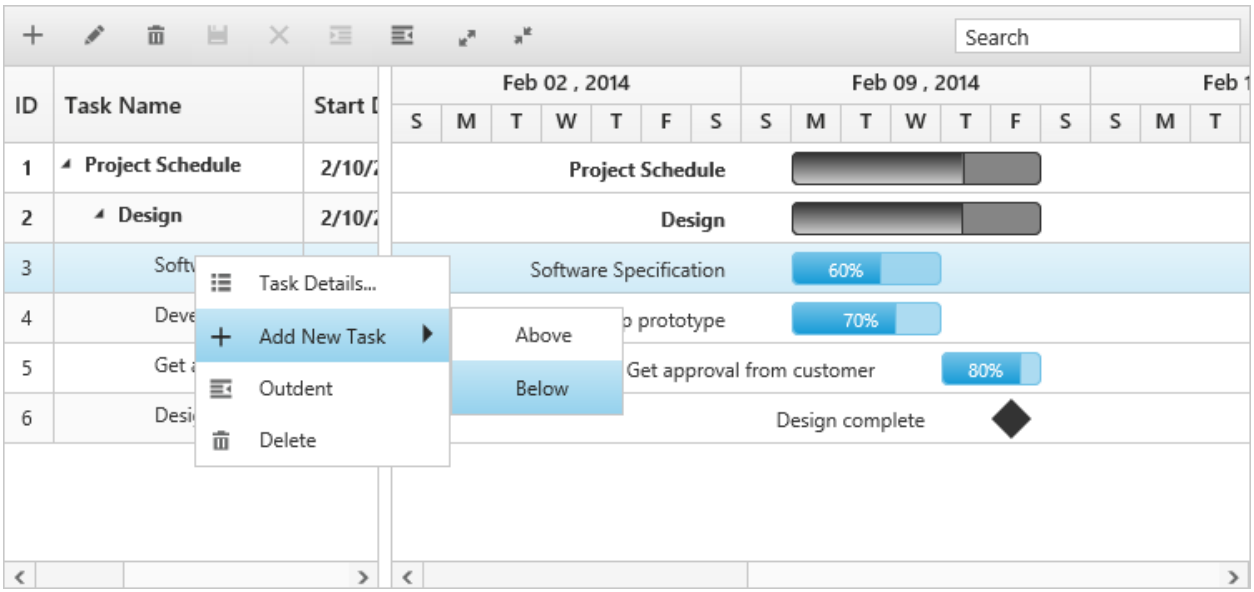
You can enable the context menu in Gantt by setting the `EnableContextMenu` as `true`.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.EnableContextMenu(true)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screen shot displays Gantt chart with Enable Context menu option.



Gantt chart with Enable Context menu option

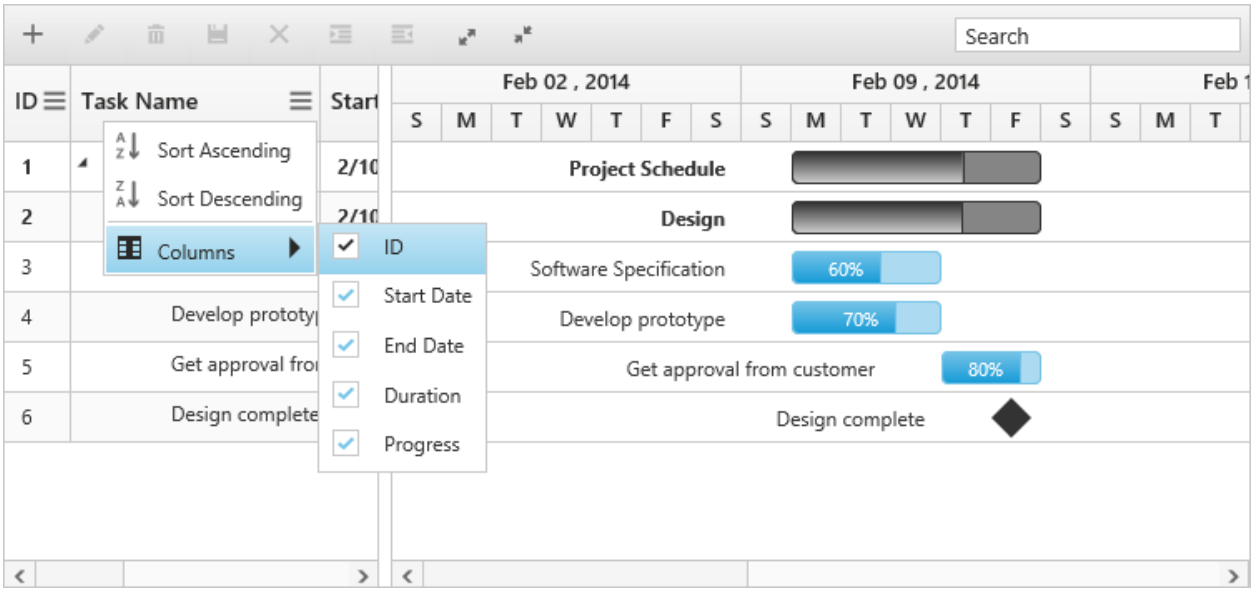
Enable Column Menu

You can enable the column menu in Gantt, by setting the ShowColumnChooser as true.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.ShowColumnChooser(true)
)
@(Html.EJ().ScriptManager())
```

The following screen shot displays Gantt control in which column chooser option is enabled



Provide tasks relationship

In Gantt, you have the predecessor support to show the relationship between two different tasks.

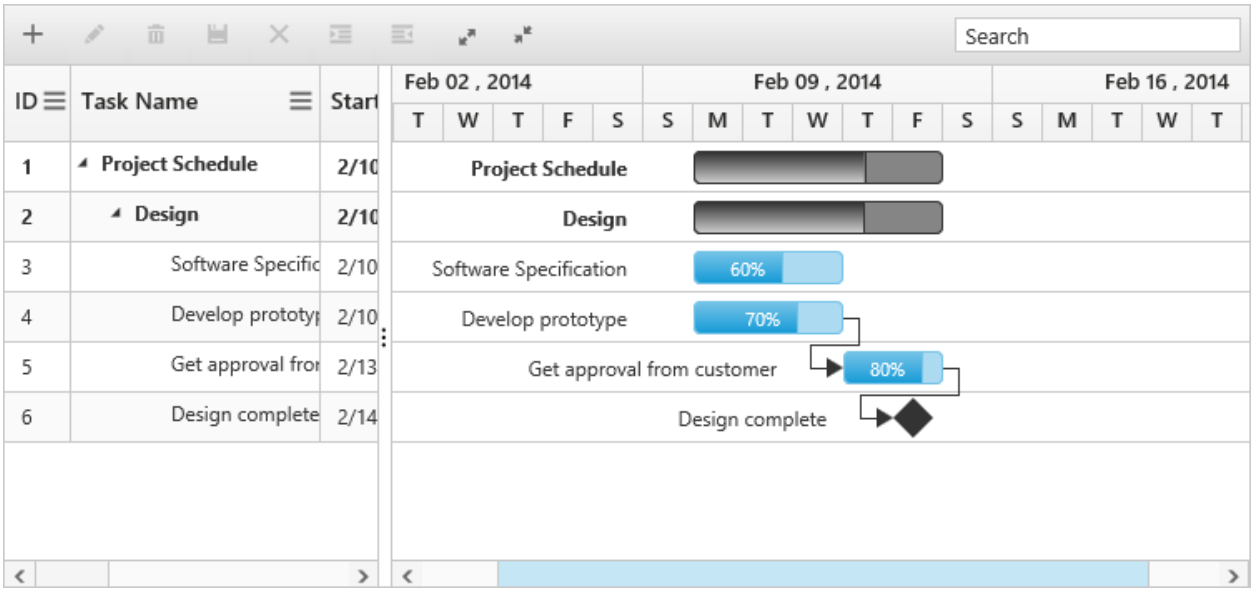
- **Start to Start (SS)** - You cannot start a task until the other task starts.
- **Start to Finish (SF)** - You cannot finish a task until the other task finishes.
- **Finish to Start (FS)** - You cannot start a task until the other task completes.
- **Finish to Finish (FF)** - You cannot finish a task until the other task completes.

You can show the relationship in tasks, by using the PredecessorsMapping property as shown in the following code example.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.PredecessorMapping("Predecessor")
)
@(Html.EJ().ScriptManager())
```

The following screen shot displays the relationship between tasks.



Gantt chart with relationships between tasks

Provide Resources

In Gantt control, you can display and assign the resource for each task. Create a collection of JSON object, which contains id and name of the resource and assign it to the resources property. Then, specify the field name for id and name of the resource in the resource collection to ResourceIdMapping and ResourceNameMapping options. The name of the field, which contains the actual resources assigned for a particular task in the DataSource is specified using the ResourceInfoMapping.

C#

```
public class Resources
{
```

```
public int ResourceID { get; set; }
public string ResourceName { get; set; }
}
public class ResourceList
{
public static List<Resources> GetData()
{
List<Resources> resourceDetails = new List<Resources>();
resourceDetails.Add(new Resources() { ResourceID = 1, ResourceName =
"Project Manager" });
resourceDetails.Add(new Resources() { ResourceID = 2, ResourceName =
"Software Analyst" });
resourceDetails.Add(new Resources() { ResourceID = 3, ResourceName =
"Developer" });
resourceDetails.Add(new Resources() { ResourceID = 4, ResourceName =
"Testing Engineer" });
return resourceDetails;
}
}
public ActionResult SimpleGantt()
{
var DataSource = GanttDefaultData.GetData();
ViewBag.datasource = DataSource;
var Resources = ResourceList.GetData();
ViewBag.resources = Resources;
return View();
}
```

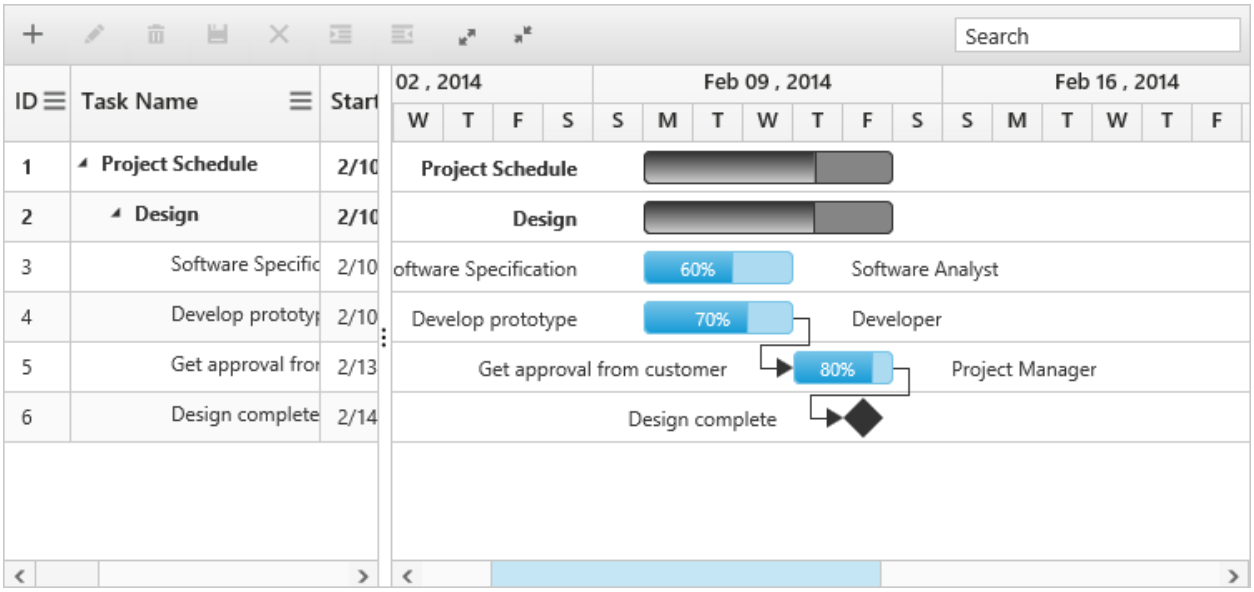
Add the following code example in the index.cshtml file, to create the Gantt control with resource in the View page.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.ResourceInfoMapping("ResourceID")//Field name which contains resource
details for the task
.ResourceNameMapping("ResourceName")//resource Name mapping
.ResourceIdMapping("ResourceID")//resource Id Mapping
//...
.Resources(ViewBag.resources)//resource collection dataSource
.Datasource(ViewBag.datasource) //Provides data source for Gantt
)
@(Html.EJ().ScriptManager())
```

The following screen shot displays resource allocation for tasks in Gantt.

Copyright © 2001 - 2020 Syncfusion Inc.



This section explains briefly about the control structure and how to create a Gantt chart.

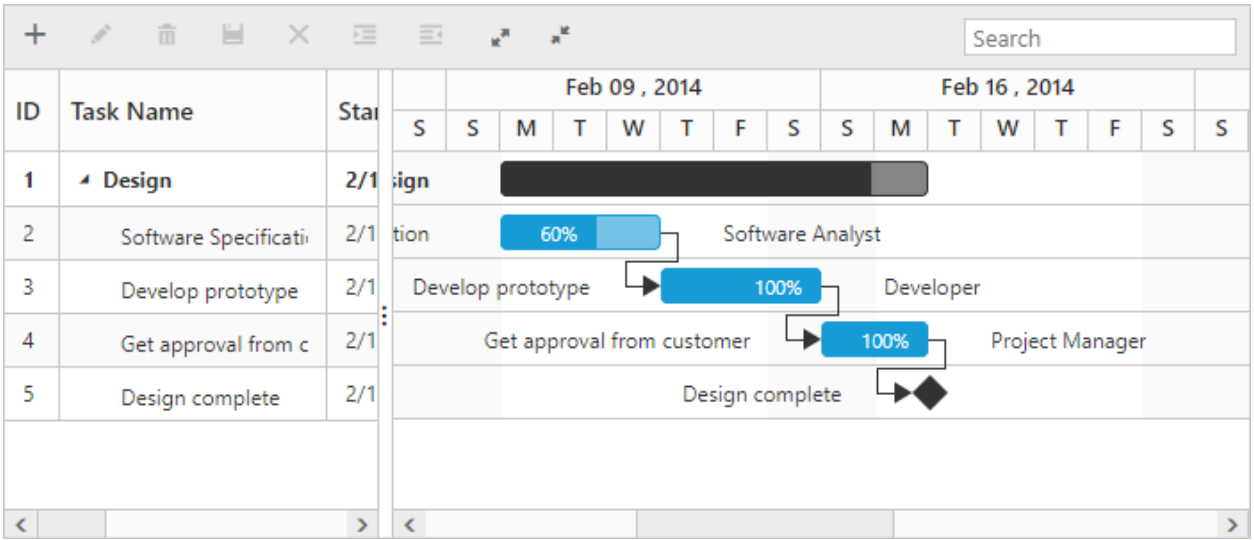
Highlight Weekend

In Gantt, you can on or off weekends high lighting by setting the HighlightWeekEnds as true or false.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.HighlightWeekends(false)
)
@(Html.EJ().ScriptManager())
```

The following screen shot displays Gantt chart in which highlight weekends is disabled:



Define dimension of Gantt

By default Gantt control was rendered with 100% width and 450px height, we can define the dimension of Gantt control by using SizeSettingsproperty. Gantt control width and height can be

Copyright © 2001 - 2020 Syncfusion Inc.

defined by either Height and Width properties or by defining inline style in Gantt container element. The below code example shows how to define width and height for Gantt control.

ASPX-CS

```
<!--<div id="GanttContainer" style="width:700px;height:350px"></div>-->
<div id="GanttContainer"></div>
<script>
@(Html.EJ().Gantt("GanttContainer")
//...
.SizeSettings(size=>size.Height("350px").Width("700px"))
)
@(Html.EJ().ScriptManager())
</script>
```

Note: Gantt control will automatically update the width and height value based on container element on window resize action, this can be enabled by setting IsResponsive property as true for this Height and Width value will be defined in percentage.

Add notes in tasks

In Gantt, we can add additional information about the tasks, this information can be defined in data source and this field was mapped to Gantt control by using NotesMapping property. Notes values can be defined as string or in HTML string format. This notes content was displayed in Notes column and notes value can be updated by using cell editing and dialog editing. The following code example shows how to use the NotesMapping property.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.NotesMapping("notesContent")
)
@(Html.EJ().ScriptManager())
```

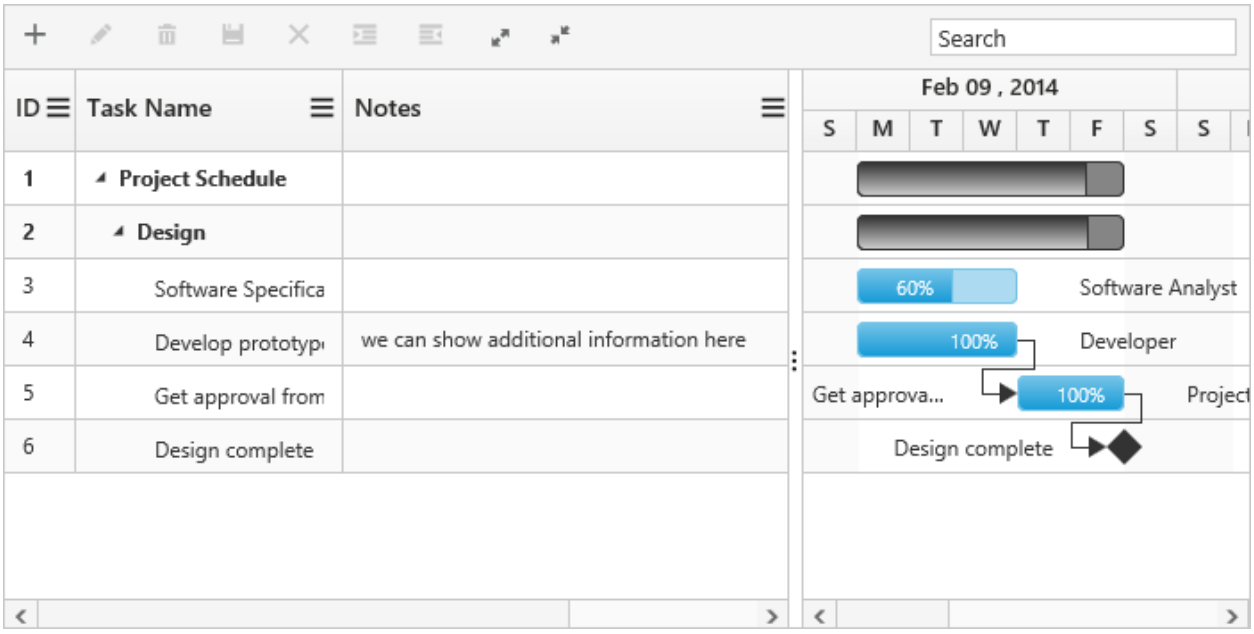
C#

```
public class GanttController : Controller
{
//
// GET: /Default/
public ActionResult Default()
{
var DataSource = GanttDefaultData.GetData();
ViewBag.datasource = DataSource;
return View();
}
public class GanttDefaultData
{
public static List<DefaultData> GetData()
{
List<DefaultData> list = new List<DefaultData>();
//..
list.Add(new DefaultData()
{
```

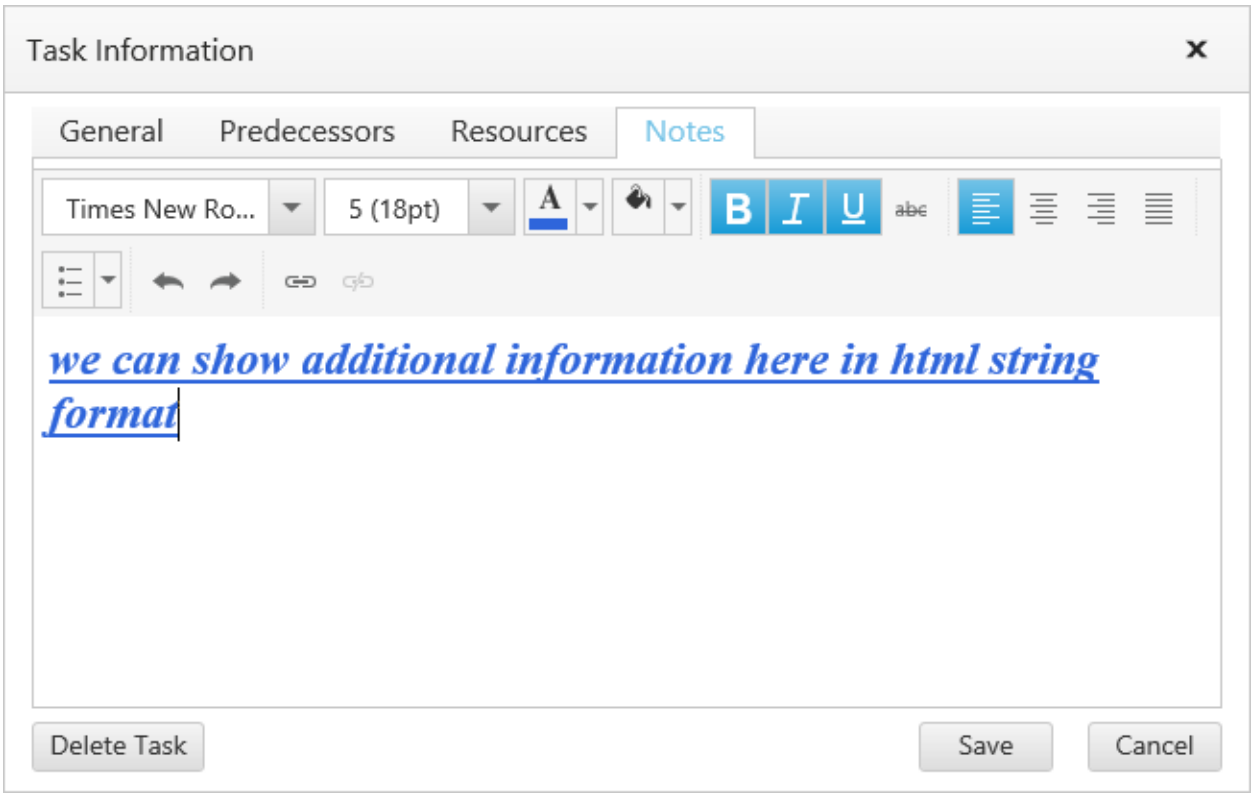
Copyright © 2001 - 2020 Syncfusion Inc.

```
Id = 4,
Name = "Develop prototype",
notesContent = "we can show additional information here",
//..
});
return list;
}
}
public class DefaultData
{
public int Id { get; set; }
public string Name { get; set; }
public string notesContent { get; set; }
}
}
```

The below screenshot shows the output of above code example.



Notes column in Gantt



Editing notes in edit dialog

Note: Notes value was displayed as plain text in Grid part and also when we edit the notes value by cell editing, value was stored as string value. We can use edit dialog to update the notes value of task in HTML string format.

Milestones in Gantt

Milestones are used to denote the important event/stages in project management. Milestones start date and end date value will be same and duration value will be 0. Using MilestoneMapping property we can map the datasource with Milestone mapping field and render Gantt tasks as milestone based on its mapping value. The below code example shows how to use this property.

ASPX-CS

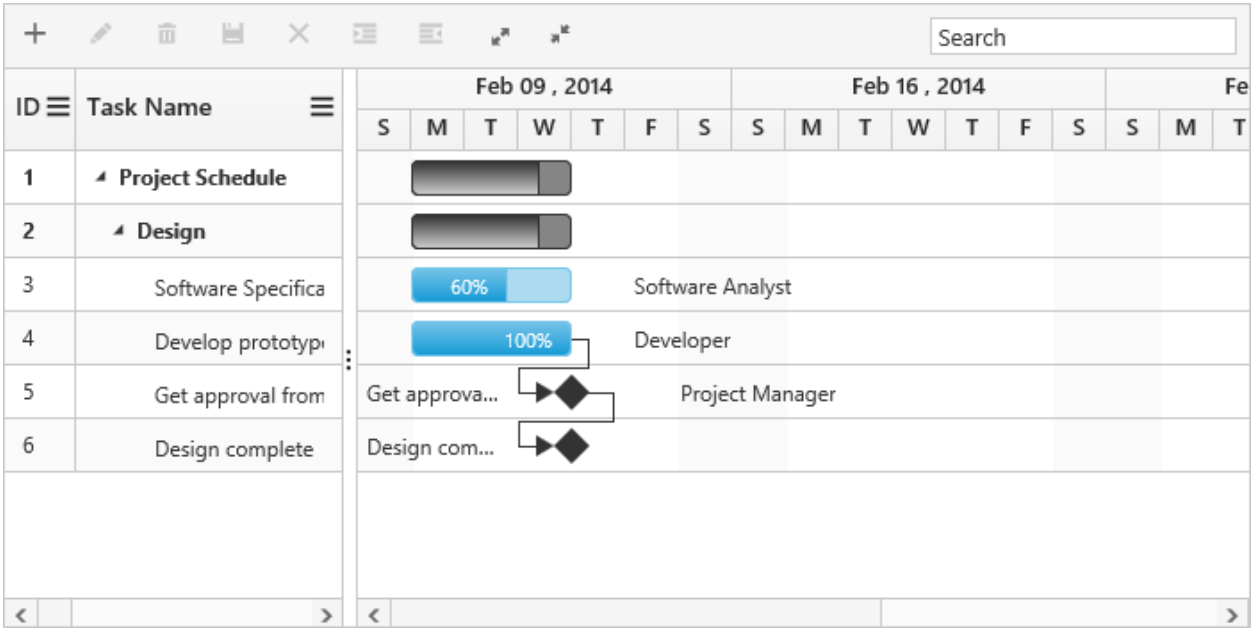
```
@(Html.EJ().Gantt("GanttContainer")
//...
.MilestoneMapping("isMileStone")
)
@(Html.EJ().ScriptManager())
```

C#

```
public class GanttController : Controller
{
//
// GET: /Default/
public ActionResult Default()
{
var DataSource = GanttDefaultData.GetData();
```

```
ViewBag.datasource = DataSource;
return View();
}
public class GanttDefaultData
{
public static List<DefaultData> GetData()
{
List<DefaultData> list = new List<DefaultData>();
//..
list.Add(new DefaultData()
{
Id = 4,
Name = "Develop prototype",
isMileStone = false,
//..
});
list.Add(new DefaultData()
{
Id = 5,
Name = "Get approval from customer",
StartDate = new Date("02/10/2014"),
EndDate = new Date("02/14/2014"),
Duration = 2,
isMileStone = true,
//..
});
return list;
}
}
}
```

The below screenshot shows the output of above code example.



Data Binding

Data binding is the process that establishes a connection between the application and different kinds of data sources such as business objects. And it is possible to bind local data and remote data in Gantt.

You can set the data source for Gantt control by using DataSource property.

Local Data Binding

In Local Data Binding, datasource for rendering the Gantt control is retrieved from the same application locally.

Two types of Data Binding are possible with Gantt control,

- Hierarchical datasource binding
- Self-referential data binding (Flat data)

Hierarchical data-source binding

In hierarchical data binding subtasks or child tasks collections are identified by using ChildMapping property.

The following code example explains how to bind the hierarchical data in Gantt.

ASPX-CS

```
@using Syncfusion.JavaScript
@using Syncfusion.MVC.EJ
<!DOCTYPE html>
<html>
<head>
@*Add script reference and style reference here*@
</head>
<body>
@(Html.EJ().Gantt("ganttsample2")
.TaskIdMapping("Id")
.TaskNameMapping("Name")
.StartDateMapping("StartDate")
.DurationMapping("Duration")
.ProgressMapping("PercentDone")
.TreeColumnIndex(1)
.ChildMapping("Children")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
</body>
</html>
```

C#

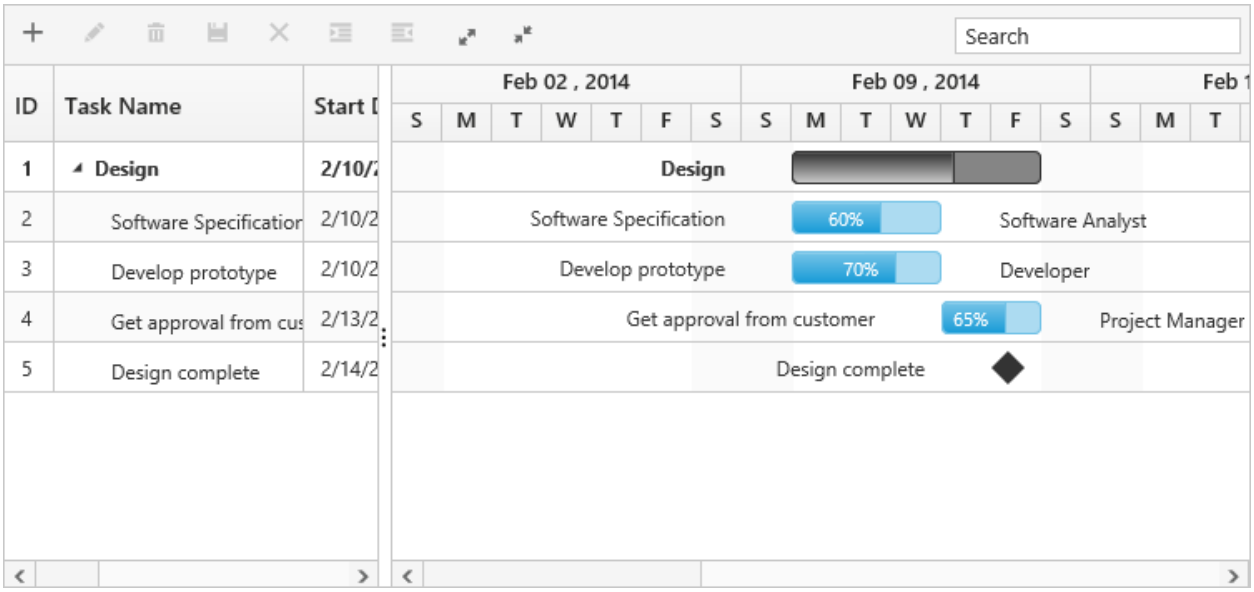
```
public class GanttController : Controller
{
//
// GET: /Default/
public ActionResult Default()
{
var DataSource = GanttDefaultData.GetData();
ViewBag.datasource = DataSource;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
return View();
}
public class GanttDefaultData
{
public static List<DefaultData> GetData()
{
List<DefaultData> list = new List<DefaultData>();
list.Add(new DefaultData()
{
Id = 1,
Name = "Design",
StartDate = "02/10/2014",
EndDate = "02/14/2014",
Duration = 5,
PercentDone = 40,
Children = (new List<DefaultData>()
{
new DefaultData()
{
Id = 2,
Name = "Software Specification",
StartDate = "02/10/2014",
EndDate="02/12/2014",
Duration = 5,
PercentDone = 40
},
new DefaultData()
{
Id = 3,
Name = "Develop Prototype",
StartDate = "02/10/2014",
EndDate="02/12/2014",
Duration = 4,
PercentDone = 40,
Predecessor = "2"
},
//..
})
});
return list;
}
}
public class DefaultData
{
public string StartDate { get; set; }
public string EndDate { get; set; }
public int Id { get; set; }
public string Name { get; set; }
public int Duration { get; set; }
public int PercentDone { get; set; }
public List<DefaultData> Children { get; set; }
public string Predecessor { get; set; }
}
}
```

The output of the above steps is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Self-Referential Data Binding (Flat Data)

Gantt can be rendered from self-referential data structures, by mapping the task ID and parent task ID fields.

- Task ID field- This field must contain unique values to identify the nodes. It should be mapped to the `TaskIdMapping` property.
- Parent task ID field- This field must contain values to identify the parent nodes. It should be mapped to the `ParentTaskIdMapping` property.

ASPX-CS

```
@(Html.EJ().Gantt("ganttsample2")
.TaskIdMapping("Id")
.TaskNameMapping("Name")
.StartDateMapping("StartDate")
.DurationMapping("Duration")
.ProgressMapping("PercentDone")
.ParentTaskIdMapping("ParentId")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

C#

```
public class GanttController : Controller
{
//
// GET: /GanttSelfReference/
public ActionResult GanttSelfReference()
{
var DataSource = GanttSelfData.GetData();
ViewBag.datasource = DataSource;
return View();
}
```

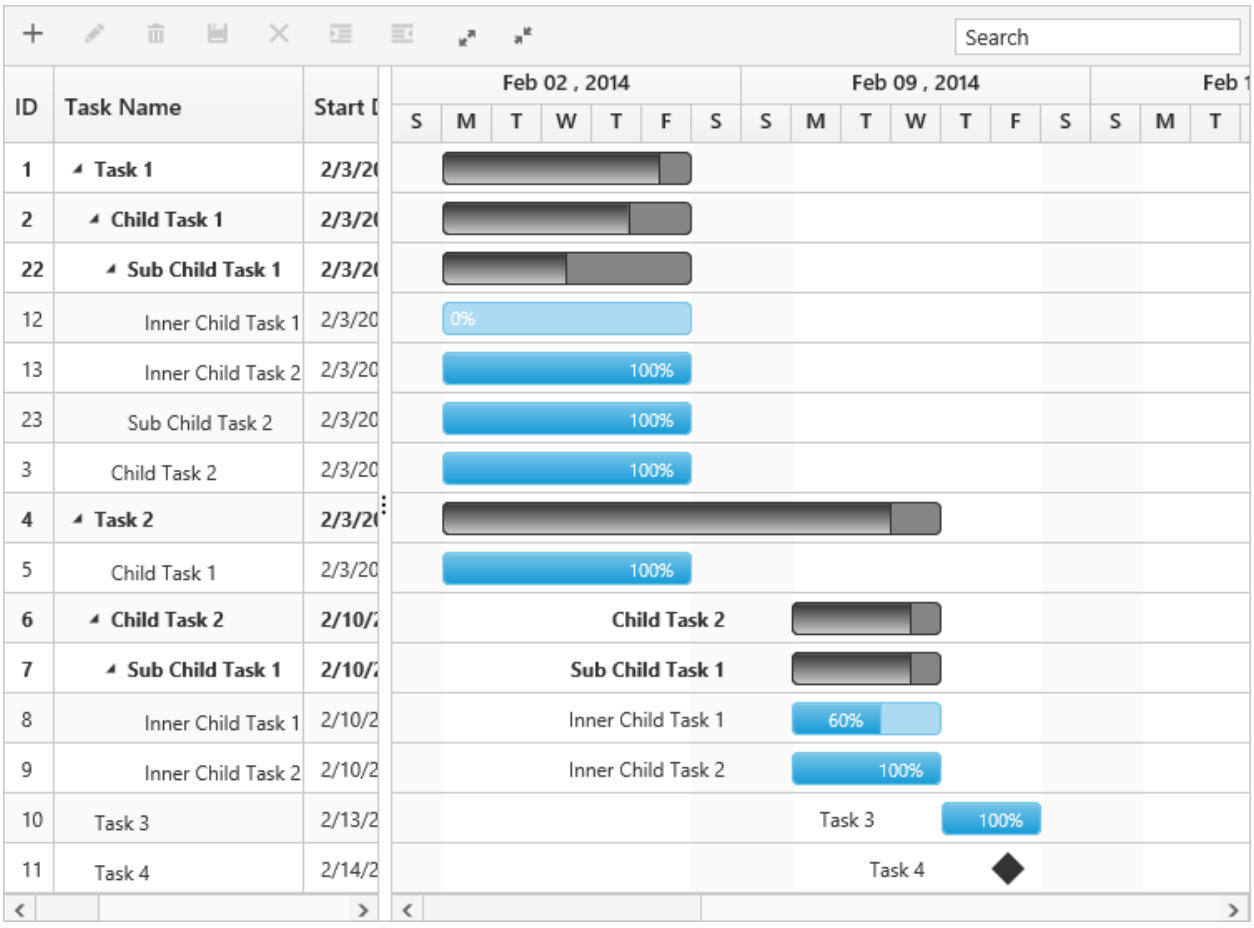
Copyright © 2001 - 2020 Syncfusion Inc.

```
public class GanttSelfData
{
public static List<SelfData> GetData()
{
List<SelfData> data = new List<SelfData>();
data.Add(new SelfData()
{
Id = 1,
Name = "Task 1",
StartDate = "02/03/2014",
Duration = 5,
PercentDone = 40,
ParentId = null
});
data.Add(new SelfData()
{
Id = 2,
Name = "Child Task 1",
StartDate = "02/03/2014",
Duration = 5,
PercentDone = 40,
ParentId = 1
});
data.Add(new SelfData()
{
Id = 3,
Name = "Child Task 2",
StartDate = "02/03/2014",
Duration = 5,
PercentDone = 40,
ParentId = 1
});
data.Add(new SelfData()
{
Id = 22,
Name = "Sub Child Task 1",
StartDate = "02/03/2014",
Duration = 5,
PercentDone = 40,
ParentId = 2
});
data.Add(new SelfData()
{
Id = 23,
Name = "Sub Child Task 2",
StartDate = "02/03/2014",
Duration = 5,
PercentDone = 40,
ParentId = 2
});
data.Add(new SelfData()
{
Id = 12,
Name = "Inner Child Task 1",
StartDate = "02/03/2014",
Duration = 5,
PercentDone = 40,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
ParentId = 5
});
//..
return data;
}
}
public class SelfData
{
public string StartDate { get; set; }
public int Id { get; set; }
public string Name { get; set; }
public int Duration { get; set; }
public int PercentDone { get; set; }
public string Predecessor { get; set; }
public int? ParentId { get; set; }
}
}
```

The following screenshot shows the output of the above steps.



You can find the online demo sample for binding self-referential data here

Remote data

OData

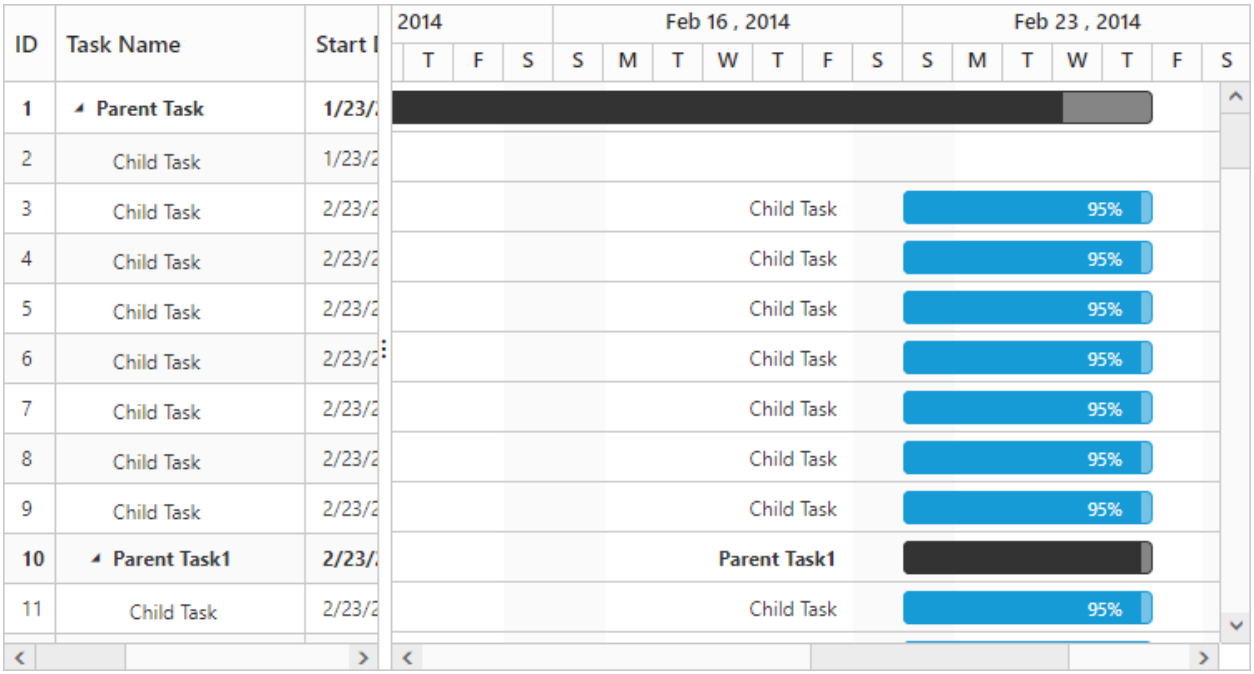
OData is a standardized protocol for creating and consuming data. You can provide the OData service URL directly to the ej.DataManager class and then you can assign it to Gantt dataSource.

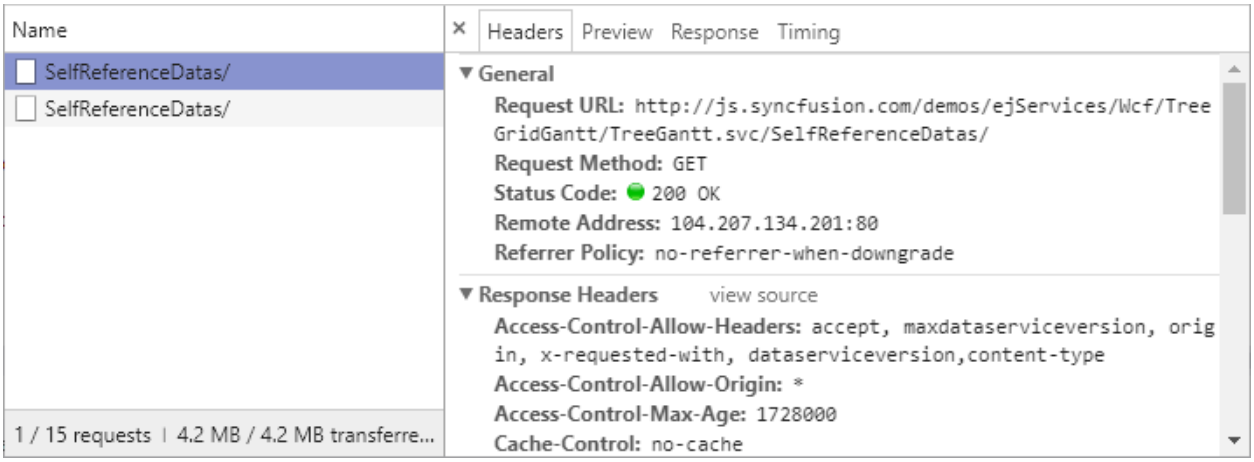
The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
.TaskIdMapping("TaskID")
.TaskNameMapping("TaskName")
.ParentTaskIdMapping("ParentID")
.StartDateMapping("StartDate")
.EndDateMapping("EndDate")
.Datasource(ds =>
ds.URL("http://js.syncfusion.com/demos/ejServices/Wcf/TreeGridGantt/TreeGantt.svc/SelfReferenceDatas"))
)
@(Html.EJ().ScriptManager())
```

The following output is displayed for the code above,





WebAPI

You can bind WebApi service data to Gantt. The data from WebApi service must be returned as object that has property Items with its value as datasource and this object can be pass to dataSource property of Gantt control.

The following code example describes the above behavior.

ASPX-CS

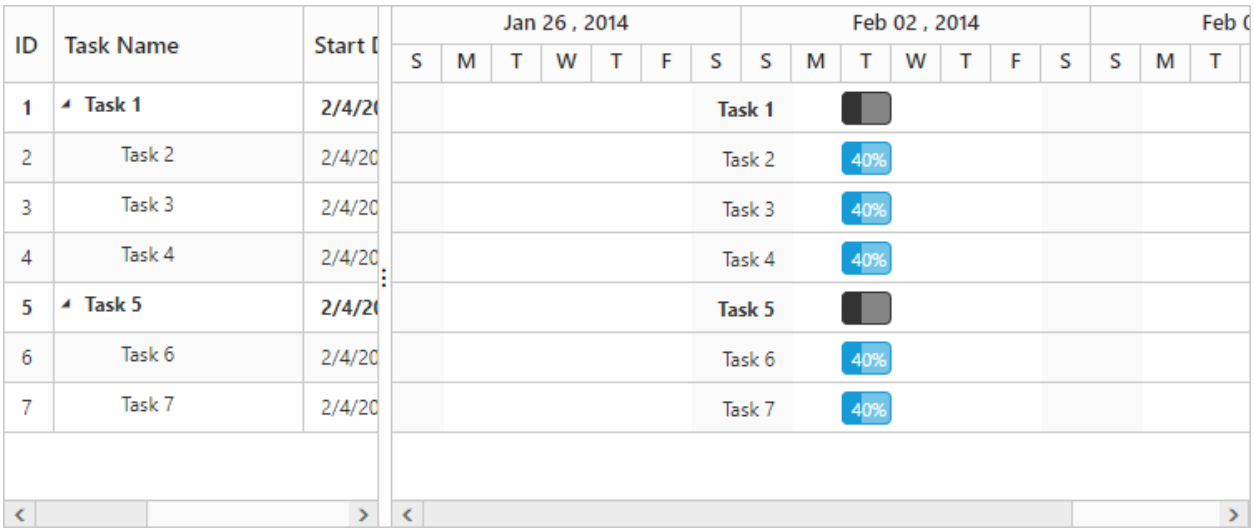
```
@(Html.EJ().Gantt("GanttContainer")
.TaskIdMapping("TaskID")
.TaskNameMapping("TaskName")
.ParentTaskIdMapping("ParentID")
.StartDateMapping("StartDate")
.EndDateMapping("EndDate")
.Datasource(ds => ds.URL("api/Home/GetGanttData"))
)
@(Html.EJ().ScriptManager())
```

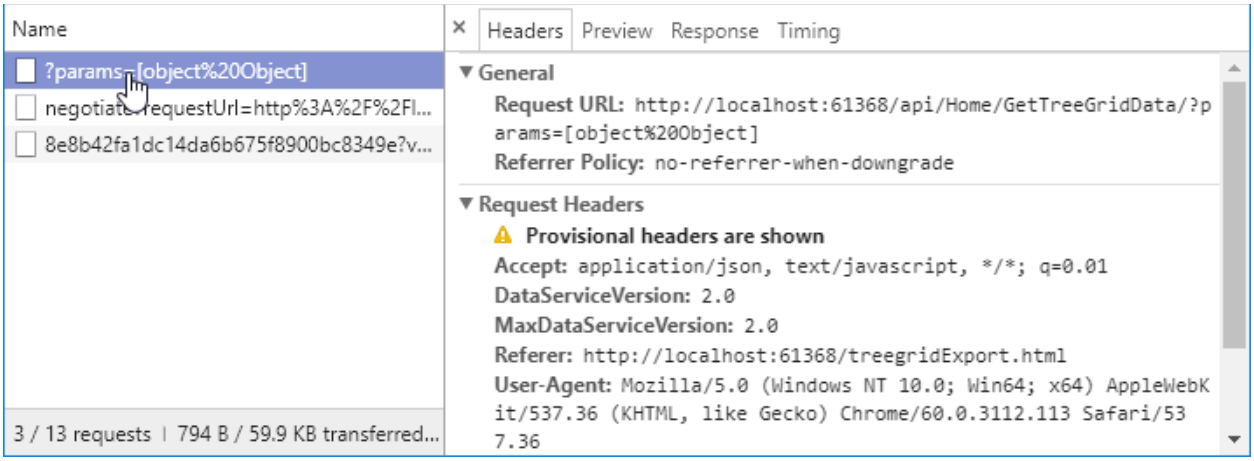
C#

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Net;
using System.Net.Http;
using System.Web.Http;
using GanttExportService.Models;
namespace GanttExportService {
public class HomeController: ApiController {
GanttDataEntities data = new GanttDataEntities();
public object GetGanttData() {
var Data = data.Table1.ToList();
return Data;
}
}
}
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.





Virtualization mode in Gantt

Virtualization support was used to render large number tasks in Gantt with effective performance, in this mode all the tasks are fetched from data source initially then some of the records are rendered in DOM which are compact to the current viewport area.

While scrolling tasks are updated in DOM as per current viewport position.

This mode can be enabled by setting `EnableVirtualization` property as `true`.

The below code example shows how to use this property.

ASPX-CS

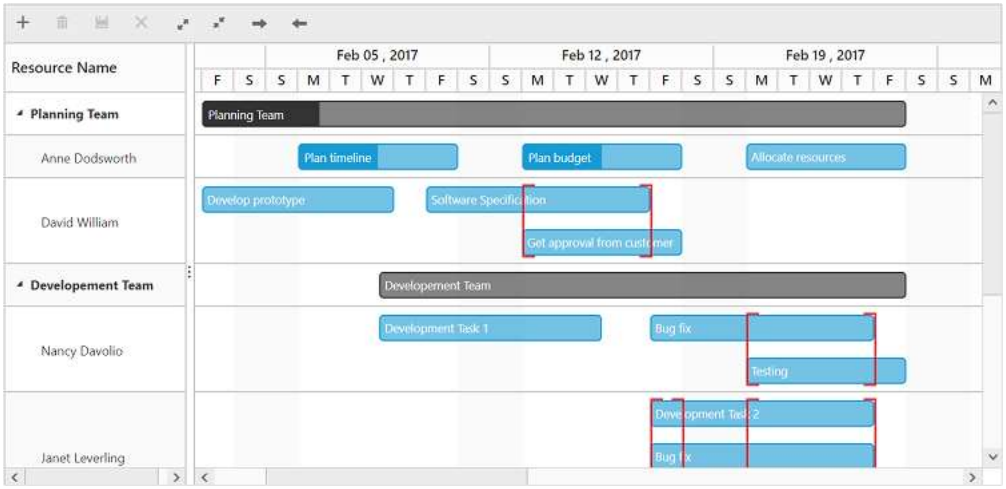
```
@(Html.EJ().Gantt("GanttContainer")
.EnableVirtualization(true)
//..
)
@(Html.EJ().ScriptManager())
```

You can find the online demo sample of Gantt with virtualization mode here.

Copyright © 2001 - 2020 Syncfusion Inc.

Resource Allocation View

Resource allocation view is used to visualize the resource usage in a project. Resources are displayed in separate rows and all the tasks assigned to a specific resource will be displayed in the chart side. In this view, a user can able to easily identify the overallocation of resources in a project.



Data Binding

User can bind two types of data structure to Gantt in resource allocation view,

- Hierarchical data source binding
- Flat data binding

Hierarchical data source binding

The following code example explains how to bind the hierarchical data.

ASPX-CS

```
@(Html.EJ().Gantt("ResourceViewGantt")
.ViewType(GanttViewType.ResourceView)
.TaskCollectionMapping("Tasks")
.ResourceNameMapping("ResourceName")
//...
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

C#

```
public class TaskDetails
{
public int TaskID { get; set; }
public string TaskName { get; set; }
public string StartDate { get; set; }
public string EndDate { get; set; }
public int Duration { get; set; }
public string Progress { get; set; }
public List<TaskDetails> SubTasks { get; set; }
public List<object> ResourceID { get; set; }
public string Predecessors { get; set; }
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
public class ResourceDetails
{
public string ResourceName { get; set; }
public List<TaskDetails> Tasks { get; set; }
}
public List<ResourceDetails> GetResourceData()
{
List<ResourceDetails> data = new List<ResourceDetails>() {
new ResourceDetails()
{
ResourceName = "Anne Dodsworth",
Tasks = new List<TaskDetails>()
{
new TaskDetails() { TaskID = 1, TaskName= "Plan timeline", StartDate=
"02/06/2017", EndDate = "02/10/2017", Duration= 5, Progress= "50"},
new TaskDetails() { TaskID= 2, TaskName= "Plan budget", StartDate=
"02/13/2017", EndDate= "02/17/2017", Duration= 5, Progress= "50"},
new TaskDetails() { TaskID= 3, TaskName= "Allocate resources", StartDate=
"02/20/2017", EndDate= "02/24/2017", Duration= 5, Progress= "0"}
}
}
};
//...
return data;
}
public ActionResult ResourceView()
{
ViewBag.datasource = GetResourceData();
return View();
}
```

Flat data binding

The following code example explains how to bind the flat data.

ASPX-CS

```
@(Html.EJ().Gantt("ResourceViewGantt")
.ViewType(GanttViewType.ResourceView)
.ResourceIdMapping("ResourceId")
.ResourceInfoMapping("ResourceID")
.ResourceNameMapping("ResourceName")
.TaskIdMapping("TaskID")
//...
.Resources(ViewBag.resources)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

C#

```
public class TaskDetails
{
public int TaskID { get; set; }
public string TaskName { get; set; }
public string StartDate { get; set; }
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public string EndDate { get; set; }
public int Duration { get; set; }
public string Progress { get; set; }
public string Priority { get; set; }
public bool Approved { get; set; }
public List<TaskDetails> SubTasks { get; set; }
public List<Object> ResourceID{ get; set; }
public bool IsManual { get; set; }
}
public class GanttResources
{
public string ResourceName { get; set; }
public int ResourceId { get; set; }
public int TeamId { get; set; }
}
public List<GanttResources> GetResources()
{
List<GanttResources> data = new List<GanttResources>(){
new GanttResources(){ ResourceId = 1, ResourceName = "Anne Dodsworth" },
new GanttResources(){ ResourceId = 2, ResourceName = "David William"},
new GanttResources(){ ResourceId = 3, ResourceName = "Nancy Davolio"},
//...
};
return data;
}
public List<TaskDetails> GetResourceFlatData()
{
List<TaskDetails> data = new List<TaskDetails>() {
new TaskDetails() { TaskID = 1, TaskName= "Plan timeline", StartDate=
"02/06/2017", EndDate = "02/10/2017", Duration= 5, Progress= "50",
ResourceID= new List<object>(){1}},
new TaskDetails() { TaskID= 2, TaskName= "Plan budget", StartDate=
"02/13/2017", EndDate= "02/17/2017", Duration= 5, Progress= "50",
ResourceID= new List<object>(){1}},
new TaskDetails() { TaskID= 3, TaskName= "Allocate resources", StartDate=
"02/20/2017", EndDate= "02/24/2017", Duration= 5, Progress= "0", ResourceID=
new List<object>(){1}},
//..
}
return data;
}
public ActionResult ResourceView()
{
ViewBag.datasource = GetResourceFlatData();
ViewBag.resources = GetResources();
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Grouping

The resources and the tasks assigned to those resources can be grouped into categories. The property GroupCollection is used to define the groups to be displayed in the project. The properties GroupIdMapping and GroupNameMapping are used to map the group details.

The below code snippet explains grouping of the resources in resource allocation view.

ASPX-CS

```
@(Html.EJ().Gantt("ResourceViewGantt")
.ViewType(GanttViewType.ResourceView)
.ResourceIdMapping("ResourceId")
.ResourceInfoMapping("ResourceID")
.ResourceNameMapping("ResourceName")
.GroupNameMapping("TeamName")
.GroupIdMapping("TeamId")
.TaskIdMapping("TaskID")
//...
.GroupCollection(ViewBag.groups)
.Resources(ViewBag.resources)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

C#

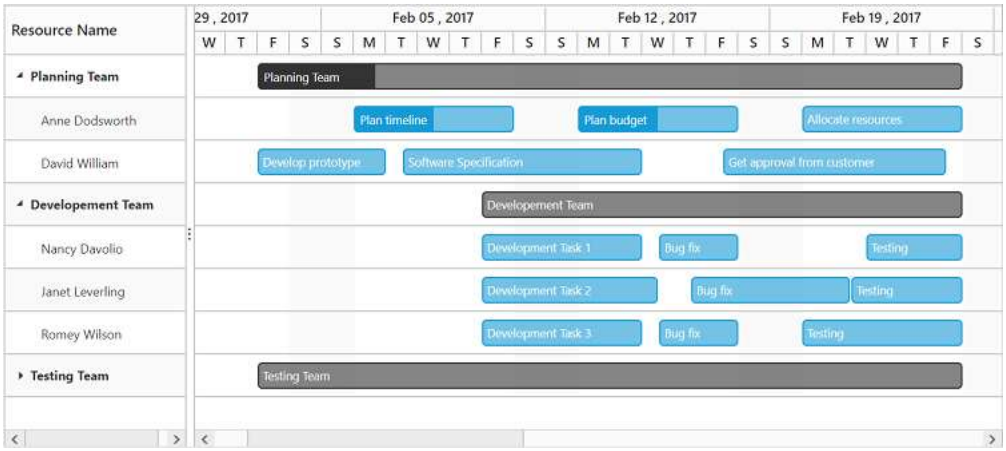
```
public class TaskDetails
{
public int TaskID { get; set; }
public string TaskName { get; set; }
public string StartDate { get; set; }
public string EndDate { get; set; }
public int Duration { get; set; }
public string Progress { get; set; }
public string Priority { get; set; }
public bool Approved { get; set; }
public List<TaskDetails> SubTasks { get; set; }
public List<Object> ResourceID{ get; set; }
public bool IsManual { get; set; }
}
public class GanttResources
{
public string ResourceName { get; set; }
public int ResourceId { get; set; }
public int TeamId { get; set; }
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
public List<GanttResources> GetResources()
{
List<GanttResources> data = new List<GanttResources>(){
new GanttResources(){ ResourceId = 1, ResourceName = "Anne
Dodsworth",TeamId=1 },
new GanttResources(){ ResourceId = 2, ResourceName = "David William",
TeamId=1},
new GanttResources(){ ResourceId = 3, ResourceName = "Nancy Davolio",
TeamId=2},
//...
};
return data;
}
public class ResourceGroupDetails
{
public string TeamName { get; set; }
public int TeamId { get; set; }
}
public List<ResourceGroupDetails> GetResourceGroups()
{
List<ResourceGroupDetails> data = new List<ResourceGroupDetails>(){
new ResourceGroupDetails(){ TeamName="Planning Team", TeamId=1},
new ResourceGroupDetails(){ TeamName="Development Team", TeamId=2},
new ResourceGroupDetails(){ TeamName="Testing Team", TeamId=3}
};
return data;
}
public List<TaskDetails> GetResourceFlatData()
{
List<TaskDetails> data = new List<TaskDetails>() {
new TaskDetails() { TaskID = 1, TaskName= "Plan timeline", StartDate=
"02/06/2017", EndDate = "02/10/2017", Duration= 5, Progress= "50",
ResourceID= new List<object>(){1}},
new TaskDetails() { TaskID= 2, TaskName= "Plan budget", StartDate=
"02/13/2017", EndDate= "02/17/2017", Duration= 5, Progress= "50",
ResourceID= new List<object>(){1}},
new TaskDetails() { TaskID= 3, TaskName= "Allocate resources", StartDate=
"02/20/2017", EndDate= "02/24/2017", Duration= 5, Progress= "0", ResourceID=
new List<object>(){1}},
//..
}
return data;
}
public ActionResult ResourceView()
{
ViewBag.datasource = GetResourceFlatData();
ViewBag.resources = GetResources();
ViewBag.groups = GetResourceGroups();
return View();
}
```

The below screen shot depicts a resource view in a project with 3 groups.

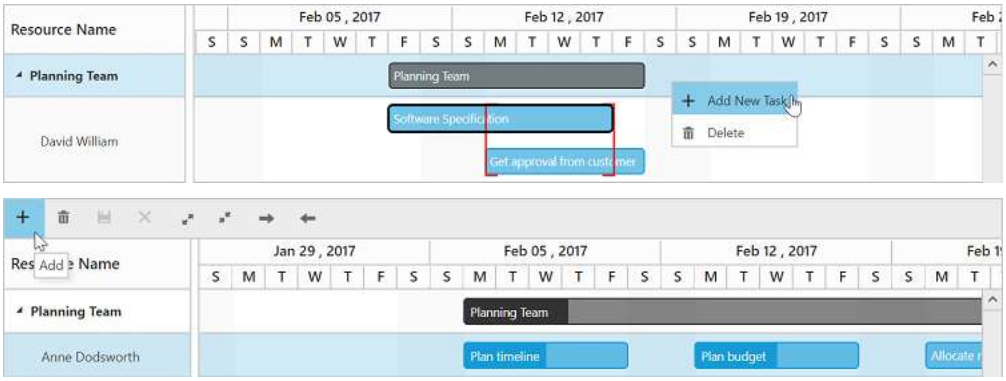
Copyright © 2001 - 2020 Syncfusion Inc.



CRUD data operations

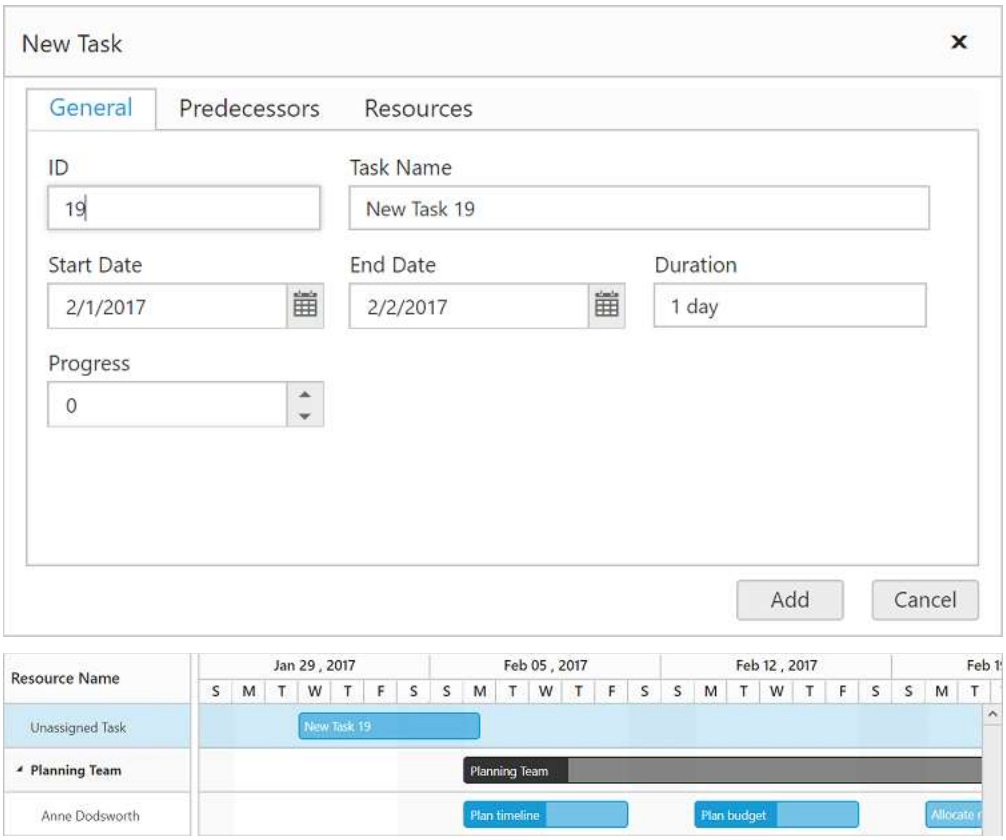
Adding a task

It is possible to add a task dynamically either by using toolbar insert icon or by context menu add option. The below screen shot shows the toolbar add and context menu add options.

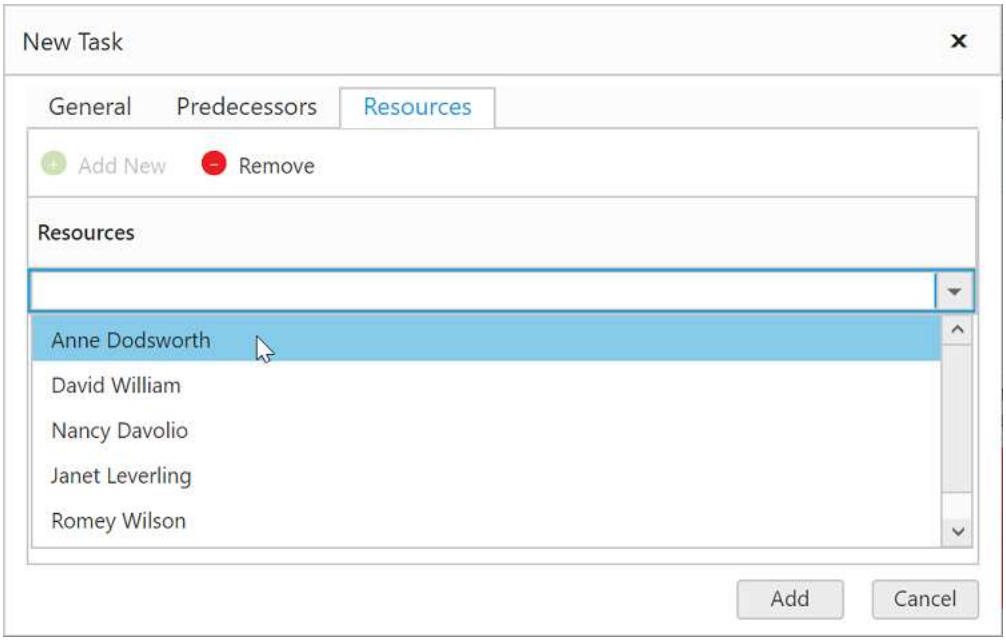


When the insert option is clicked, the add dialog will be displayed prompting the user to provide the task details. After providing the task details, when user click the save button without providing the resource information or without assigning any resource to the task, the task will be added at the top by default.

Copyright © 2001 - 2020 Syncfusion Inc.

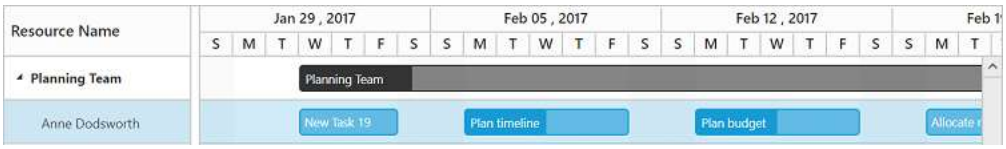


If the newly added task should be assigned to a specific resource, user can able to select the resource information in the resource tab of add dialog.



The below screen shot depicts a new task being assigned to a resource Anne Dodsworth.

Copyright © 2001 - 2020 Syncfusion Inc.



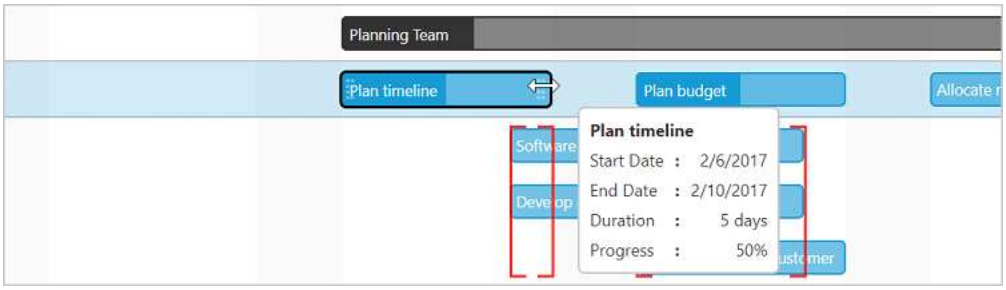
Note: It is not possible to add a resource to the project dynamically.

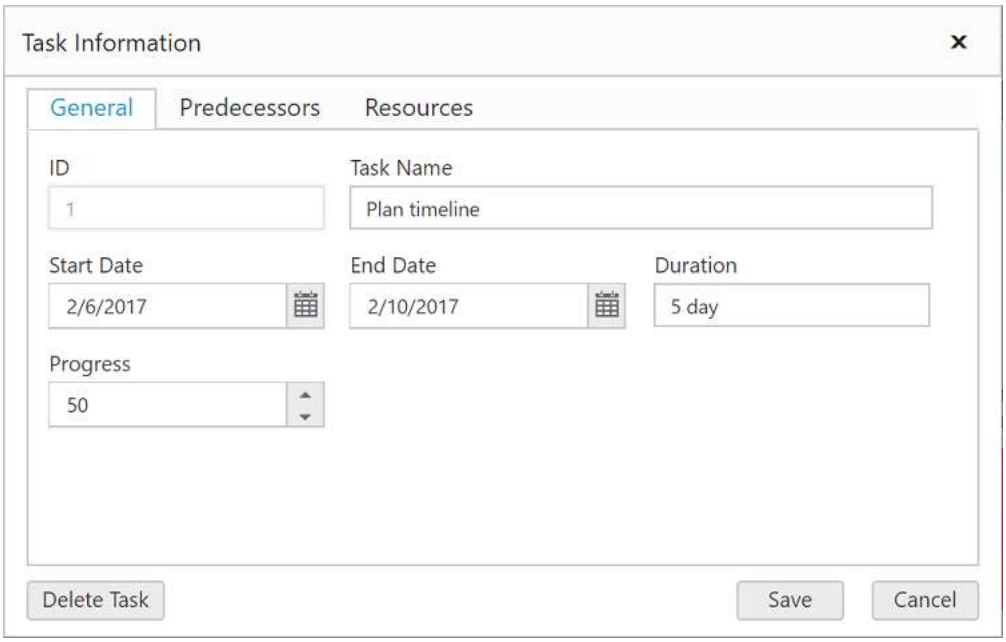
A task can be assigned to one or more resource while adding.

Editing

Editing a Task

A task can be edited either by using edit dialog or by mouse interactions. A user can edit a task using edit dialog by performing double click action on the taskbar, user can then edit the task information in the edit dialog.





A task's schedule can be changed by left resizing, right resizing or dragging the task across the dates.

Copyright © 2001 - 2020 Syncfusion Inc.

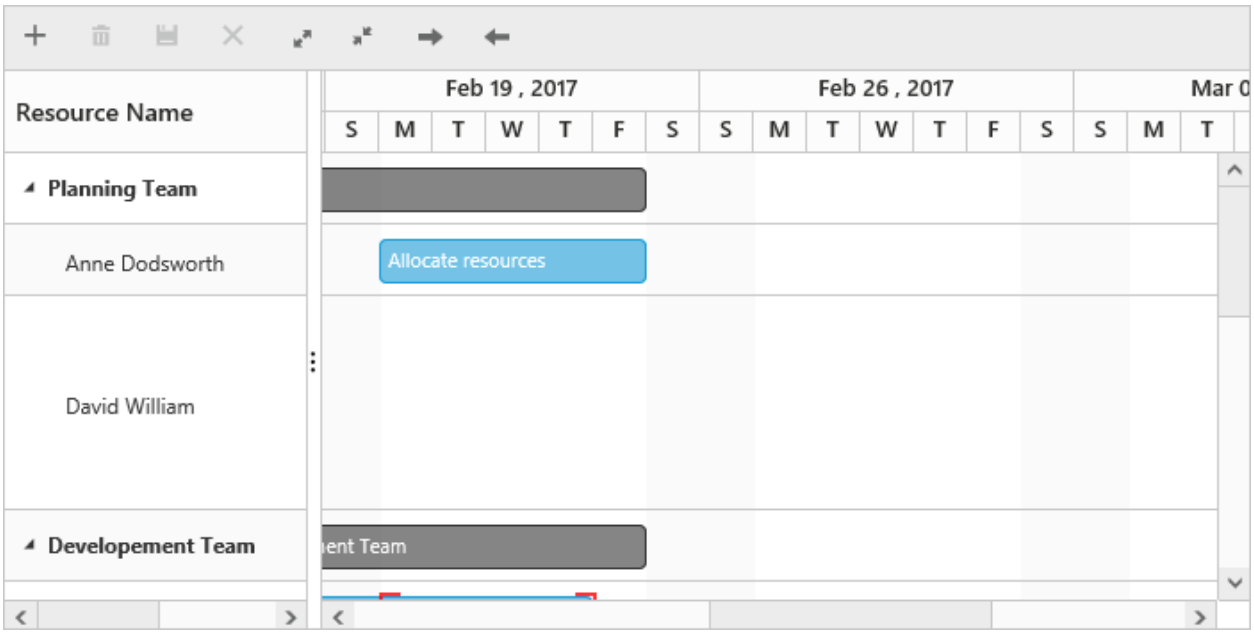
Update task values dynamically

In resource allocation view also, we can update the task details dynamically on any action like external button click by using updateRecordByTaskId method. The below code example explains how to use this method in resource allocation view.

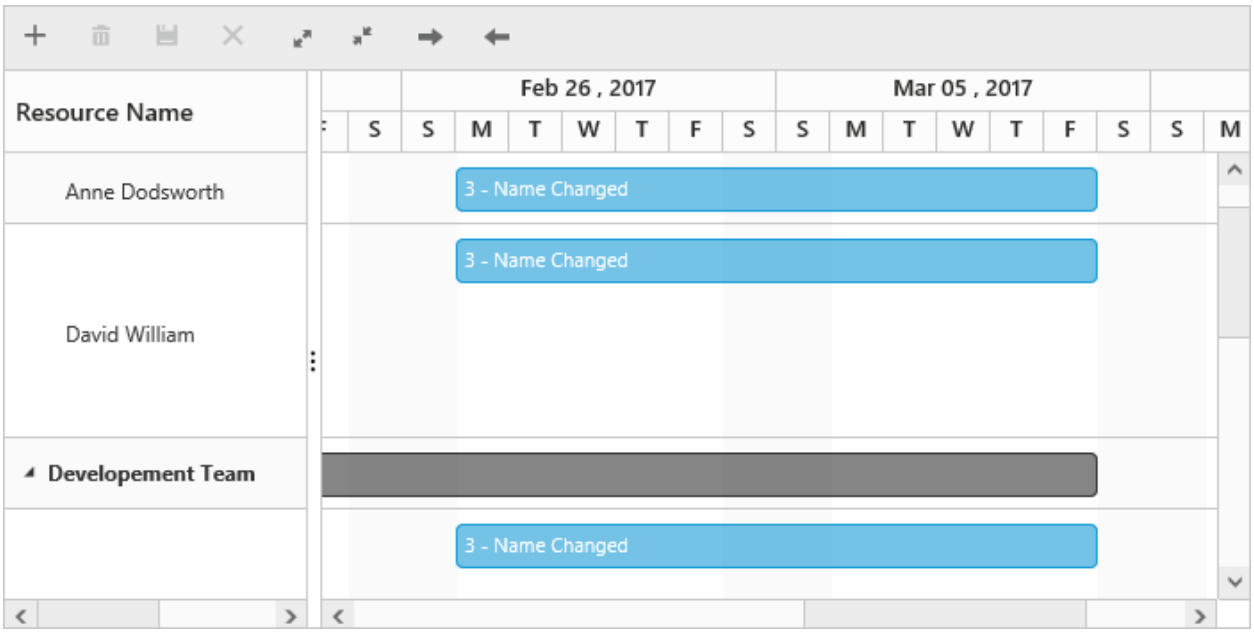
ASPX-CS

```
@(Html.EJ().Gantt("ResourceViewGantt")
.ViewType(GanttViewType.ResourceView)
//...
)
<button id="update">Update Tasks</button>
<script type="text/javascript">
$("#update").click(function () {
var ganttObject = $("#ResourceViewGantt").ejGantt("instance");
var task = {};
task.TaskID = 3;
task.ResourceID = [1, 2, 3];
task.StartDate = new Date("02/25/2017")
task.Duration = 10;
task.TaskName = task.TaskID + " - Name Changed";
ganttObject.updateRecordByTaskId(task);
});
</script>
```

The below screenshot shows the result of above code example.



Before update

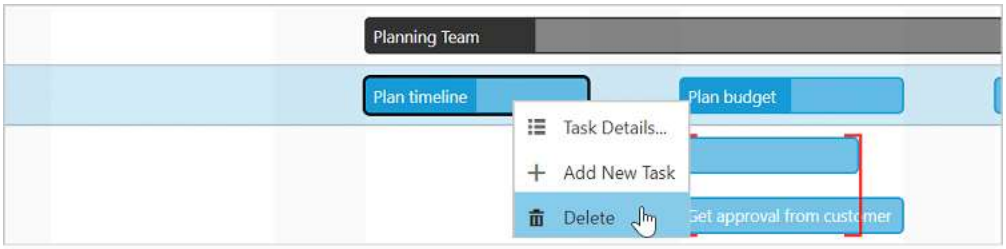


After update

Deleting

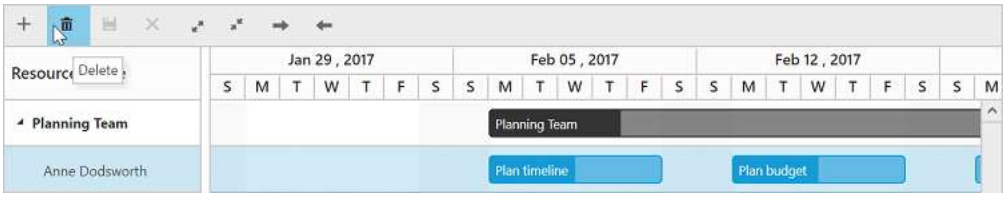
Deleting Task

User should select a task to be removed from the project, and then the task can be deleted using context menu delete button.



Deleting Resource

User can able to delete a resource and the tasks assigned to it using toolbar and context menu delete options. After selecting the resource row, when clicking the delete toolbar icon, the resource will be removed from the project and the tasks assigned to that resource will be listed in unassigned tasks' list. The same will happen for context menu delete option.



The below screen shot depicts the tasks of the removed resource added as unassigned tasks to the project.

Copyright © 2001 - 2020 Syncfusion Inc.

Unassigned Tasks and Resources

There may be some instances, where one or more resources are not yet included in the project plan. Therefore, those resources are left with no tasks assigned to them. Those resources are termed as unassigned resource. The right side of the resource row will be left blank with no tasks.

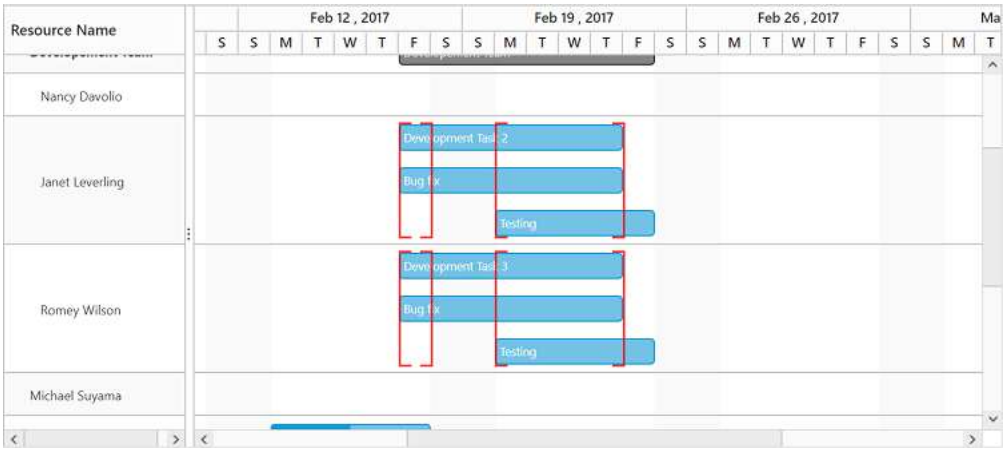
The below code snippet shows a resource with no tasks assigned to it.

C#

```
public List<ResourceDetails> GetResourceData()
{
List<ResourceDetails> data = new List<ResourceDetails>() {
new ResourceDetails()
{
ResourceName = "Anne Dodsworth",
Tasks = new List<TaskDetails>()
{
new TaskDetails() { TaskID = 1, TaskName= "Plan timeline", StartDate=
"02/06/2017", EndDate = "02/10/2017", Duration= 5, Progress= "50"},
new TaskDetails() { TaskID= 2, TaskName= "Plan budget", StartDate=
"02/13/2017", EndDate= "02/17/2017", Duration= 5, Progress= "50"},
new TaskDetails() { TaskID= 3, TaskName= "Allocate resources", StartDate=
"02/20/2017", EndDate= "02/24/2017", Duration= 5, Progress= "0"}
}
},
new ResourceDetails()
{
ResourceName = "Nancy Davolio",
Tasks = new List<TaskDetails>() {}
}
//...
};
return data;
}
```

In the below screen shot, the resource Nancy Davolio is the unassigned resource.

Copyright © 2001 - 2020 Syncfusion Inc.



There may be instances where some tasks are not yet assigned with resources. Those tasks that are not assigned to any resources are termed as unassigned tasks. Unassigned tasks are displayed at bottom, with resource name as Unassigned Task. Unassigned tasks can be assigned to any resources in the project.

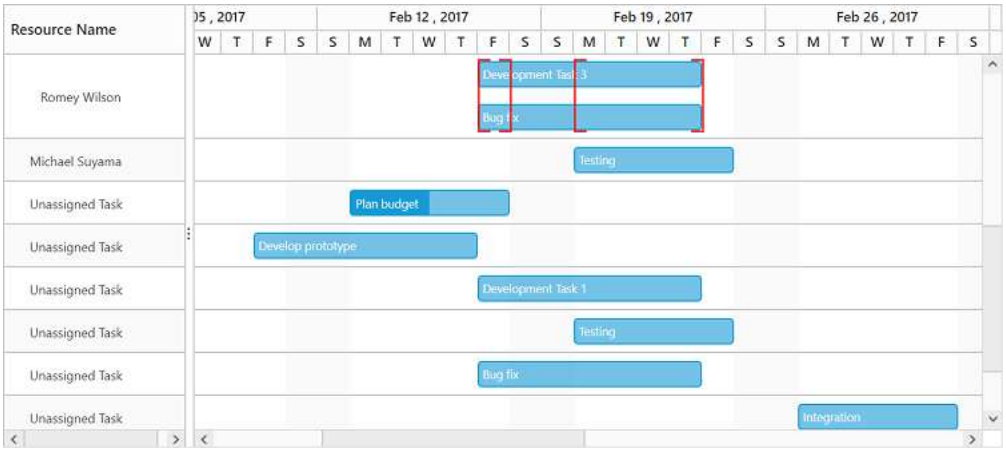
The below code snippet shows a task with no resource assigned to it.

C#

```
public class GanttResources
{
public string ResourceName { get; set; }
public int ResourceId { get; set; }
public int TeamId { get; set; }
}
public List<GanttResources> GetResources()
{
List<GanttResources> data = new List<GanttResources>(){
new GanttResources(){ ResourceId = 1, ResourceName = "Anne
Dodsworth",TeamId=1 },
new GanttResources(){ ResourceId = 2, ResourceName = "David William",
TeamId=1},
new GanttResources(){ ResourceId = 3, ResourceName = "Nancy Davolio",
TeamId=2},
//...
};
return data;
}
public List<TaskDetails> GetResourceFlatData()
{
List<TaskDetails> data = new List<TaskDetails>() {
//...
new TaskDetails() { TaskID= 2, TaskName= "Plan budget", StartDate=
"02/13/2017", EndDate= "02/17/2017", Duration= 5, Progress= "50"},
//..
}
return data;
}
```

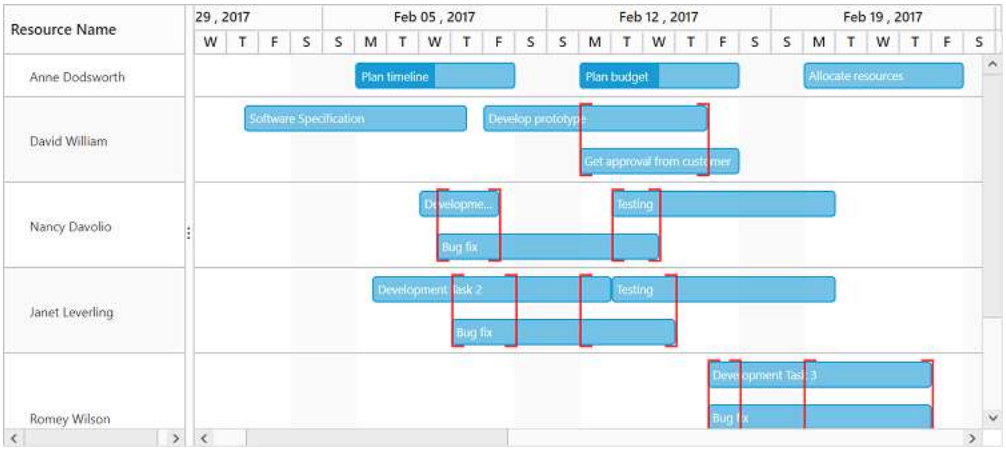
In the below screen shot, there more instances of unassigned tasks.

Copyright © 2001 - 2020 Syncfusion Inc.



Resource Overallocation

By default, a resource can work 8 hours a work day, but when a resource is forced to work more than 8 hours it is termed as overallocation. Or when a resource is assigned with two or more tasks which is occurring in a same date range, this state is termed as over allocation for a resource. The overlapped tasks are highlighted like in the below screen shot. The overlapped tasks will be displayed one below the other with an overlapped highlighted region.



Resource Histogram

A resource histogram displays the scheduled working time range of resources for its assigned tasks. Using this, you can easily identify the resource's availability and its working time. The resource histogram is used to allocate the resources properly throughout the project and find the details about allocated resources and the allocated time ranges of a specific resource.

Databinding

You can render the histogram view for both project view Gantt and resource view Gantt by using the `ViewType` as `GanttViewType.HistogramView`.

The following code example explains how to bind the resource histogram view for project view Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
.TaskIdMapping("TaskID")
.TaskNameMapping("TaskName")
.StartDateMapping("StartDate")
```

```
.DurationMapping("Duration")
.ProgressMapping("Progress")
.ResourceInfoMapping("ResourceID")
.ResourceNameMapping("ResourceName")
.ResourceIdMapping("ResourceID")
.ChildMapping("SubTasks")
.ViewType(GanttViewType.ProjectView)
//..
.Resources(ViewBag.resources)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().Gantt("HistogramContainer")
.ViewType(GanttViewType.HistogramView)
.TaskIdMapping("TaskID")
.TaskNameMapping("TaskName")
.StartDateMapping("StartDate")
.DurationMapping("Duration")
.ProgressMapping("Progress")
.ChildMapping("SubTasks")
.ResourceInfoMapping("ResourceID")
.ResourceNameMapping("ResourceName")
.ResourceIdMapping("ResourceID")
//..
.Resources(ViewBag.resources)
.Datasource(ViewBag.histogramData)
)
@(Html.EJ().ScriptManager())
```

Note: You should bind the data source and necessary mapping properties to render the histogram view. You can differentiate whether the bound data source is project view data or resource view data using the ganttObject.isProjectViewData boolean property and Load event. Set this property to true if the provided data is project view and set to false for resource view data.

Synchronize resource histogram view Gantt with other views

You can synchronize the splitter position and horizontal scroller position in chart side and task values of the project view/resource view Gantt control with resource histogram view Gantt by using the ActionComplete and SplitterResized events.

Synchronize with project view

The following code snippet shows how to synchronize the resource histogram view Gantt with project view Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
.TaskIdMapping("TaskID")
.TaskNameMapping("TaskName")
.StartDateMapping("StartDate")
.DurationMapping("Duration")
.ProgressMapping("Progress")
.ResourceInfoMapping("ResourceID")
.ResourceNameMapping("ResourceName")
.ResourceIdMapping("ResourceID")
.ChildMapping("SubTasks")
.ViewType(GanttViewType.ProjectView)
```

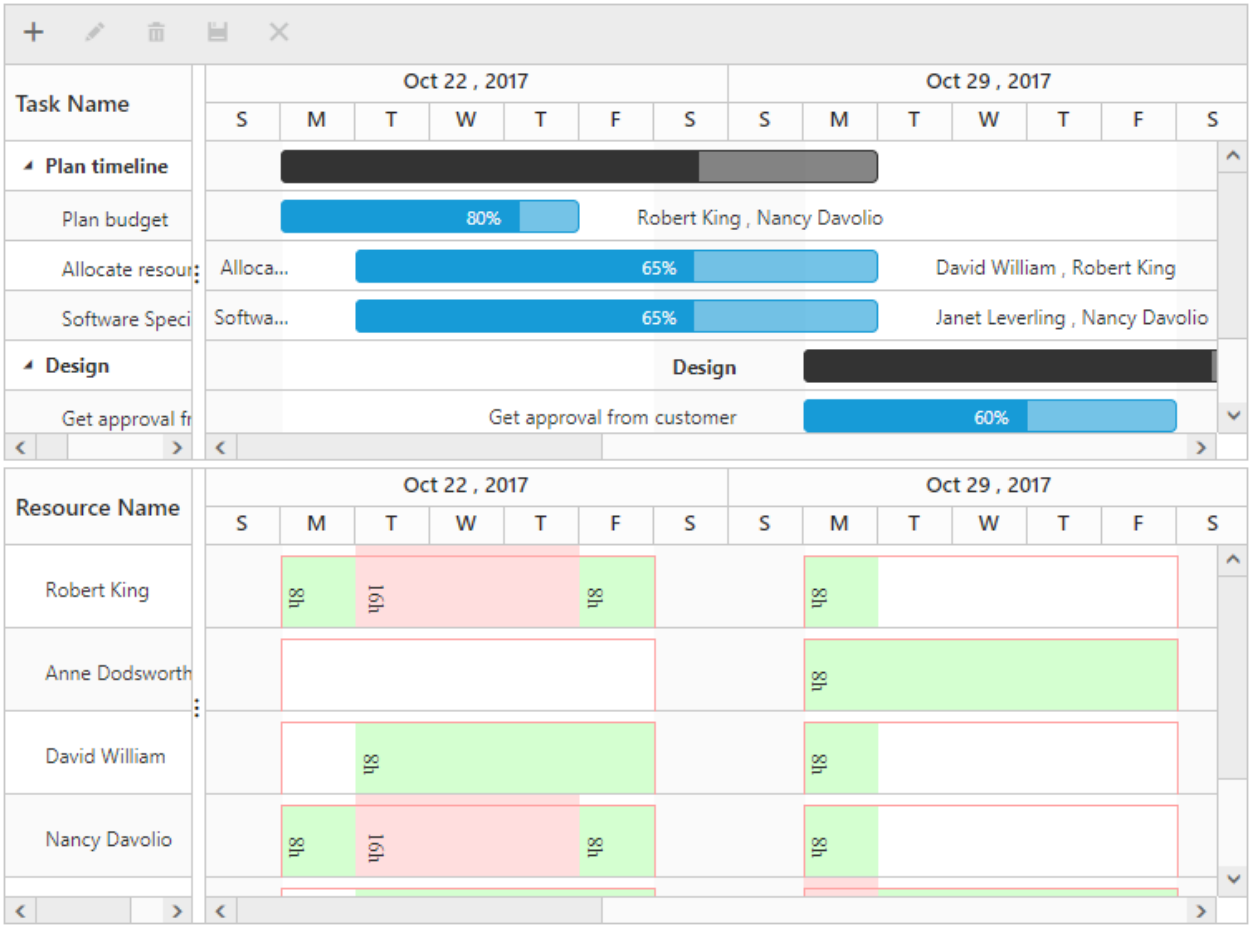
Copyright © 2001 - 2020 Syncfusion Inc.

```
.ClientSideEvents(cs => {
cs.SplitterResized("splitterResized").ActionComplete("actionComplete");
})
//..
.Resources(ViewBag.resources)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().Gantt("HistogramContainer")
.ViewType(GanttViewType.HistogramView)
.TaskIdMapping("TaskID")
.TaskNameMapping("TaskName")
.StartDateMapping("StartDate")
.DurationMapping("Duration")
.ProgressMapping("Progress")
.ChildMapping("SubTasks")
.ResourceInfoMapping("ResourceID")
.ResourceNameMapping("ResourceName")
.ResourceIdMapping("ResourceID")
.ClientSideEvents(cs => {
cs.Load("load").SplitterResized("splitterResized").ActionComplete("actionCom
plete");
})
//..
.Resources(ViewBag.resources)
.Datasource(ViewBag.histogramData)
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function load(args) {
this.isProjectViewData = true;
}
function splitterResized(args) {
if (args.isOnResize == false) return;
if (this._id == "GanttContainer") {
$("#HistogramContainer").ejGantt("setSplitterPosition",
args.currentSplitterPosition);
} else if (this._id == "HistogramContainer") {
$("#GanttContainer").ejGantt("setSplitterPosition",
args.currentSplitterPosition);
}
}
function actionComplete(args) {
if (args.requestType == "scroll" && args.scrollDirection == "horizontal") {
var scrollLeft = args.scrollLeft;
if (this._id == "GanttContainer" && !args.isScrollByMethod) {
$("#HistogramContainer").ejGantt("setChartScrollLeft", scrollLeft);
} else if (this._id == "HistogramContainer" && !args.isScrollByMethod) {
$("#GanttContainer").ejGantt("setChartScrollLeft", scrollLeft);
}
} else if (args.requestType == "recordUpdate") {
$("#HistogramContainer").ejGantt("updateHistogramTask", args.data,
"update");
if (args.updatedRecords && args.updatedRecords.length > 0) {
for (var count = 0; count < args.updatedRecords.length; count++) {
$("#HistogramContainer").ejGantt("updateHistogramTask",
args.updatedRecords[count], "update");
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
} else if (args.requestType == "save" && args.modifiedRecord) {
$("#HistogramContainer").ejGantt("updateHistogramTask", args.modifiedRecord,
"update");
} else if (args.requestType == "save" && args.addedRecord) {
$("#HistogramContainer").ejGantt("updateHistogramTask", args.addedRecord,
"add");
} else if (args.requestType == "delete") {
$("#HistogramContainer").ejGantt("updateHistogramTask", args.data,
"delete");
}
}
</script>
```

The following screenshot shows the resource histogram with project view Gantt.



Please find our online demo sample for further reference

[ResourceHistogram]

Synchronize with resource view

The following code snippet shows how to synchronize the resource histogram view Gantt with resource view Gantt.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().Gantt("GanttContainer")
.TaskIdMapping("TaskID")
.TaskNameMapping("TaskName")
.StartDateMapping("StartDate")
.EndDateMapping("EndDate")
.DurationMapping("Duration")
.ProgressMapping("Progress")
.GroupNameMapping("TeamName")
.GroupIdMapping("TeamId")
.ViewType(GanttViewType.ResourceView)
.ResourceIdMapping("ResourceId")
.ResourceInfoMapping("ResourceID")
.ResourceNameMapping("ResourceName")
//..
.ClientSideEvents(cs => {
cs.ActionComplete("actionComplete");
cs.SplitterResized("splitterResized");
})
.GroupCollection(ViewBag.groups)
.Resources(ViewBag.resources)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().Gantt("HistogramContainer")
.TaskIdMapping("TaskID")
.TaskNameMapping("TaskName")
.StartDateMapping("StartDate")
.EndDateMapping("EndDate")
.DurationMapping("Duration")
.ProgressMapping("Progress")
.GroupNameMapping("TeamName")
.GroupIdMapping("TeamId")
.ViewType(GanttViewType.HistogramView)
.ResourceIdMapping("ResourceId")
.ResourceInfoMapping("ResourceID")
.ResourceNameMapping("ResourceName")
//..
.ClientSideEvents(cs => {
cs.Load("load");
cs.ActionComplete("actionComplete");
cs.SplitterResized("splitterResized");
})
.GroupCollection(ViewBag.groups)
.Resources(ViewBag.resources)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function load(args) {
this.isProjectViewData = false;
}
function splitterResized(args) {
if (args.isOnResize == false) return;
if (this._id == "GanttContainer") {
$("#HistogramContainer").ejGantt("setSplitterPosition",
args.currentSplitterPosition);
} else if (this._id == "HistogramContainer") {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$("#GanttContainer").ejGantt("setSplitterPosition",
args.currentSplitterPosition);
}
}
function actionComplete(args) {
if (args.requestType == "scroll" && args.scrollDirection == "horizontal") {
var scrollLeft = args.scrollLeft;
if (this._id == "GanttContainer" && !args.isScrollByMethod) {
$("#HistogramContainer").ejGantt("setChartScrollLeft", scrollLeft);
} else if (this._id == "HistogramContainer" && !args.isScrollByMethod) {
$("#GanttContainer").ejGantt("setChartScrollLeft", scrollLeft);
}
}
//task drag and drop action and edit action
else if (args.requestType == "save" && args.modifiedRecord ||
args.requestType == "recordUpdate") {
var data = args.requestType == "save" ? args.modifiedRecord : args.item ?
args.item : args.data;
$("#HistogramContainer").ejGantt("updateHistogramTask", data, "update");
//row delete & group delete
if (args.updatedRecords) {
for (var i = 0; i < args.updatedRecords.length; i++) {
var data = args.updatedRecords[i];
$("#HistogramContainer").ejGantt("updateHistogramTask", data, "update");
}
}
}
//add row
else if (args.requestType == "save" && args.addedRecord) {
$("#HistogramContainer").ejGantt("updateHistogramTask", args.addedRecord,
"add");
}
//task delete
else if (args.requestType == "delete") {
$("#HistogramContainer").ejGantt("updateHistogramTask", args.data,
"delete");
}
}
</script>
```

The following screenshot shows the resource histogram for resource view Gantt.

Editing

The Gantt control provides in-built support to add, insert and update the tasks. The following are the types of editing available in Gantt.

- Cell Editing
- Normal Editing
- Taskbar Editing
- Dependency Editing

Cell Editing

Initialize cell edit mode

Update the task details through grid cell editing by setting `EditSettings.EditMode` as `cellEditing`.

The following code example shows you how to enable the `cellEditing` in Gantt control.

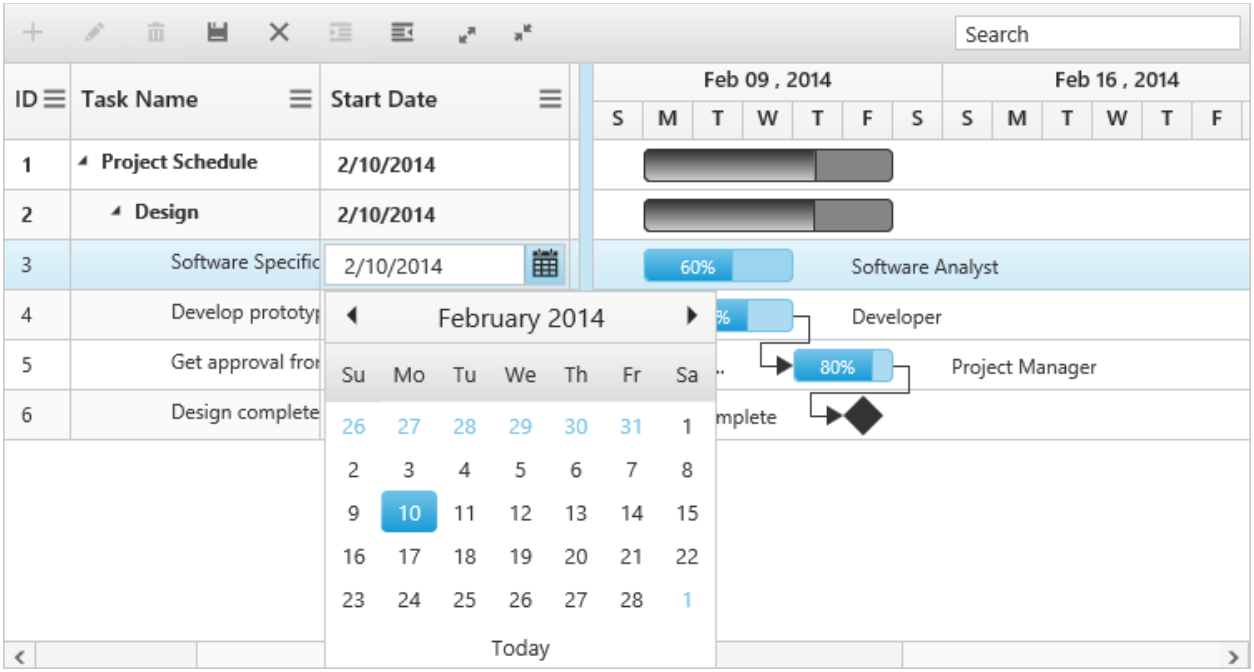
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit=>{
edit.AllowEditing(true);
edit.EditMode("cellEditing");
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The output of Gantt with cellEditing is as follows.



Save editing cell

Currently editing cell value can be saved by clicking the save toolbar icon or clicking on any other cell element in the grid and also editing cell can be saved by using saveEdit method, using this method we can save the current editing cell dynamically on any action like external button click, please refer the following code example.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit=>{
edit.AllowEditing(true);
edit.EditMode("cellEditing");
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
$("#save_button").click(function () {
$("#Gantt").ejGantt("instance").saveEdit();
});
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Cancel editing cell

Currently editing cell value can be restored with old value by using cancel toolbar icon or by pressing Esc key. And also this can be done by using cancelEdit method on any other external actions like button click, please refer the following code example.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit=>{
edit.AllowEditing(true);
edit.EditMode("cellEditing");
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
$("#cancel_button").click(function () {
$("#Gantt").ejGantt("instance").cancelEdit();
});
</script>
```

Prevent Cell Editing

In cell editing action BeginEdit and EndEdit client side events are triggered before and after the editing action. Cell editing for particular column or specific cell can be prevented by using BeginEdit client side event, please refer following code example for this.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit=>{
edit.AllowEditing(true);
edit.EditMode("cellEditing");
})
.ClientSideEvents(cs => cs.BeginEdit("beginEdit"))
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
function beginEdit(args) {
if (args.columnIndex == 1)
args.cancel = true;
}
</script>
```

Normal Editing

Initialize Normal edit mode

Update the task details through edit dialog by setting EditMode as normal. The following code example shows you how to enable normal editing in Gantt control.

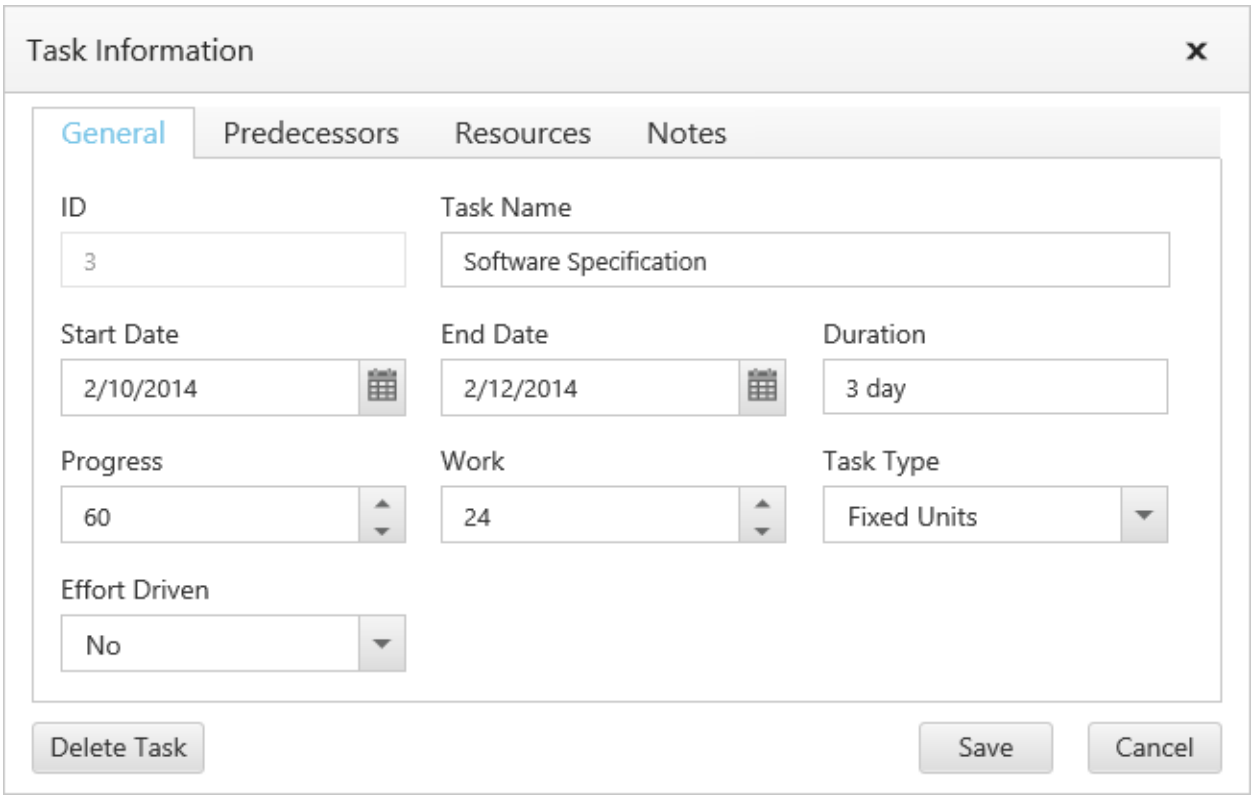
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//...
.EditSettings(edit=>{
edit.AllowEditing(true);
edit.EditMode("normal");
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the output of normal editing.



Define required fields in add/edit dialog

In Gantt we can define the editing fields available in add and edit dialogs by using AddDialogFields and EditDialogFields properties. Each editing fields are defined with Field and EditType properties. The following code example shows how to define EditDialogFields property.

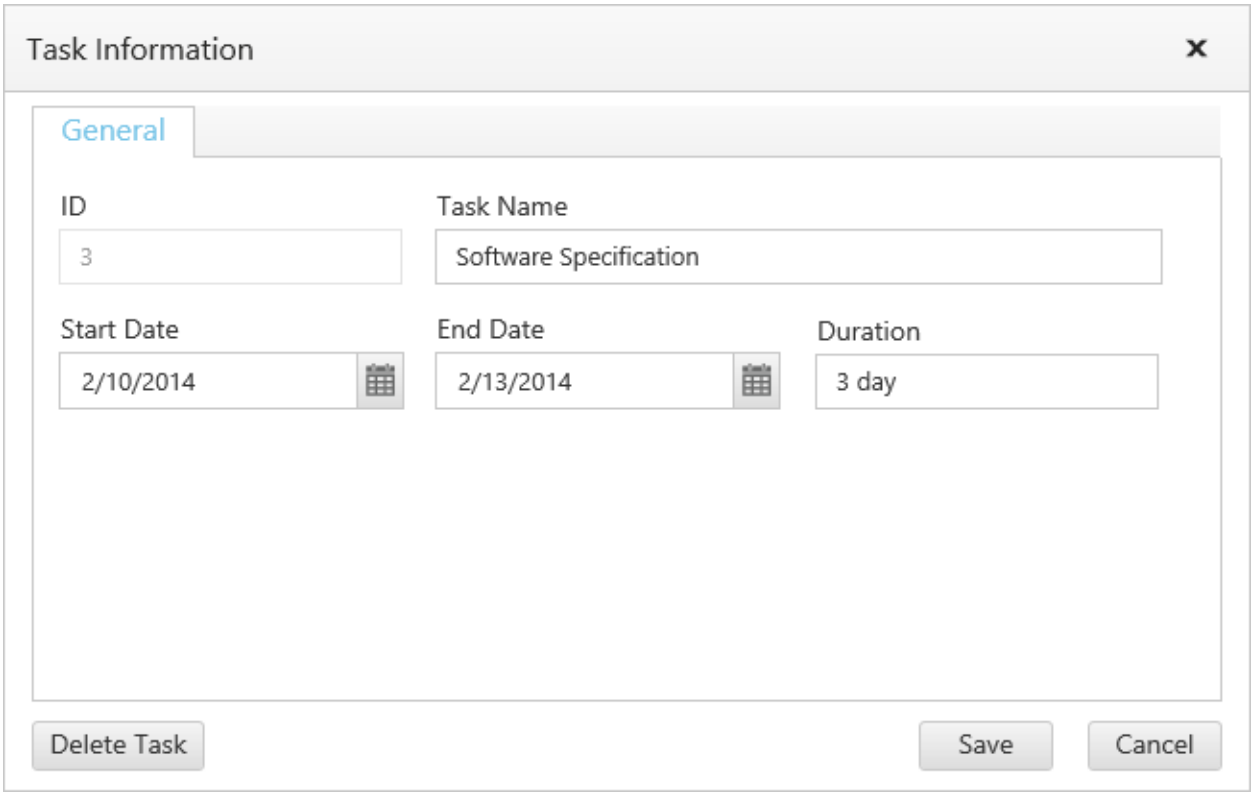
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit=>{
edit.AllowEditing(true);
edit.EditMode("normal");
})
.EditDialogFields(editDialog =>
{
editDialog.Field("TaskID").EditType("stringedit").Add();
editDialog.Field("TaskName").EditType("stringedit").Add();
editDialog.Field("StartDate").EditType("datepicker").Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
editDialog.Field("EndDate").EditType("datepicker").Add();
editDialog.Field("Duration").EditType("stringedit").Add();
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following screenshot show the output of above code example.



Note: Similarly we can define the required fields in add dialog with AddDialogFields.Field and AddDialogFields.EditType properties.

Add custom column fields in General tab

By default custom column fields are included in add/edit dialog's custom field tab but we can display this column field in General tab by setting DisplayInGeneralTab property as true in AddDialogFields and EditDialogFields properties. The following code example shows how to add custom column field in General tab of edit dialog.

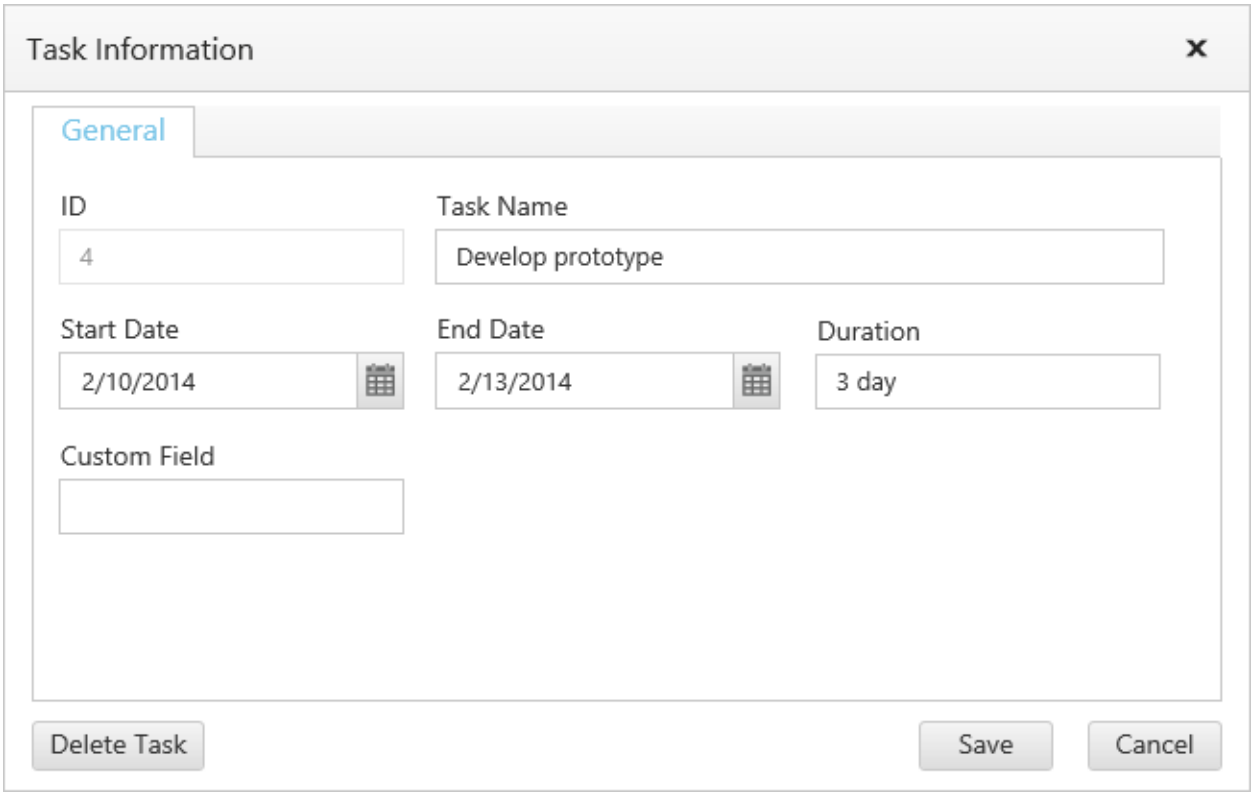
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit=>{
edit.AllowEditing(true);
edit.EditMode("normal");
})
.EditDialogFields(editDialog =>
{
editDialog.Field("TaskID").EditType("stringedit").Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
editDialog.Field("TaskName").EditType("stringedit").Add();
editDialog.Field("StartDate").EditType("datepicker").Add();
editDialog.Field("EndDate").EditType("datepicker").Add();
editDialog.Field("Duration").EditType("stringedit").Add();
editDialog.Field("CustomField").EditType("stringedit").DisplayInGeneralTab(t
rue).Add();
})
.ClientSideEvents(cs => cs.Load("load"))
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
function load(args) {
var column = { field: "CustomField", mappingName: "CustomField", headerText:
"Custom Field" };
this.getColumns().push(column);
}
</script>
```

The following screenshot show the output of above code example.



Note: Similarly we can include custom fields in add dialog's General tab by setting `DisplayInGeneralTab` as `true` in `AddDialogFields` collection.

Note: Default columns predecessors, resources and notes are displayed in separate tabs, we can't include this in General tab of add/edit dialog.

Copyright © 2001 - 2020 Syncfusion Inc.

Open add/edit dialog dynamically

Gantt add and edit dialogs can be opened dynamically by using openAddDialog and openEditDialog methods. The following code example shows how to open add and dialog on separate button click actions.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit=>{
edit.AllowEditing(true);
edit.EditMode("normal");
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
$("#openAddDialog").click(function(){
$("#Gantt").ejGantt("instance").openAddDialog();
});
$("#openEditDialog").click(function(){
$("#Gantt").ejGantt("instance").openEditDialog();
});
</script>
```

Note: We should select any one of the row in Gantt to open the edit dialog.

Taskbar Editing

Update the task details by interactions such as resizing and dragging the taskbar. Taskbar editing can be enabled by setting AllowGanttChartEditing as true. The following code example shows you how to enable taskbar resizing in Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowGanttChartEditing(true)
)
@(Html.EJ().ScriptManager())
```

You can also enable or disable the progress bar resizing by using the EnableProgressBarResizing. The following code example shows how to disable this property.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EnableProgressBarResizing(false)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

Prevent taskbar editing for particular task

On taskbar edit action TaskbarEditing and TaskbarEdited client side event will be triggered. We can prevent the taskbar from editing by using TaskbarEditing event and we can revert taskbar edit action by using TaskbarEdited event. The following code example shows how to achieve this.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowGanttChartEditing(true)
.ClientSideEvents(cs =>
cs.TaskbarEditing("taskbarEditing").TaskbarEdited("taskbarEdited"))
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
function taskbarEditing(args) {
if (args.rowData.taskId == 4) // We can't edit Task Id 4
args.cancel = true;
}
function taskbarEdited(args) {
if (args.data.taskId == 5) // We can edit task id 5 task but changes
reverted on mouse up action
args.cancel = true;
}
</script>
```

Dependency Editing

In Gantt, we can add, edit, update the task dependencies by mouse interactions, edit dialog and public methods. The code example shows how to enable dependency editing in Gantt.

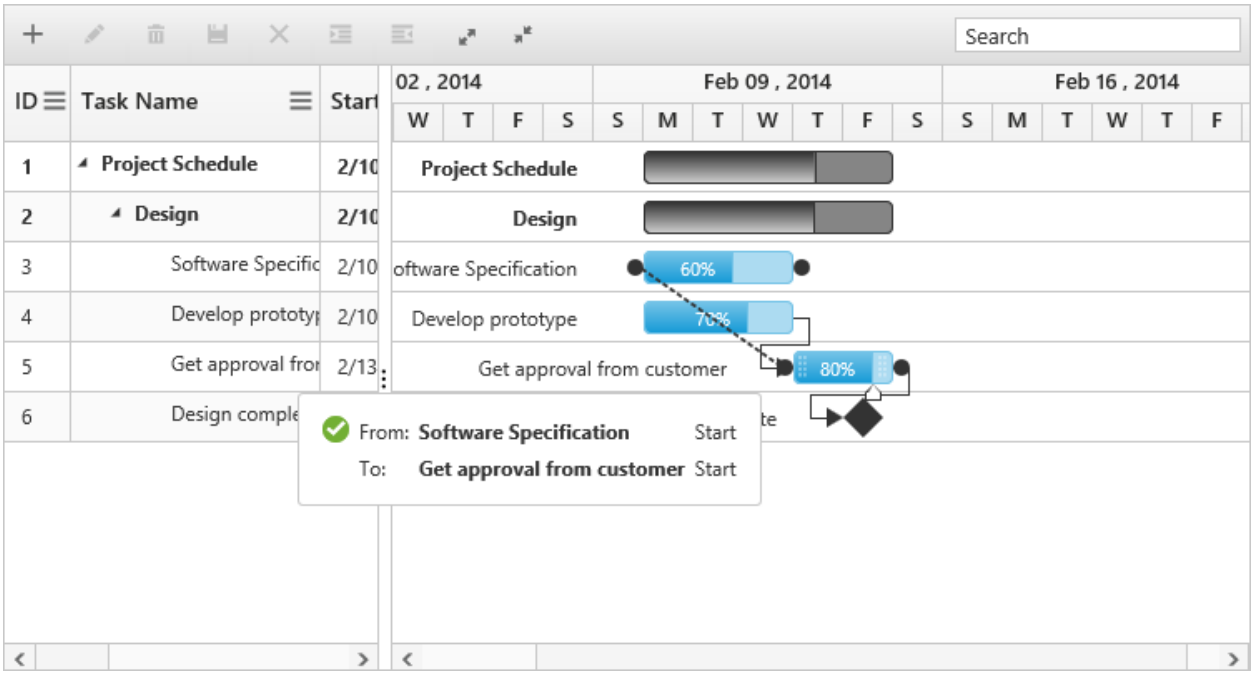
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowGanttChartEditing(true)
.PredecessorMapping("Predecessors")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Add Dependency

Task dependency can be added by mouse interactions by connecting connector points in predecessor and successor tasks. The following screen shot shows the add dependency action.

Copyright © 2001 - 2020 Syncfusion Inc.



Edit Dependency

Task dependency value can be edited by using edit dialog and updateDependency method. Dependency edit dialog can be opened by double clicking on corresponding dependency line.

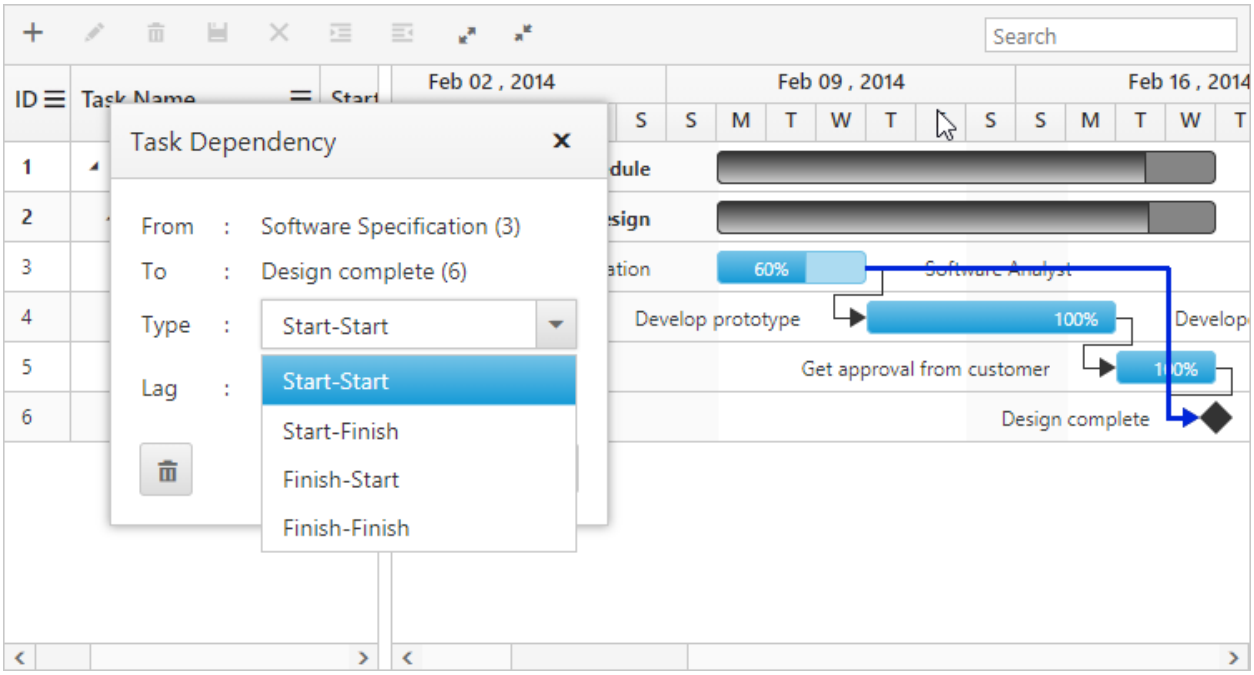
Client side ActionBegin event will be triggered twice with different requestType argument values while opening of dependency dialog. First time, event will be triggered with requestType argument values as beforeDependencyEditDialogOpen, in this event we can get the current editing dependency line information, next ActionBegin client side event will be triggered with requestType argument value as afterDependencyEditDialogOpen, in this event we can get the information about current editing dependency line and editing elements in edit dialog. Using this event we can customize the dependency edit dialog elements.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowGanttChartEditing(true)
.PredecessorMapping("Predecessors")
.ClientSideEvents(cs => cs.ActionBegin("actionBegin"))
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
function actionBegin(args) {
if(args.requestType == "beforeDependencyEditDialogOpen") {
}
else if(args.requestType == "afterDependencyEditDialogOpen") {
}
}
</script>
```

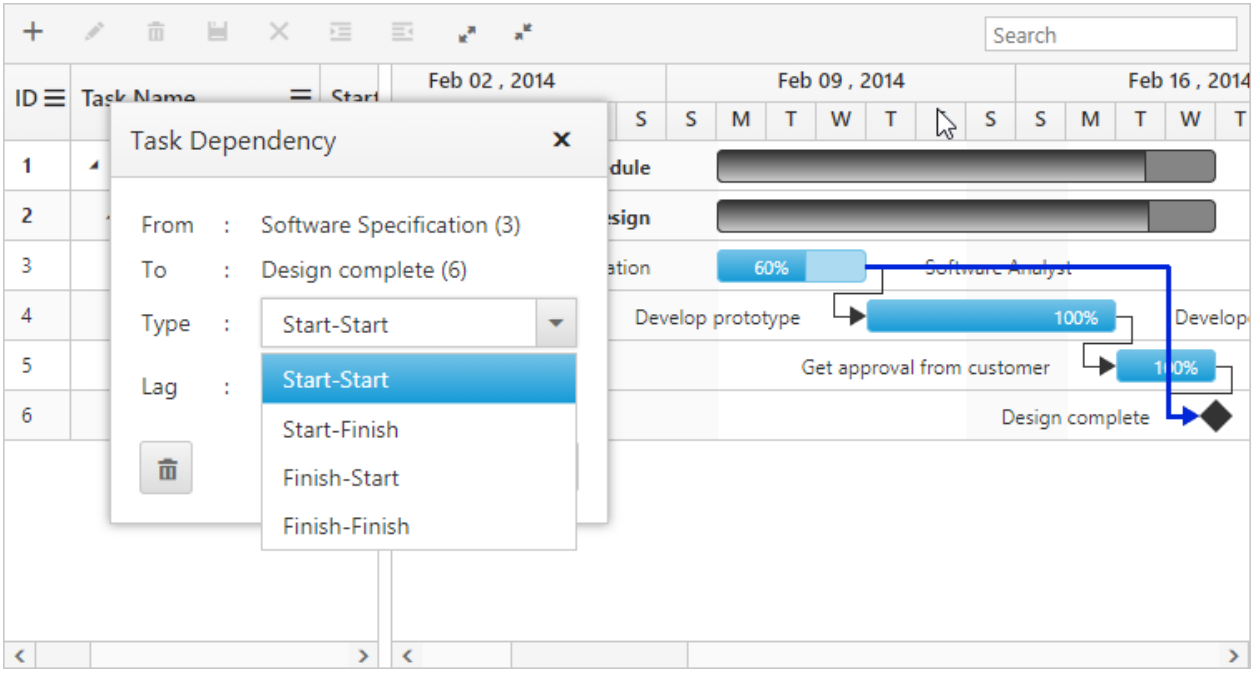
The following screen shot shows the dependency edit dialog.

Copyright © 2001 - 2020 Syncfusion Inc.



Delete Dependency

Task dependency can be deleted by using edit dialog and deleteDependency method. The following screen shot shows the dependency edit dialog with delete option.



Click here to view the online demo sample for editing in Gantt.

Update Gantt record value dynamically

Gantt record's value can be dynamically updated by using updateRecordByTaskId or updateRecordByIndex method. updateRecordByTaskId method used to update the Gantt record by using it's task id value and updateRecordByIndex method was used to update Gantt record value by row

index value. We can invoke this method on any external button click action, the following code example shows how to use this methods.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
$("#updateRecordByTaskId").click(function () {
var ganttObj = $("#Gantt").ejGantt("instance"),
data = {
taskID: 4,
taskName: "Updated by task id",
startDate: new Date("02/10/2014"),
endDate: new Date("02/14/2014"),
duration: 5,
progress: "80",
resourceId: [2]
};
ganttObj.updateRecordByTaskId(data);
});
$("#updateRecordByRowIndex").click(function () {
var ganttObj = $("#Gantt").ejGantt("instance"),
data = {
taskID: 5,
taskName: "Updated by index value",
startDate: new Date("02/10/2014"),
endDate: new Date("02/14/2014"),
duration: 3, progress: "100",
predecessor: "4SS",
resourceId: [2]
};
ganttObj.updateRecordByIndex(4, data);
});
</script>
```

Note: Using these methods we can't update the task id value.

Delete confirmation message

Delete confirmation message is used to get the confirmation from the user before deleting the record. This confirmation message can be enabled by setting `EditSettings.ShowDeleteConfirmDialog` property as `true`.

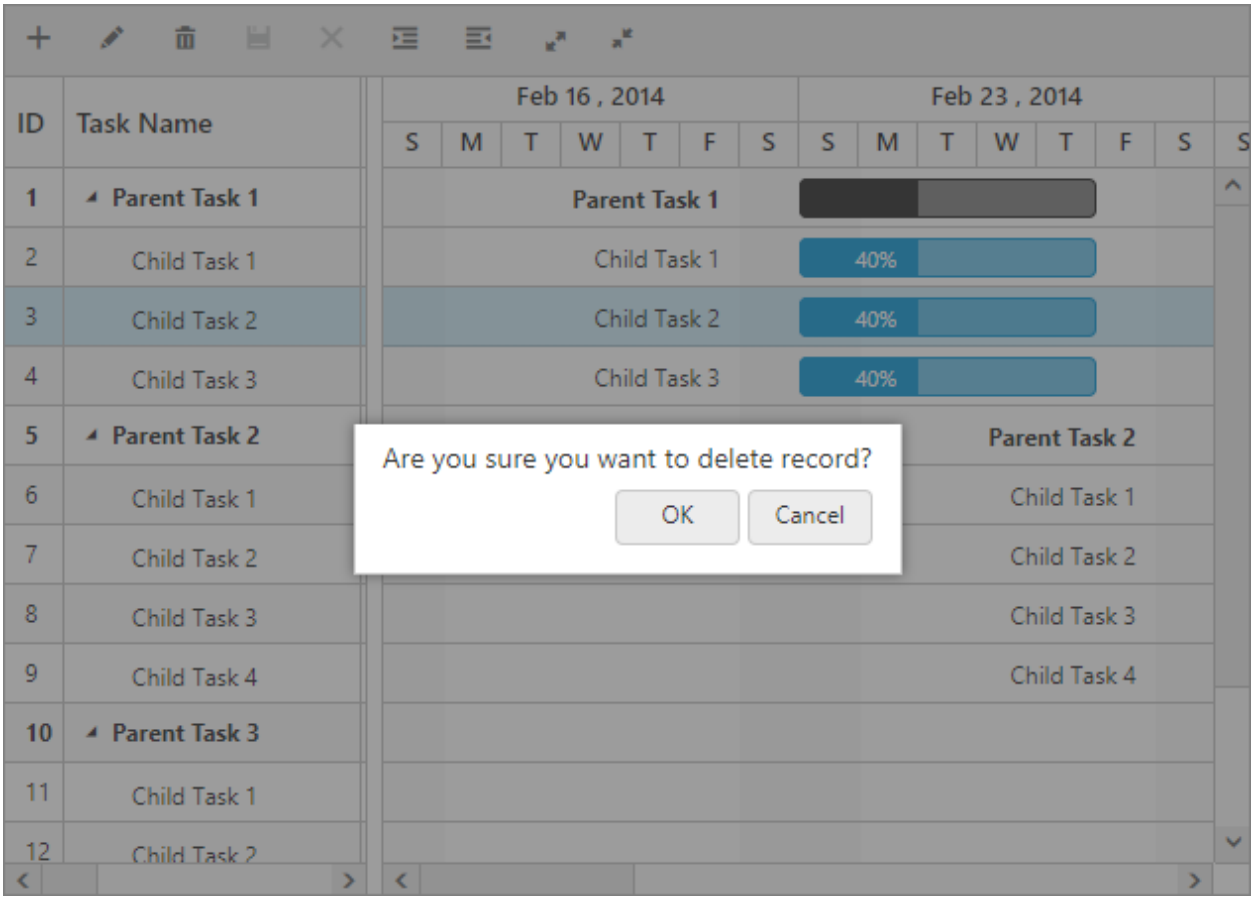
The following code snippet explains how to enable delete confirmation message in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit =>
{
edit.AllowDeleting(true);
edit.ShowDeleteConfirmDialog(true);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
)
@(Html.EJ().ScriptManager())
```



The above screen shot shows the appearance of delete confirmation message in Gantt.

Task Indent

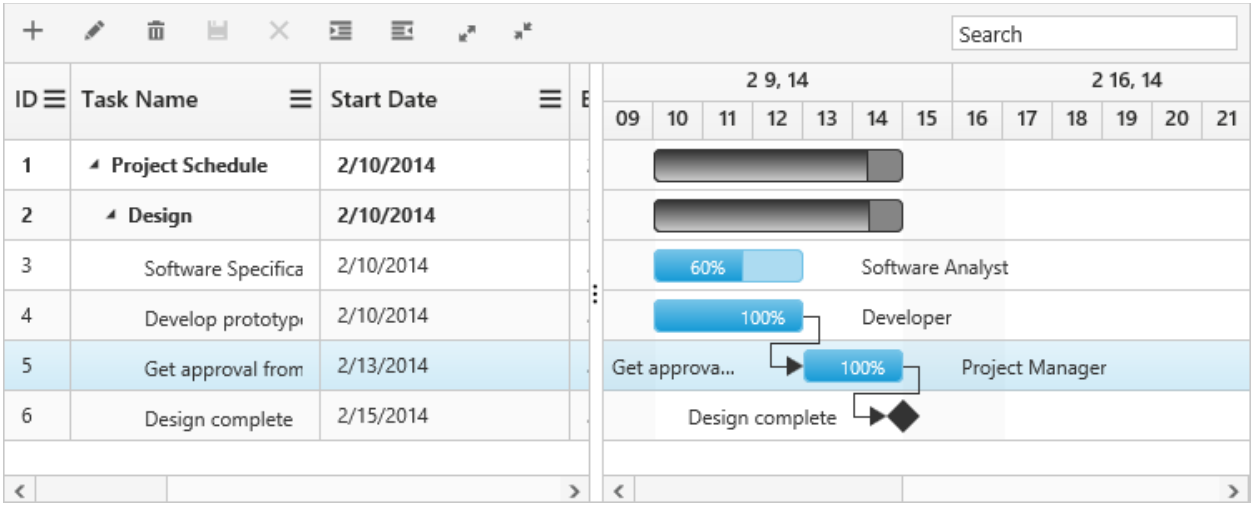
Task indent option in Gantt was enabled by setting EditSettings.AllowIndent as true. Tasks can be indented by clicking on indent toolbar item or by using indentItem method. We can invoke this method dynamically on any action like external button click. The below code example shows how to enable indent option in Gantt.

ASPX-CS

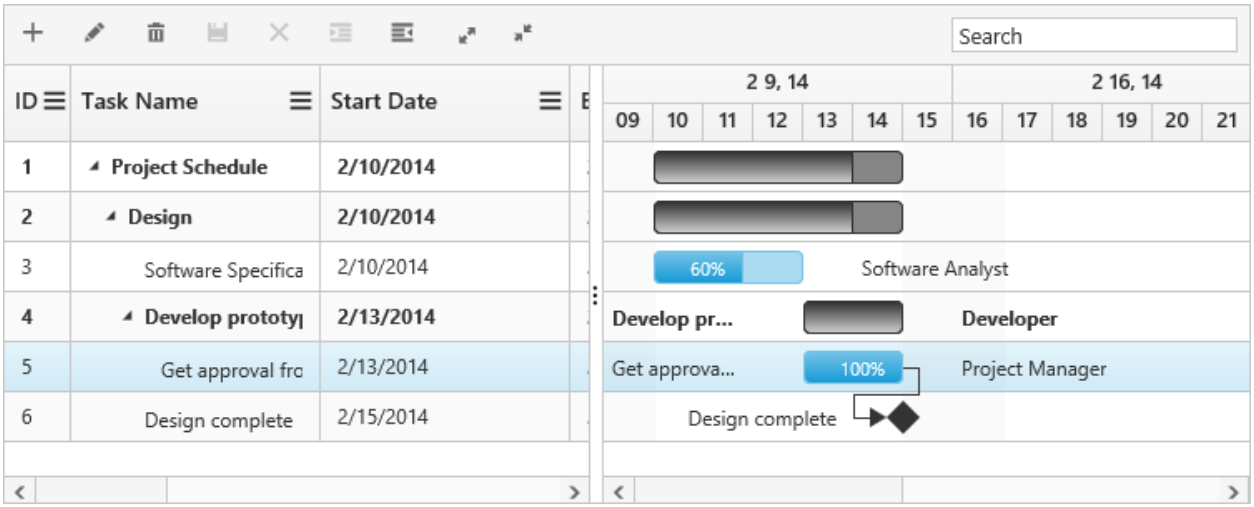
```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit =>
{
edit.AllowIndent(true);
})
.ToolbarSettings(toolbar =>
{
toolbar.ShowToolbar(true);
toolbar.ToolbarItems(new List<GanttToolBarItems>()
{
//...
```

```
GanttToolBarItems.Indent,
});
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
$("#indentTask").click(function () {
var ganttObj = $("#Gantt").ejGantt("instance");
if (ganttObj.selectedRowIndex() != -1)
ganttObj.indentItem();
});
</script>
```

The following screenshots shows the output of above code example.



Before Indent



After Indent

Note: We should select any one of the row in Gantt to perform task indent action.

Copyright © 2001 - 2020 Syncfusion Inc.

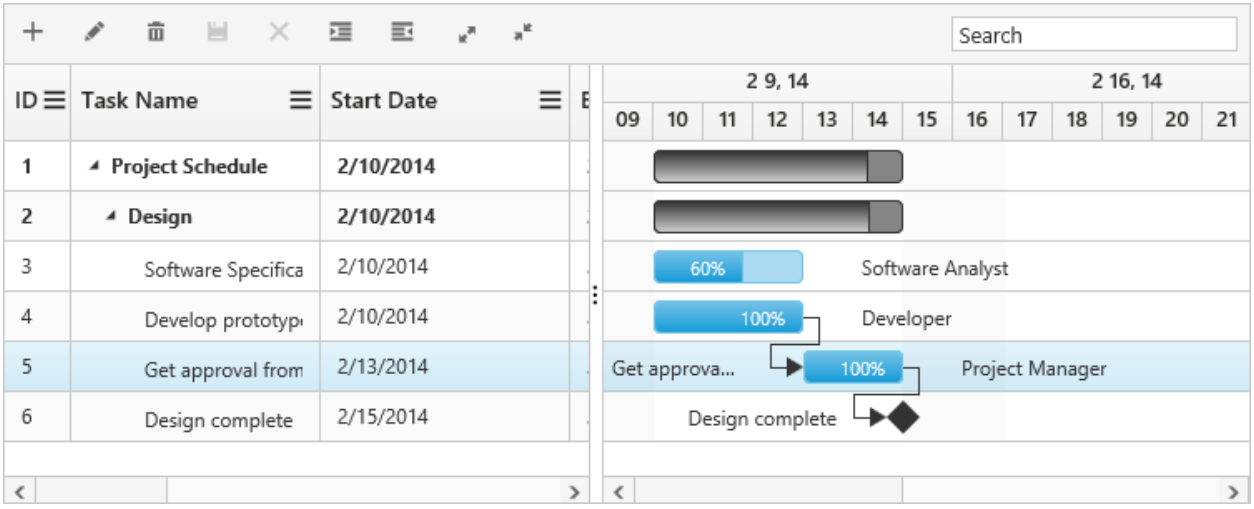
Task Outdent

Task outdent option in Gantt was enabled by setting EditSettings.AllowIndent as true. Tasks can be outdent by clicking on outdent toolbar item or by using outdentItem method. We can invoke this method dynamically on any action like external button click. The below code example shows how to enable outdent option in Gantt.

ASPX-CS

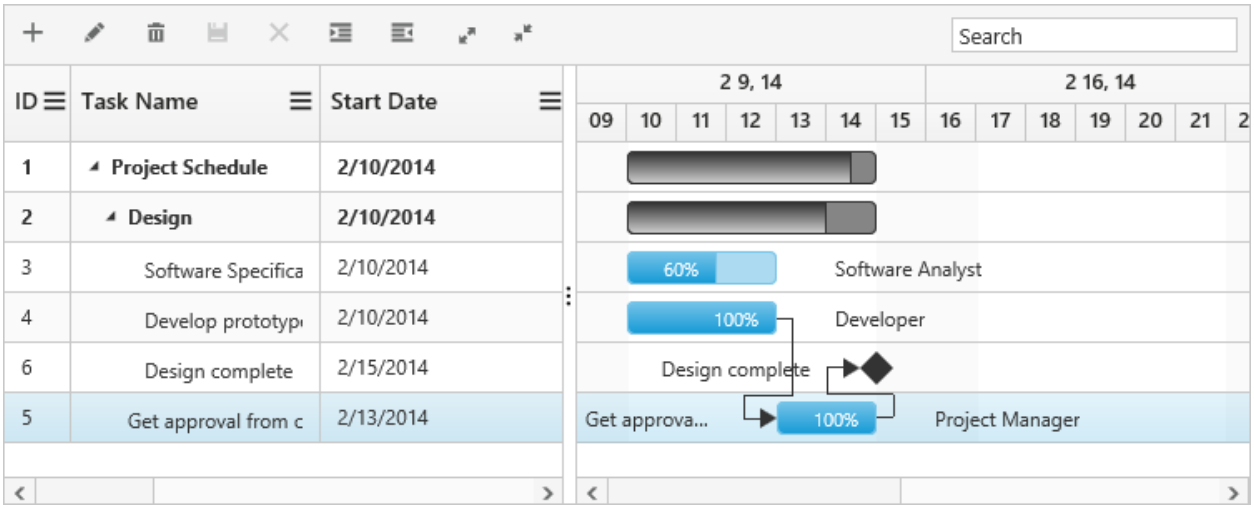
```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit =>
{
edit.AllowIndent(true);
})
.ToolbarSettings(toolbar =>
{
toolbar.ShowToolbar(true);
toolbar.ToolbarItems(new List<GanttToolBarItems>()
{
//...
GanttToolBarItems.Outdent,
});
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
$("#outdentTask").click(function () {
var ganttObj = $("#Gantt").ejGantt("instance");
if (ganttObj.selectedRowIndex() != -1)
ganttObj.outdentItem();
});
</script>
```

The following screenshots shows the output of above code example.



Before Outdent

Copyright © 2001 - 2020 Syncfusion Inc.



After Outdent

Note: We should select any one of the row in Gantt to perform task outdent action.

Task Delete

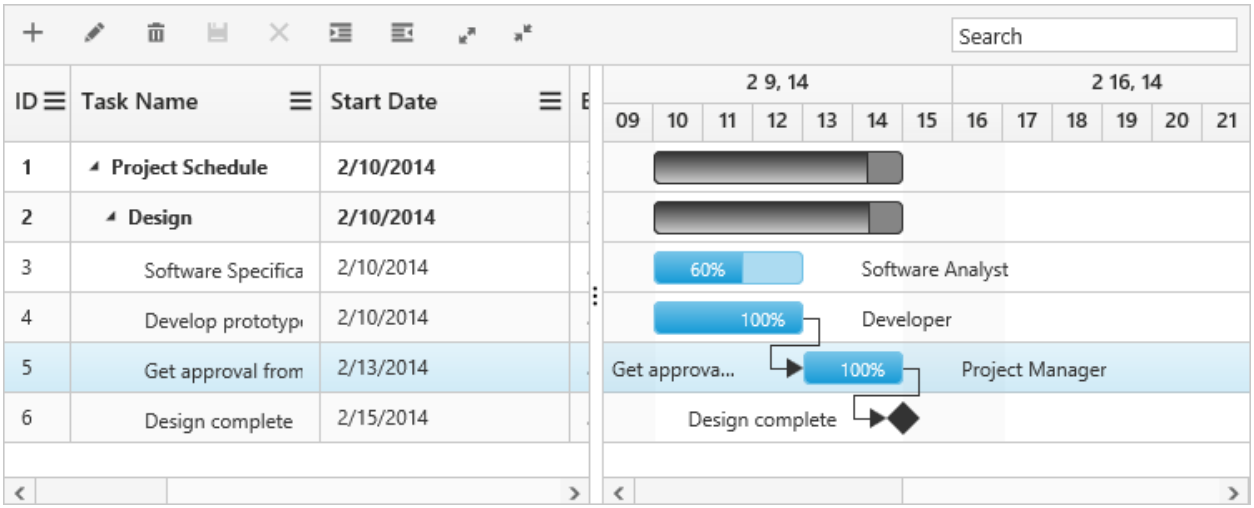
Task delete option in Gantt was enabled by setting `EditSettings.AllowDeleting` as `true`. Tasks can be delete by clicking on delete toolbar item or by using deleteItem method. We can invoke this method dynamically on any action like external button click. The below code example shows how to enable delete option in Gantt.

ASPX-CS

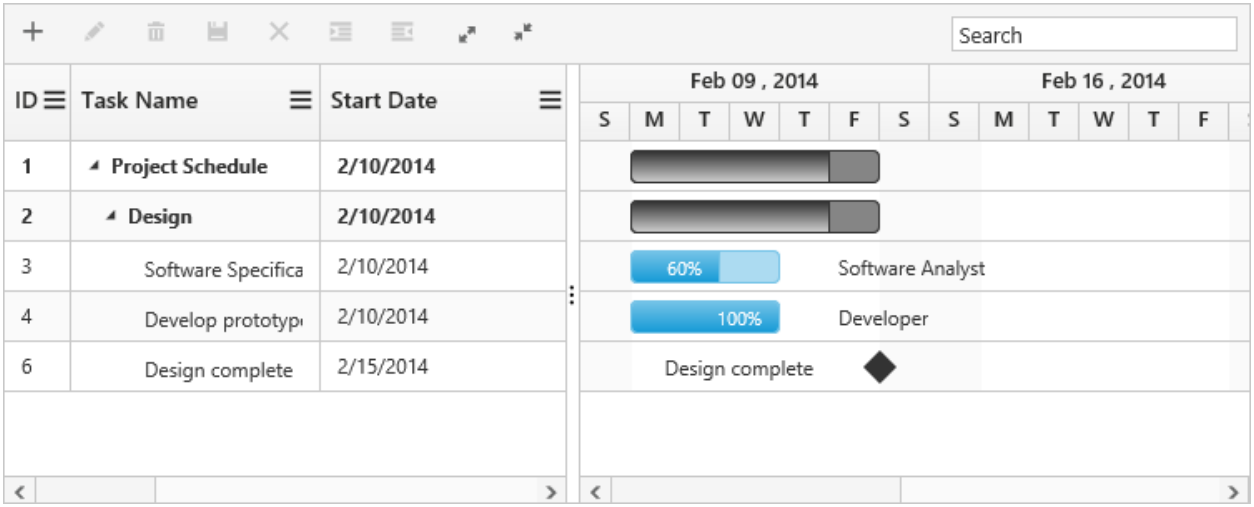
```
@(Html.EJ().Gantt("Gantt")
//...
.EditSettings(edit =>
{
edit.AllowDeleting(true);
})
.ToolbarSettings(toolbar =>
{
toolbar.ShowToolbar(true);
toolbar.ToolbarItems(new List<GanttToolBarItems>()
{
//...
GanttToolBarItems.Delete,
});
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script>
$("#deleteTask").click(function () {
var ganttObj = $("#Gantt").ejGantt("instance");
if (ganttObj.selectedRowIndex() != -1)
ganttObj.deleteItem();
});
</script>
```

The following screenshots shows the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Before Delete



After Delete

Note: We should select any one of the row in Gantt to perform task delete action.

Read-only Gantt

In Gantt, all editing options can be disabled by setting ReadOnly property as true. The following code example shows how to make Gantt control as read-only.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.ReadOnly(true)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Timescale customization

Gantt contains built-in support to switch over to various schedule mode. You can achieve this by defining a schedule header type for the Gantt.

Copyright © 2001 - 2020 Syncfusion Inc.

Schedule Header Types

Gantt contains the following built-in schedule header types:

- Hour – Minute
- Day – Hour
- Week – Day
- Month – Week
- Year – Month

Time scale mode in Gantt can be defined by using `ScheduleHeaderType` property and

the following code example illustrates you on how to change the schedule mode.

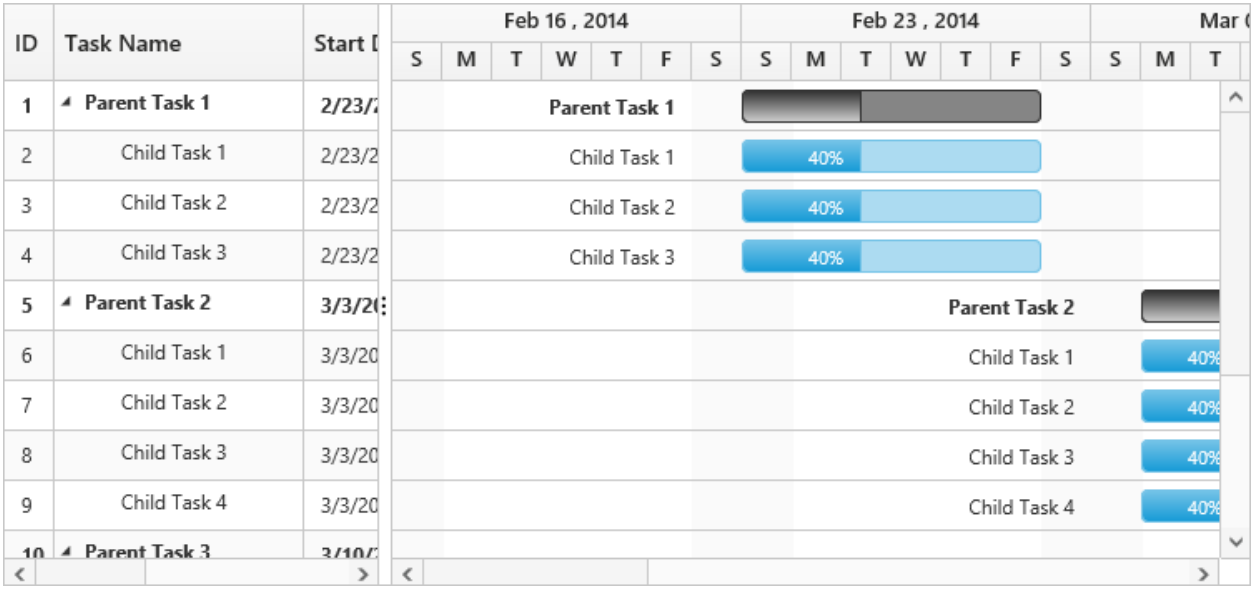
Week Schedule Mode

In the Week schedule mode, the upper part of the schedule header displays the weeks whereas the bottom half of the header displays the days. Refer the following code example.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.ScheduleHeaderSettings(sh=>sh.ScheduleHeaderType(GanttScheduleHeaderType.We
ek)
.WeekHeaderFormat("MMM dd , yyyy ")
.DayHeaderFormat("ddd "))
)
@(Html.EJ().ScriptManager())
```

The following screenshot illustrates the Week Schedule in Gantt control.



Week Schedule in Gantt control

Month Schedule Mode

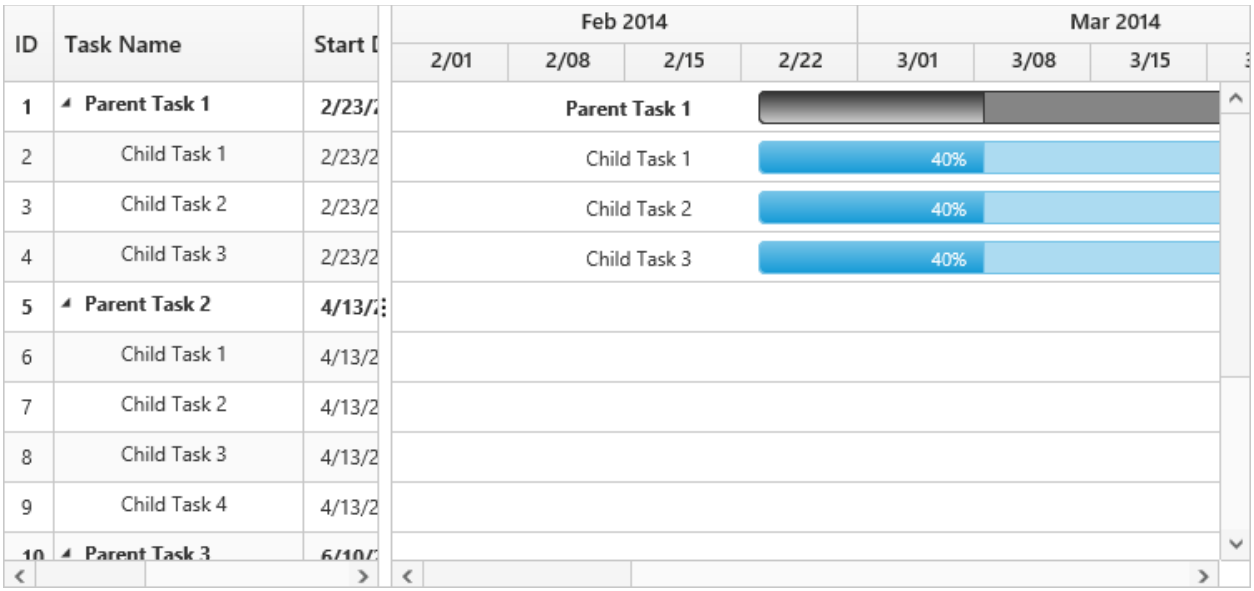
In the Week schedule mode, the upper part of the schedule header displays the Months whereas the bottom header of the schedule displays its corresponding Weeks. Refer the following code example.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.ScheduleHeaderSettings(sh=>sh.ScheduleHeaderType(GanttScheduleHeaderType.Mo
nth)
.MonthHeaderFormat("MMM yyyy")
.WeekHeaderFormat("M/dd"))
)
@(Html.EJ().ScriptManager())
```

The following screenshot illustrates the Month Schedule in Gantt control.



Month Schedule in Gantt control

Year Schedule Mode

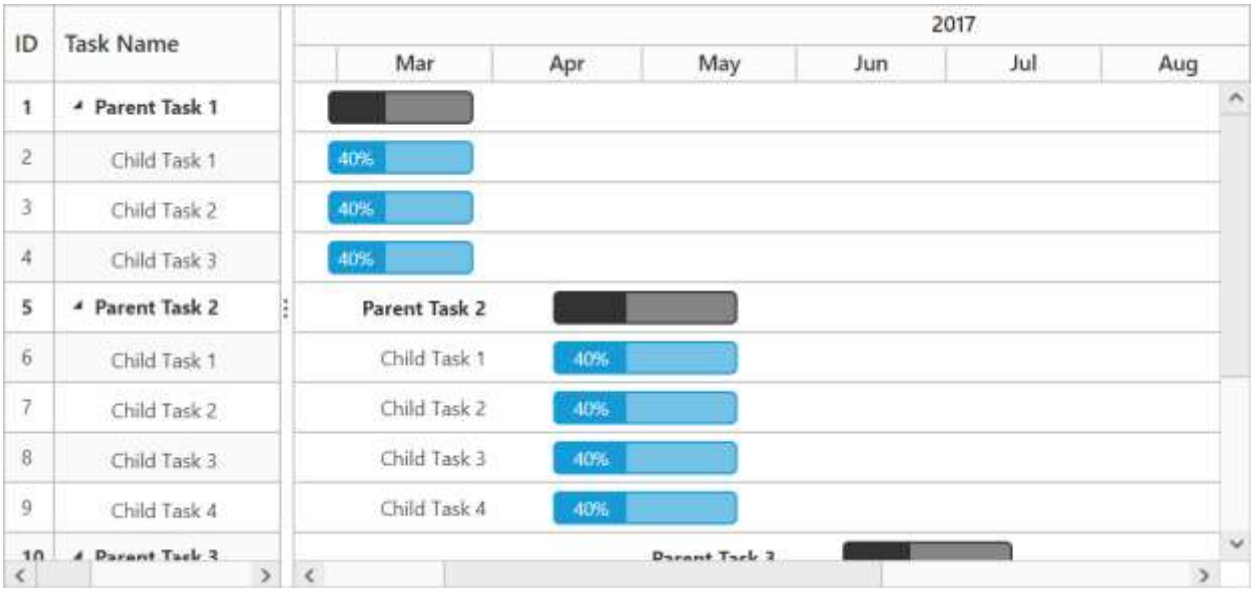
In the Week schedule mode, the upper schedule header displays the Years whereas the bottom header displays its corresponding Months. Refer the following code example.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.ScheduleHeaderSettings(sh=>sh.ScheduleHeaderType(GanttScheduleHeaderType.Ye
ar)
.YearHeaderFormat("yyyy")
.MonthHeaderFormat("MMM"))
)
@(Html.EJ().ScriptManager())
```

The following screen shot shows the Year Schedule in Gantt control.

Copyright © 2001 - 2020 Syncfusion Inc.



Year Schedule in Gantt control

Day Schedule Mode

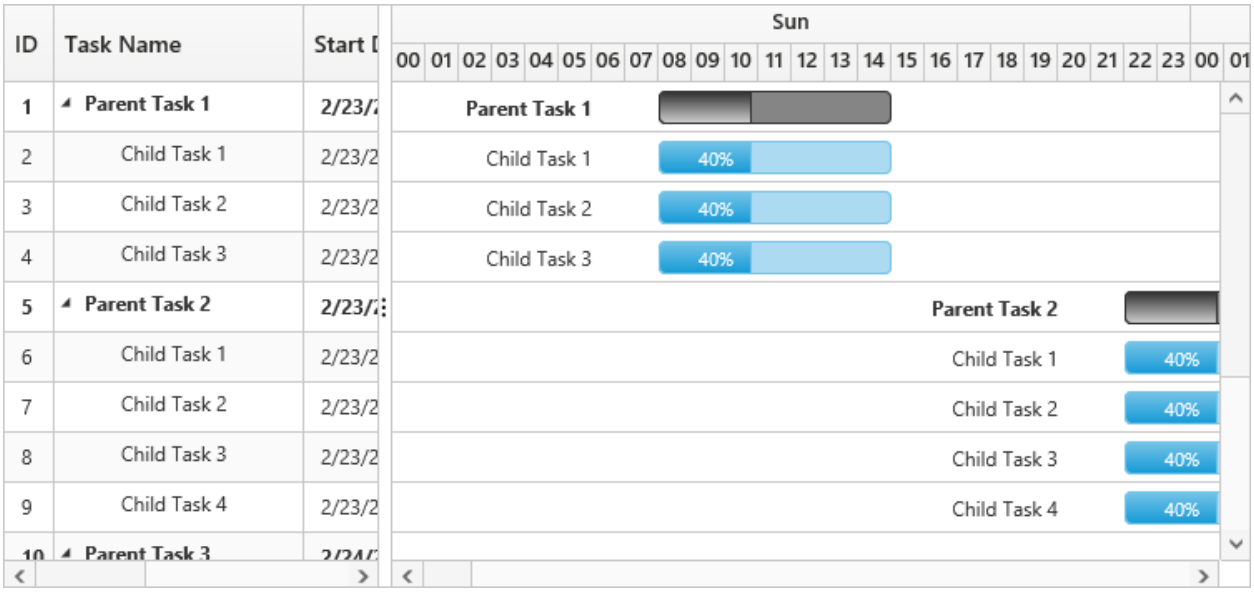
In the Week schedule mode, the upper part of the header displays the Days whereas the bottom schedule header displays its corresponding Hours. Refer the following code example.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.ScheduleHeaderSettings(sh=>sh.ScheduleHeaderType(GanttScheduleHeaderType.Day)
.DayHeaderFormat("ddd ")
.HourHeaderFormat("HH"))
)
@(Html.EJ().ScriptManager())
```

The following screenshot illustrates the Day Schedule in Gantt control.

Copyright © 2001 - 2020 Syncfusion Inc.



Day Schedule in Gantt control

Hour Schedule Mode

An Hour-Minute Schedule Mode tracks the tasks in minutes scale. In this mode, upper schedule header displays hour scale and the lower schedule header displays its corresponding Minutes. The minute split-up in the lower schedule header can be defined by using the MinutesPerIntervalEnum property. The enumeration values of the MinutesPerInterval are,

- Auto
- OneMinute
- FiveMinutes
- FifteenMinutes
- ThirtyMinutes

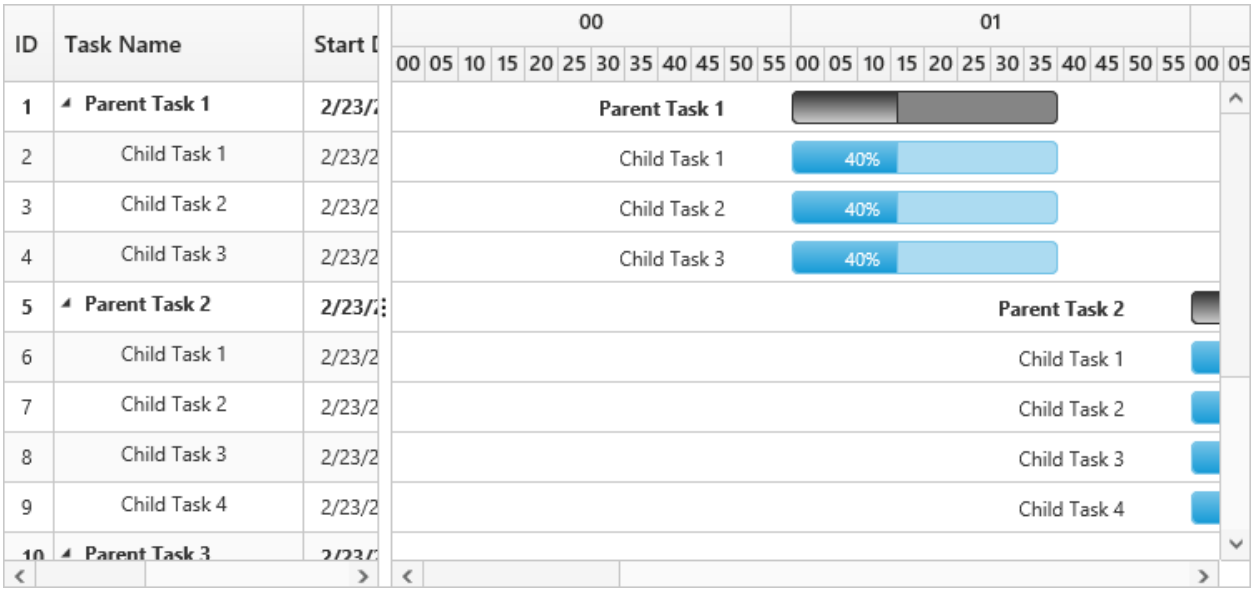
The value, Auto, automatically calculates the interval depending upon the ScheduleStartDate and ScheduleEndDate, whereas the other enumeration values splits up accordingly.

The Hour Schedule Mode supports both the Minute and Hour duration units.

ASPX-CS

```
@(Html.EJ().Gantt("ganttContainer")
.DateFormat("M/d/yyyy hh:mm:ss tt")
.DurationUnit(GanttDurationUnit.Minute)
.ScheduleHeaderSettings(sh =>
{
sh.ScheduleHeaderType(GanttScheduleHeaderType.Hour);
sh.MinutesPerInterval(GanttMinutesPerInterval.FiveMinutes);
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



Hour-Minute schedule mode in Gantt control

Week start day customization

In Gantt, we can customize week start day by using WeekStartDay property.

By default the weekStartDay will be assigned with 0 which specifies the start day of the week.

In week schedule mode, week starts with Sunday by default. But we can customize the week start day by using below code example

ASPX-CS

```
@(Html.EJ().Gantt("ganttContainer")
.ScheduleHeaderSettings(sh =>
{
sh.ScheduleHeaderType(GanttScheduleHeaderType.Week);
sh.WeekStartDay(3);
})
)
@(Html.EJ().ScriptManager())
```

Rounding off timescale (schedule) start date

You can able to round off the schedule start date in a project by using the TimescaleStartDateMode property. It is possible to set the following values to the property,

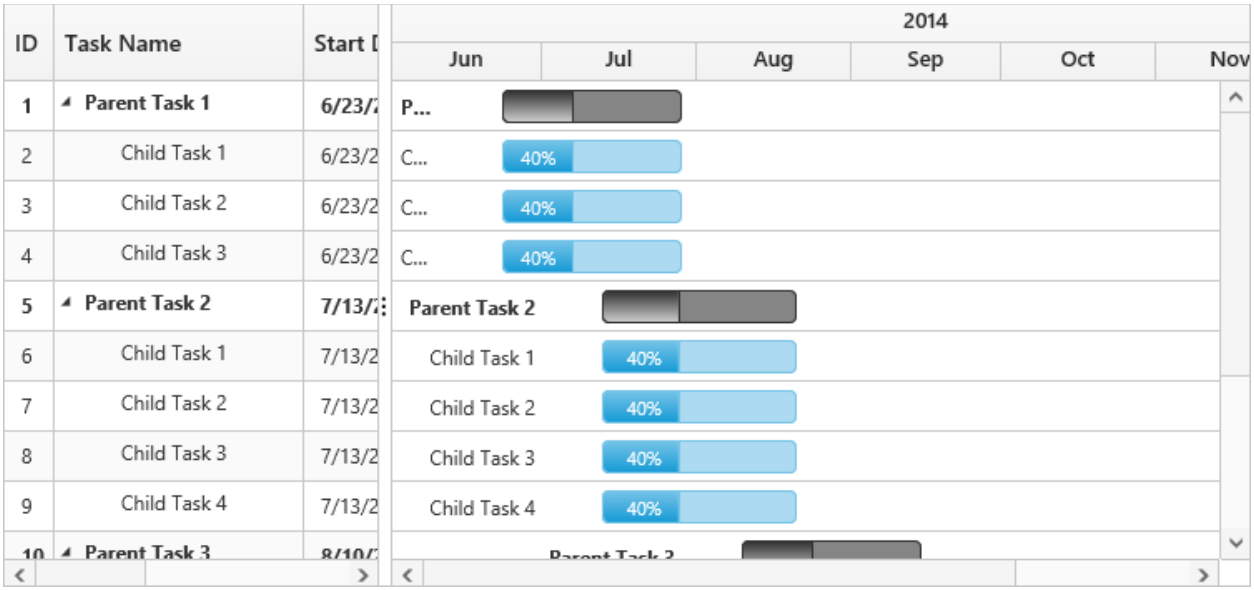
- Auto
- Month
- Week
- Year

The value Auto, automatically calculates the schedule header depending on the datasource values, whereas the other enumeration values rounds off the schedule header accordingly. For Instance, in year schedule if you set TimescaleStartDateMode as Month then the schedule header will start from the immediate month of the schedule instead of starting from beginning of the year.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Gantt("ganttContainer")
.ScheduleHeaderSettings(sh =>
{
sh.ScheduleHeaderType(GanttScheduleHeaderType.Year);
sh.TimescaleStartDateMode(GanttTimescaleRoundMode.Month);
})
)
@(Html.EJ().ScriptManager())
```



Click here to view the timescale modes in Gantt.

Customize automatic timescale update action

In Gantt, schedule timeline will be automatically updated when the tasks are edited beyond the schedule start date and end date range. This can be enabled/disabled by using UpdateTimescaleView property.

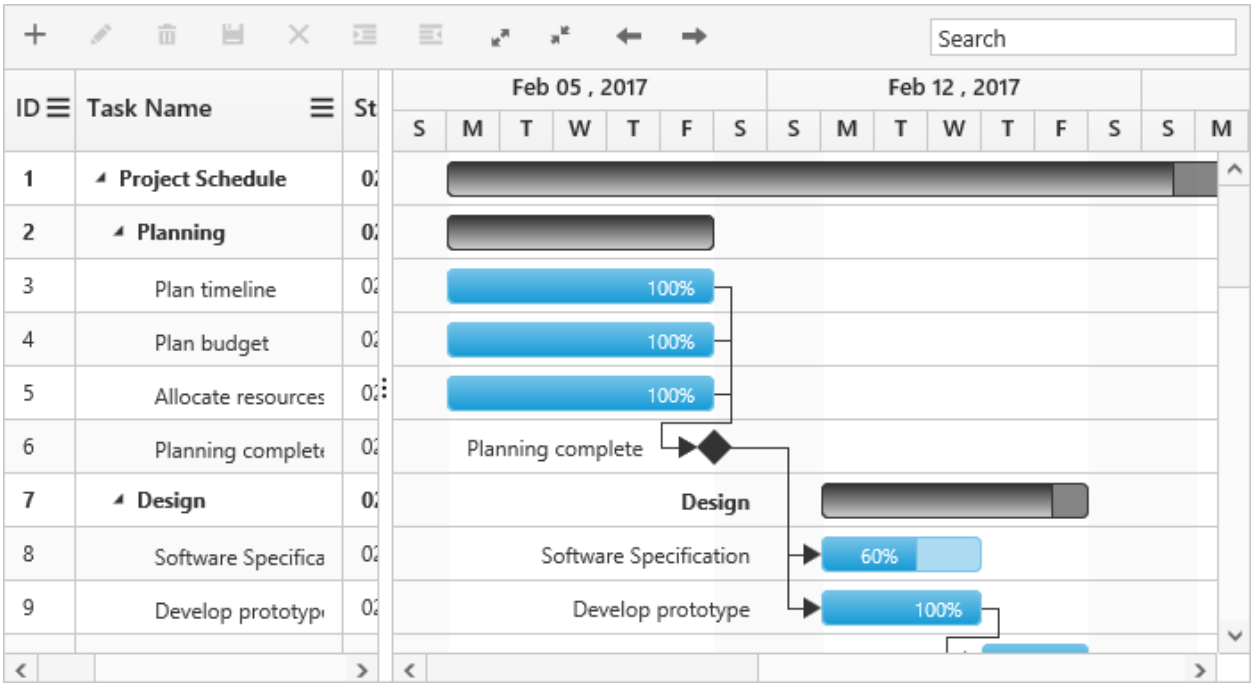
The following code snippets shows how to prevent the automatic timescale update in Gantt.

ASPX-CS

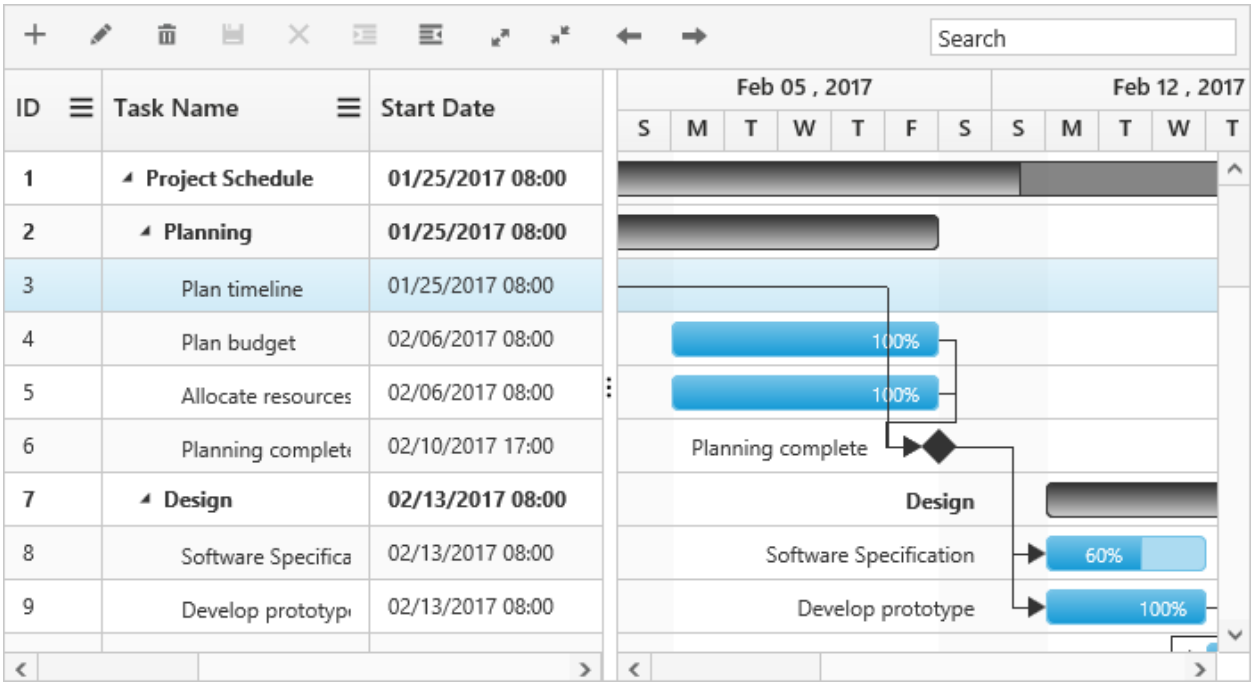
```
@(Html.EJ().Gantt("ganttContainer")
.ScheduleHeaderSettings(sh =>
{
sh.ScheduleHeaderType(GanttScheduleHeaderType.Week);
sh.UpdateTimescaleView(false);
})
)
```

The following screenshot shows the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.

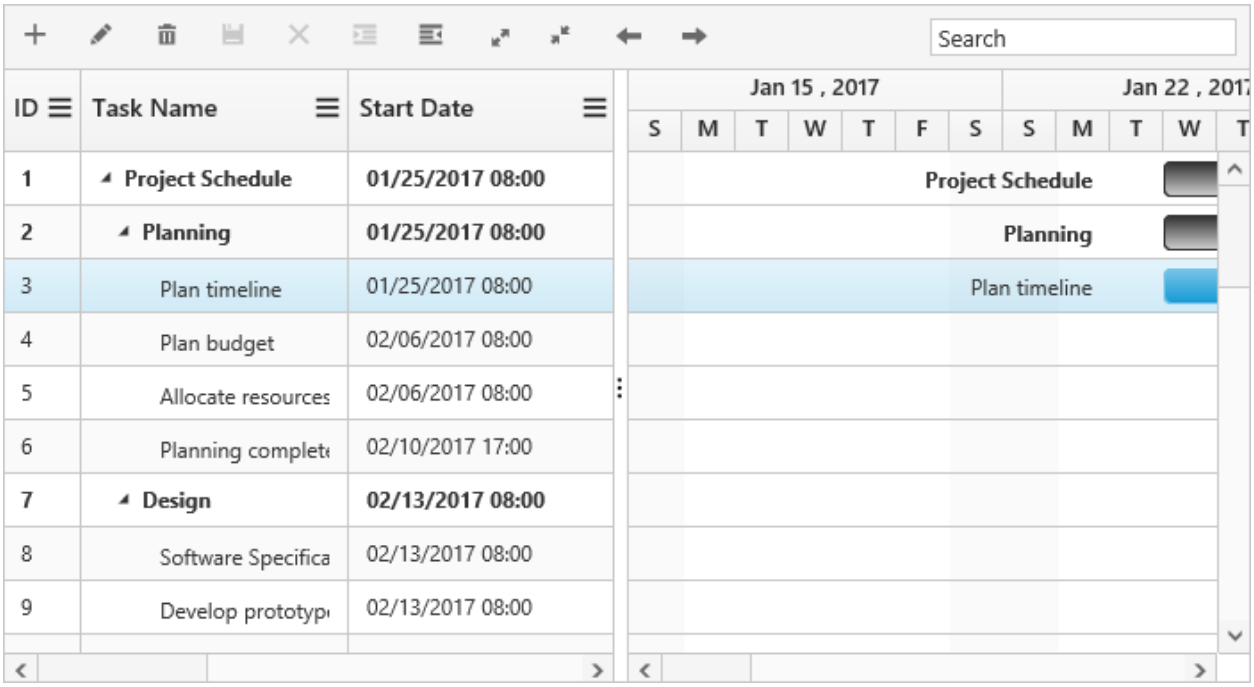


At Initial load



`updateTimescaleView` property as `false`

Copyright © 2001 - 2020 Syncfusion Inc.



updateTimescaleView property as true

Critical Path

The critical path in a project is indicated by a single task or a series of tasks in a project, critical path describes the calculated start date or end date of a project. If a task in a critical path is delayed, then the entire project will be delayed.

The critical path can be enabled in Gantt by using built-in toolbar button or showCriticalPath method.

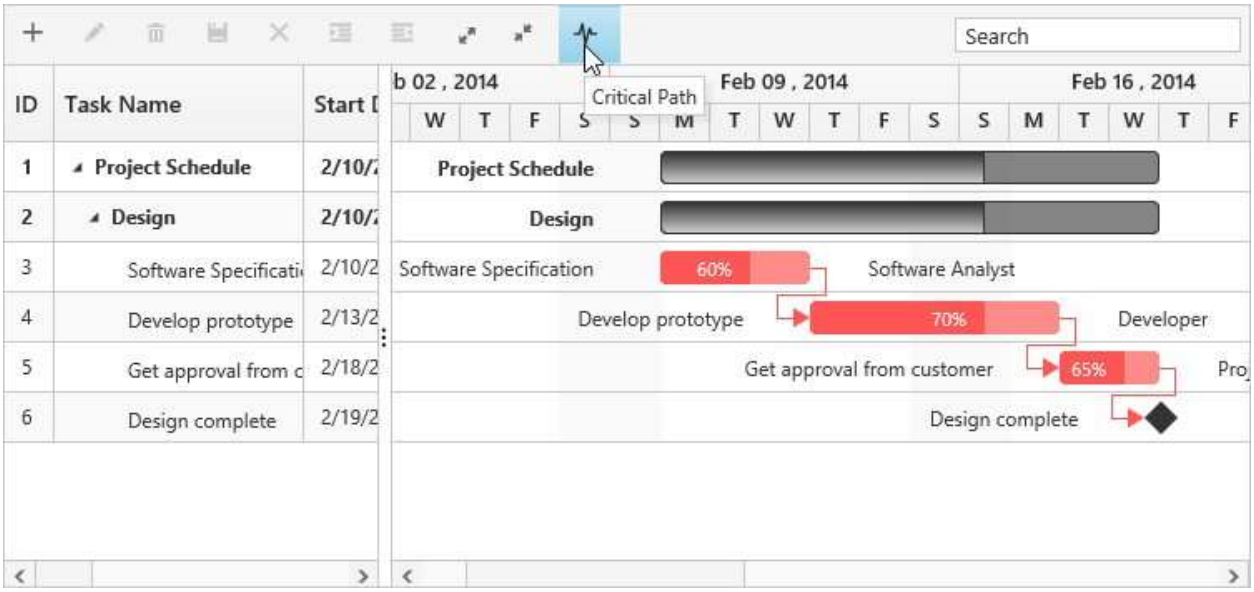
Using Toolbar Icon

You can enable/disable the critical path in Gantt by using toolbar button, and this button can be enabled in the Gantt toolbar by using the following code example.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.ToolbarSettings(toolbar =>
{
toolbar.ShowToolbar(true);
toolbar.ToolbarItems(new List<GanttToolBarItems>()
{
//..
GanttToolBarItems.CriticalPath
});
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the online demo sample for critical path in Gantt.

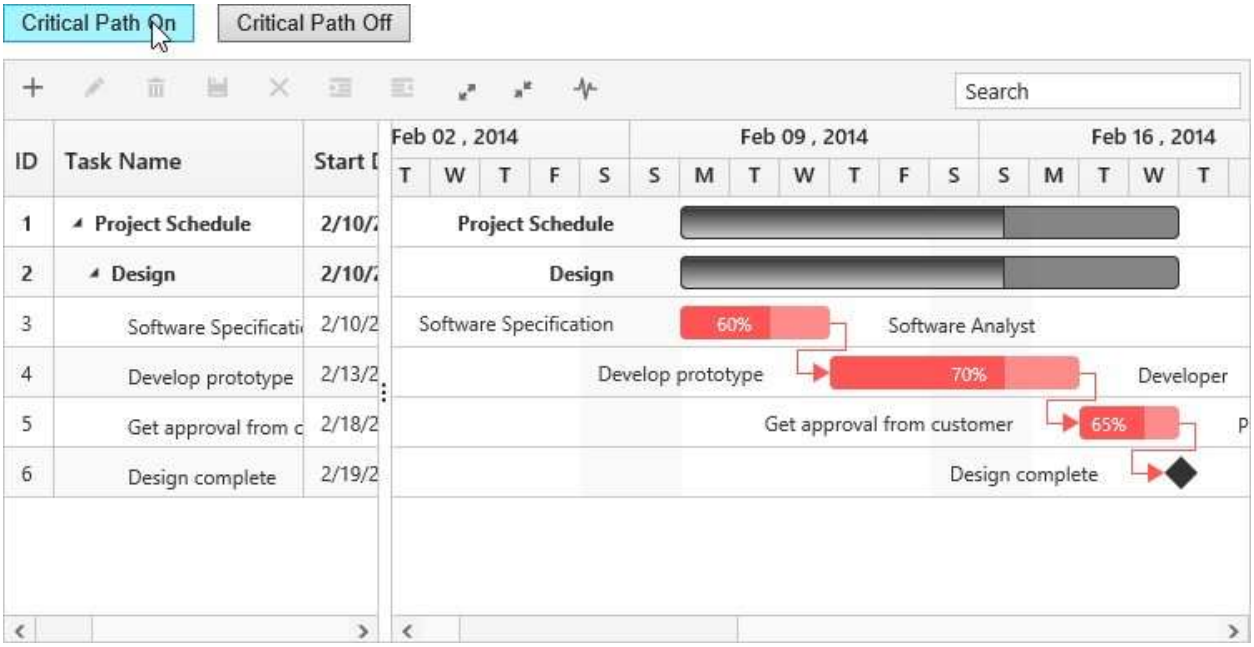
Using Method

You can enable the critical path by using showCriticalPath method with parameter as true. And critical path can be disabled using the same method with parameter as false.

ASPX-CS

```
<script>
$("#buttonOn").click(function (args) {
ganttObj = $("#Gantt").data("ejGantt");
ganttObj.showCriticalPath(true);
})
$("#buttonOff").click(function (args) {
ganttObj = $("#Gantt").data("ejGantt");
ganttObj.showCriticalPath(false);
})
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.



Customizing critical path background

You can customize the critical task background by setting custom color codes to the critical task element's class names,

Taskbar–.e-ganttchart .e-criticaltaskbar

Progressbar–.e-ganttchart .e-criticalprogressbar

Connector line–.e-ganttchart .e-criticalconnectorline

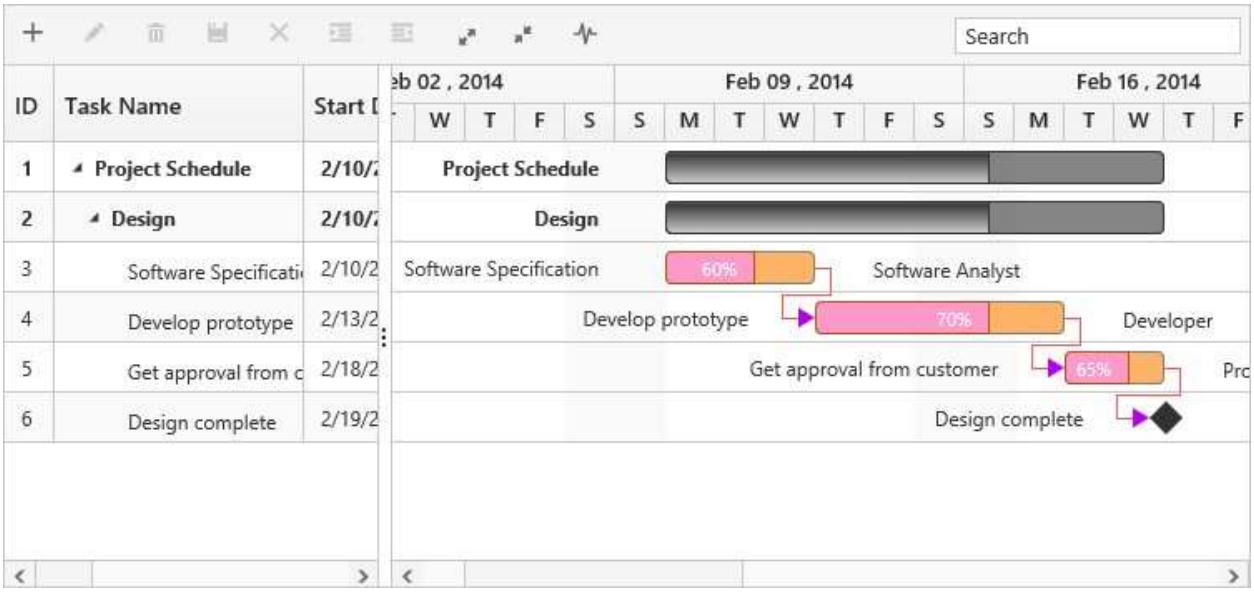
Connector line left arrow– .e-ganttchart .e-criticalconnectorlineleftarrow

Connector line right arrow– .e-ganttchart .e-criticalconnectorlinerightarrow

ASPX-CS

```
<style>
.e-ganttchart .e-criticaltaskbar {
background-color : #ffb366!important;
border-color : gray!important
}
.e-ganttchart .e-criticalprogressbar {
background-color : #ff99cc!important;
border-color : #b35900!important
}
.e-ganttchart .e-criticalconnectorline {
background-color : #b800e6!important;
}
.e-ganttchart .e-criticalconnectorlineleftarrow {
border-right-color : #b800e6!important;
}
.e-ganttchart .e-criticalconnectorlinerightarrow{
border-left-color : #b800e6!important;
}
</style>
```

Copyright © 2001 - 2020 Syncfusion Inc.



Gantt Columns

Gantt column displays the information from a bounded data source and it will be editable to update the task details through TreeGrid.

Column Edit Types

Gantt supports the following types of column editors,

- String
- Date
- Datetime
- Numeric
- Maskedit
- Currency
- Dropdown

You can change the width of the column in TreeGrid to show the entire text of the column by resizing the column. The following code example shows you how to enable the column resize feature at Gantt initialize.

Format Column

It is possible to format a column using Load event. The following code examples show how to format the progress column with percentage value.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.ClientSideEvents(eve=>
{
eve.Load("load");
})
)
@(Html.EJ().ScriptManager())
<script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
function load(args){
var columns = this.getColumns();
columns[5]["format"] = "{0:p0}";
}
</script>
```

Note: For more numeric format strings, please refer to this link.

Note: For more date format strings, please refer to this link.

Column Resizing

You can change the width of the column to show the entire text of the column by resizing the column.

In Gantt column resizing can be enabled by setting `AllowColumnResize` property as `true`.

The following code example shows you how to enable the column resize feature in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowColumnResize(true)
)
@(Html.EJ().ScriptManager())
```

Column Template

Column template is used to customize the column's look and feel, based on requirement.

The following code example shows you how to display a column with resource images.

ASPX-CS

```
<script type="text/x-jsrender" id="columnTemplate">
{{"{{"}}if #data['resourceNames']{{}}}}
<div style="display:inline-block;position:relative;left:10px;top:1px">
<img src="images/Gantt/{{'{{'}}:#data['resourceNames']{{}}}}.png"
height="40px" />
</div>
<div style='display:inline-
block;width:100%;position:relative;left:10px;top:2px'>{{:#data['resourceName
s']{{}}}}</div>
{{"{{"}}/if{{}}}}
</script>
@(Html.EJ().Gantt("Gantt")
//...
.ResourceInfoMapping("ResourceID")
.ResourceNameMapping("ResourceName")
.ResourceIdMapping("ResourceID")
.ClientSideEvents(eve=>
{
eve.Load("load");
})
.Resources(ViewBag.datasource1)
)
@(Html.EJ().ScriptManager())
<script>
function load(args){
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
var Gantt = $("#Gantt").ejGantt("instance");
var columns = Gantt.getColumns();
columns[2].visible = columns[3].visible = false;
columns[4].isTemplateColumn = true;
columns[4].templateID = "columnTemplate";
columns[4].width = "172";
}
</script>
```

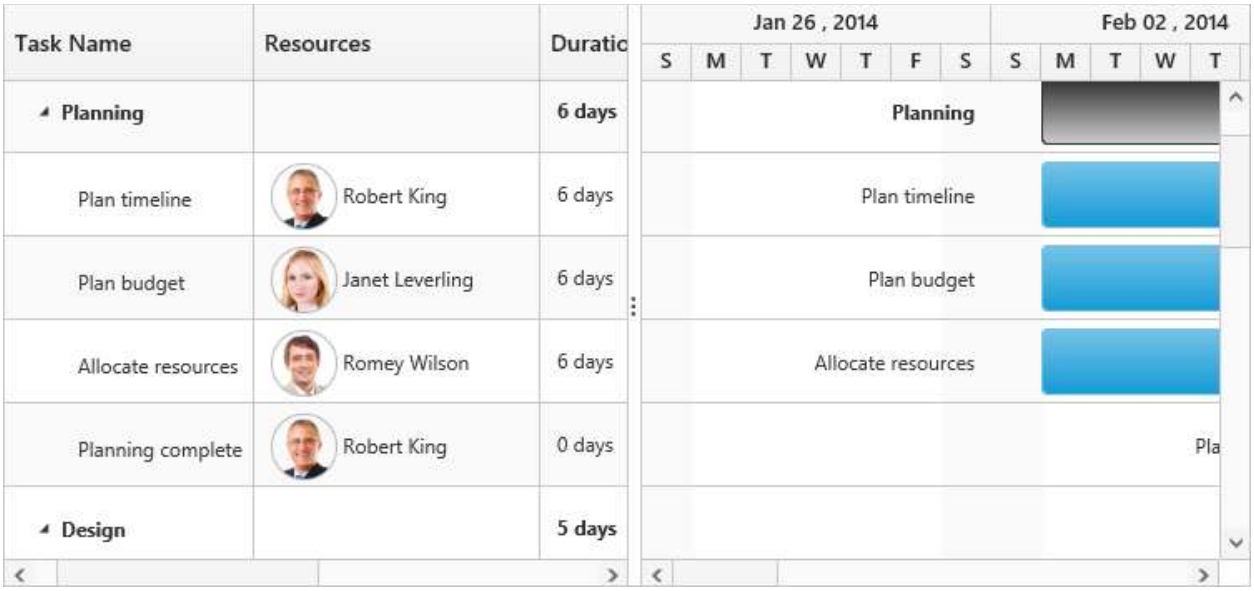
C#

```
public class GanttController : Controller
{
// GET: /GanttColumnTemplate/
public ActionResult GanttColumnTemplate()
{
var DataSource = GetTaskData();
ViewBag.datasource = DataSource;
return View();
}
public class TaskDetails
{
public int TaskID { get; set; }
public string TaskName { get; set; }
public string StartDate { get; set; }
public string EndDate { get; set; }
public int Duration { get; set; }
public string Progress { get; set; }
public List<TaskDetails> SubTasks { get; set; }
public List<object> ResourceID { get; set; }
public string Predecessors { get; set; }
}
public List<TaskDetails> GetTaskData()
{
List<TaskDetails> tasks = new List<TaskDetails>();
tasks.Add(new TaskDetails()
{
TaskID = 1,
TaskName = "Project Schedule",
StartDate = "02/06/2017",
EndDate = "03/10/2017"
});
tasks[0].SubTasks = new List<TaskDetails>();
tasks[0].SubTasks.Add(new TaskDetails()
{
TaskID = 2,
TaskName = "Planning",
StartDate = "02/06/2017",
EndDate = "02/10/2017"
});
tasks[0].SubTasks[0].SubTasks = new List<TaskDetails>();
tasks[0].SubTasks[0].SubTasks.Add(new TaskDetails()
{
TaskID = 3,
TaskName = "Plan timeline",
StartDate = "02/06/2017",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
EndDate = "02/10/2017",
Duration = 5,
Progress = "100",
ResourceID = new List<object>() { 1 }
});
//..
}
}
```

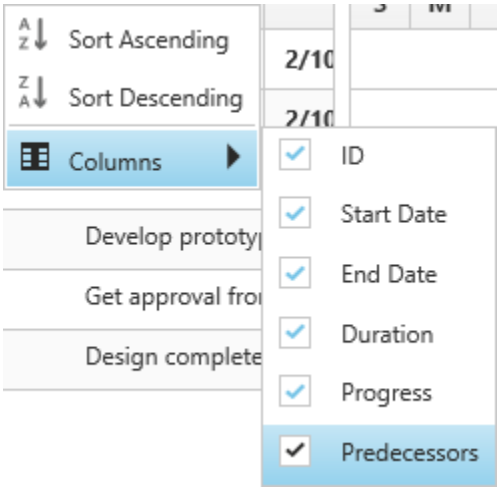
The following screenshot displays the customized column in Gantt control.



Column Menu

Show column chooser

Gantt supports enabling and disabling the visibility of the columns dynamically with the ShowColumnChooser property. The visibility of the custom columns can also be toggled with this property. Column chooser option is rendered as a sub menu item within the column menu in the Gantt columns.



The column menu is enabled with the ShowColumnChooser property, where the default value for this property is false.

The column menu provides the following options:

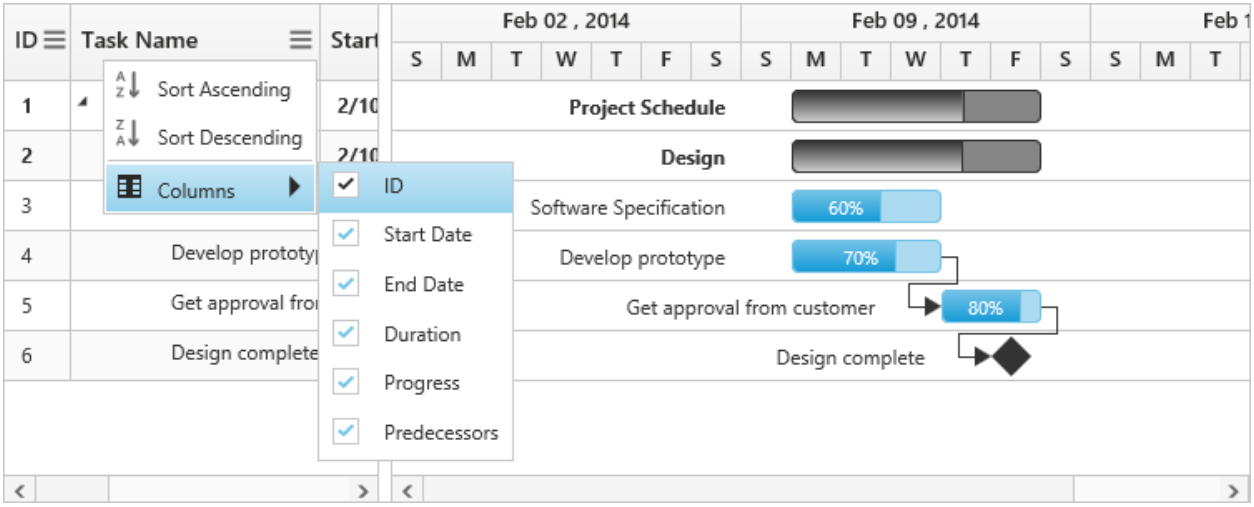
- Sort Ascending
- Sort Descending
- Columns

Sort Ascending and Sort Descending options can be enabled or disabled with the AllowSorting property. Single level sorting can be performed with these options. To perform multilevel sorting, the AllowMultiSorting property should be enabled. You can also disable the visibility of a particular column in the column collection manually by setting the visible property to false.

ASPX-CS

```
@(Html.EJ().Gantt("gantt")
// ...
.ShowColumnChooser(true)
.AllowSorting(true)
.AllowMultiSorting(true)
)
@(Html.EJ().ScriptManager())
```

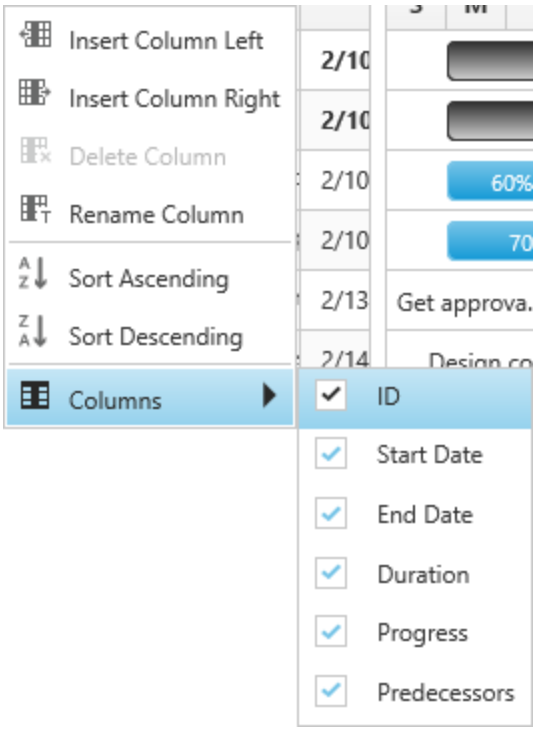
The following screenshot displays the column chooser in the Gantt control.



Show Column Options

You can customize the column with some more options with the ShowColumnOptions property. Use this property to insert a new column, delete a column and to update the header text of the column.

Copyright © 2001 - 2020 Syncfusion Inc.



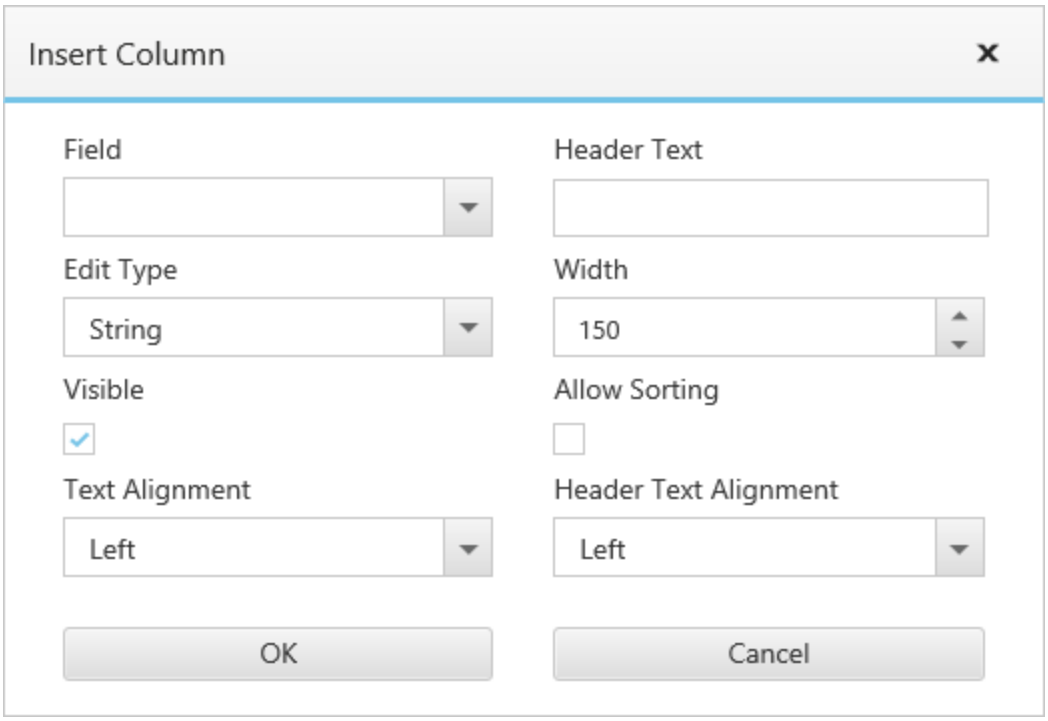
The column options can be enabled or disabled with the `ShowColumnOptions` property, where the default value for this property is `false`.

The column options provide the following options:

- Insert column left
- Insert column right
- Delete column
- Rename column

Inserting column provides the dialog to enter the details for the column.

Copyright © 2001 - 2020 Syncfusion Inc.

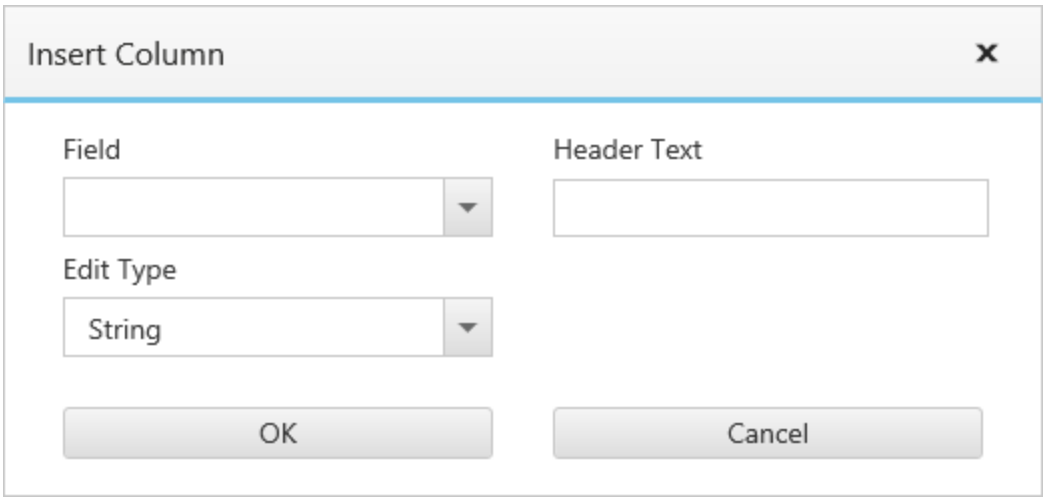


These fields can be customized with the ColumnDialogFields property. The following code sample shows you how to customize these fields.

ASPX-CS

```
@(Html.EJ().Gantt("gantt")
// ...
.ShowColumnChooser(true)
.ShowColumnOptions(true)
.ColumnDialogFields(new List <GanttColumnDialogFields>(){
GanttColumnDialogFields.Field,
GanttColumnDialogFields.HeaderText,
GanttColumnDialogFields.EditType
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



Change visibility of the columns dynamically

Gantt columns visibility can be changed dynamically by using showColumn and hideColumn methods. The below code example shows how to change the visibility of the column in Gantt dynamically.

ASPX-CS

```
<button id="hide_column">Hide</button>
<button id="show_column">Show</button>
@(Html.EJ().Gantt("gantt")
//..
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#hide_column").click(function () {
var ganttObj = $("#gantt").ejGantt("instance");
var column = ganttObj.getColumns()[0];
ganttObj.hideColumn(column.headerText);
});
$("#show_column").click(function () {
var ganttObj = $("#gantt").ejGantt("instance");
var column = ganttObj.getColumns()[0];
ganttObj.showColumn(column.headerText);
});
</script>
```

Change Tree/Expander Column

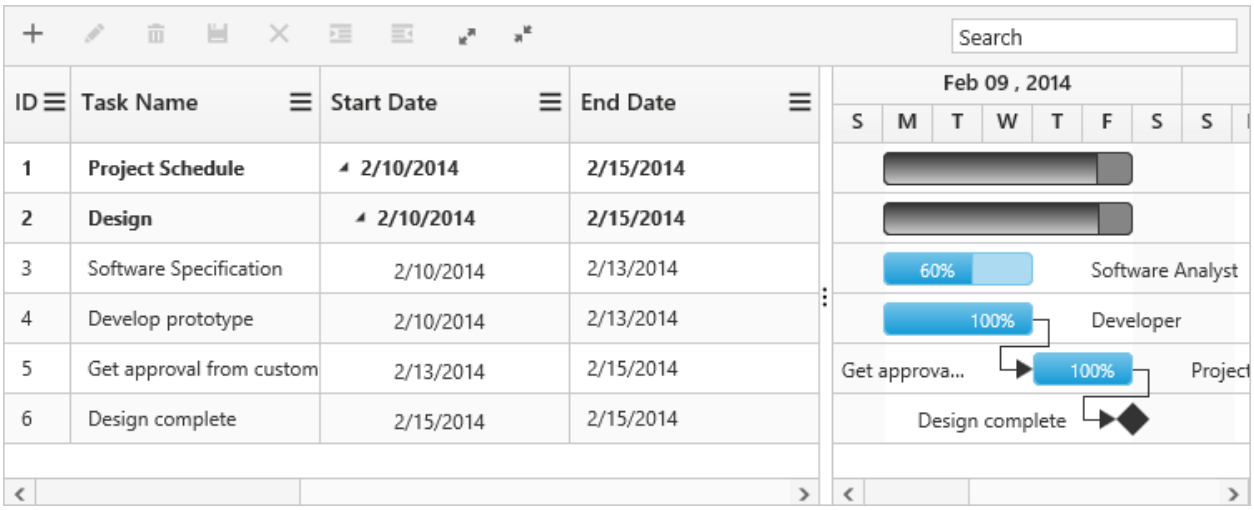
Tree/Expander column is a column in Gantt which has icons to expand/collapse the parent records. We can define the tree column index in Gantt by using `TreeColumnIndex` property, default value of this property was `0`. The following code example shows how to use this property.

ASPX-CS

```
@(Html.EJ().Gantt("gantt")
// ...
.TreeColumnIndex(2)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

The below screenshot shows the output of above code example.



Sequencing Tasks

How to enable serial number column in Gantt?

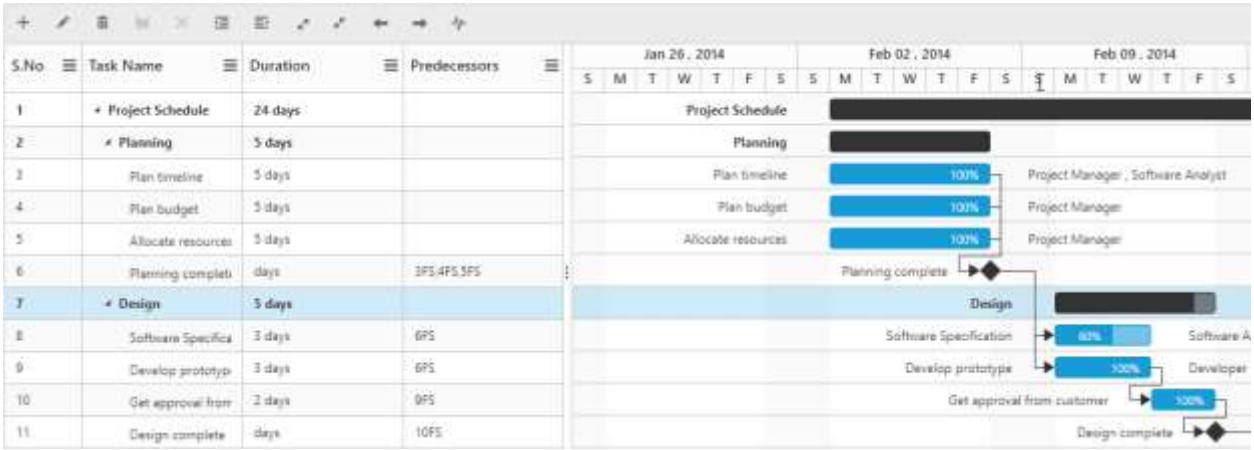
The serial or sequence number support in Gantt is used to index the tasks in a project. The Serial number column can be rendered by enabling the `EnableSerialNumber` property. On enabling this property the serial number column will be displayed and the Task Id column will be hidden, the tasks will be identified using the serial numbers. Further the column values for task predecessors will also be displayed using the serial numbers of the corresponding tasks, instead of task IDs.

Code snippets for enabling the serial number is as follows.

ASPX-CS

```
@(Html.EJ().Gantt("GanttSerialNumber")
//...
.EnableSerialNumber(true)
)
@(Html.EJ().ScriptManager())
```

The following screenshot displays the Serial number column in Gantt control.



The serial number column will be resequenced automatically on performing any actions which will change the row indexes of the tasks such as row drag and drop, deleting, adding.

Rows

Row represents a task information from the data source, and it is possible to perform the following actions in Gantt rows.

Adding a row

A row can be added in the following ways in Gantt.

- Toolbar
- Context menu
- Adding a row programmatically

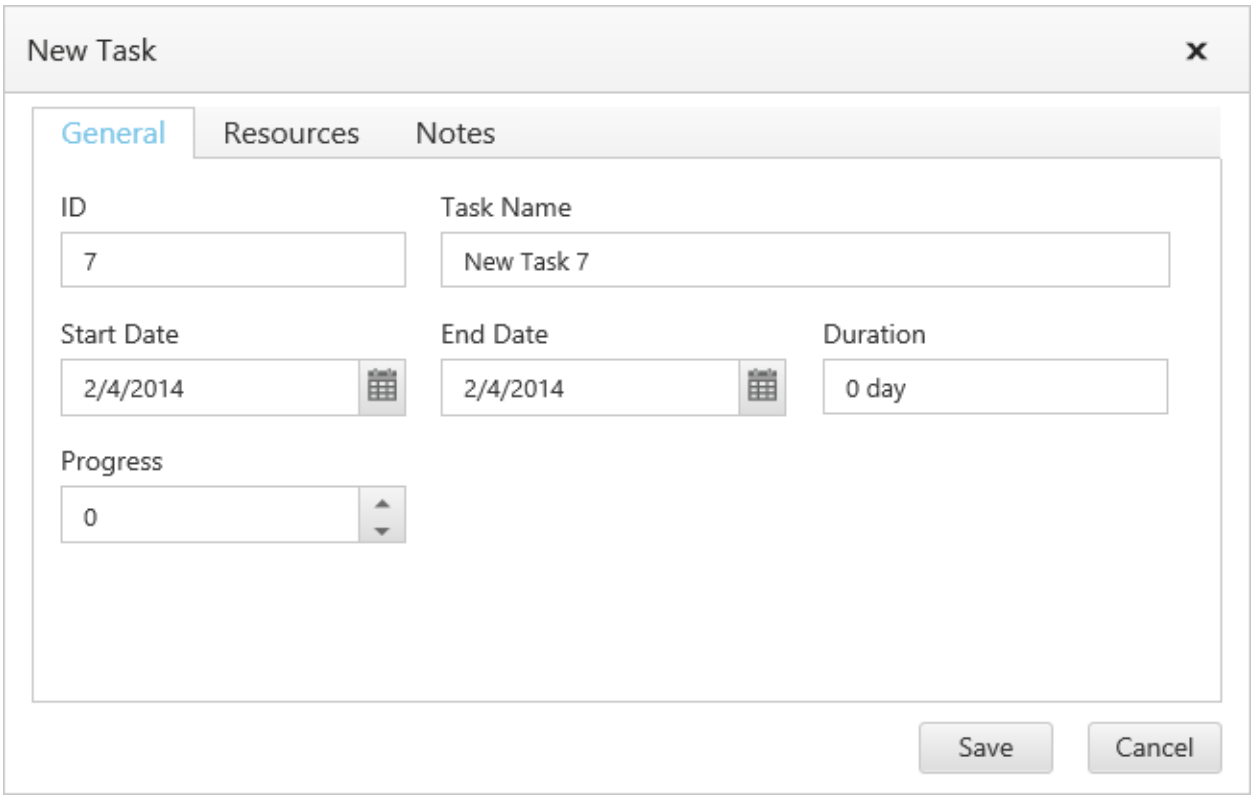
Toolbar adding

Row can be added in Gantt from toolbar while the EditSettings.AllowAdding property is set to true. On clicking the toolbar add icon, you need to provide the task information in the add dialog. If a row is previously selected, then the new row will be added below and in the same hierarchical level as that of the selected row. If there are no rows selected in Gantt, by default the new row will be added as the top most row in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.EditSettings(edit=>
{
edit.AllowAdding(true);
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



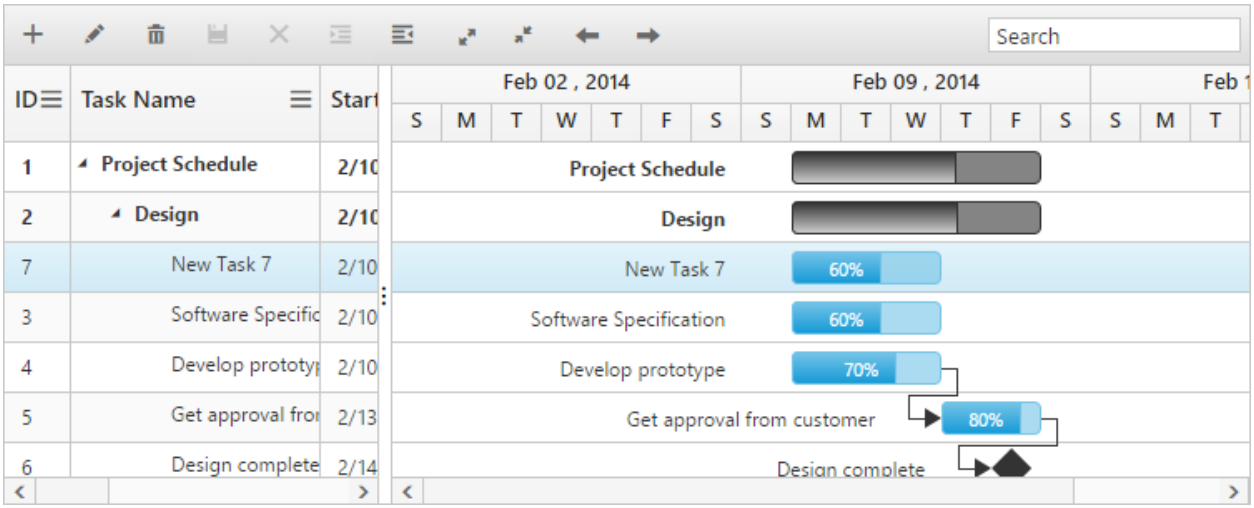
Context menu adding

New rows can either be added above or below the selected rows by using the default context menu, while the EnableContextMenu is set to true. The new row added will have the same task information similar to the selected row.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.EnableContextMenu(true)
.EditSettings(edit=>
{
edit.AllowAdding(true);
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



Adding a row programmatically

You can add rows in the below positions dynamically using addRecord public method and we can define the default new record add position by using rowPosition property.

- Top of all the rows
- Bottom to all the existing rows
- Above the selected row
- Below the selected row
- As child to the selected row

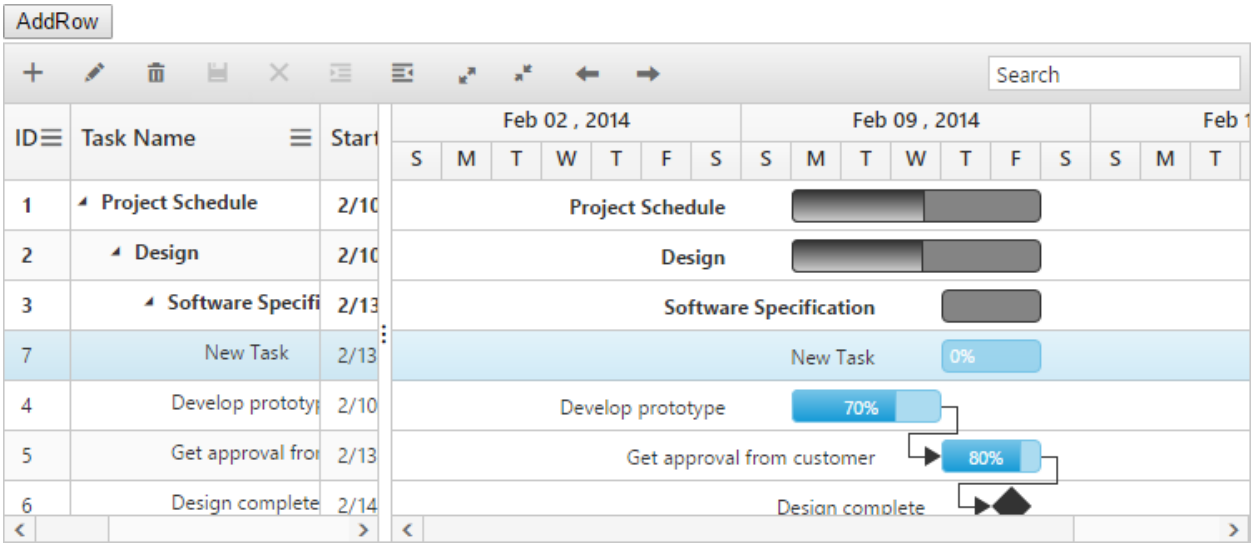
The below code example explains on adding a row using a custom button.

ASPX-CS

```
<button id="addRow"
style="top:27px;left:50px;position:absolute">AddRow</button>
@(Html.EJ().Gantt("GanttContainer")
//...
)
@(Html.EJ().ScriptManager())
$("#addRow").click(function(args) {
//Create Gantt object
var ganttObj = $("#GanttContainer").data("ejGantt");
// data to be added
var data = {
taskID: 7,
taskName: "New Task",
startDate: "02/13/2014",
endDate: "02/14/2014",
duration: 2
};
ganttObj.addRecord(data, ej.Gantt.AddRowPosition.Child);
})
```

The following screen shot shows to add new row as child.

Copyright © 2001 - 2020 Syncfusion Inc.



Note: While adding a new record ActionComplete event will be triggered with arguments addedRecord value as new record and requestType value as save, using this event we can update new record information in server database.

Row drag and drop

It is possible to dynamically re-arrange the rows in the Gantt control by using the AllowDragAndDrop property. With this property, row drag and drop can be enabled or disabled. Rows can be inserted above, below as a sibling or as a child to the existing row with the help of this feature. A default tooltip is rendered while dragging the Gantt row and this tooltip can be customized by the DragTooltip property. This property has inner properties such as ShowTooltip, TooltipItems and TooltipTemplate.

The ShowTooltip property is used to enable or disable the tooltip. By default, this property value is false.

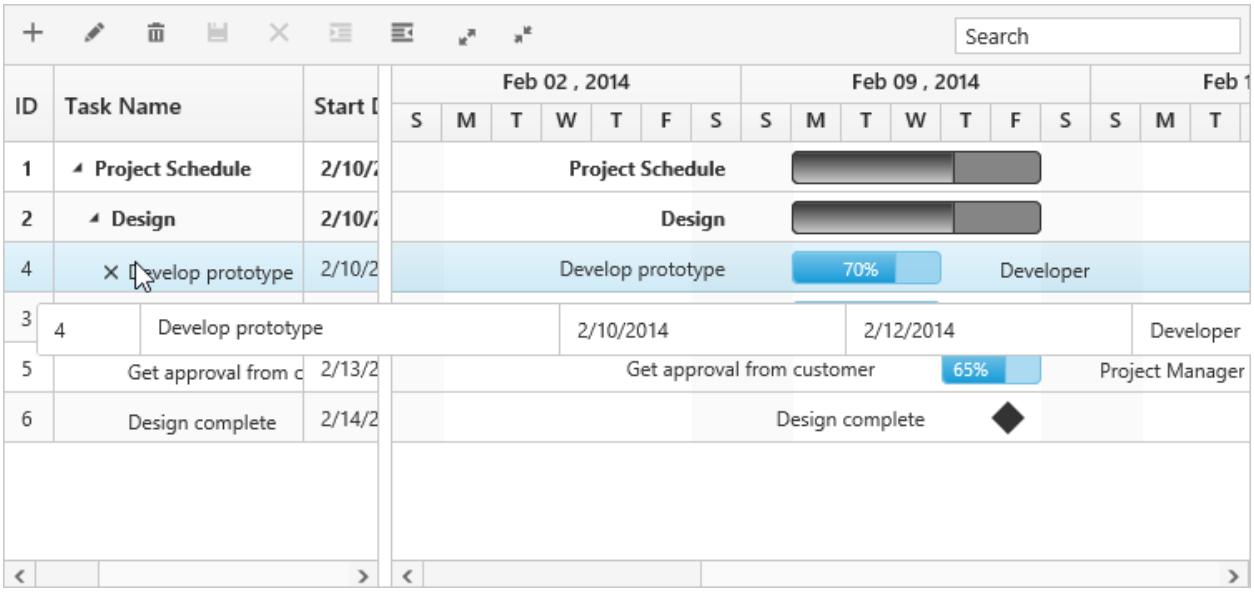
The following code explains about enabling the row drag and drop with the default tooltip in the Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowDragAndDrop(true)
.DragTooltip(dt =>
{
dt.ShowTooltip(true);
})
)
@(Html.EJ().ScriptManager())
```

The following screenshot depicts a row drag and drop in the Gantt widget.

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the online demo sample for row drag and drop in Gantt.

Customizing drag tooltip

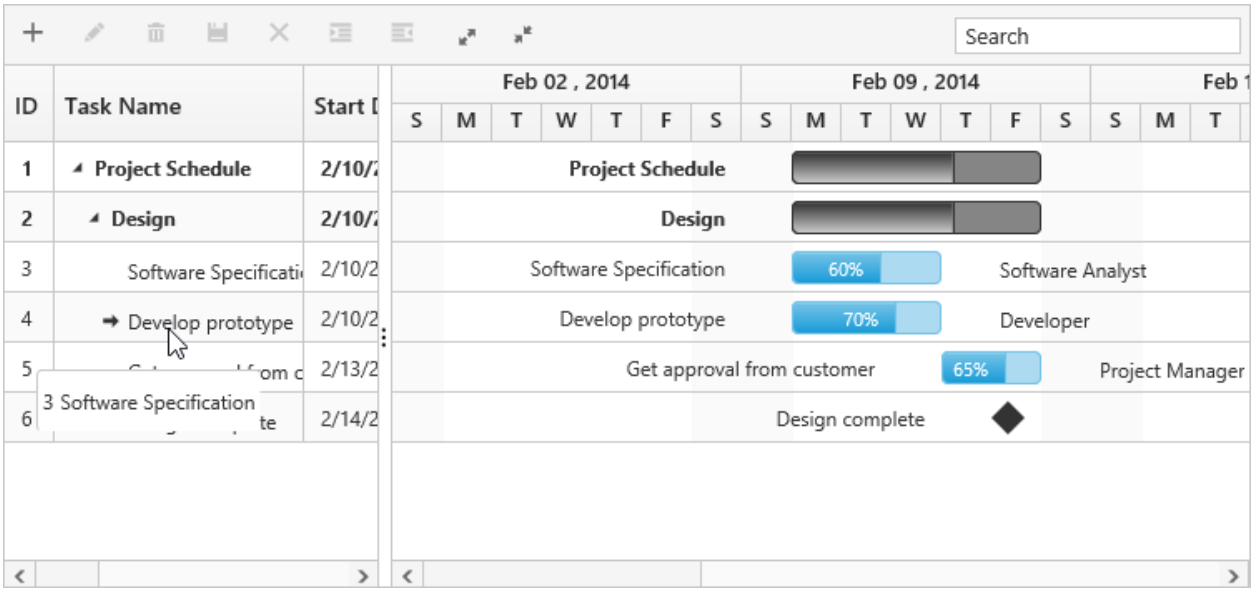
The TooltipItems property is used to customize the tooltip items. By using this property, specific fields can be rendered in the tooltip. By default this property value is null, and all the defined field items are rendered in the tooltip.

The TooltipTemplate property renders the template tooltip for row drag and drop in the Gantt control by using the JsRender template. You can provide either the id value of the script element or the script element to the property.

The following code shows how to render row drag tooltip with tooltip template.

ASPX-CS

```
<script id="customTooltip" type="text/x-jsrender">
<tr>
<td class="border" style='height:30px;'>
<div>{{"{{"}}:#data['TaskId'] {{}}}}</div>
</td>
<td class="border" style='height:30px;'>
<div>{{"{{"}}:#data['TaskName'] {{}}}}</div>
</td>
</tr>
</script>
@(Html.EJ().Gantt("Gantt")
//...
.AllowDragAndDrop(true)
.DragTooltip(dt =>
{
dt.ShowTooltip(true);
dt.TooltipTemplate("#customTooltip");
})
)
@(Html.EJ().ScriptManager())
```



Customize row drag and drop action

In Gantt, RowDragStart, RowDrag and RowDragStop events are triggered on row drag and drop action. Using this event we can prevent drag and drop action of particular task and validate the drop position on particular row. The below code example shows how to use this events.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowDragAndDrop(true)
.ClientSideEvents(eve =>
{
eve.RowDrag("rowDrag");
eve.RowDragStart("rowDragStart");
eve.RowDragStop("rowDragStop");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function rowDrag(args) {
if (args.targetRow.taskId == 5 && args.dropPosition == "insertAsChild") //
Can't drop task as child on Task Id 5
args.canDrop = false;
}
function rowDragStart(args) {
if (args.draggedRow.taskId == 6) // Task Id 6 can't be dragged
args.cancel = true;
}
function rowDragStop(args) {
if (args.targetRow.taskId == 6) // Can't drop any task on Task Id 6
args.cancel = true;
}
```

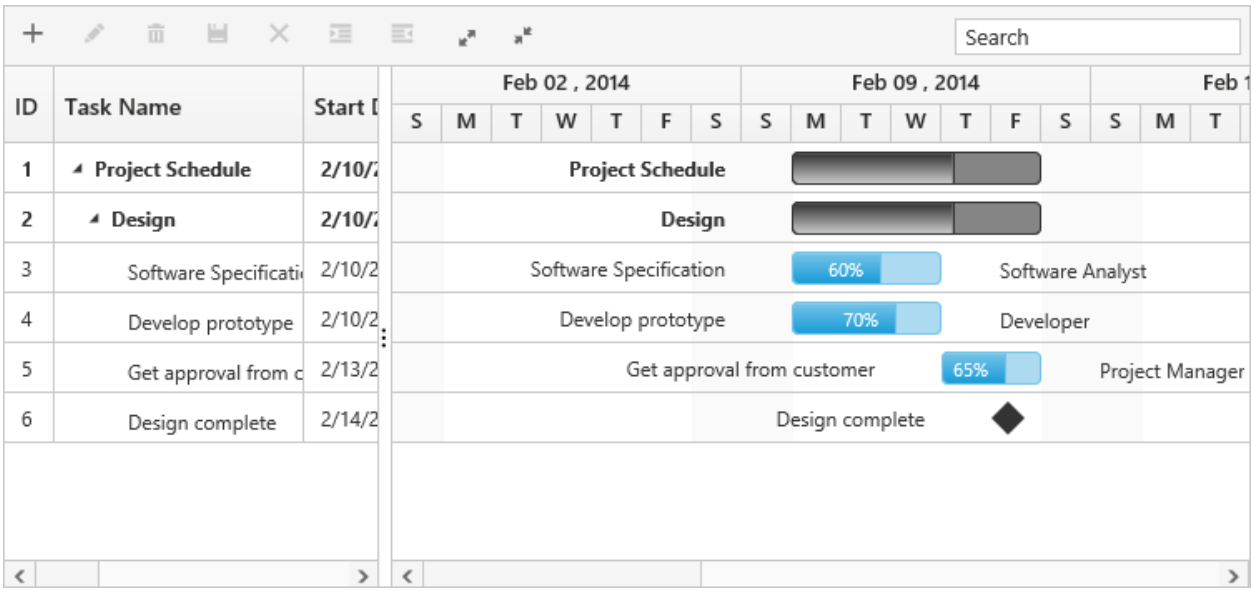
Copyright © 2001 - 2020 Syncfusion Inc.

Alternate row background

In Gantt, it is possible to enable or disable the alternate row background using the EnableAltRow property. The following code example shows you to disable the alternate row color in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EnableAltRow(false)
)
@(Html.EJ().ScriptManager())
```



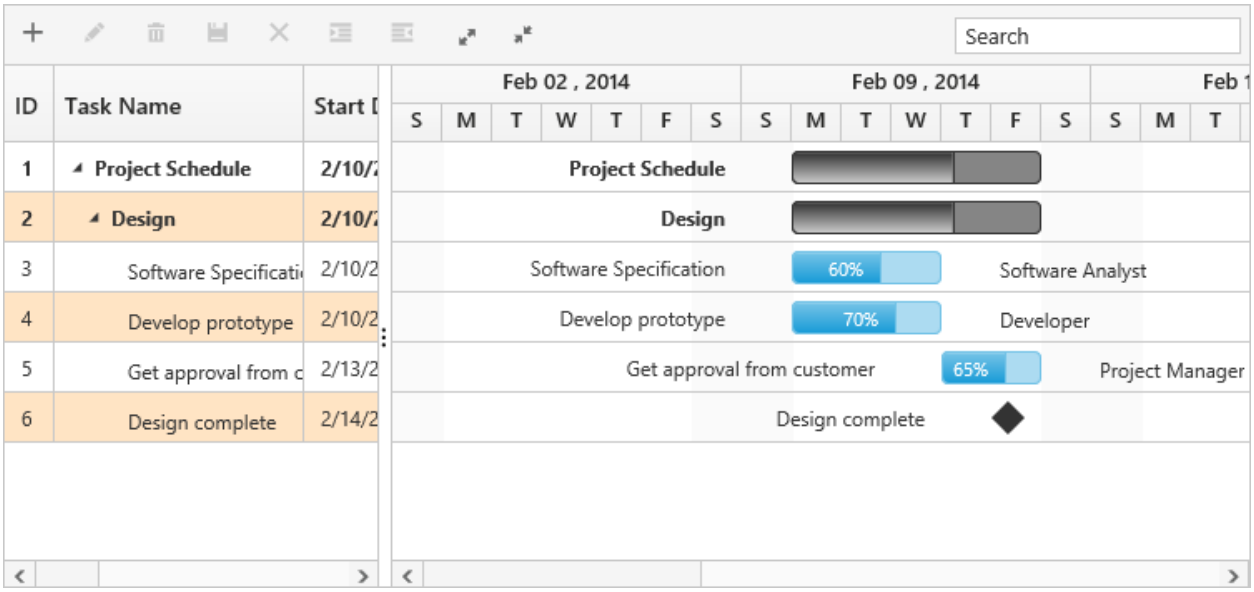
Change alternate rows background

The alternate rows background can be changed by setting the background color for the alternate row elements using CSS. The following code example shows you how to change the alternate rows background color in Gantt.

ASPX-CS

```
<head>
<style>
.e-treegrid .e-alt-row {
background-color: Bisque;
}
</style>
</head>
@(Html.EJ().Gantt("Gantt")
//...
.EnableAltRow(true)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

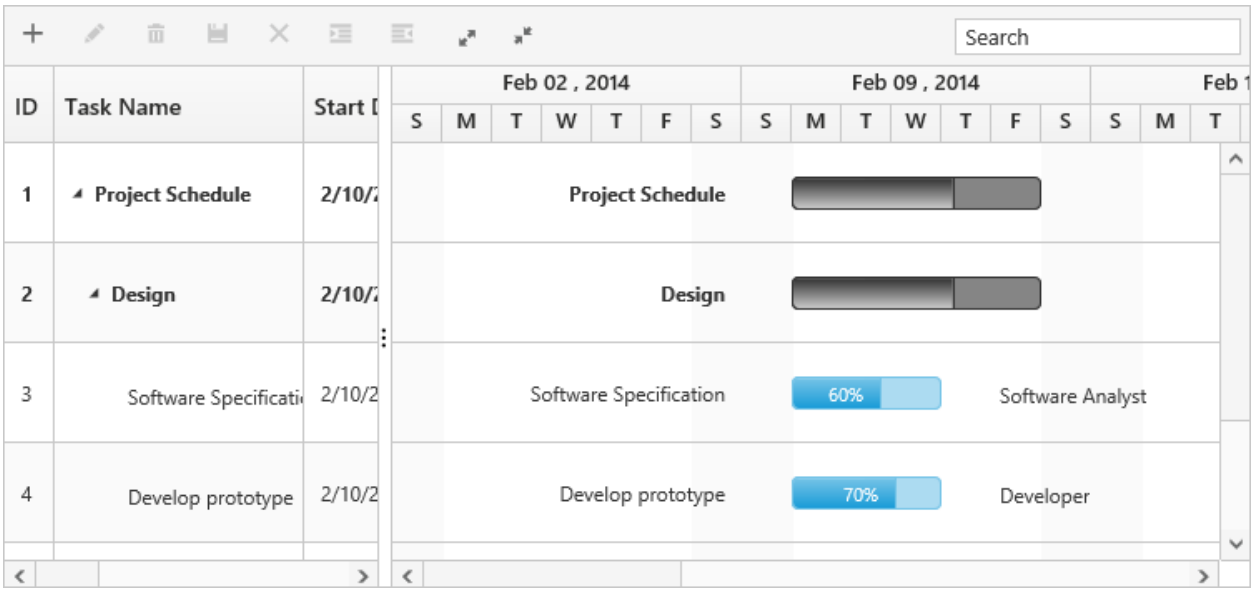


Row height

It is possible to change the height of the row in Gantt by setting row height in pixels to the RowHeight property. The following code example explains how to change the row height in Gantt at load time.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.RowHeight(60)
)
@(Html.EJ().ScriptManager())
```



Copyright © 2001 - 2020 Syncfusion Inc.

Expand/Collapse Row

In Gantt parent tasks are expanded/collapsed by using expand/collapse icons, expand all/collapse all toolbar items and by using public methods. By default all tasks in Gantt was rendered in expanded state but we can change this status in Gantt.

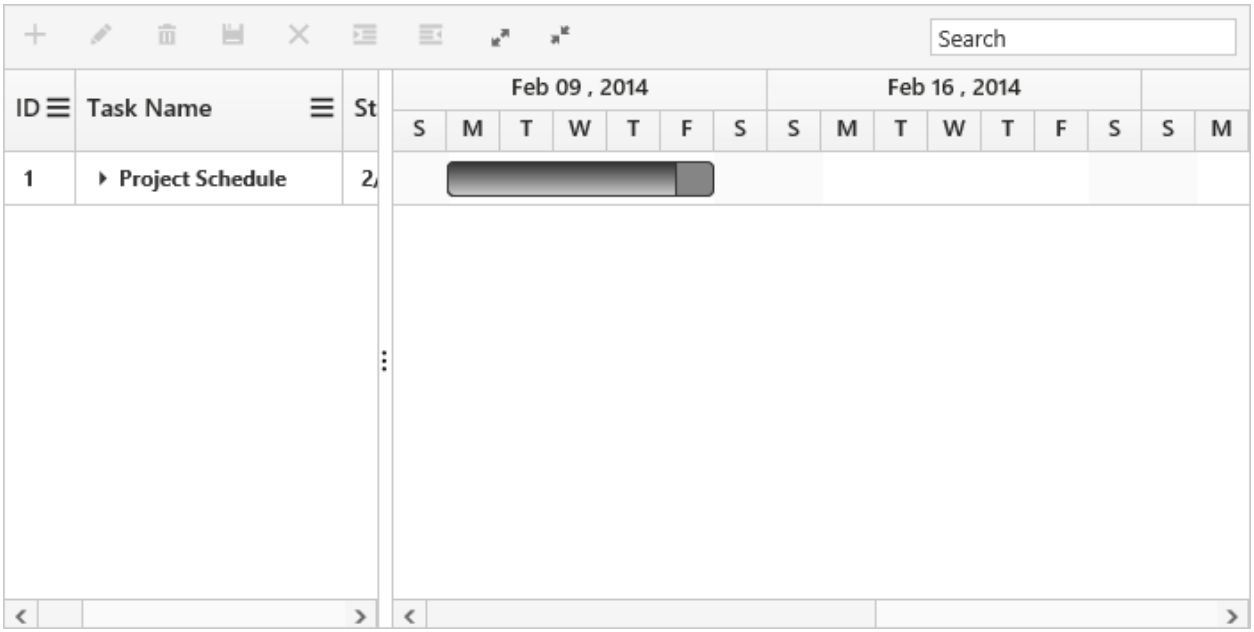
Collapse all tasks at Gantt load

All tasks available in Gantt was rendered in collapsed state by setting `EnableCollapseAll` property as `true`. The following code example shows how to use this property.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EnableCollapseAll(true)
)
@(Html.EJ().ScriptManager())
```

The below screenshot shows the output of above code example.



Define expand/collapse status of tasks at Gantt load

In Gantt, we can render some tasks in collapsed state and some tasks in expanded state, this can done by defining expand status of the task in data source. This value was mapped to Gantt control by using `ExpandStateMapping` property. The following code example shows how to use this property.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.ExpandStateMapping("ExpandState")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

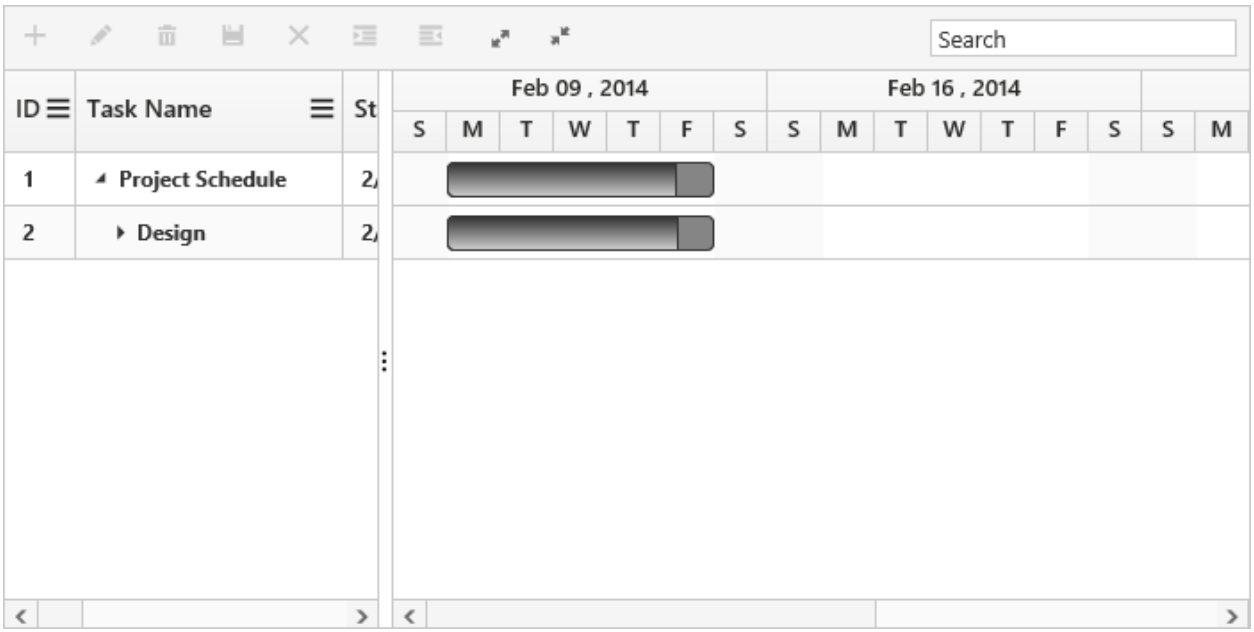
C#

Copyright © 2001 - 2020 Syncfusion Inc.

```
public class GanttController : Controller
{
//
// GET: /Default/
public ActionResult Default()
{
var DataSource = GanttDefaultData.GetData();
ViewBag.datasource = DataSource;
return View();
}
public class GanttDefaultData
{
public static List<DefaultData> GetData()
{
List<DefaultData> list = new List<DefaultData>();
list.Add(new DefaultData()
{
Id = 1,
Name = "Project Schedule",
ExpandState = true,
Children = (new List<DefaultData>()
{
new DefaultData()
{
Id = 2,
Name = "Design",
ExpandState = false,
},
//..
})
});
return list;
}
}
}
```

The below screenshot shows the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Expand/Collapse the task dynamically

Gantt tasks can be expanded/collapsed dynamically by using expandCollapseRecord method. The following code example shows how to use this method.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#expandCollapseTask").click(function () {
var ganttObj = $("#GanttContainer").ejGantt("instance");
ganttObj.expandCollapseRecord(2);
});
</script>
```

Note: This method was used to toggle the expand status of Gantt task, when we pass the id of task which is in expanded state to this method and this task will be collapsed, similarly collapsed task will be expanded.

Expand/Collapse all the tasks dynamically

All the tasks in Gantt will be expanded/collapsed by clicking expandAll and collapseAll toolbar items or by using expandAllItems and collapseAllItems methods. We can invoke this methods dynamically on any action like external button click. The below code example shows how to use this methods.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.ToolbarSettings(ts =>
{
ts.ShowToolbar(true);
ts.ToolbarItems(new List<GanttToolBarItems>()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
//..
GanttToolBarItems.ExpandAll,
GanttToolBarItems.CollapseAll
});
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#expandAllTasks").click(function () {
var ganttObj = $("#GanttContainer").ejGantt("instance");
ganttObj.expandAllItems();
});
$("#collapseAllTasks").click(function () {
var ganttObj = $("#GanttContainer").ejGantt("instance");
ganttObj.collapseAllItems();
});
</script>
```

Customize expand/collapse action

On expand action Expanding and Expanded event will be triggered with current expanding row's information. Similarly on collapse action Collapsing and Collapsed event will be triggered. Using this events and it's arguments we can customize the expand/collapse action. The following code example shows how to prevent the particular row from expand/collapse action using Expanding and Collapsing event.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.ExpandStateMapping("ExpandState")
.ClientSideEvents(eve =>
{
eve.Expanding("expanding");
eve.Collapsing("collapsing");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function expanding(args) {
if (args.data.taskId == 2) // we can't expand Task Id 2
args.cancel = true;
}
function collapsing(args) {
if (args.data.taskId == 1) // we can't collapse Task Id 1
args.cancel = true;
</script>
```

Task Dependencies

Task dependencies or task relationship can be established between two task in Gantt. This dependencies effect the project schedule, if we change the predecessor of one task it will affect the successor task, which effect next task and so on.

Copyright © 2001 - 2020 Syncfusion Inc.

Task Relationship Types

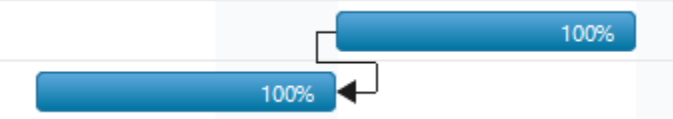
Task relationships are categorized into four types based on the start and finish date of the task.

Start to Start(SS)

You cannot start a task until the other task also starts.

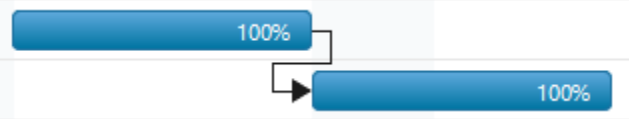
Start to Finish(SF)

You cannot finish a task until the other task is started.



Finish to Start(FS)

You cannot start a task until the other task is completed.



Finish to Finish(FF)

You cannot finish a task until the other task is completed.

Define task relationship

Task relationships are defined in data source as string value and this values are mapped to Gantt control by using PredecessorMapping property. The following code example shows you how to enable the predecessor in the Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.PredecessorMapping("Predecessor")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

C#

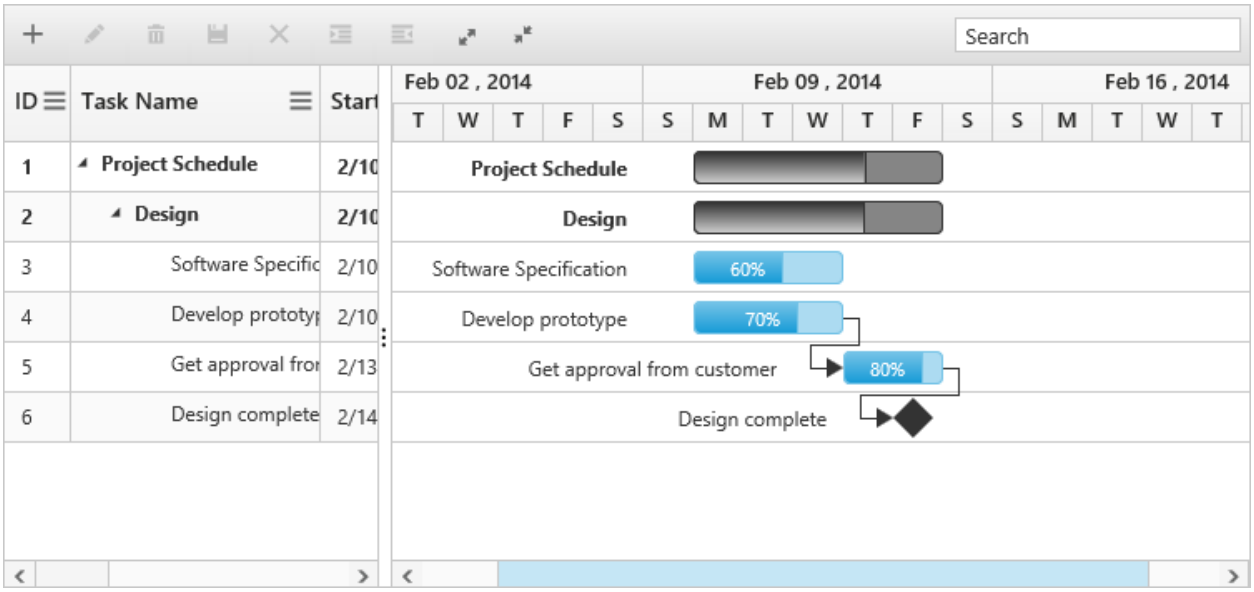
```
public class GanttController : Controller
{
//
// GET: /Default/
public ActionResult Default()
{
var DataSource = GanttDefaultData.GetData();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
ViewBag.datasource = DataSource;
return View();
}
public class GanttDefaultData
{
public static List<DefaultData> GetData()
{
List<DefaultData> list = new List<DefaultData>();
list.Add(new DefaultData()
{
//..
Children = (new List<DefaultData>()
{
new DefaultData()
{
Id = 4,
Name = "Develop prototype"
},
new DefaultData()
{
Id = 5,
Name = "Get approval from customer",
Predecessor: "4FS",
},
new DefaultData()
{
Id = 6,
Name = "Design complete",
Predecessor: "5FS",
},
//..
})
});
return list;
}
}
}
```

The following screenshot displays the output of the above code.

Copyright © 2001 - 2020 Syncfusion Inc.



Task relationship

Predecessor offset with duration units

In Gantt, predecessor offset can be defined with the following duration units.

- Day
- Hour
- Minute

We can define offset with various offset duration units for predecessors by using the below code example.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.PredecessorMapping("Predecessor")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

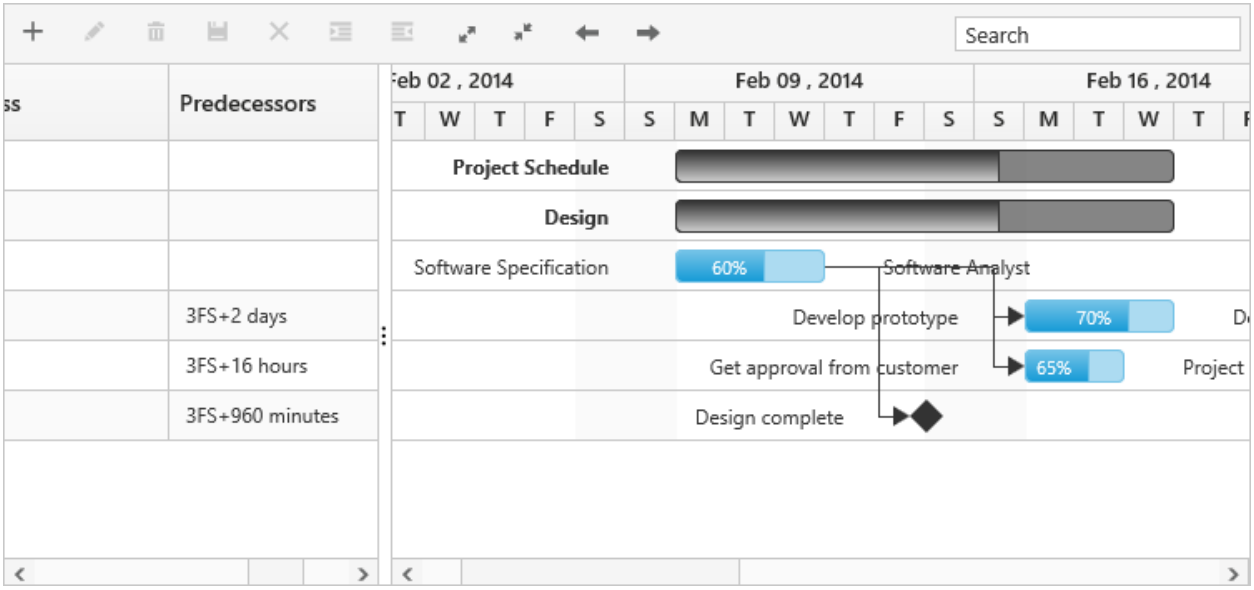
C#

```
public class GanttController : Controller
{
//
// GET: /Default/
public ActionResult Default()
{
var DataSource = GanttDefaultData.GetData();
ViewBag.datasource = DataSource;
return View();
}
public class GanttDefaultData
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public static List<DefaultData> GetData()
{
List<DefaultData> list = new List<DefaultData>();
list.Add(new DefaultData()
{
//..
Children = (new List<DefaultData>()
{
new DefaultData()
{
//..
Predecessor: "3FS+2d",
},
new DefaultData()
{
//..
Predecessor: "3FS+16h",
},
new DefaultData()
{
//..
Predecessor: "3FS+960m",
},
//..
})
});
return list;
}
}
}
```

The following screen shot depicts the duration unit support in the predecessor offset.



Copyright © 2001 - 2020 Syncfusion Inc.

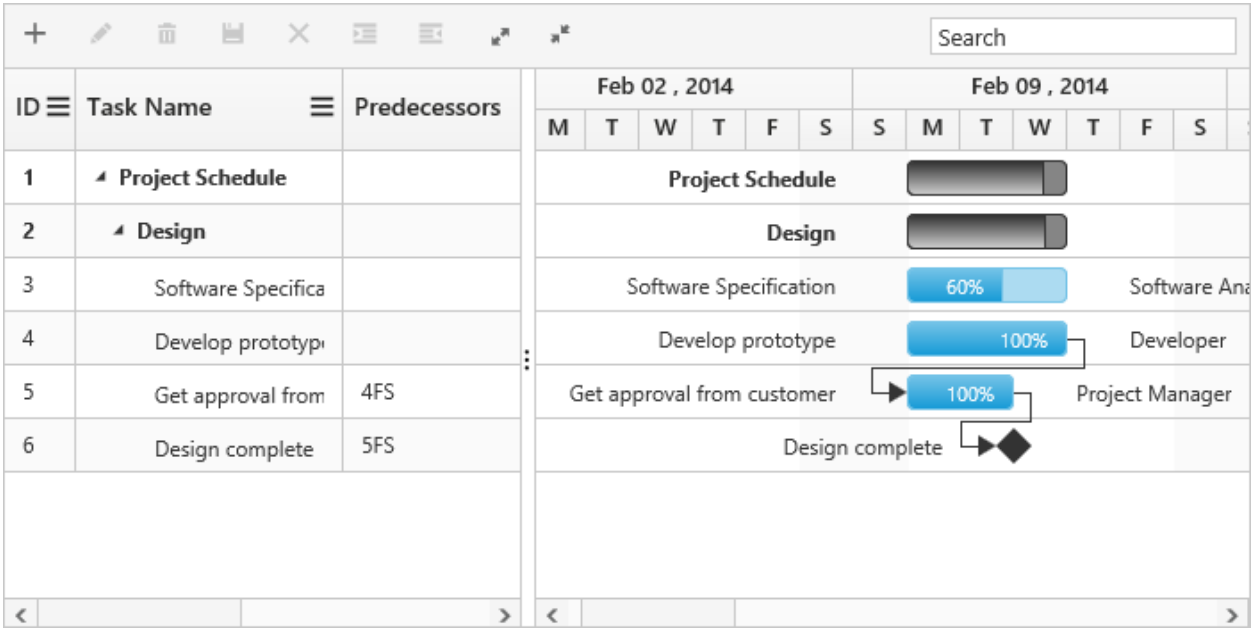
Enable/disable predecessor validation

By default Gantt tasks date values are validated as per predecessor task and it's relationship type, we can disable/enable this validation by using `EnablePredecessorValidation` property. The following code example shows how to disable predecessor validation in Gantt.

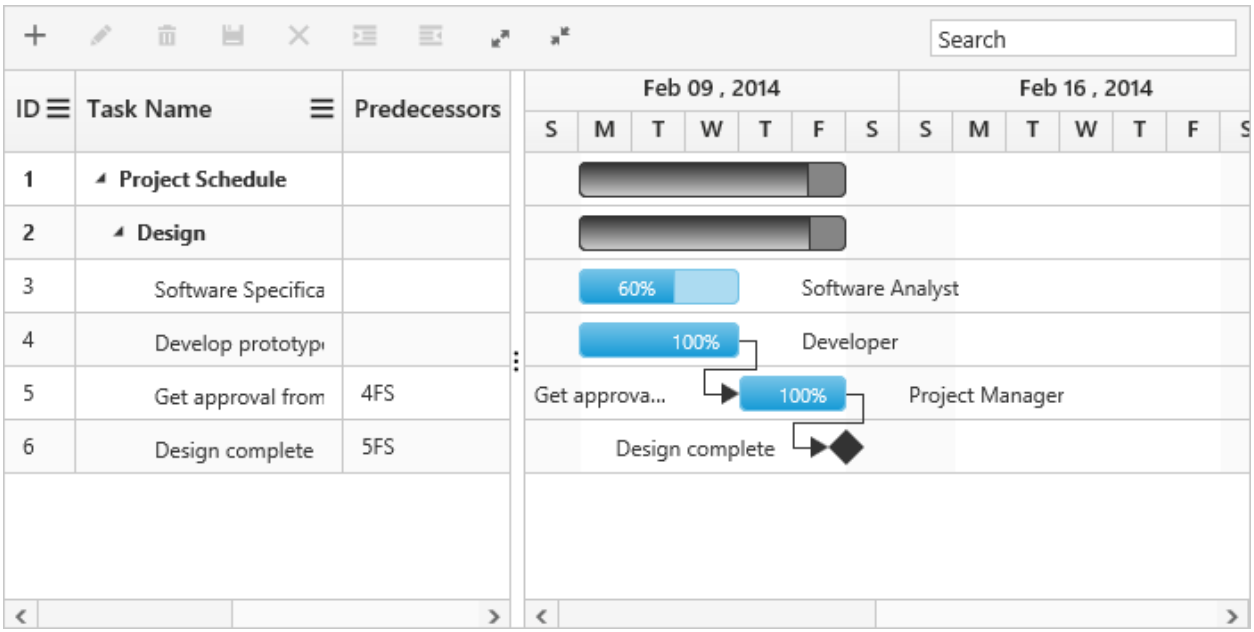
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EnablePredecessorValidation(false)
.PredecessorMapping("Predecessor")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The below screenshot shows the output of above code example.



Predecessor validation disabled mode



Predecessor validation enabled mode

Validate predecessor links on editing

In Gantt, it is possible to validate the taskbar editing based on the predecessor connections. Below are the following ways to validate the taskbar editing.

- Using ActionBegin event
- Using Validation dialog

Using ActionBegin event

The ActionBegin event with requestType argument as **validateLinkedTask** will be triggered when editing a task with predecessor links.

It is possible to validate the editing within the ActionBegin event using the **validateMode** event argument. The validateMode event argument has the following properties.

Argument	Default value	Description
args.validateMode.respectLink	false	In this validation mode, the predecessor links will be considered as high priority. With this mode enabled, when the successor task is moved before predecessor task's end date, the editing will be reverted and dates will be validated based on the dependency links.
args.validateMode.removeLink	false	In this validation mode, the taskbar editing will be considered as high priority, where in the case of inappropriate task dates the dependency links will be removed and tasks will be moved to the edited date.

Copyright © 2001 - 2020 Syncfusion Inc.

args.validateMode.preserveLinkWithEditing	true	In this validation mode, taskbar editing will be considered along with the dependency links. There will be no validations in task editing.

By default, the **preserveLinkWithEditing** validation mode will be enabled thus the validations will not occur when editing the linked tasks.

The below code snippet explains enabling the **respectLink** validation mode while editing the linked tasks in the ActionBegin event.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.ClientSideEvents(eve =>
{
eve.ActionBegin("actionBegin");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function actionBegin(args) {
if (args.requestType == "validateLinkedTask") {
args.validateMode.respectLink = true;
}
}
</script>
```

Using validation dialog

When disabling all the validation modes in the ActionBegin event, a validation popup will be displayed prompting the user to select the validation mode to validate taskbar editing.

This validation popup will display different options based on the successor task's start date after editing.

If the user moved the successor task, that starts after predecessor task's end date then the dialog will be rendered with below options,

- Cancel, Keep the existing link.
- Remove the link and move the task to start on edited date.
- Move the task to start on edited date and keep the link.

If the user moved the successor task, that starts before the predecessor task's end date then the dialog will be rendered with below options.

If the user moved the successor task, that starts before the predecessor task's end date then the dialog will be rendered with below options.

- Cancel, Keep the existing link.
- Remove the link and move the task to start on edited date.

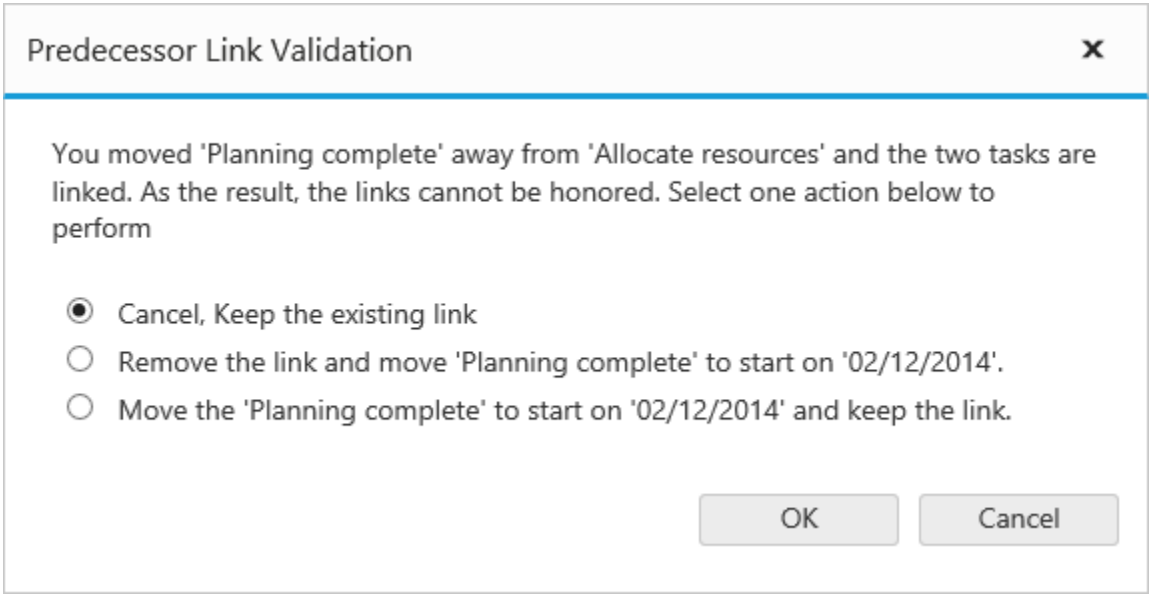
Copyright © 2001 - 2020 Syncfusion Inc.

The following code example explains this.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.ClientSideEvents(eve =>
{
eve.ActionBegin("actionBegin");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function actionBegin(args) {
if (args.requestType == "validateLinkedTask") {
args.validateMode.preserveLinkWithEditing = false;
}
}
</script>
```

In this case, if the user dragging action violated the predecessor type then the following dialog will be rendered to perform operation.



Time Options

Start date and End date in the datasource defines the starting point and ending point of a task in the project. It can be of two data types,

- Date
- Datetime

The datetime data type for start date and end date defines the exact starting point and ending point of a task along with time details of a day. There are two types of time scales available based on working hours,

- TimeScale8Hours for 8 hour working scale
- TimeScale24Hours for 24 hour working scale

Use the following code example for setting different time scales of working hours.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.WorkingTimeScale(GanttWorkingTimeScale.TimeScale24Hours)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Use the following code example for including time options in start date and end date of a task.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.TaskIdMapping("TaskId")
.TaskNameMapping("TaskName")
.StartDateMapping("StartDate")
.DurationMapping("Duration")
.ProgressMapping("Progress")
.DateFormat("M/d/yyyy hh:mm:ss tt")
.ScheduleStartDate("02/01/2014 00:00:00 AM")
.WorkingTimeScale(GanttWorkingTimeScale.TimeScale24Hours)
.ScheduleEndDate("03/14/2016 00:00:00 PM")
.ChildMapping("SubTasks")
.TreeColumnIndex(1)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

C#

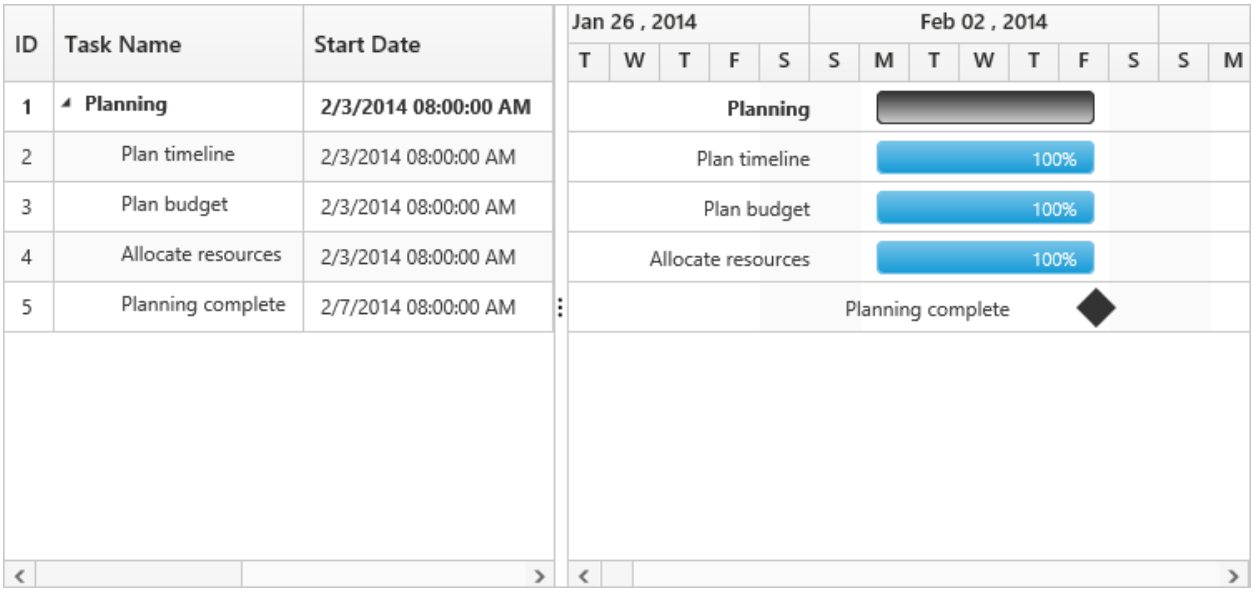
```
public class GanttController : Controller
{
// GET: /Gantt/
public ActionResult Gantt()
{
ViewBag.datasource = this.GetDataSource();
return View();
}
private List<Data> GetDataSource()
{
List<Data> DataCollection = new List<Data>();
Data ParentData = new Data()
{
TaskId = 1,
TaskName = "Planning",
StartDate = "02/03/2014 08:00:00 AM",
EndDate = "02/07/2014 05:00:00 PM",
Duration = 5
};
Data ChildData = new Data()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
TaskId = 2,
TaskName = "Plan timeline",
StartDate = "02/03/2014 08:00:00 AM",
EndDate = "02/07/2014 05:00:00 PM",
Duration = 5,
Progress = "100",
};
ParentData.SubTasks = new List<Data>();
ParentData.SubTasks.Add(ChildData);
ChildData = new Data()
{
TaskId = 3,
TaskName = "Plan Budget",
StartDate = "02/03/2014 08:00:00 AM",
EndDate = "02/07/2014 05:00:00 PM",
Duration = 5,
Progress = "100",
};
ParentData.SubTasks.Add(ChildData);
ChildData = new Data()
{
TaskId = 4,
TaskName = "Allocate Resources",
StartDate = "02/03/2014 08:00:00 AM",
EndDate = "02/07/2014 05:00:00 PM",
Duration = 5,
Progress = "100",
};
ParentData.SubTasks.Add(ChildData);
ChildData = new Data()
{
TaskId = 5,
TaskName = "Planing complete",
StartDate = "02/07/2014 08:00:00 AM",
EndDate = "02/07/2014 05:00:00 PM",
Duration = 0,
};
ParentData.SubTasks.Add(ChildData);
DataCollection.Add(ParentData);
return DataCollection;
}
public class Data
{
public int TaskId { get; set; }
public string TaskName { get; set; }
public string  StartDate { get; set; }
public string  EndDate { get; set; }
public int Duration { get; set; }
public List<Data> SubTasks { get; set; }
public string Progress { get; set; }
}
}
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.



Validating Schedule Dates

Validating schedule dates is used to change the schedule start date and end date dynamically. By this support, ScheduleStartDate and ScheduleEndDate can be automatically updated from the data source. When you change the date of any task item to the date that is beyond ScheduleStartDate or ScheduleEndDate through cell editing, taskbar editing, dialog editing or toolbar operation, then the ScheduleStartDate and ScheduleEndDate can be dynamically updated based on that task item's date.

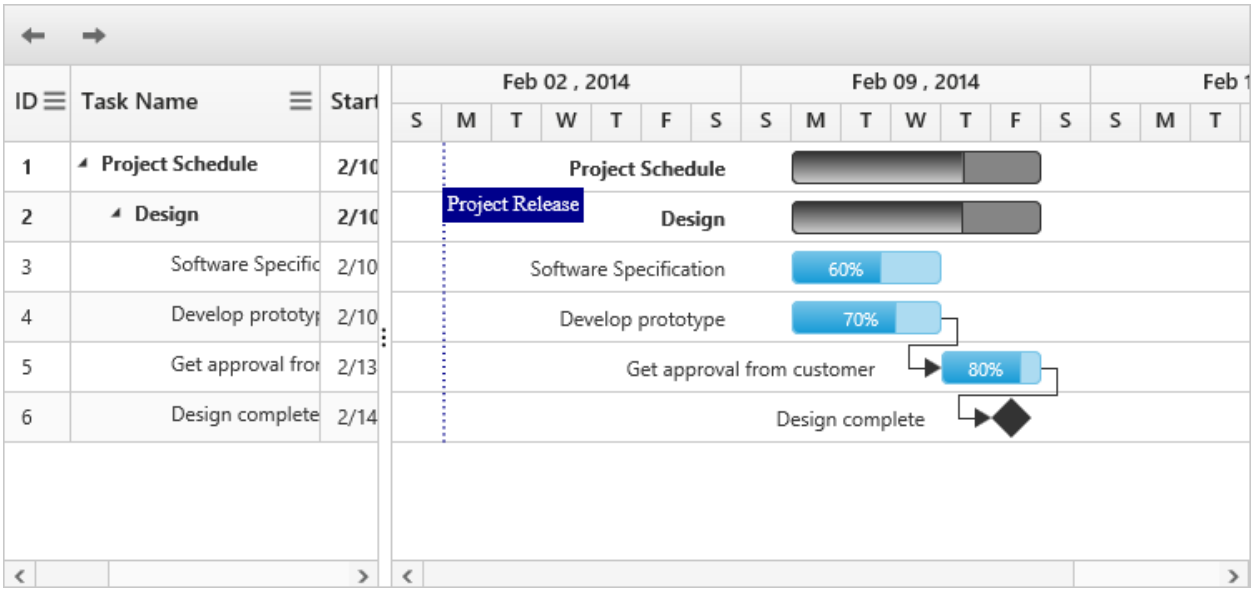
PrevTimeSpan and NextTimeSpan toolbar items are used to create new time span based on the schedule mode.

ASPX-CS

```
@(Html.EJ().Gantt("gantt")
// ...
.ScheduleStartDate("02/01/2014")
.ScheduleEndDate("03/14/2014")
.ToolbarSettings(tbs=>
{
tbs.ShowToolbar(true);
tbs.ToolbarItems(new List<GanttToolBarItems>(){
GanttToolBarItems.PrevTimeSpan,
GanttToolBarItems.NextTimeSpan,
});
})
)
@(Html.EJ().ScriptManager())
```

The following screenshot illustrates the output of the above code.

Copyright © 2001 - 2020 Syncfusion Inc.



Task Scheduling Modes

The Gantt provides support for automatic and manual task scheduling modes. Scheduling mode of a task is used to indicate whether the start and end dates of a task will be automatically validated or not. Using the property TaskSchedulingMode we can able to change the scheduling mode of a task. The following are the enumeration values that can be set to the property TaskSchedulingMode.

- Auto
- Manual
- Custom

Automatically Scheduled Tasks

When the TaskSchedulingMode property is set as Auto scheduling mode, all the tasks in the project will be rendered as automatically scheduled tasks. Thus the start and end dates of the tasks in the project will be automatically validated. The tasks will be automatically scheduled based on the factors such as dependencies between the tasks, non-working days like holidays and weekends. Tasks automatically recalculate the scheduling date when its predecessor task has been affected. But still we can schedule the tasks and reset the start and end dates by manual editing. Summary tasks will also be automatically scheduled, but its start date, end date and duration values cannot be edited manually.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.TaskSchedulingMode(GanttTaskSchedulingMode.Auto)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Note: Automatic scheduling mode is the default task scheduling mode in Gantt.

Copyright © 2001 - 2020 Syncfusion Inc.

Manually Scheduled Tasks

When the TaskSchedulingMode property is set as Manual scheduling mode, all the tasks in the project will be rendered as manually scheduled tasks. Thus the dates of the tasks will not get validated automatically by the system. The tasks will not get rescheduled and dates will not be recalculated automatically based on the factors such as task dependencies and non-working days and hence manual scheduled tasks will lie on weekends and holidays. We can restrict this mode in predecessor editing alone, that is we can make to automatically validate the dates of the manual tasks on predecessor editing by enabling the property ValidateManualTasksOnLinking. By enabling this property, the dates of the manual tasks will recalculate automatically, when its predecessor task's dates have been changed.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.TaskSchedulingMode(GanttTaskSchedulingMode.Manual)
.ValidateManualTasksOnLinking(false)
)
@(Html.EJ().ScriptManager())
```

Custom

When the TaskSchedulingMode property is set as Custom, the scheduling mode for each tasks will be mapped form the data source field. The property TaskSchedulingModeMapping is used to map the scheduling mode field from the data source.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.TaskSchedulingMode(GanttTaskSchedulingMode.Manual)
.ValidateManualTasksOnLinking(false)
)
@(Html.EJ().ScriptManager())
```

C#

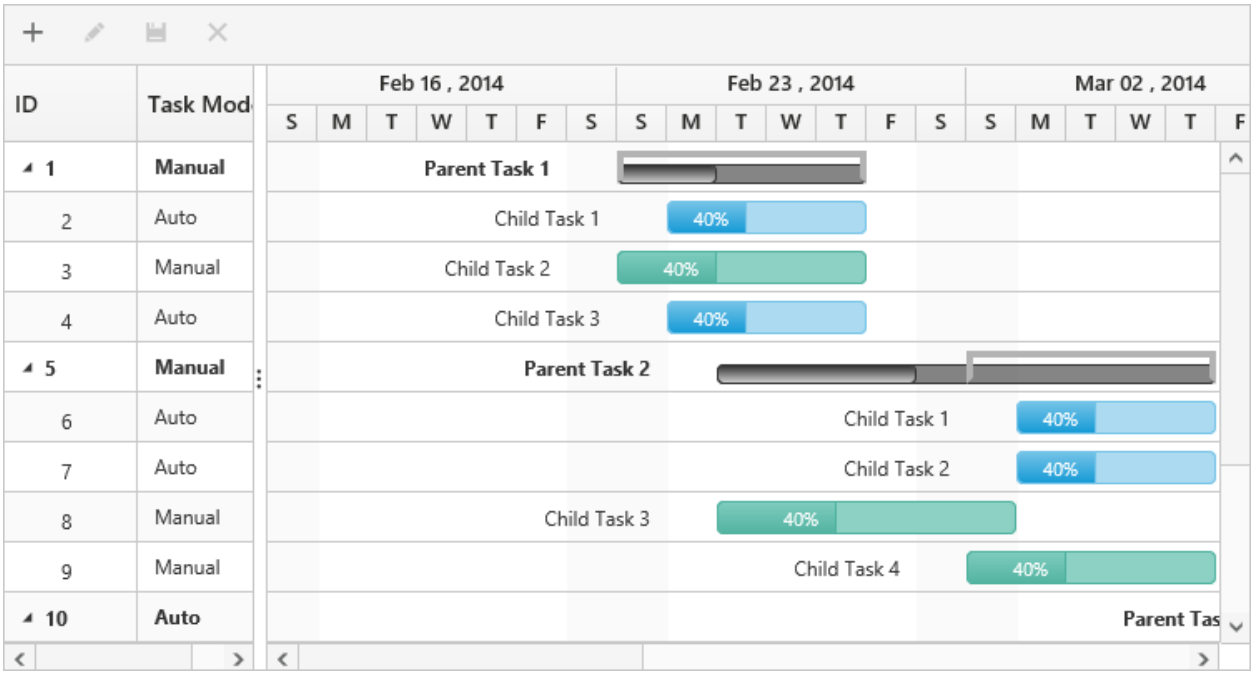
```
public class GanttController : Controller
{
//
// GET: /Default/
public ActionResult Default()
{
var DataSource = GanttDefaultData.GetData();
ViewBag.datasource = DataSource;
return View();
}
public class GanttDefaultData
{
public static List<DefaultData> GetData()
{
List<DefaultData> list = new List<DefaultData>();
list.Add(new DefaultData()
{
Id = 1,
Name = "Design",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
StartDate = "02/10/2014",
EndDate = "02/14/2014",
isManual = true,
Children = (new List<DefaultData>()
{
new DefaultData()
{
Id = 2,
Name = "Software Specification",
StartDate = "02/10/2014",
EndDate = "02/12/2014",
},
new DefaultData()
{
Id = 3,
Name = "Develop Prototype",
StartDate = "02/10/2014",
EndDate = "02/12/2014",
isManual = true,
},
//..
})
});
return list;
}
}
}
```

Click here to view the online demo sample for task scheduling modes.

The following screen shot depicts a project with custom scheduling mode, where both automatic and manual scheduling modes are mapped to the tasks.



Unscheduled Tasks

Unscheduled tasks are planned for a project but do not have definite schedule dates. Now, the Gantt control supports rendering the unscheduled tasks. You can create or update the tasks with anyone of start date, end date and duration values or none. You can enable or disable the unscheduled tasks by using the AllowUnscheduledTask property.

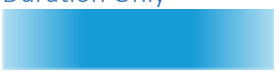
Unscheduled Task Types

Unscheduled tasks have various task types with only either start date, end date or duration.

Start Date Only

End Date Only

Duration Only



Milestone

The milestone task, one without a start and end date, but having a duration value of zero is represented as follows.

Define unscheduled tasks in data source

You can define the various types of unscheduled tasks in the data source as follows.

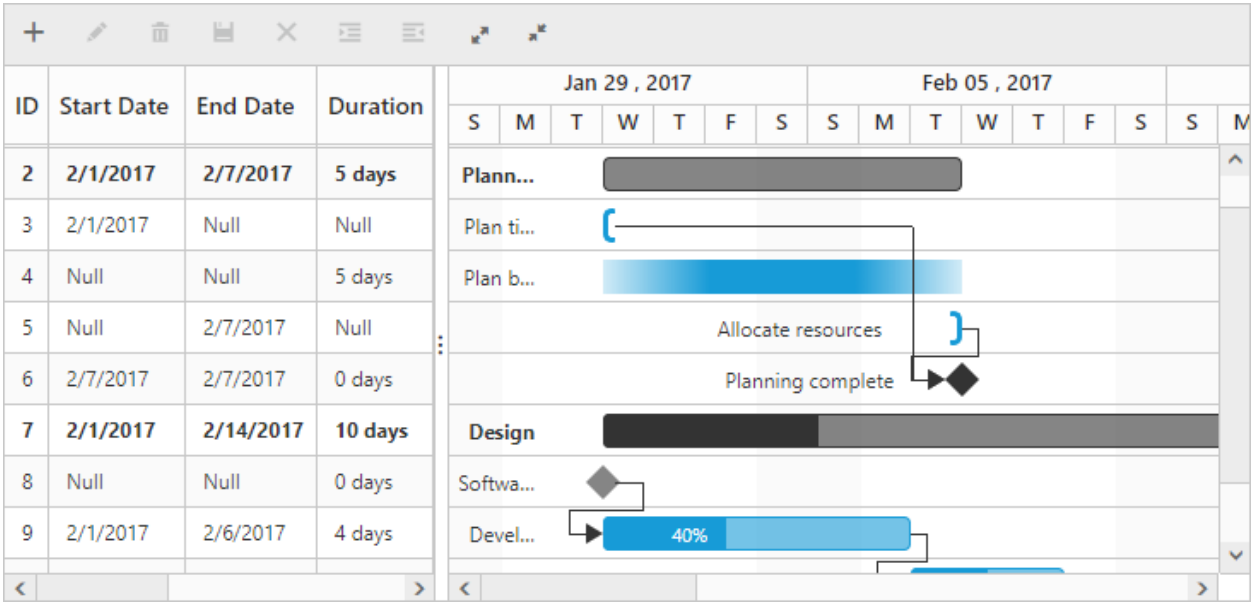
ASPX-CS

```
public List<GanttTaskDetails> GetUnscheduledData()
{
List<GanttTaskDetails> tasks = new List<GanttTaskDetails>();
// Start Date only
tasks[0].SubTasks[0].SubTasks.Add(new GanttTaskDetails()
{
TaskID = 3,
TaskName = "Plan timeline",
StartDate = "02/01/2017",
Duration = null,
EndDate = null,
Progress = "100",
ResourceID = new List<object>() { 1 }
});
//Duration only
tasks[0].SubTasks[0].SubTasks.Add(new GanttTaskDetails()
{
TaskID = 4,
TaskName = "Plan budget",
StartDate = null,
EndDate = null,
Duration = 5,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Progress = "100",
ResourceID = new List<object>() { 5 }
});
//End date only
tasks[0].SubTasks[0].SubTasks.Add(new GanttTaskDetails()
{
TaskID = 5,
TaskName = "Allocate resources",
StartDate = null,
EndDate = "02/7/2017",
Duration = null,
Progress = "100",
ResourceID = new List<object>() { 6 }
});
// Milestone
tasks[0].SubTasks[1].SubTasks.Add(new GanttTaskDetails()
{
TaskID = 8,
TaskName = "Software Specification",
StartDate = null,
EndDate = null,
Duration = 0,
Progress = "60",
ResourceID = new List<object>() { 2 }
});
//...
return tasks;
}
@(Html.EJ().Gantt("GanttContainer")
//... .
.AllowUnscheduledTask(true)
)
@(Html.EJ().ScriptManager())
```

The following screenshot displays the output of the above code.



Copyright © 2001 - 2020 Syncfusion Inc.

Note: If the AllowUnscheduledTask property is set to false for unplanned task, the Gantt control will automatically calculate the scheduled dates with a default value of duration 1 and the project scheduled start date is considered as the start date for the task.

Show/hide null text in Gantt columns

You can show/hide the null text cell value for start date, end date and duration columns by using the showNullText column property. This can be customized in load event of Gantt. You can change the Null string by using the nullText property in the localization text file of the Gantt control. The following code snippets explain this behavior.

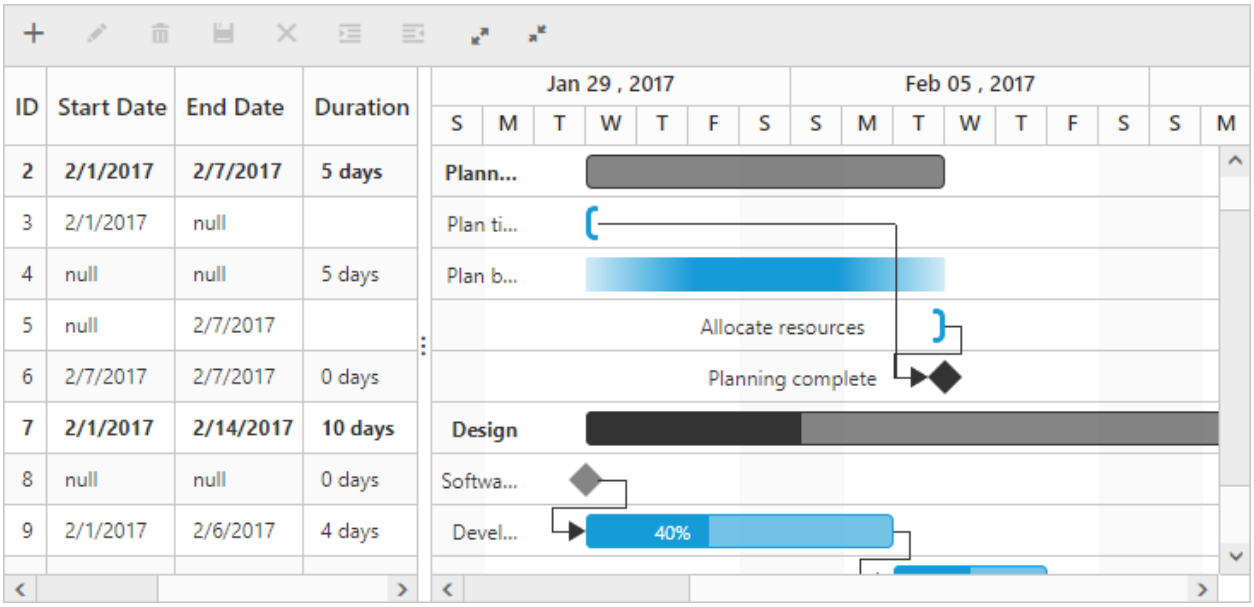
ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//... .
.AllowUnscheduledTask(true)
.ClientSideEvents(eve =>{ eve.Load("loadEvent"); })  // Client-side event
triggered at load time.
)
@(Html.EJ().ScriptManager())
```

JAVASCRIPT

```
function loadEvent(args) {
//…
var columns = this.getColumns();
columns[1].showNullText = true;
columns[2].showNullText = true;
column[3].showNullText = false;
}
ej.Gantt.Locale["en-Us"] = {
nullText: "null"
}
```

The following screenshot displays the output of the above code.



Copyright © 2001 - 2020 Syncfusion Inc.

Context Menu

Default Menu Items

Context menu in Gantt has the following default menu items.

- Task Details
- Add New Task
- Indent
- Outdent
- Delete

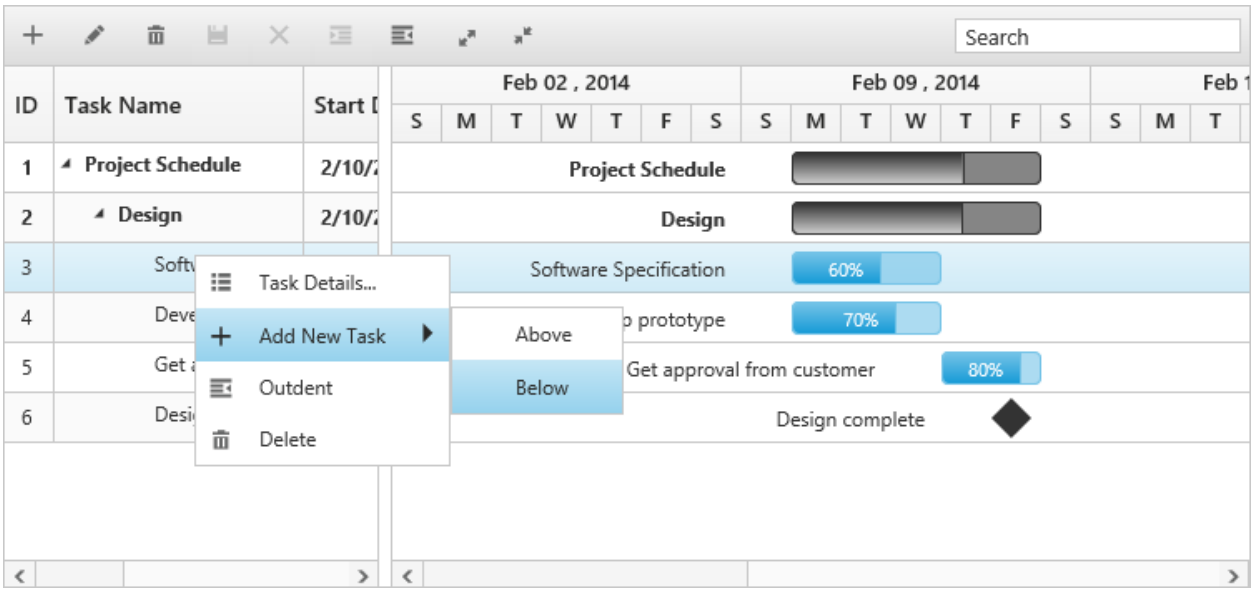
Context menu in Gantt can be enabled by using `EnableContextMenu` property.

The following code example explains how to enable the context menu in Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//.
.EnableContextMenu(true)
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the default context menu in Gantt control.



Custom Menu Item

It is possible to add a custom context menu item in Gantt control by using `ContextMenuOpen` event. The following code example explains on how to add the custom context menu item.

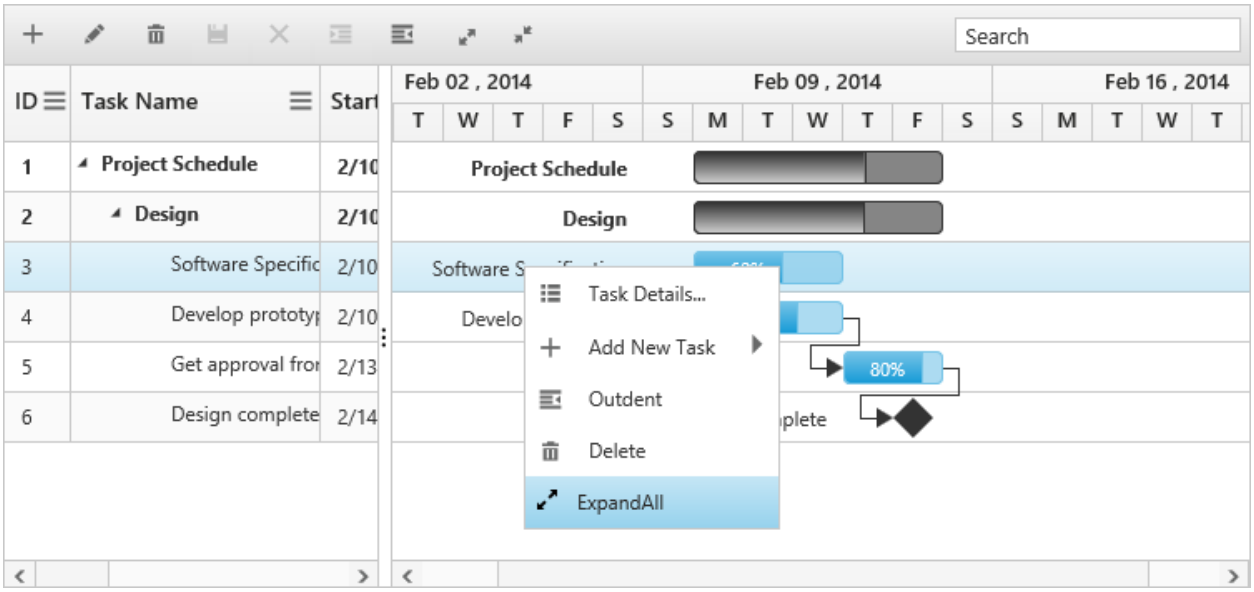
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//..
.EnableContextMenu(true)
.ClientSideEvents(eve=>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
eve.ContextMenuOpen("contextMenuOpen");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function contextMenuOpen(args) {
args.contextMenuItems.push({
headerText: "Expand/Collapse",
menuId: "expand",
iconPath: "url(Expand-02-WF.png)",
eventHandler: function () {
//event handler for custom menu items
}
})
}
</script>
```

The screenshot of the custom context menu items in Gantt control is as follows.



Custom menu item with sub menu item

It is possible to create a custom menu item with a sub menu, by mapping the parentMenuId property from the contextMenuItems argument in the ContextMenuOpen event.

The following code example explains on how to add sub context menu for custom menu items.

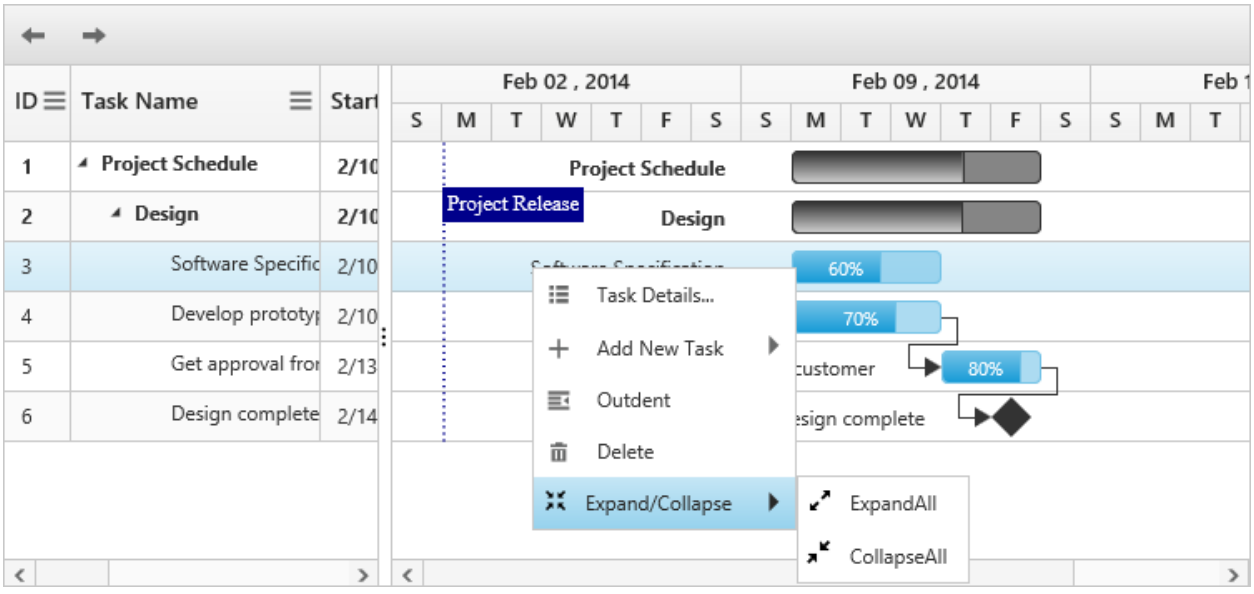
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//..
.EnableContextMenu(true)
.ClientSideEvents(eve=>
{
eve.ContextMenuOpen("contextMenuOpen");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
args.contextMenuItems.push({
headerText: "Expand/Collapse",
menuId: "expand",
iconPath: "url(Navigation-Up-02-WF.png)",
eventHandler: function () {
//event handler for custom menu items
}
});
args.contextMenuItems.push({
headerText: "ExpandAll",
menuId: "expandAll",
parentMenuId: "expand",
iconPath: "url(Expand-02-WF.png)",
eventHandler: function () {
//event handler for custom menu items
}
});
args.contextMenuItems.push({
headerText: "CollapseAll",
menuId: "collapseAll",
parentMenuId: "expand",
iconPath: "url(shrink2.png)",
eventHandler: function () {
//event handler for custom menu items
}
});
}
</script>
```

The screenshot of the custom context menu items in Gantt control is as follows.



Click here to view the online demo sample for custom context menu in Gantt.

Customizations

Gantt provides support for the following UI customizations,

- Taskbar template
- Task label template
- Tooltip template

Taskbar template

You can design your own taskbars to view the tasks in Gantt by using TaskbarTemplate property. And it is possible to map the JsRender script or script element's ID to this property. It is also possible to customize the parent taskbars and milestones with custom templates by using ParentTaskbarTemplate and MilestoneTemplate properties.

The following code example shows how to define template for taskbars in Gantt.

ASPX-CS

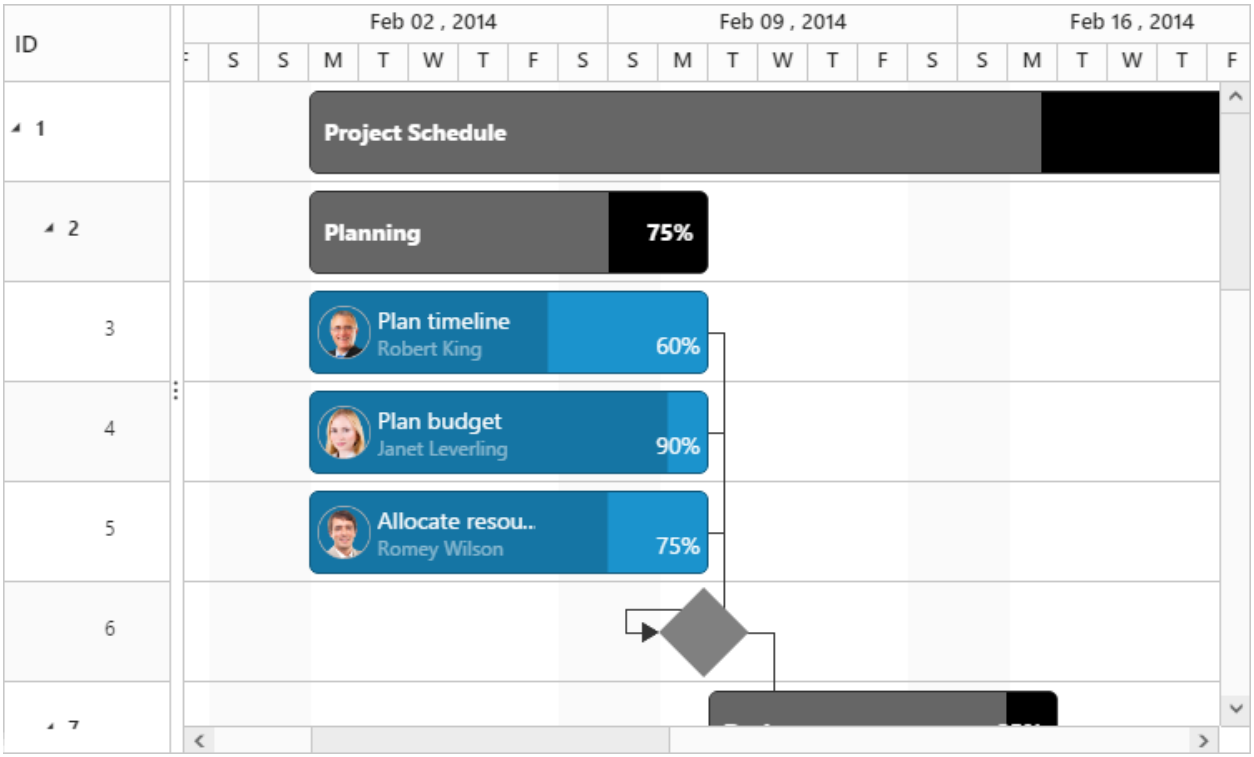
```
<script type="text/x-jsrender" id="taskbarTemplate">
<div class="e-gantt-template-taskbar bg-color">
<div>
//…
</div>
<div class="e-gantt-template-progressbar">
</div>
</div>
</script>
<script type="text/x-jsrender" id="parentTaskbarTemplate">
<div class="e-gantt-template-taskbar">
//…
<div class="e-gantt-template-progressbar">
</div>
</div>
</script>
<script type="text/x-jsrender" id="milestoneTemplate">
<div class="e-gantt-template-milestone" style="background-
color:transparent;">
<div class="e-gantt-milestone milestone-top"></div>
<div class="e-gantt-milestone milestone-bottom"></div>
</div>
</script>
@(Html.EJ().Gantt("Gantt")
//...
.TaskbarTemplate("#taskbarTemplate")
.ParentTaskbarTemplate("#parentTaskbarTemplate")
.MilestoneTemplate("#milestoneTemplate")
)
@(Html.EJ().ScriptManager())
```

The DOM structure and class names mentioned in the above code snippet is mandatory for providing the editing support in custom templates.

Click here to view the online demo sample for Taskbar templates in Gantt.

The following screenshot shows the template for taskbars in Gantt.

Copyright © 2001 - 2020 Syncfusion Inc.



Task label template

By default, task name will be displayed to the left and resource names will be displayed to the right of the taskbars as task labels. We can enable/disable this default task labels by using ShowTaskNames and ShowResourceNames properties. But these task labels are customizable.

Mapping data source fields as task labels

It is also possible to set any data source fields as task labels using RightTaskLabelMapping and LeftTaskLabelMapping properties.

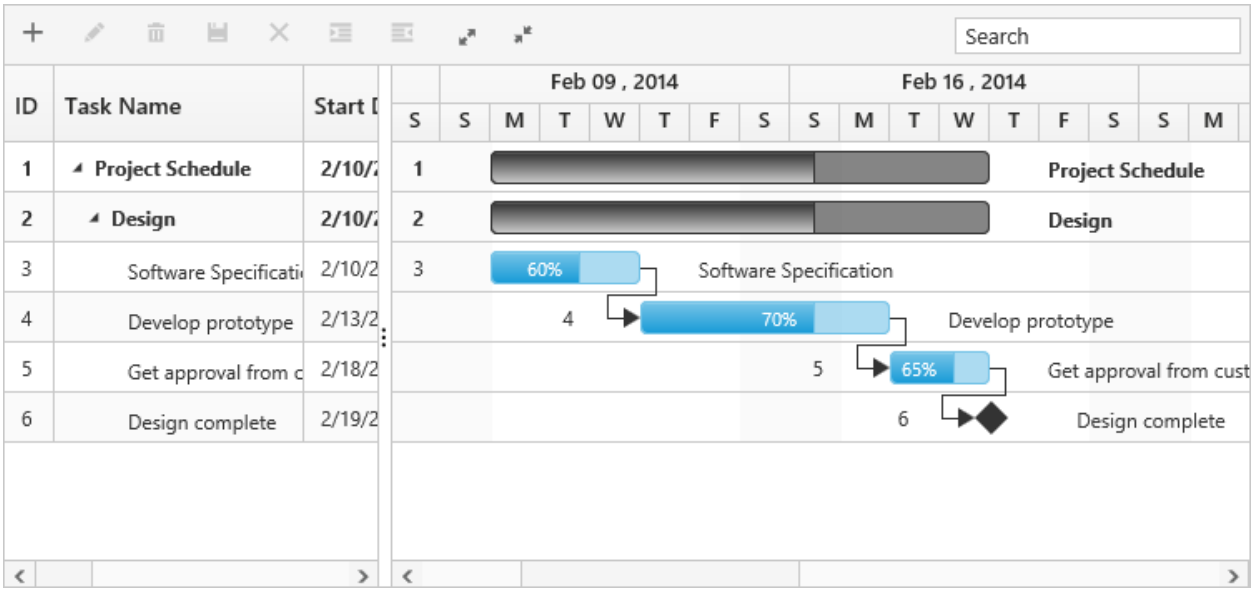
The following code example explains how to set task name field as right label and task ID field as left label,

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.LeftTaskLabelMapping("TaskName")
.RightTaskLabelMapping("TaskID")
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows Gantt with task labels mapped with different data source fields

Copyright © 2001 - 2020 Syncfusion Inc.



Task label templates

It is possible to customize the task labels with templates, by using RightTaskLabelTemplate and LeftTaskLabelTemplate properties. The following code example explains how to map custom templates to task labels.

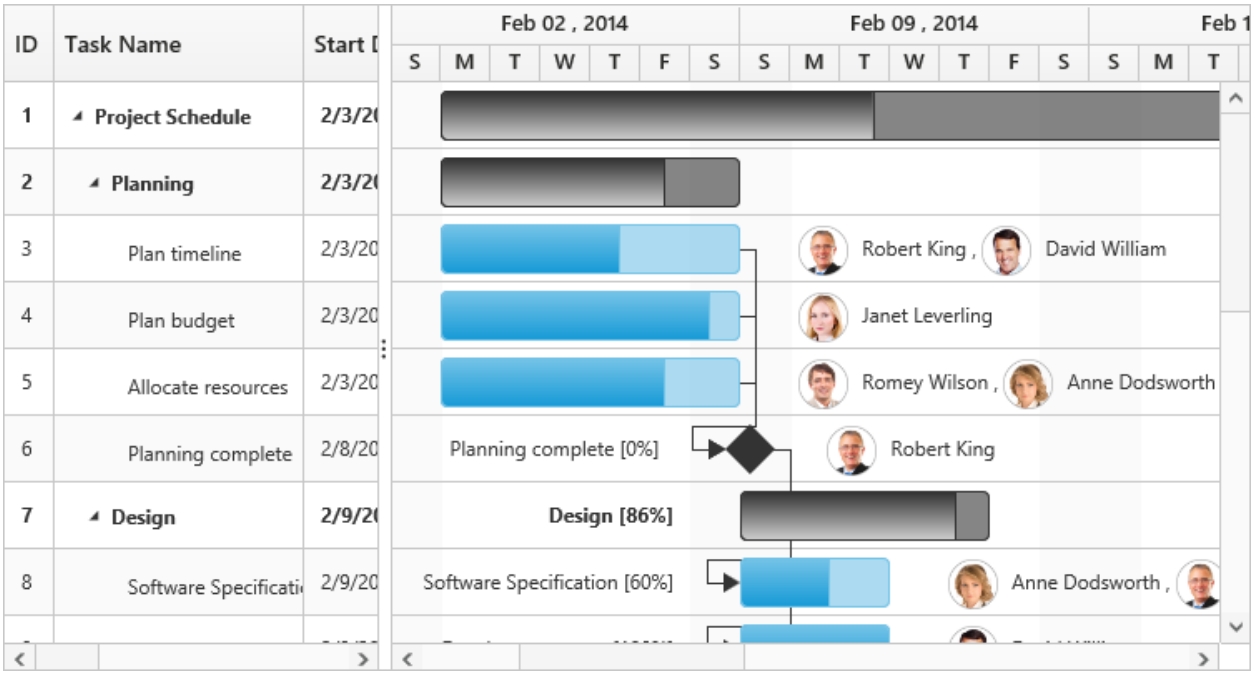
ASPX-CS

```
<script id="rightLabelTemplate" type="text/x-jsrender">
{{"{{"}}if #data['resourceNames']{{}}}}
<div>
{{"{{"}}for resourceInfo{{}}}}
<img src="themes/web/content/images/gantt/{{"{{"}}:resourceName{{}}}}.png"
height="30px" />
<span style="margin-left:5px;">{{"{{"}}:resourceName{{}}}}</span>
{{"{{"}}:~_getSeparator(#get("array").data.length,#index){{}}}}
{{"{{"}}/for{{}}}}
</div>
{{/if}}
</script>
<script id="leftLabelTemplate" type="text/x-jsrender">
<div style="padding-top:5px;">
<span>{{"{{"}}:#data['taskName']{{}}}}  [{{"{{"}}:status{{}}}}%]</span>
</div>
</script>
@(Html.EJ().Gantt("Gantt")
//...
.RightTaskLabelTemplate("#rightLabelTemplate")
.LeftTaskLabelTemplate("#leftLabelTemplate")
)
@(Html.EJ().ScriptManager())
```

You can find the online demo sample for task label templates in Gantt here

The following screenshot shows Gantt with task label templates.

Copyright © 2001 - 2020 Syncfusion Inc.



Tooltip template

Taskbar tooltip

The default tooltip in Gantt can be customized by using the `TaskbarTooltipTemplateId` property. We need to map the JsRender script element's ID value to this property.

The following code example shows how to customize the tooltip.

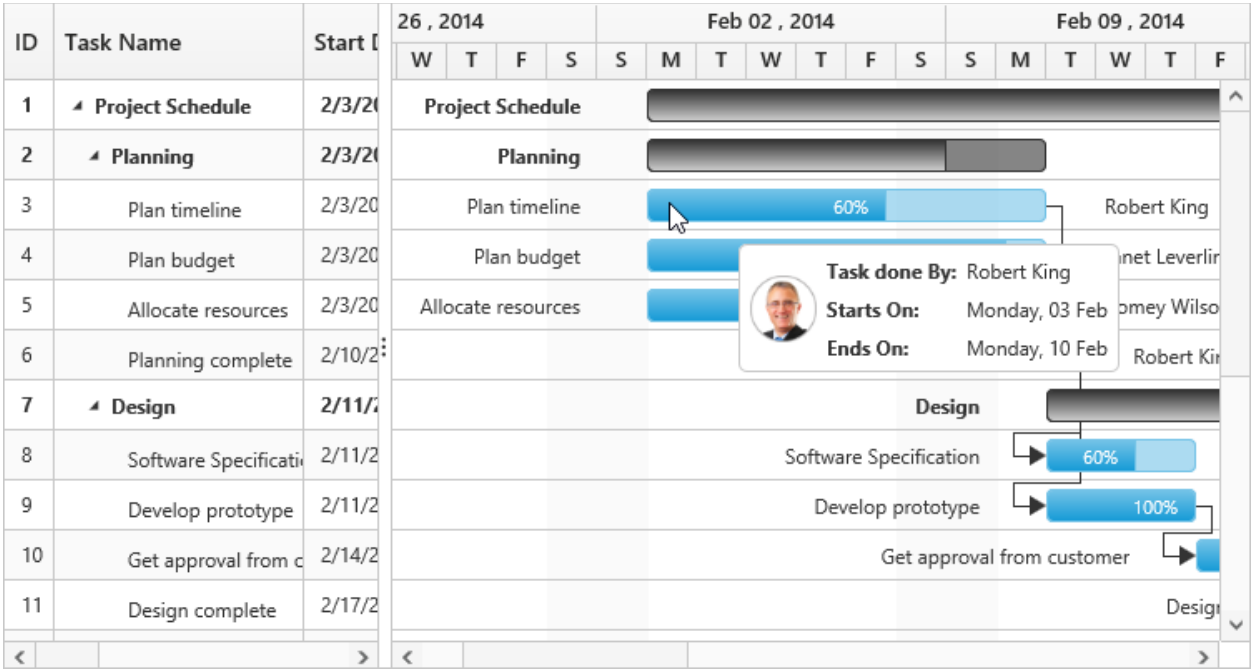
ASPX-CS

```
<script type="text/x-jsrender" id="tooltipTemplate">
<table>
{{"{{"}}if #data['resourceNames']{{}}}}
<tr>
<td rowspan="3" style="padding:3px"><img
src="themes/web/content/images/gantt/{{"{{"}}:#data['resourceNames']{{}}}}.p
ng" height="40px" /></td>
<td style="padding:3px"><b>Task done By:</b></td>
<td style="padding:3px">{{"{{"}}:#data['resourceNames']{{}}}}</td>
</tr>
{{/if{{}}}}
<tr>
<td style="padding:3px"><b>Starts On:</b></td>
<td
style="padding:3px">{{"{{"}}:~_ganttDateFormatter("startDate"){{}}}}</td>
</tr>
<tr>
<td style="padding:3px"><b>Ends On:</b></td>
<td style="padding:3px">{{"{{"}}:~_ganttDateFormatter("endDate"){{}}}}</td>
</tr>
</table>
</script>
@(Html.EJ().Gantt("Gantt")
//...
.TaskbarTooltipTemplateId("tooltipTemplate")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows Gantt with task tooltip customization.



Dependency tooltip

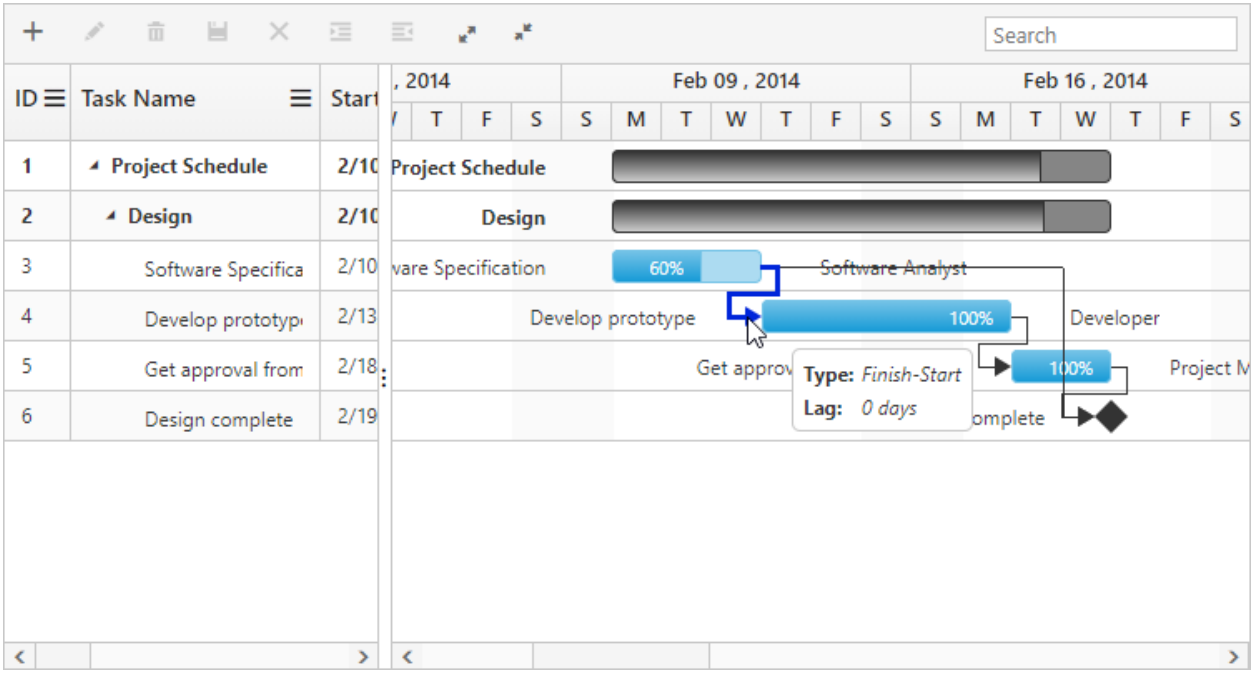
The default dependency tooltip in Gantt can be customized by using PredecessorTooltipTemplate property. We can map value to this property as JsRender template script id with prefix of '#' or HTML elements in string format. The following code example shows how to use the PredecessorTooltipTemplate property.

ASPX-CS

```
<script type="text/javascript">
$.views.helpers({
_Type: getType,
_Lag: getLag
});
function getType() {
return this.data.linkText;
}
function getLag() {
return this.data.offset + " " + this.data.offsetUnit;
}
</script>
<script id="ToolTipTemplate" type="text/x-jsrender">
<table>
<tr>
<td><b>Type:</b></td>
<td><i>{{:~_Type()}}</i></td>
</tr>
<tr>
```

```
<td><b>Lag:</b></td>
<td><i>{{:~_Lag()}}</i></td>
</tr>
</table>
</script>
@(Html.EJ().Gantt("Gantt")
//...
.EnableTaskbarTooltip(true)
.PredecessorTooltipTemplate("#ToolTipTemplate")
)
@(Html.EJ().ScriptManager())
```

The following screenshot show the output of above code example.



Cell tooltip

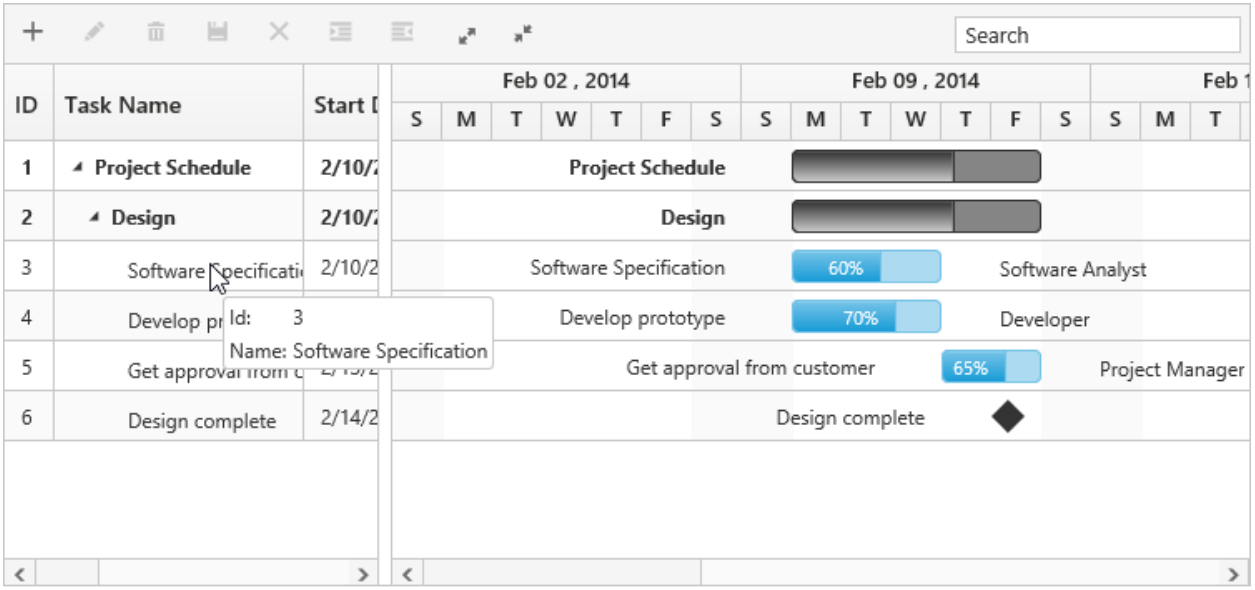
TreeGrid part tooltip can also be customized using CellTooltipTemplate property. We need to map the script element or element id to this property. The following code explains how to customize the cell tooltip in Gantt.

ASPX-CS

```
<script type="text/javascript">
$.views.helpers({
_TaskID: getTaskID,
_TaskName: getTaskName
});
function getTaskID() {
return this.data.record["taskId"];
}
function getTaskName() {
return this.data.record["taskName"];
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script id="CustomToolTip" type="text/x-jsrender">
<table>
<tr>
<td>Id:</td>
<td>{{"{{"}}:~_TaskID(){{}}}}</td>
</tr>
<tr>
<td>Name:</td>
<td>{{"{{"}}:~_TaskName(){{}}}}</td>
</tr>
</table>
</script>
@(Html.EJ().Gantt("Gantt")
//...
.ShowGridCellTooltip(true)
.CellTooltipTemplate("#CustomToolTip")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```



You can find the online demo sample for tooltip templates for taskbars here

Taskbar Editing Tooltip

Editing tooltip is used to show the updated start date, end date, duration and progress values of a task while resizing, dragging and progress bar resizing actions. Currently two editing tooltips are available in Gantt.

- Taskbar editing tooltip
- Progress bar editing tooltip

We can customize the default taskbar editing tooltip and progress bar editing tooltip in Gantt.

Copyright © 2001 - 2020 Syncfusion Inc.

Customize taskbar editing tooltip

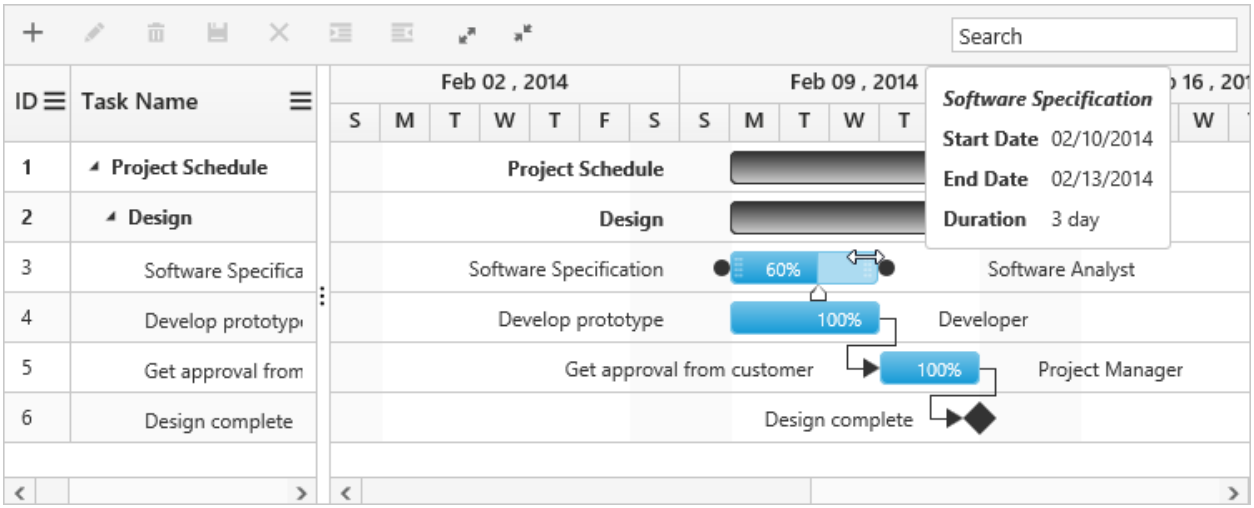
Taskbar editing tooltip can be customized by using TaskbarEditingTooltipTemplate and TaskbarEditingTooltipTemplateId properties. The below code example shows how to customize the taskbar editing tooltip in Gantt.

ASPX-CS

```
<script type="text/javascript">
$.views.helpers({
getStartDate: function () {
return ej.format(this.data.startDate, "MM/dd/yyyy", "en-US");
},
getEndDate: function () {
return ej.format(this.data.endDate, "MM/dd/yyyy", "en-US");
}
});
</script>
<script id="taskbar_editing_tooltip_template" type="text/x-jsrender">
<table>
<tr>
<td colspan="2" style="padding:3px;font-weight:bold;font-
style:italic">{{:taskName}}</td>
</tr>
<tr>
<td style="padding:3px;font-weight:bold">Start Date</td>
<td style="padding:3px">{{:~getStartDate(#data)}}</td>
</tr>
<tr>
<td style="padding:3px;font-weight:bold">End Date</td>
<td style="padding:3px">{{:~getEndDate(#data)}}</td>
</tr>
<tr>
<td style="padding:3px;font-weight:bold">Duration</td>
<td style="padding:3px">{{:duration}} {{:durationUnit}}</td>
</tr>
</table>
</script>
@(Html.EJ().Gantt("Gantt")
//...
.TaskbarEditingTooltipTemplateId("taskbar_editing_tooltip_template")
)
@(Html.EJ().ScriptManager())
```

The below screenshot shows the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Customize progress bar editing tooltip

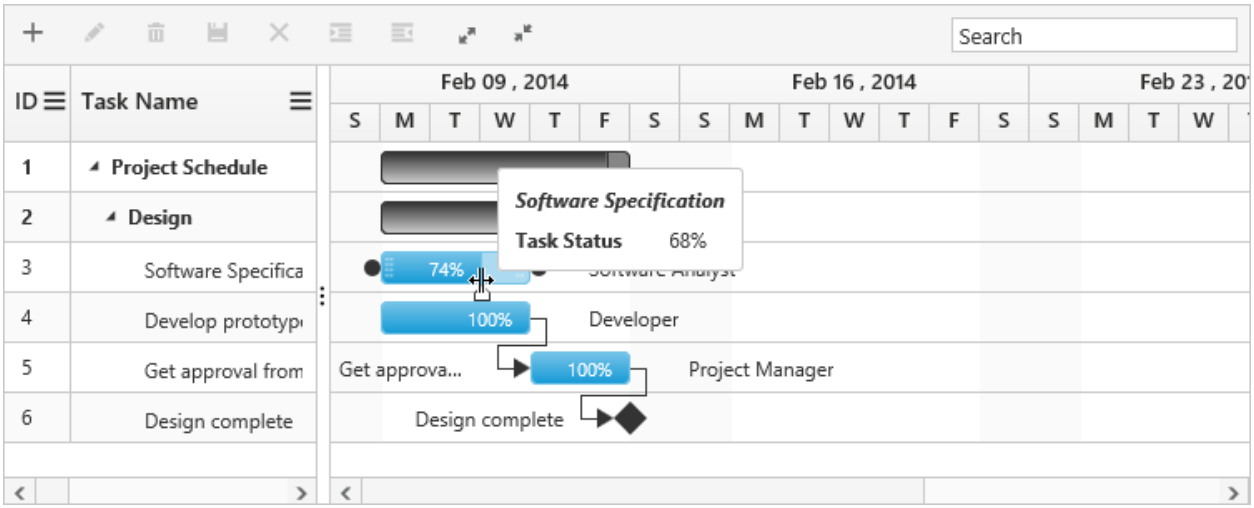
Progress bar editing tooltip can be customized by using `ProgressbarTooltipTemplate` and `ProgressbarTooltipTemplateId` properties. The below code example shows how to customize the progress bar editing tooltip in Gantt.

ASPX-CS

```
<script id="progressbar_editing_tooltip_template" type="text/x-jsrender">
<table>
<tr>
<td colspan="2" style="padding:3px;font-weight:bold;font-
style:italic">{{:taskName}}</td>
</tr>
<tr>
<td style="padding:3px;font-weight:bold">Task Status</td>
<td style="padding:3px">{{:status}}%</td>
</tr>
</table>
</script>
@(Html.EJ().Gantt("Gantt")
//...
.ProgressbarTooltipTemplateId("progressbar_editing_tooltip_template")
)
@(Html.EJ().ScriptManager())
```

The below screenshot shows the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Selection

Row selection

The row selection in Gantt can be enabled or disabled, by using the `AllowSelection` property. You can able to get the selected row object using the `selectedItem` property from the Gantt model. The following code example shows how to disable the row selection in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowSelection(true)
)
@(Html.EJ().ScriptManager())
```

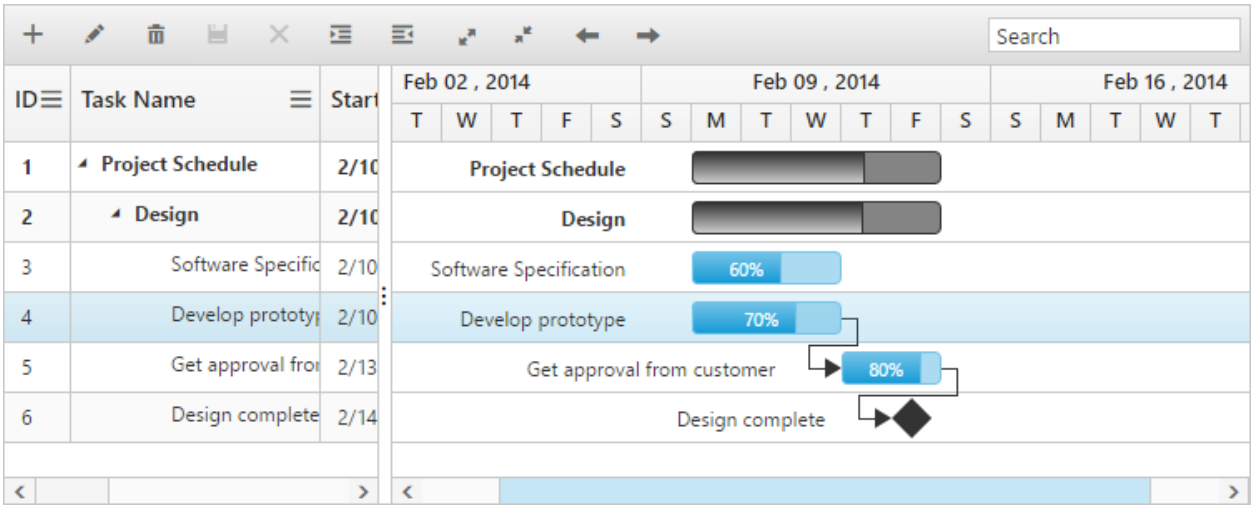
Selecting a row on initial load

You can select a row on load time by setting the index of the row to `SelectedRowIndex` property. Find the following code example for details.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.SelectedRowIndex(3)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



Selecting a row programmatically

You can also select a row programmatically by setting index of the row value to SelectedRowIndex property. The following code shows to select a row programmatically with a custom button click action,

ASPX-CS

```
<button onclick="selectRow()">SelectRow</button>
@(Html.EJ().Gantt("Gantt")
//...
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function selectRow() {
$("#Gantt ").ejGantt("option", "selectedRowIndex", 4);
}
</script>
```

Multiple row selection

It is also possible to select multiple rows by setting SelectionType as Multiple. You can select more than one row by holding down CTRL key while selecting multiple rows.

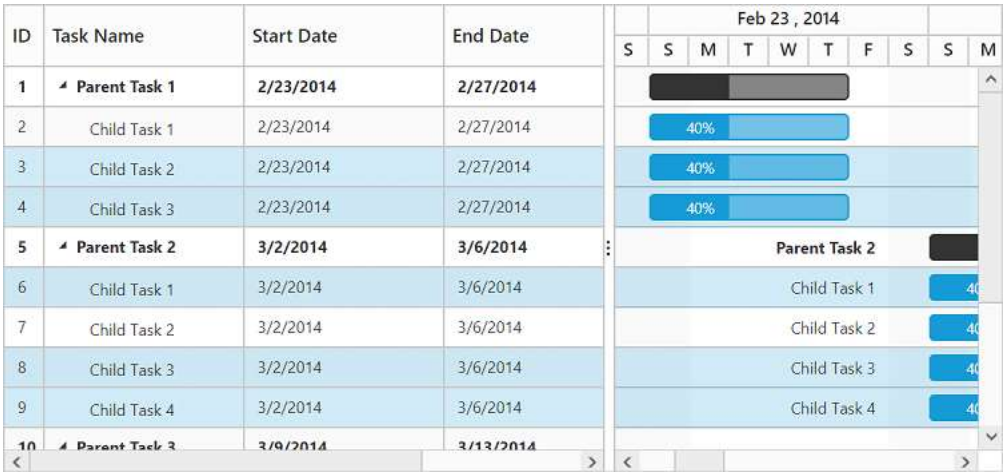
The following code example explains how to enable multiple selection in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowSelection(true)
.SelectionType(GanttSelectionType.Multiple)
.SelectionMode(GanttSelectionMode.Row)
)
@(Html.EJ().ScriptManager())
```

The output of the Gantt with multiple row selection is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Selecting multiple rows programmatically

You can also select multiple rows programmatically by using selectMultipleRows public method. The following code example explains how to enable multiple selection in Gantt.

ASPX-CS

```
<button onclick="selectMultipleRow()">selectMultipleRow</button>
@(Html.EJ().Gantt("Gantt")
.SelectionType(GanttSelectionType.Multiple)
.SelectionMode(GanttSelectionMode.Row)
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function selectMultipleRow() {
var ganttObj = $("#Gantt").data("ejGantt"),
multipleRowIndex = [1,0,5,7];
ganttObj.selectMultipleRows(multipleRowIndex);
}
<script>
```

Customize row selection action

While selecting a row in Gantt, RowSelecting and RowSelected event will be triggered. Row selecting event will be triggered on initialization of row selection action. In RowSelecting event we can get the previously selected row and current selecting row's information, using this information we can prevent selection of particular row. The RowSelected event will be triggered on completion of row selection action, in this event we can get the current selected row's information. The following code example shows how to prevent the selection of particular row using RowSelecting event.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//
.AllowSelection(true)
.SelectionType(GanttSelectionType.Multiple)
.SelectionMode(GanttSelectionMode.Row)
.ClientSideEvents(eve =>
{
eve.RowSelecting("rowSelecting");
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function rowSelecting(args) {
if (args.data.taskId == 5) // prevent selection of Task id 5
args.cancel = true;
}
</script>
```

Cell selection

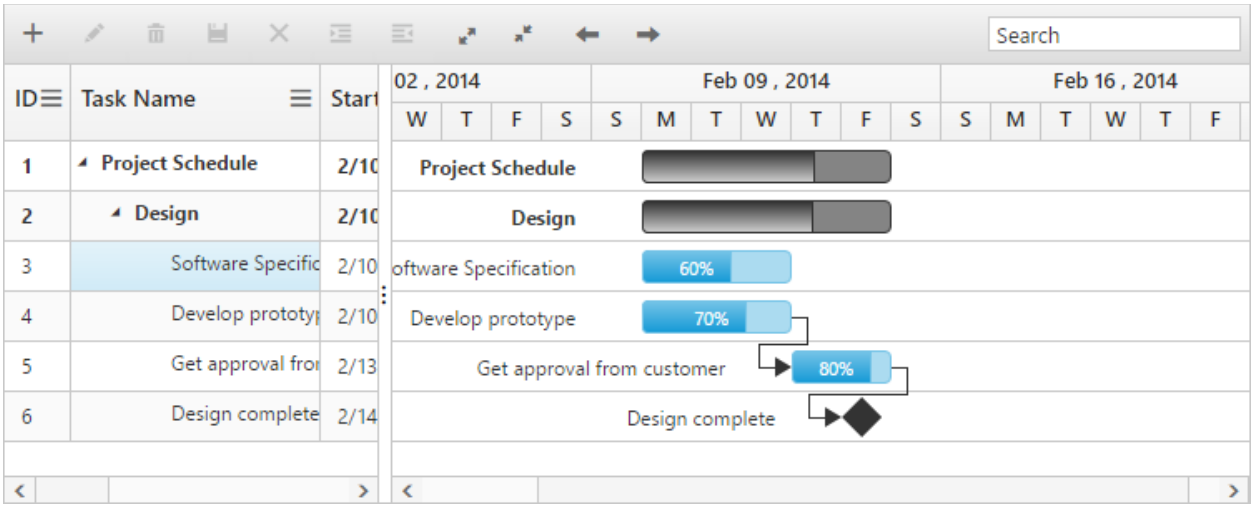
You can select a cell in Gantt by setting SelectionMode property as Cell. And you can able to get the selected cell information using selectedCellIndexes property from the Gantt object. selectedCellIndexes is an object collection, which has the cell index and row index information of the selected cells.

Find the code example below to enable the cell selection in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//
.SelectionMode(GanttSelectionMode.Cell)
)
@(Html.EJ().ScriptManager())
```

The following screen shots shows you cell selection.



Selecting multiple cells

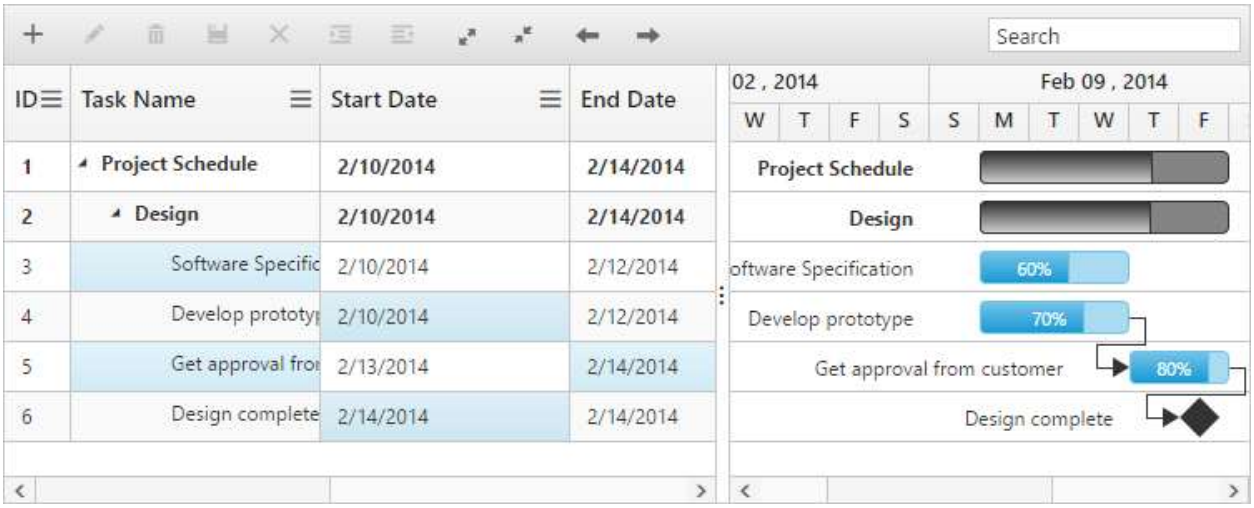
You can also select multiple cells by setting SelectionType property as Multiple while SelectionMode property is set to cell. Multiple cells can be selected by holding the ctrl key and to click on the cells. The following code example shows you to select multiple cells.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//
.SelectionType(GanttSelectionType.Multiple)
.SelectionMode(GanttSelectionMode.Cell)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().ScriptManager())
```



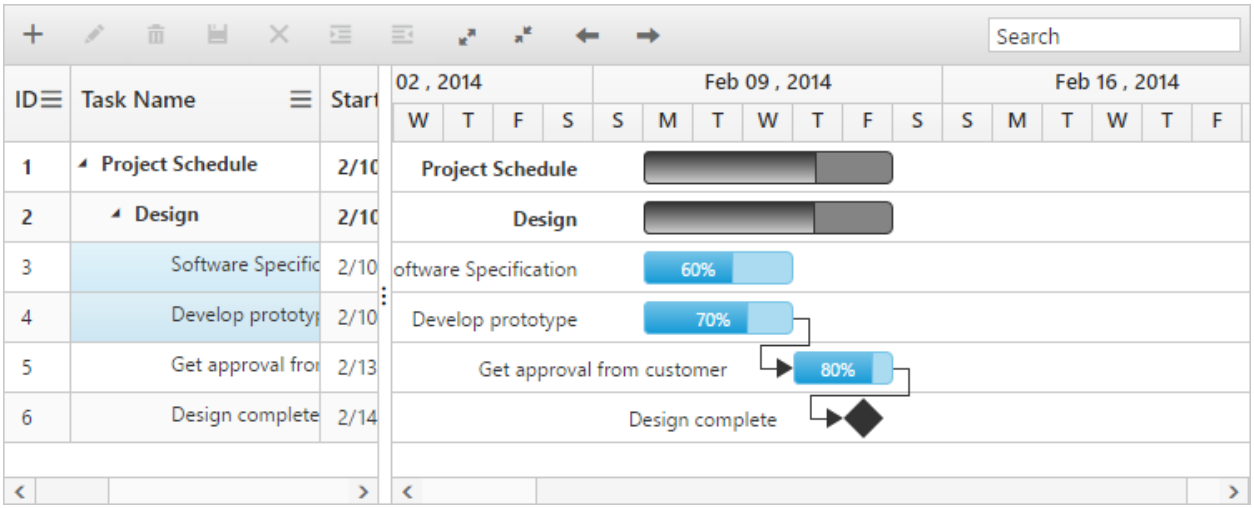
Select cells programmatically

You can select the cells programmatically using selectCells public method. Find the code example below for details.

ASPX-CS

```
<button onclick="selectCells()">selectCells</button>
@(Html.EJ().Gantt("Gantt")
.SelectionType(GanttSelectionType.Multiple)
.SelectionMode(GanttSelectionMode.Cell)
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function selectCells() {
var ganttObj = $("#GanttContainer").data("ejGantt");
cellIndex = [{
rowIndex: 2,
cellIndex: 1
}, {
rowIndex: 3,
cellIndex: 1
}];
ganttObj.selectCells(cellIndex);
}
<script>
```

Copyright © 2001 - 2020 Syncfusion Inc.



Customize cell selection action

While selecting a cell in Gantt, CellSelecting and CellSelected event will be triggered.

Cell selecting event will be triggered on initialization of cell selection action.

In CellSelecting event we can get the current selecting cell information, using this information we can prevent selection of particular cell in particular row.

The CellSelected event will be triggered on completion of cell selection action, in this event we can get the current selected cell's information. The following code example shows how to prevent the selection of particular cell using CellSelecting event.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//
.AllowSelection(true)
.SelectionType(GanttSelectionType.Multiple)
.SelectionMode(GanttSelectionMode.Row)
.ClientSideEvents(eve =>
{
eve.CellSelecting("cellSelecting");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function cellSelecting(args) {
if (args.data.taskId == 5 && args.cellIndex == 1) // prevent selection of
Task Name cell of Task id 5
args.cancel = true;
</script>
```

MultiSelection – Touch Option

It is possible to select rows using touch action in Gantt. Gantt provides support for both single selection and multiple row selection using touch action. For multiple row selection, when we tap on a cell, a helper icon will be displayed using which we can select multiple rows.

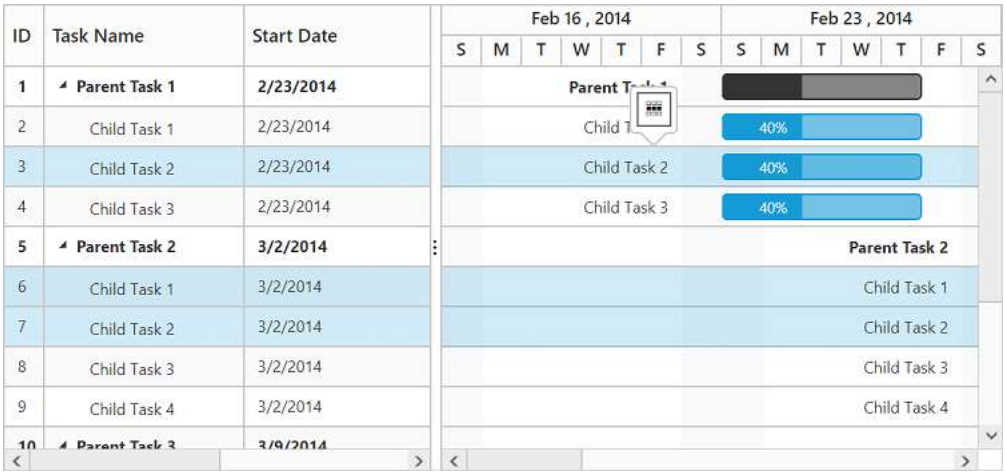
The following code example describes how to enable multiple selection in Gantt.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.SelectionType(GanttSelectionType.Multiple)
.SelectionMode(GanttSelectionMode.Row)
)
@(Html.EJ().ScriptManager())
```

The following output is displayed the result of multiple selection in touch device environment.



Export

Gantt provides support to export the contents in PDF and excel.

To export the contents, the ExcelExport and PdfExport toolbar items must be included in the ToolbarSettings.ToolbarItems property.

And you need to call the export method with the export mapper as parameter in the toolbar button click action. We can export multiple Gantt control in same file by using multiple exporting support, this can be enabled by setting AllowMultipleExporting property as true.

The below code snippet explains the above behavior,

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<GanttToolBarItems>()
{
GanttToolBarItems.PdfExport,
GanttToolBarItems.ExcelExport
});
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

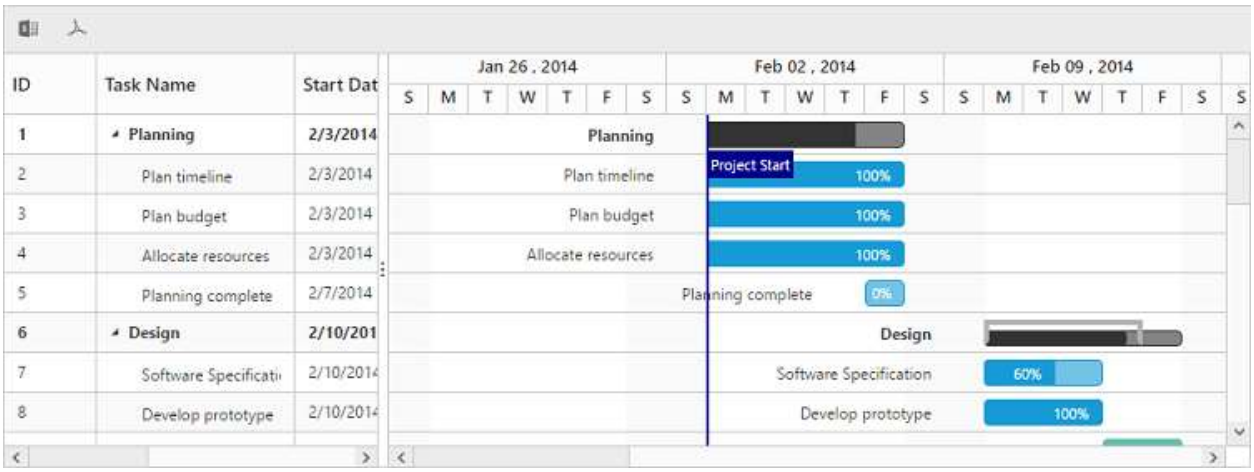
C#

```
public class GanttController : Controller
{
public ActionResult GanttExporting()
{
ViewBag.datasource = this.GetDataSource();
return View();
}
public void ExportToPdf(string GanttModel)
{
PdfExport exp = new PdfExport();
var datasource = this.DataSource();
GanttProperties obj = ConvertGanttObject(GanttModel);
GanttPdfExportSettings settings = new GanttPdfExportSettings();
settings.Theme = GanttExportTheme.FlatSaffron;
settings.Locale = Request.Form["locale"];
exp.Export(obj, datasource, settings, "Gantt");
}
public void ExportToExcel(string GanttModel)
{
ExcelExport exp = new ExcelExport();
var DataSource = this.GetEditingDataSource();
GanttProperties obj = ConvertGanttObject(GanttModel);
exp.Export(obj, DataSource, "GanttExport.xlsx", ExcelVersion.Excel2010, new
GanttExportSettings() { Theme = ExportTheme.FlatSaffron });
}
private GanttProperties ConvertGanttObject(string gridProperty)
{
JavaScriptSerializer serializer = new JavaScriptSerializer();
IEnumerable div = (IEnumerable)serializer.Deserialize(gridProperty,
typeof(IEnumerable));
GanttProperties gridProp = new GanttProperties();
foreach (KeyValuePair<string, object> ds in div)
{
var property = gridProp.GetType().GetProperty(ds.Key, BindingFlags.Instance
| BindingFlags.Public | BindingFlags.IgnoreCase);
if (property != null)
{
Type type = property.PropertyType;
string serialize = serializer.Serialize(ds.Value);
object value = serializer.Deserialize(serialize, type);
property.SetValue(gridProp, value, null);
}
}
return gridProp;
}
}
```

The PDF and Excel exporting services for Gantt are explained in detail here.

The below screen shot shows Gantt with excel and PDF exporting enabled.

Copyright © 2001 - 2020 Syncfusion Inc.



Server dependencies

Export Helper functions are available in the Assembly Syncfusion.EJ.Export, which is available in the Essential Studio & Essential ASP.NET MVC builds. The list of assemblies needed for Gantt Export as follows

- Syncfusion.EJ
- Syncfusion.EJ.Export
- Syncfusion.Linq.Base
- Syncfusion.Compression.Base
- Syncfusion.XlsIO.Base
- Syncfusion.PDF.Base

Supported Export Types

Currently server helper function allows following two types of exporting.

- Excel
- PDF

Export Mapper in MVC

Mappers is used to change the default routing path for exporting. By using Mappers you can change any action name in controller and the action can be in any controller (Need not to be in Gantt View Page Controller).

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.Mappers(map =>
map.ExportToPdfAction("PdfAction").ExportToExcelAction("ExcelAction"))
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<GanttToolBarItems>()
{
GanttToolBarItems.PdfExport,
GanttToolBarItems.ExcelExport
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
//...
)
@(Html.EJ().ScriptManager())
```

C#

```
public partial class GanttController : Controller
{
public void PdfAction(string GanttModel)
{
PdfExport exp = new PdfExport();
var DataSource = this.GetEditingDataSource();
GanttProperties obj = ConvertGanttObject(GanttModel);
GanttPdfExportSettings settings = new GanttPdfExportSettings();
settings.Theme = GanttExportTheme.FlatSaffron;
settings.Locale = sRequest.Form["locale"];
exp.Export(obj, DataSource, settings, "Gantt");
}
public void ExcelAction(string GanttModel)
{
ExcelExport exp = new ExcelExport();
var DataSource = this.GetEditingDataSource();
GanttProperties obj = ConvertGanttObject(GanttModel);
exp.Export(obj, DataSource, "GanttExport.xlsx", ExcelVersion.Excel2010, new
GanttExportSettings() { Theme = ExportTheme.FlatSaffron });
}
}
```

Multiple exporting

Multiple export is used for export more than one Gantt object in the same file. Multiple export in Gantt can be enabled by setting AllowMultipleExporting property to true. Gantt properties of all the Gantt which are available in current page are passed as string array parameter to controller action method.

The following code example describes exporting multiple Gantt in PDF format

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.AllowMultipleExporting(true)
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<GanttToolBarItems>()
{
GanttToolBarItems.PdfExport
});
})
.Mappers(map => map.ExportToPdfAction("MultipleExportToPDF"))
.Datasource(ViewBag.datasource)
)
@(Html.EJ().Gantt("GanttContainer1")
//...
.Datasource(ViewBag.datasource1)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
@(Html.EJ().Gantt("GanttContainer2")
//...
.Datasource(ViewBag.datasource2)
)
@(Html.EJ().ScriptManager())
```

C#

```
public partial class GanttController : Controller
{
public void MultipleExportToPDF(string[] GanttModel)
{
PdfExport exp = new PdfExport();
var PlanData = this.GetPlanDataSource();
var DesignData = this.GetDesignDataSource();
var ImplementationData = this.GetImplementationDataSource();
PdfDocument document = null;
GanttPdfExportSettings settings = new GanttPdfExportSettings();
settings.Theme = GanttExportTheme.FlatSaffron;
settings.Locale = Request.Form["locale"];
int controlCount = 1;
foreach (string ganttProperty in GanttModel)
{
GanttProperties ganttProp = this.ConvertGanttObject(ganttProperty);
if (controlCount == 1)
{
document = exp.Export(ganttProp, (IEnumerable)PlanData, settings, false);
}
else if (controlCount == 2)
{
document = exp.Export(ganttProp, (IEnumerable)DesignData, settings,
document, false);
}
else
{
exp.Export(ganttProp, (IEnumerable)ImplementationData, settings, "Gantt",
document, true);
}
count++;
}
}
}
```

Click here to view the online demo sample for multiple exporting.

Export Theme

The Gantt export supports the below themes,

- flat-azure
- flat-azure-dark
- flat-lime
- flat-lime-dark
- flat-saffron

Copyright © 2001 - 2020 Syncfusion Inc.

- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark
- bootstrap-theme

The desired theme should be passed as a parameter to the Export method and the code snippet for this as follows

C#

```
public void ExportToExcel(string GanttModel)
{
ExcelExport exp = new ExcelExport();
var DataSource = this.GetEditingDataSource();
GanttProperties obj = ConvertGanttObject(GanttModel);
exp.Export(obj, DataSource, "GanttExport.xlsx", ExcelVersion.Excel2010, new
GanttExportSettings() { Theme = ExportTheme.FlatSaffron });
}
```

Customization

In Gantt, we can customize Grid cells, taskbars in Excel and PDF files by using exporting events. While exporting the Gantt as Excel or PDF files, events are triggered to customize the Grid cells and taskbars.

Customize Excel cell

Excel cells can be customized by using ServerExcelQueryCellInfo event, in this event we can get the details about current record, Excel cell and current column information. Using this information we can customize the background color, font color and value of Excel cell, please find the event argument details below.

Name	Description	Type
Data	Returns the current row details	GanttRecordDetails
Cell	Returns current Excel cell information	IRange
Column	Returns current column information	GanttColumn

The following code snippets shows how to bind ServerExcelQueryCellInfo event in Web API controller and how to customize Excel cell using this event.

C#

```
public partial class GanttController : Controller
{
public ActionResult GanttConditionalExporting()
{
ViewBag.dataSource = GetExportDataSource();
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
GanttProperties.GanttEJExportEventHandler queryExcelCellDelegate = new
GanttProperties.GanttEJExportEventHandler(GanttExcelQueryCell);
public void ConditionalExcel(string GanttModel)
{
ExcelExport export = new ExcelExport();
var DataSource = GetExportDataSource();
GanttProperties obj = ConvertToGanttObject(GanttModel);
`obj.ServerExcelQueryCellInfo = queryExcelCellDelegate;`
export.Export(obj, DataSource, "GanttExport.xlsx", ExcelVersion.Excel2010,
new GanttExportSettings() { Theme = ExportTheme.FlatSaffron });
}
public static void GanttExcelQueryCell(object model, object args)
{
var record = (GanttRecordDetails)((Dictionary<string, object>)args)["Data"];
var cell = (IRange)((Dictionary<string, object>)args)["Cell"];
var column = (GanttColumn)((Dictionary<string, object>)args)["Column"];
var ganttModel = (GanttProperties)model;
if (column.MappingName == ganttModel.ProgressMapping && !record.IsParentRow)
{
if (float.Parse(cell.Value) > 80)
{
cell.CellStyle.Color = new PdfColor(165, 105, 189);
cell.CellStyle.Font.Color = ExcelKnownColors.White;
}
else if (float.Parse(cell.Value) < 20)
{
cell.CellStyle.Color = new PdfColor(240, 128, 128);
cell.CellStyle.Font.Color = ExcelKnownColors.White;
}
}
}
private GanttProperties ConvertToGanttObject(string gridProperty)
{
JavaScriptSerializer serializer = new JavaScriptSerializer();
IEnumerable div = (IEnumerable)serializer.Deserialize(gridProperty,
typeof(IEnumerable));
GanttProperties gridProp = new GanttProperties();
foreach (KeyValuePair<string, object> ds in div)
{
var property = gridProp.GetType().GetProperty(ds.Key, BindingFlags.Instance
| BindingFlags.Public | BindingFlags.IgnoreCase);
if (property != null)
{
Type type = property.PropertyType;
string serialize = serializer.Serialize(ds.Value);
object value = serializer.Deserialize(serialize, type);
property.SetValue(gridProp, value, null);
}
}
return gridProp;
}
}
```

Click here to view the online demo sample with above code example.

Copyright © 2001 - 2020 Syncfusion Inc.

Note: Refer this link to know more about what are the properties are available in Excel cell and it's type values.

Customize PDF cell

PDF cells in Gantt can be customized by using ServerPdfQueryCellInfo event, in this event we can get the details about current record, PDF cell and current column information. Using this information we can customize the background color and font color of PDF cells, please find the event argument details below.

Name	Description	Type
Data	Returns the current row details	GanttRecord
Cell	Returns current Excel cell information	PdfTreeGridCell
Column	Returns current column information	GanttColumn

The following code snippets shows how to bind ServerPdfQueryCellInfo event in Web API controller and how to customize PDF cell using this event.

C#

```
public partial class GanttController : Controller
{
public ActionResult GanttConditionalExporting()
{
ViewBag.datasource = GetExportDataSource();
return View();
}
GanttProperties.GanttEJExportEventHandler queryExcelCellDelegate = new
GanttProperties.GanttEJExportEventHandler(GanttExcelQueryCell);
public void ConditionalPdf(string GanttModel)
{
PdfExport exp = new PdfExport();
var DataSource = GetExportDataSource();
GanttProperties obj = ConvertToGanttObject(GanttModel);
`obj.ServerPdfQueryCellInfo = queryCellDelegate;`
GanttPdfExportSettings settings = new GanttPdfExportSettings();
settings.Theme = GanttExportTheme.FlatSaffron;
settings.Locale = Request.Form["locale"];
settings.IsFitToWidth = true;
exp.Export(obj, DataSource, settings, "Gantt");
}
public static void GanttPdfQueryCell(object model, object args)
{
var record = (GanttRecord)((Dictionary<string, object>)args)["Data"];
var cell = (PdfTreeGridCell)((Dictionary<string, object>)args)["Cell"];
var column = (GanttColumn)((Dictionary<string, object>)args)["Column"];
var ganttModel = (GanttProperties)model;
if (column.MappingName == ganttModel.ProgressMapping && !record.IsParentRow)
{
if (record.Progress > 80)
{
PdfBrush color = new PdfSolidBrush(new PdfColor(165, 105, 189));
cell.Style.BackgroundBrush = color;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
else if (record.Progress < 20)
{
PdfBrush color = new PdfSolidBrush(new PdfColor(240, 128, 128));
cell.Style.BackgroundBrush = color;
}
}
}
private GanttProperties ConvertToGanttObject(string gridProperty)
{
JavaScriptSerializer serializer = new JavaScriptSerializer();
IEnumerable div = (IEnumerable)serializer.Deserialize(gridProperty,
typeof(IEnumerable));
GanttProperties gridProp = new GanttProperties();
foreach (KeyValuePair<string, object> ds in div)
{
var property = gridProp.GetType().GetProperty(ds.Key, BindingFlags.Instance
| BindingFlags.Public | BindingFlags.IgnoreCase);
if (property != null)
{
Type type = property.PropertyType;
string serialize = serializer.Serialize(ds.Value);
object value = serializer.Deserialize(serialize, type);
property.SetValue(gridProp, value, null);
}
}
return gridProp;
}
}
```

Click here to view the online demo sample with above code example.

Note: Refer this link to know more about what are the properties are available in PDF cell and it's type values.

Customize PDF taskbar

PDF taskbars in Gantt can be customized by using ServerPdfQueryTaskbarInfo event, in this event we can get the details about current record and taskbar information. Using this information we can customize the background color of taskbar and progress bar, please find the event argument details below.

Name	Description	Type
Data	Returns the current row details	GanttRecord
Taskbar	Returns current Excel cell information	PdfGanttTaskbar

The following code snippets shows how to bind ServerPdfQueryTaskbarInfo event in Web API controller and how to customize PDF taskbar using this event.

C#

```
public partial class GanttController : Controller
{
```

```
public ActionResult GanttConditionalExporting()
{
ViewBag.datasource = GetExportDataSource();
return View();
}
GanttProperties.GanttEJExportEventHandler queryTaskbarDelegate = new
GanttProperties.GanttEJExportEventHandler(GanttQueryTaskbar);
public void ConditionalPdf(string GanttModel)
{
PdfExport exp = new PdfExport();
var DataSource = GetExportDataSource();
GanttProperties obj = ConvertToGanttObject(GanttModel);
`obj.ServerPdfQueryTaskbarInfo = queryTaskbarDelegate;`
GanttPdfExportSettings settings = new GanttPdfExportSettings();
settings.Theme = GanttExportTheme.FlatSaffron;
settings.Locale = Request.Form["locale"];
settings.IsFitToWidth = true;
exp.Export(obj, DataSource, settings, "Gantt");
}
public static void GanttQueryTaskbar(object model, object args)
{
var record = (GanttRecord)((Dictionary<string, object>)args)["Data"];
var taskbar = (PdfGanttTaskbar)((Dictionary<string,
object>)args)["Taskbar"];
if (!record.IsParentRow)
{
if (record.Progress > 80)
{
taskbar.ProgressColor = new PdfColor(108, 52, 131);
taskbar.TaskBorderColor = taskbar.TaskColor = new PdfColor(165, 105, 189);
}
else if (record.Progress < 20)
{
taskbar.ProgressColor = new PdfColor(205, 92, 92);
taskbar.TaskBorderColor = taskbar.TaskColor = new PdfColor(240, 128, 128);
}
}
}
private GanttProperties ConvertToGanttObject(string gridProperty)
{
JavaScriptSerializer serializer = new JavaScriptSerializer();
IEnumerable div = (IEnumerable)serializer.Deserialize(gridProperty,
typeof(IEnumerable));
GanttProperties gridProp = new GanttProperties();
foreach (KeyValuePair<string, object> ds in div)
{
var property = gridProp.GetType().GetProperty(ds.Key, BindingFlags.Instance
| BindingFlags.Public | BindingFlags.IgnoreCase);
if (property != null)
{
Type type = property.PropertyType;
string serialize = serializer.Serialize(ds.Value);
object value = serializer.Deserialize(serialize, type);
property.SetValue(gridProp, value, null);
}
}
return gridProp;
```

Sorting

The Gantt control for JavaScript has built-in support for sorting one or more columns.

Sorting Columns

Gantt allows the tasks to be sorted in ascending or descending order based on the selected column by enabling the AllowSorting option in Gantt control. The following code example shows you how to enable sorting in Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//..
.AllowSorting(true)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Multicolumn sorting

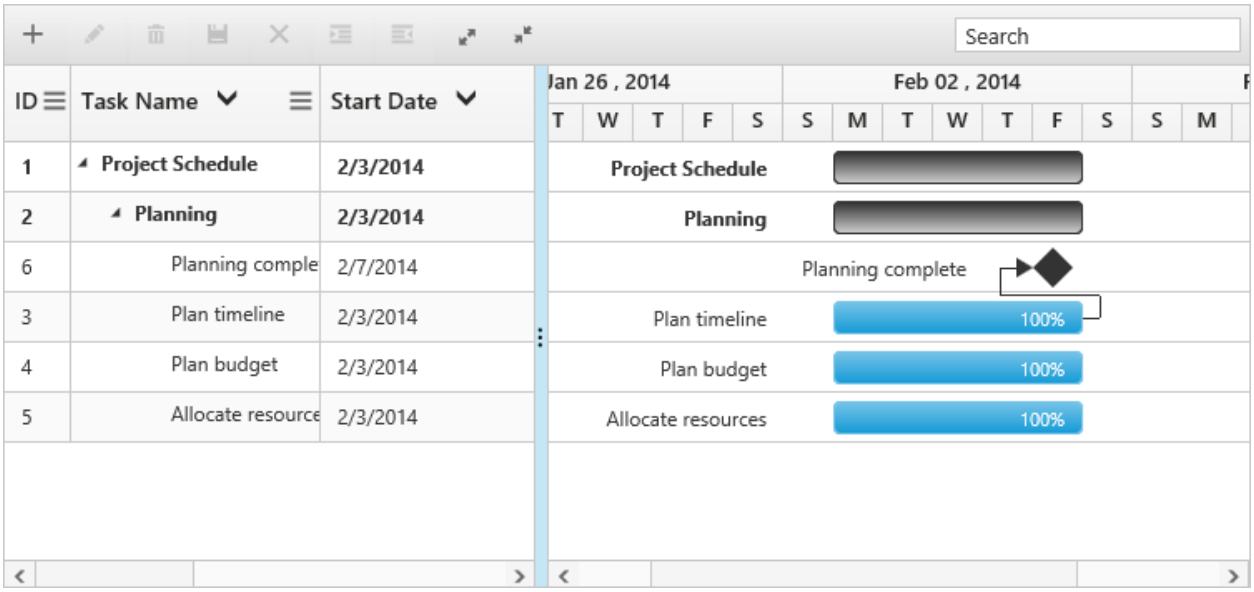
Gantt allows you to sort multiple columns by clicking the desired column headers while holding the CTRL key with AllowMultiSorting as true . The following code example shows you how to enable multicolumn sorting in Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowSorting(true)
.AllowMultiSorting(true)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the output of multicolumn sorting in Gantt control.

Copyright © 2001 - 2020 Syncfusion Inc.



Multicolumn Sorting

Sorting column on Gantt initialization

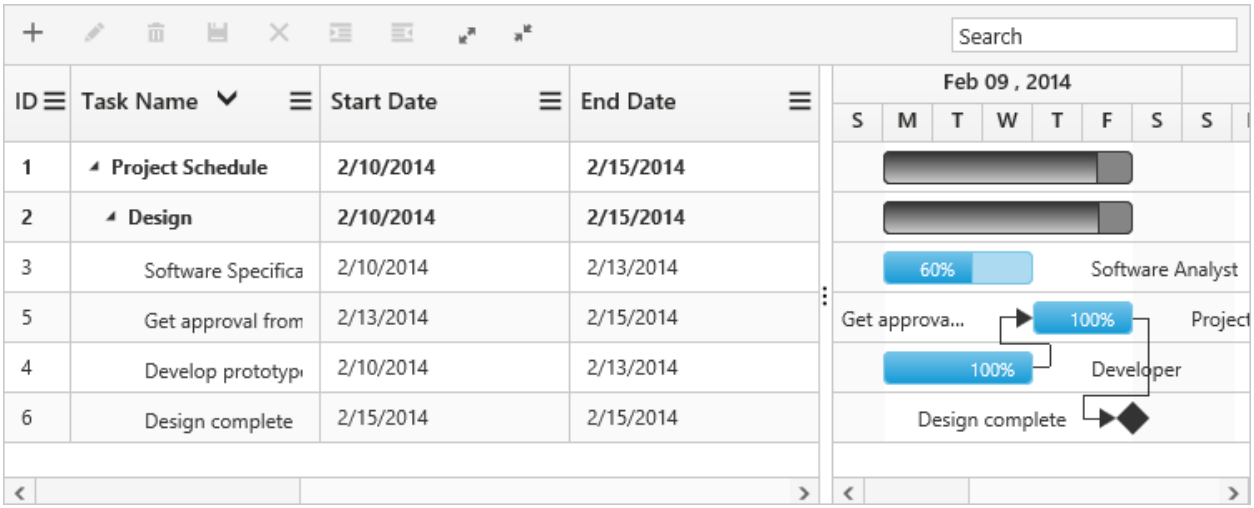
Gantt control can be rendered with sorted columns initially, this can be achieved by using SortSettings property. We can add columns which are sorted initially in SortedColumns collection. SortedColumns collection was defined with Field and Direction properties. The following code example shows how to add sorted column on Gantt initialization.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.AllowSorting(true)
.SortSettings(sort=>
{
sort.SortedColumns(sorted =>
sorted.Field("taskName").Direction(SortOrder.Descending).Add());
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



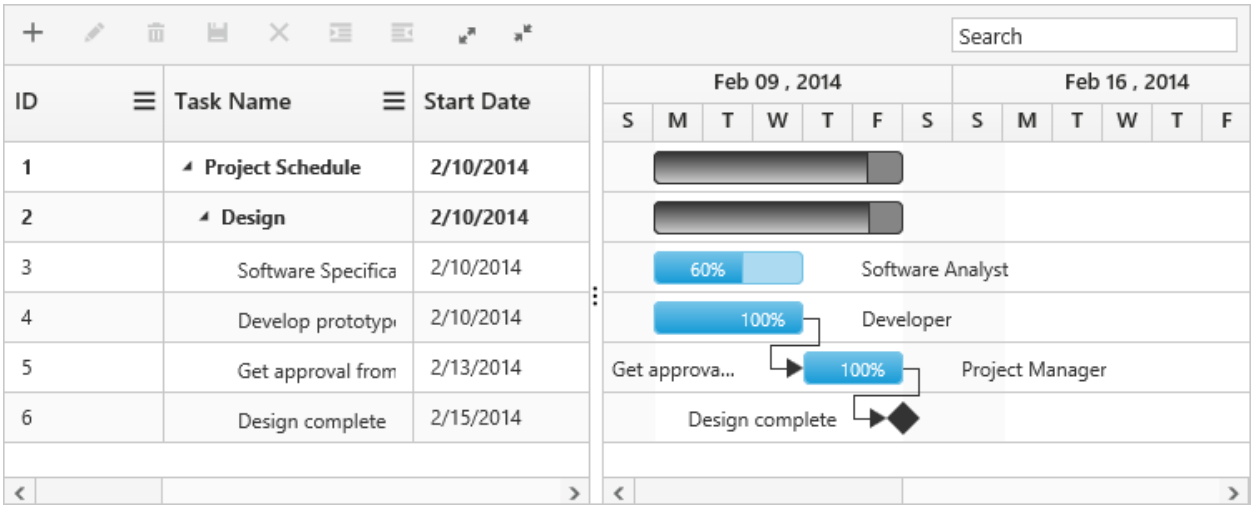
Sorting column dynamically

Columns in Gantt control can be sorted dynamically by using sortColumn method. The following code example shows how to invoke the sortColumn method on button click action.

ASPX-CS

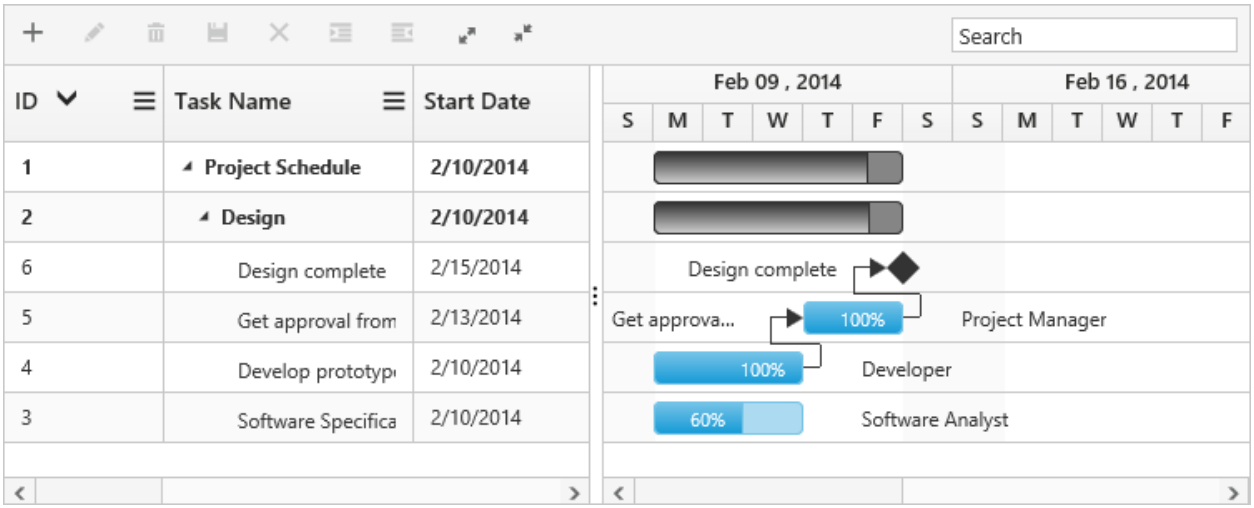
```
@(Html.EJ().Gantt("Gantt")
//...
.AllowSorting(true)
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#sort_column").click(function(){
$("#Gantt").ejGantt("sortColumn", "taskID", ej.sortOrder.Descending);
});
</script>
```

The following screenshot shows the output of above code example.



Before Sorting

Copyright © 2001 - 2020 Syncfusion Inc.



After Sorting

Note: when sorting a column using this method, previously sorted columns are cleared.

Sorting multiple columns dynamically

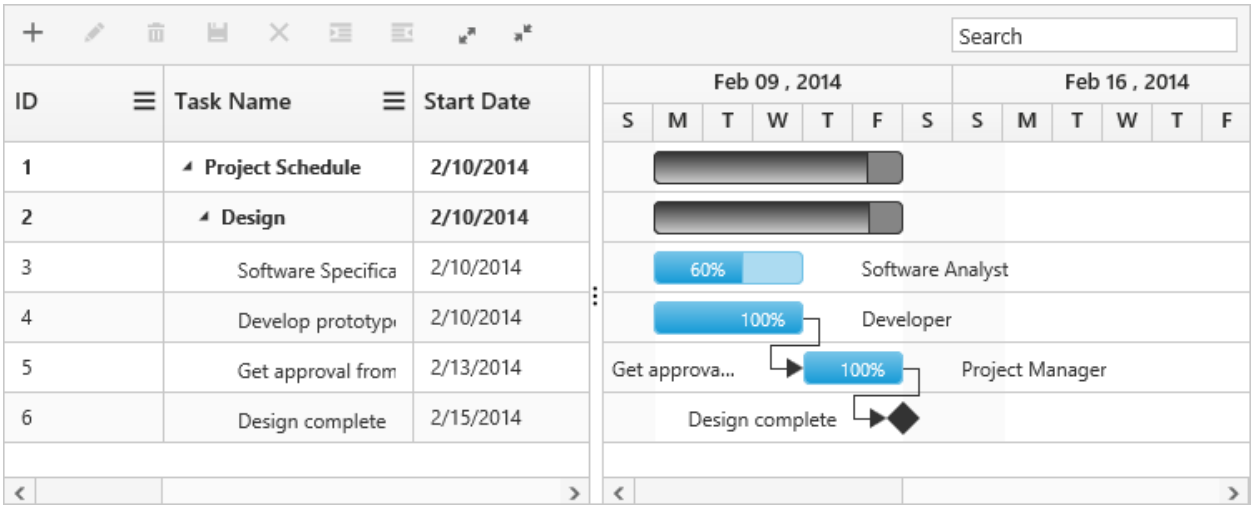
Multiple columns in Gantt can be sorted dynamically by using setModel method with sortSettingsproperty. The following code example shows how to use this method.

ASPX-CS

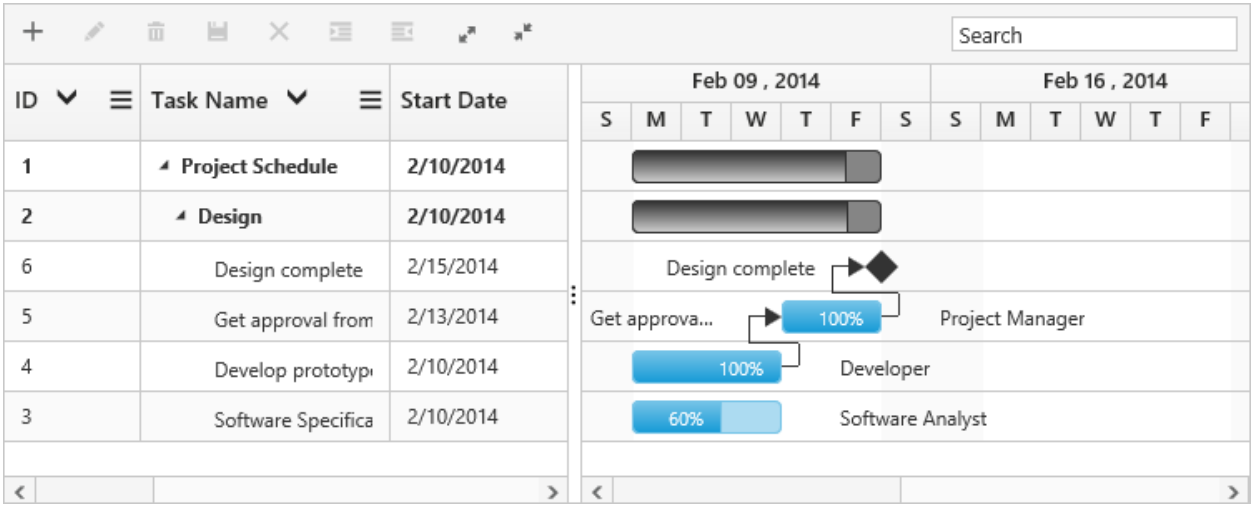
```
@(Html.EJ().Gantt("Gantt")
//...
.AllowSorting(true)
.AllowMultiSorting(true)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#sort_column").click(function() {
var sortedColumns = [
{ field: "taskID", direction: ej.sortOrder.Descending },
{ field: "taskName", direction: ej.sortOrder.Descending }
];
var sortSettings = {
sortedColumns: sortedColumns
};
var ganttObj = $("#Gantt").ejGantt("instance");
ganttObj.setModel({ "sortSettings": sortSettings });
});
</script>
```

The following screenshot shows the output of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Before Sorting



After Sorting

Searching

The Gantt control for JavaScript has in-built support for searching any content in Gantt.

Searching for content columns

In Gantt, we can search the content using the JavaScript method searchItem with search key as parameter. Also, we can integrate the search text box in Gantt toolbar by adding search toolbar item in ToolbarSettings.ToolbarItems property.

The following code example shows you how to add search option in Gantt toolbar.

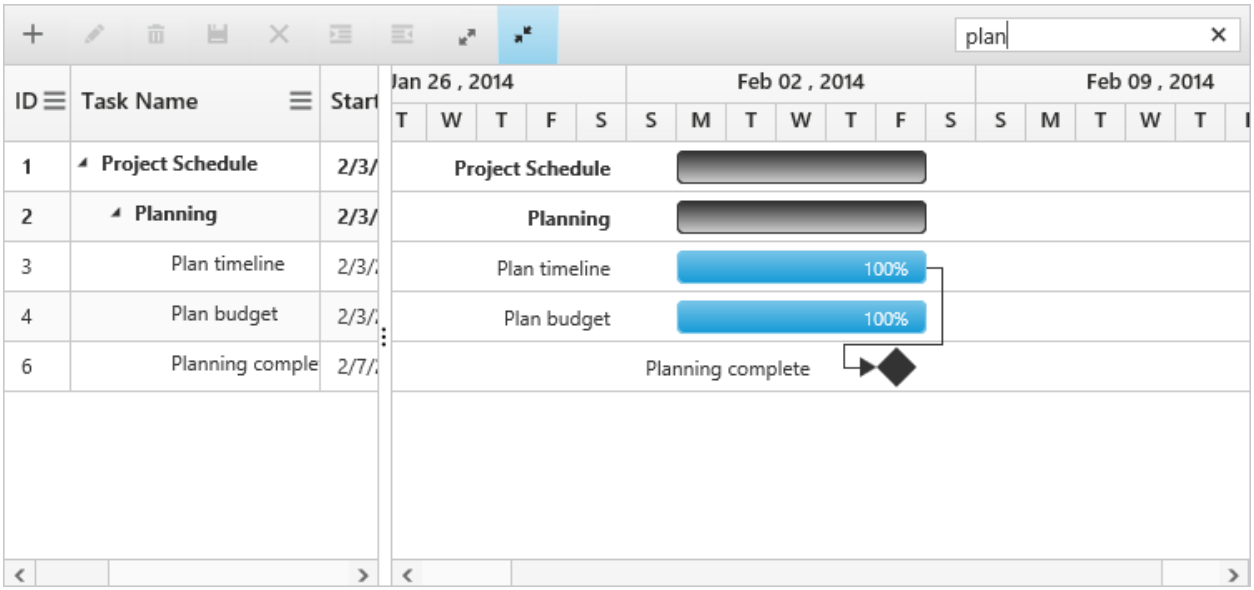
ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.ToolbarSettings(toolbar=>
{
toolbar.ShowToolbar(true);
toolbar.ToolbarItems(new List<GanttToolBarItems>(){
GanttToolBarItems.Search   //To search the task
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
});
})
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the output of searching for string in Gantt control.



Filtering

Filtering helps to view specific or related records from data source which meets a given filtering criteria. The FilterSettings property in Gantt is used to set the filtering criteria at load time.

Filter columns at initial load

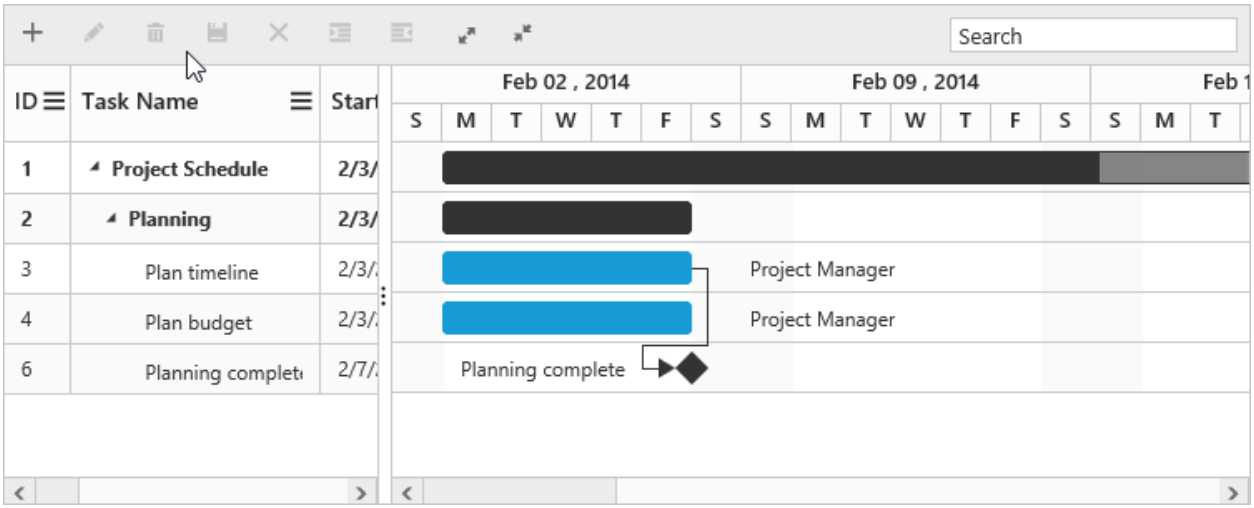
It is possible to filter one or more columns at initial load by providing the Field, Value,Predicate and Operator to the FilteredColumns property. The following code example explains how to filter a column on initial load.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
.FilterSettings(filter =>
{
filter.FilteredColumns(filtered =>
{
filtered.Value("plan").Field("taskName").Predicate("and").Operator(FilterOpe
ratorType.StartsWith).Add();
});
})
)
@(Html.EJ().ScriptManager())
```

The output of the filtering applied for a specific column is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Filtering a specific column by public method

It is possible to filter columns dynamically by using the filterColumn public method.

The below code snippet explains the above behavior.

JS

```
<button id="filterColumn">Filter Column</button>
@(Html.EJ().Gantt("GanttContainer")
//..
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#filterColumn").click(function (args) {
var obj = $("#GanttContainer").ejGantt("instance");
obj.filterColumn("taskName", "startswith", "plan");
})
</script>
```

Clearing the filter applied to Gantt

You can clear all the filtering condition done in the Gantt by using the clearFilter public method.

The below code snippet explains the above behavior.

JS

```
<button id="clearFilter">Clear Filter</button>
@(Html.EJ().Gantt("GanttContainer")
//..
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#clearFilter").click(function (args) {
var obj = $("#GanttContainer").ejGantt("instance");
obj.clearFilter();
})
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Toolbar

In Gantt we can show/hide the Toolbar by using ShowToolbar property.We can add default toolbar items by ToolbarItems. User can also create a custom toolbar items by using CustomToolbarItems.

Default Toolbar Items

Using Gantt default toolbar items we can perform below operations.

- **Add**- To add new task.
- **Edit**-To edit a selected task.
- **Delete**- To delete a selected task.
- **Cancel**- To cancel the edited changes in a task.
- **Update**- To save the edited changes in a task.
- **ExpandAll**- To expand all the Gantt rows.
- **CollapseAll**- To collapse all the Gantt rows.
- **Indent**- To indent the selected task in Gantt.
- **Outdent**- To outdent the selected task in Gantt.
- **CriticalPath**- To support critical path in Gantt.
- **PrevTimeSpan**- To navigate the Gantt timeline to previous time span.
- **NextTimeSpan**- To navigate the Gantt timeline to Next time span.
- **Search**- To perform search operation in Gantt.
- **ExcelExport**- To export Gantt in Excel format.
- **PdfExport**- To export Gantt in PDF format.

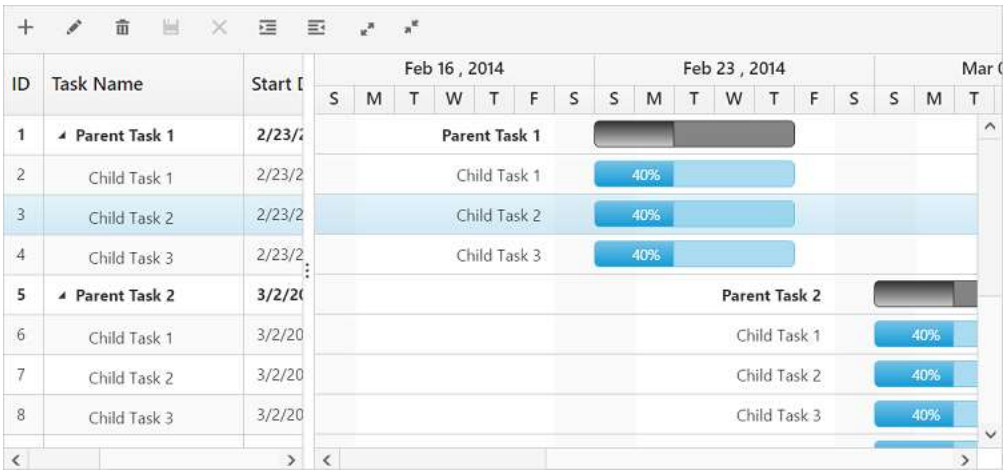
We can enable Gantt toolbar by using below code example:

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.ToolbarSettings(toolbar =>
{
toolbar.ShowToolbar(true);
toolbar.ToolbarItems(new List<GanttToolBarItems>()
{
GanttToolBarItems.Add,
GanttToolBarItems.Edit,
GanttToolBarItems.Delete,
GanttToolBarItems.Update,
GanttToolBarItems.Cancel,
GanttToolBarItems.Indent,
GanttToolBarItems.Outdent,
GanttToolBarItems.ExpandAll,
GanttToolBarItems.CollapseAll,
GanttToolBarItems.NextTimeSpan,
GanttToolBarItems.PrevTimeSpan,
GanttToolBarItems.Search,
GanttToolBarItems.PdfExport,
GanttToolBarItems.ExcelExport,
GanttToolBarItems.CriticalPath
});
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot displays the toolbar option in Gantt control.



Note: To perform add,edit,delete,cancel,update,indent,outdent using Toolbar items we need to enable add/edit/delete/indent using EditSettings.

Custom Toolbar Items

CustomToolbarItems allows us to insert custom icons and custom template in Gantt toolbar. By using below properties we can customize Gantt toolbar as per our requirement.

- **Text**- To insert the custom icons in toolbar using CSS class name selector.
- **TemplateID**-To insert the custom icons in toolbar using script templates. Using this property we can bind HTML elements and other EJ controls to Gantt toolbar.
- **TooltipText**-Displays tooltip text for the custom icons.

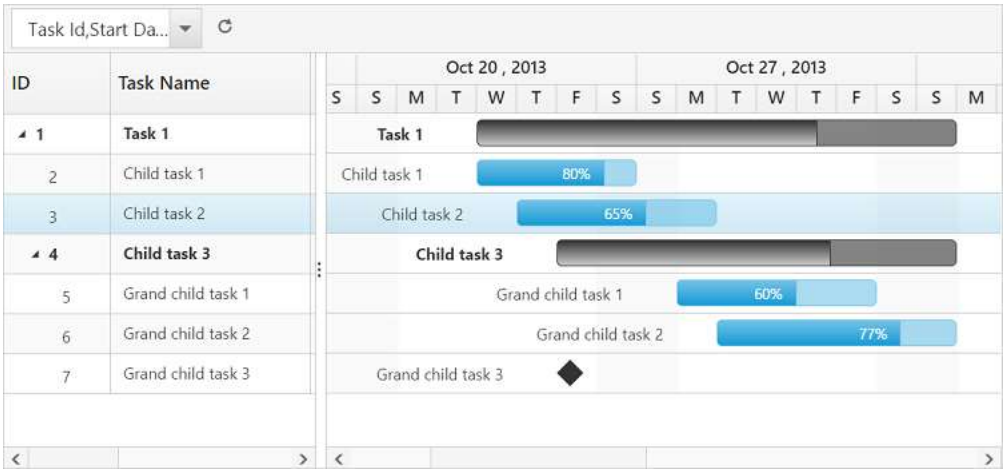
To insert EJ Controls in Gantt toolbar we need to initiate the control in Create client side event.In ToolbarClick client side event we can bind actions to the custom toolbar items.

ASPX-CS

```
@(Html.EJ().Gantt("ToolbarTemplate")
.ToolbarSettings(toolbar =>
{
toolbar.ShowToolbar(true);
toolbar.CustomToolbarItems(ct =>
{
ct.TemplateID("#ColumnVisibility").TooltipText("Column Visibility").Add();
ct.Text("Reset").TooltipText("Reset").Add();
});
})
.ClientSideEvents(cs =>
{
cs.ToolbarClick("toolbarClick");
cs.Create("create");
})
)
@(Html.EJ().ScriptManager())
<script id="ColumnVisibility" type="text/x-jsrender">
<input id="dropdownContainer" />
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script type="text/javascript">
function toolbarClick(args) {
if (args.itemName == "Reset") {
//we can bind the custom actions here
}
}
//Here we can append custom EJ controls
function create(args) {
$("#dropdownContainer").ejDropDownList({ });
}
</script>
<style type="text/css" class="cssStyles">
#ToolbarTemplate_ColumnVisibility {
padding-top: 2px;
padding-bottom: 0px;
}
.Reset:before {
content: "\e677";
}
</style>
```



Click here to view the demo sample for custom toolbar item

Baseline

Baseline is used to describe the original plan of the task and it can be the same as current duration of the task or different.

Baseline can be enabled by setting `RenderBaseline` as `true` and baseline color can be changed by `BaselineColor` property.

To render the baseline you have to map the baseline start date and baseline end date values from data source.

This can be done by using `BaselineStartDateMapping` and `BaselineEndDateMapping` properties.

The following code example shows how to enable baseline in Gantt control.

ASPX-CS

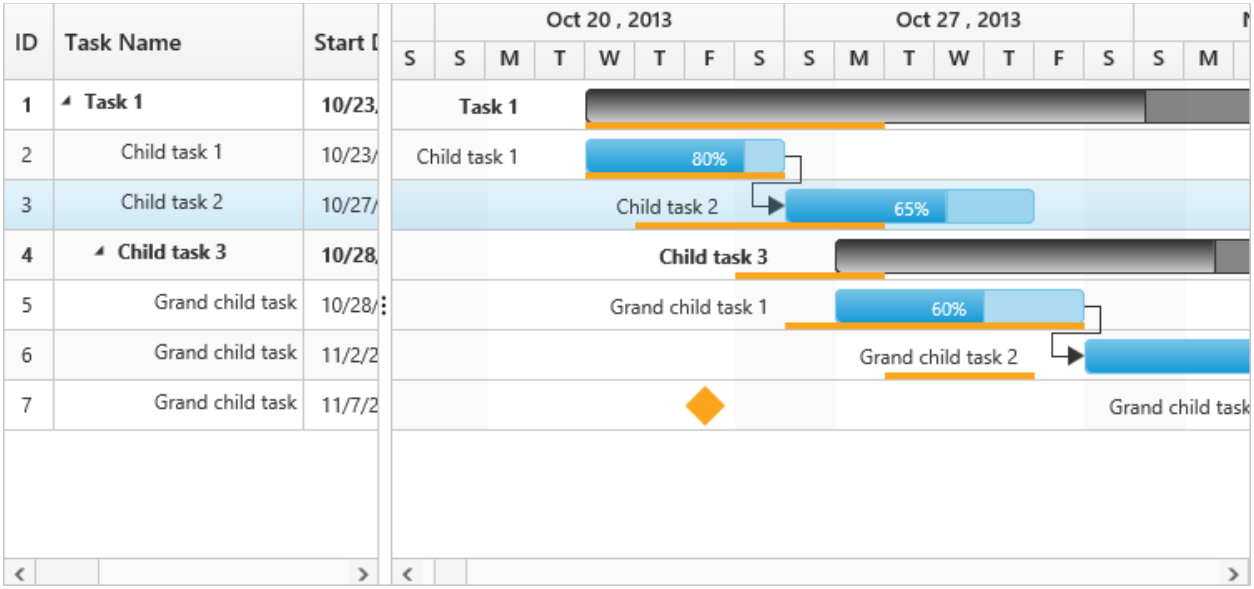
```
@(Html.EJ().Gantt("Gantt")
//...
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.BaselineStartDateMapping("baselineStartDate") //Mapping BaselineStartDate
to Gantt
.BaselineEndDateMapping("baselineEndDate") //Mapping BaselineEndDate to
Gantt
.RenderBaseline(true) //Show/Hide the baseline in Gantt
.BaselineColor("#fba41c")
)
@(Html.EJ().ScriptManager())
```

Click here to view the online demo sample for baselines in Gantt.

The following screenshot shows the baseline in Gantt control.



Work Breakdown Structure

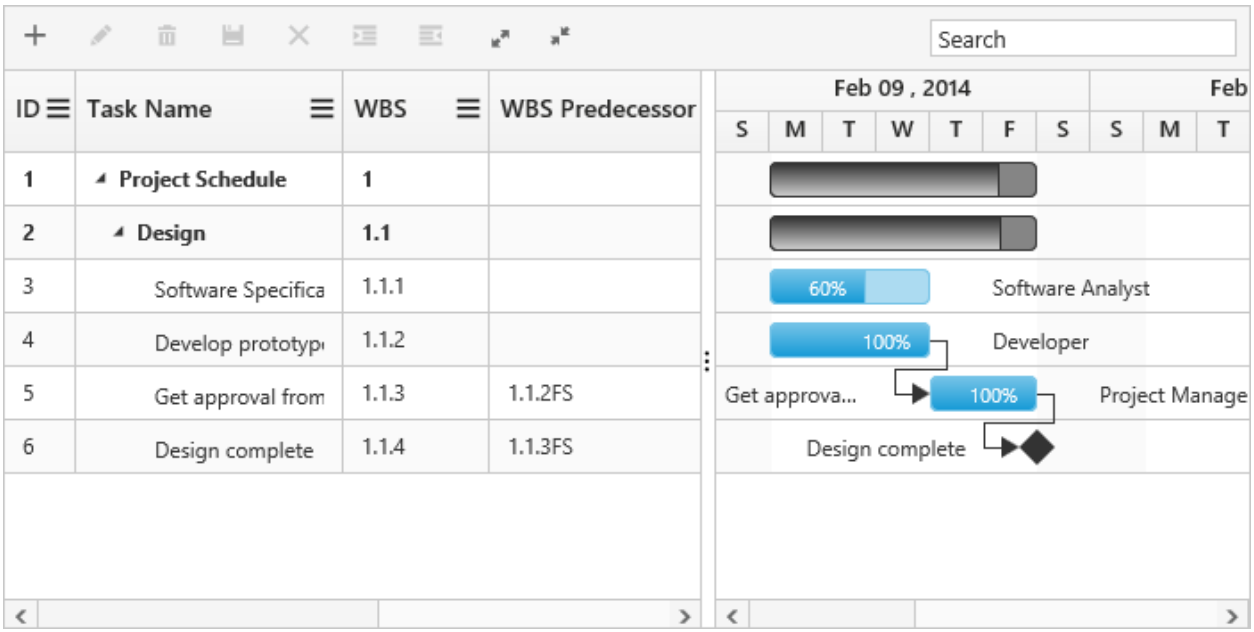
Work Breakdown Structure(WBS) in Gantt represents the entire project activities in various sub modules. It is used to split the large tasks into manageable small tasks. WBS value and WBS predecessor value of Gantt tasks are displayed in WBS column and WBS predecessor column. This can be enabled in Gantt by using `EnableWBS` and `EnableWBSPredecessor` properties. The following code example shows how to enable WBS columns in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
// ...
.EnableWBS(true)
.EnableWBSPredecessor(true)
)
@(Html.EJ().ScriptManager())
```

The below screenshot depicts the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the online demo sample for WBS in Gantt.

Resources

Resources are represented by staff, equipment and materials etc. In Gantt control you can show /allocate the resources (human resources) for each task.

Resource Collection

The resource collection contains details about the resources that are used in the project. Resources are List object that contains id and name of the resources and this collection is mapped to the Gantt control using Resources property.

Id and name field of the resources are mapped by using the ResourceIdMapping and ResourceNameMapping properties.

The following code snippets shows resource collection object and how it assinged to Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//…
.ResourceIdMapping("ResourceId")
.ResourceNameMapping("ResourceName")
.Resources(ViewBag.resource)
)
@(Html.EJ().ScriptManager())
```

C#

```
public ActionResult Resource()
{
ViewBag.resource = this.GetResources();
//...
return View();
}
// Create resource collection
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public class Resource
{
public int ResourceId { get; set; }
public string ResourceName { get; set; }
}
//...
public List<Resource> GetResources()
{
List<Resource> ResourceCollection = new List<Resource>();
ResourceCollection.Add(new Resource() { ResourceId = 1, ResourceName =
"Project Manager" });
ResourceCollection.Add(new Resource() { ResourceId = 2, ResourceName =
"Software Analyst" });
ResourceCollection.Add(new Resource() { ResourceId = 3, ResourceName =
"Developer" });
ResourceCollection.Add(new Resource() { ResourceId = 4, ResourceName =
"Testing Engineer" });
return ResourceCollection;
}
```

Assign Resource

We can assign resources for a task at initial load, using the resource id value of the resources as a collection. This collection is mapped from the DataSource to the Gantt control using the ResourceInfoMapping property.

The following code snippet shows how to assign the resource for each task and map to Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//…
.ResourceInfoMapping("Resources")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

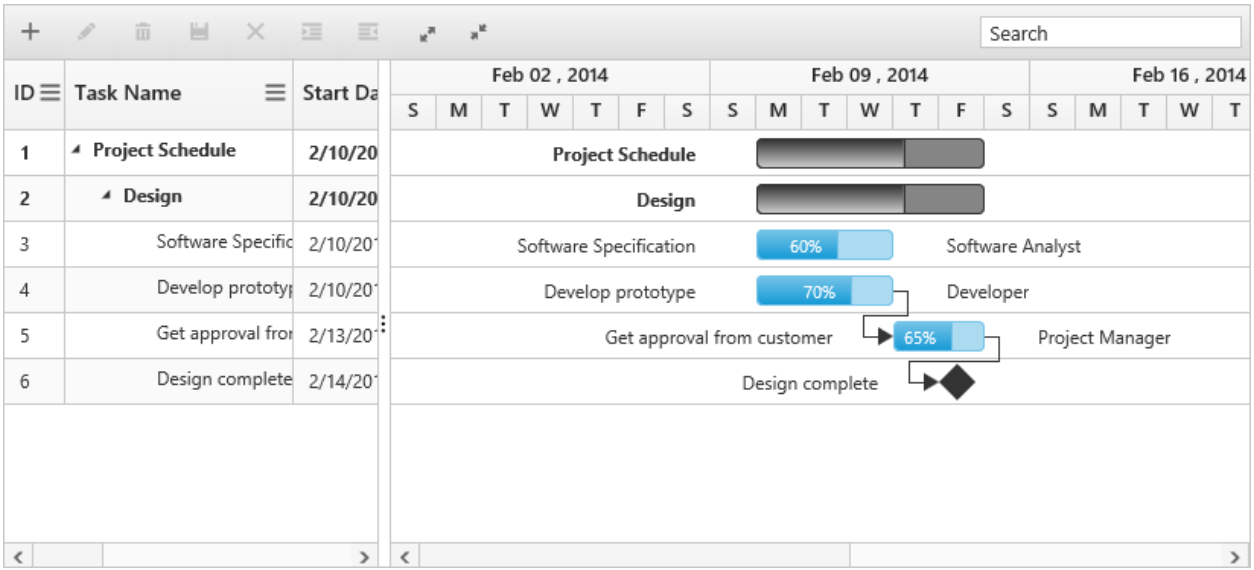
C#

```
public ActionResult Resource()
{
ViewBag.datasource = GetData();
//...
return View();
}
public class ResourceData
{
//...
public List<int> Resources { get; set; }
}
public List<ResourceData> GetData()
{
//..
List<ResourceData> list = new List<ResourceData>();
list.Add(new ResourceData()
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//...
Resources =new List<int>(){2},
//..
});
return list;
}
```

The following screenshot shows Gantt control with resources.



Assign Resources with Unit

Resource units indicates the amount of work done by a resource for the task. We can specify the resource unit for the each assigned resource for a particular task.

Resource unit value is mapped to the Gantt tasks from the datasource using `ResourceUnitMapping` property.

The below code snippets shows how to assign resource unit value.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//…
.ResourceInfoMapping("Resources")
.ResourceUnitMapping("ResourceUnit")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

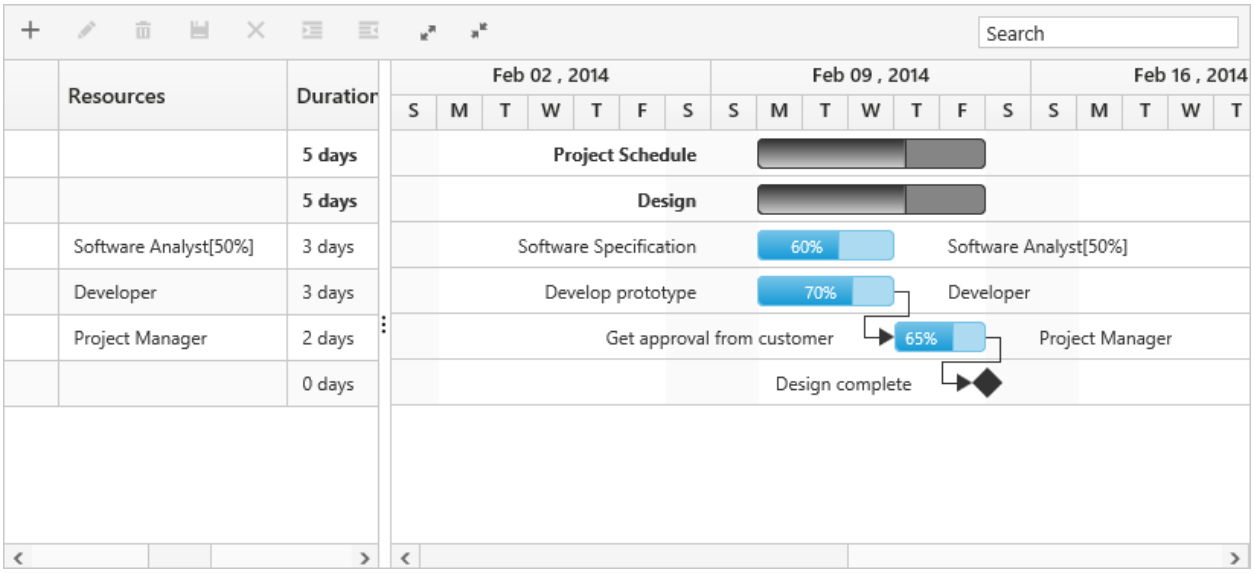
C#

```
public ActionResult Resource()
{
ViewBag.datasource = GetData();
//...
return View();
}
public class ResourceObject
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
public int ResourceId { get; set; }
public int ResourceUnit { get; set; }
}
public class ResourceData
{
//...
public List<ResourceObject> Resources { get; set; }
}
public List<ResourceData> GetData()
{
//..
List<ResourceData> list = new List<ResourceData>();
list.Add(new ResourceData()
{
//...
Resources = new List<ResourceObject>(){ new ResourceObject(){ ResourceId=2,
ResourceUnit=50}},
//..
});
return list;
}
```

The following screenshot shows Gantt control with resource units.



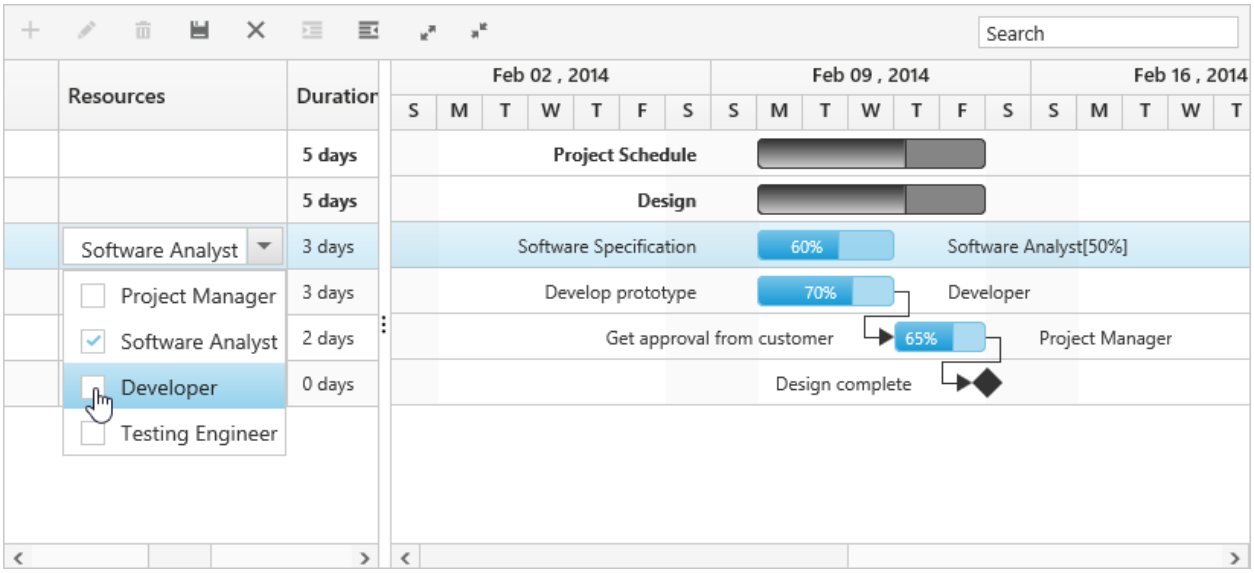
Edit Resource Collection

By using cell edit option we can add/remove the resource for particular task and by using dialog edit support we can modify the resource unit value also.

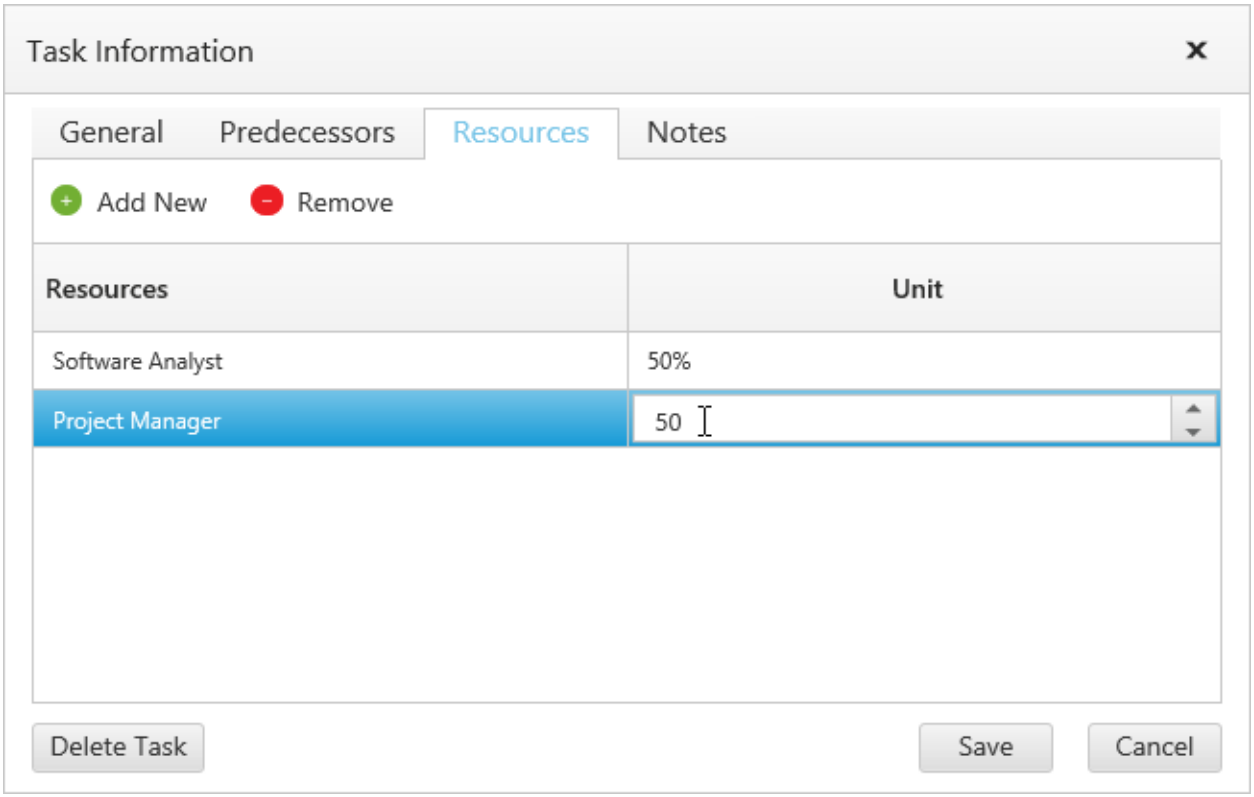
Refer this link to know more about editing in Gantt control.

The following screenshot shows the resource edit option in Gantt.

Copyright © 2001 - 2020 Syncfusion Inc.



Editing resource with cell edit



Editing resource with edit dialog

Note: While editing, resource values are saved with resource unit value when resource unit is not equal to 100% like below.

C#

```
public ActionResult Resource()
{
ViewBag.datasource = GetData();
```

```
//...
return View();
}
public class ResourceObject
{
public int ResourceId { get; set; }
public int ResourceUnit { get; set; }
}
public class ResourceData
{
//...
public List<ResourceObject> Resources { get; set; }
}
public List<ResourceData> GetData()
{
//..
List<ResourceData> list = new List<ResourceData>();
list.Add(new ResourceData()
{
//...
Resources = new List<ResourceObject>(){ new ResourceObject(){ ResourceId=2,
ResourceUnit=50}},
//..
});
return list;
}
```

Note: When resource unit is 100%, resource value is stored with ID only.

C#

```
public ActionResult Resource()
{
ViewBag.datasource = GetData();
//...
return View();
}
public class ResourceData
{
//...
public List<int> Resources { get; set; }
}
public List<ResourceData> GetData()
{
//..
List<ResourceData> list = new List<ResourceData>();
list.Add(new ResourceData()
{
//...
Resources =new List<int>(){2},
//..
});
return list;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Note: The unit values are updated to the resources assigned to the Gantt tasks, only when mapping resource units data source field using the ResourceUnitMapping property.

Resource unit will be updated while editing the duration and work fields with respective to task type.

Work

The Work is the total labor hours necessary to complete a task. Work can be mapped from the data source field using the property WorkMapping and when the work value is mapped from the data source, the end date and duration of the task will be calculated automatically based on the work and resource unit values from the data source.

The below code snippet explains mapping the work value from the data source.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
// ...
.WorkMapping("estimatedWork")
)
@(Html.EJ().ScriptManager())
```

Note:

- When the work is mapped from the data source and if the resource unit is not defined for a task, the work will be calculated as 0 and task will be displayed as a milestone.
- When the work field is mapped from the data source, the default task type will be fixed work.

When the work value for a task is not mapped from the data source using the WorkMapping property, it will be calculated internally based on the number of resources assigned to the task and the duration of the task.

Note:

- By Default, the work field value for a task will be calculated based on the duration and assigned resource unit.
- If an assigned resource has resource unit value of 100% for a task, i.e. if a resource is dedicatedly assigned to a task, the work per day will be **8 hours**.

Work can be measured in hours, days and minutes, and it is measured in 'hours' scale by default and this can be changed by using the workUnit property.

The below code snippet explains how to change work unit property in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
// ...
.WorkUnit(GanttWorkUnit.Minute)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

Task type

The work, duration and resource unit fields of a task depends upon each other values and will change automatically on editing any one of these fields. But we can also set these field's values as constant using the taskType property. The following values can be set to the type property,

Fixed Duration - Duration task field will remain constant while updating resource unit or work field.

Fixed Work - Work field will remain constant while updating resource unit or duration fields.

Fixed Unit - Resource units will remain constant while updating duration or work field.

The following code snippet explains how to set taskType property in Gantt,

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
// ...
.TaskType(GanttTaskType.FixedWork)
)
@(Html.EJ().ScriptManager())
```

Following table explains how the work, duration and resource unit fields will gets updated on changing any of the fields

Task Type	Changes in Duration	Changes in Work	Changes in Resource units
Fixed Duration	Work field updates	Resource unit updates	Work field updates
Fixed Work	Resource unit updatesNote: For manually scheduled task work will update.	Duration field updatesNote: For manually scheduled task resource unit updates.	Duration will updateNote: For manually scheduled task work field updates.
Fixed Unit	Work field updates	Duration field updatesNote: For manually scheduled task resource unit updates.	Duration will updateNote: For manually scheduled task work field updates.

Note:

- **Fixed Unit** is the default taskType in Gantt.
- The above calculations are not applicable for Milestones.

Effort driven tasks

The effortDriven field is used to define whether the total labor hours or the work need to split or to be extended among the resources when adding or removing a resource to a task.

Note:

- Effort driven field is effective only on adding or removing a resource in a task.

The below table illustrates the effects of effort driven field with TaskType property.

Task Type	Effort driven tasks	Task without effort driven

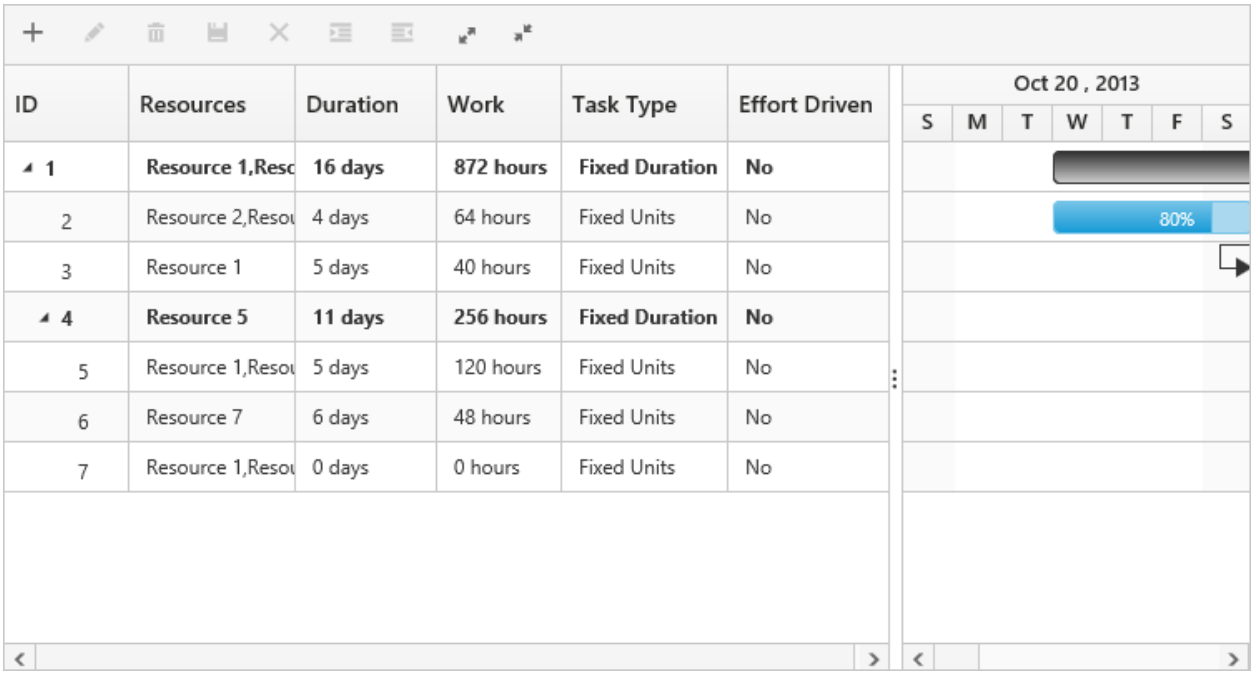
Copyright © 2001 - 2020 Syncfusion Inc.

Fixed Duration	Resource unit updates	Work field updates
Fixed Work	Duration field updatesNote: For Fixed Work effort driven is always true.In this task type the effort driven field is non-editable.	Not applicable
Fixed Unit	Duration field updates	Work field updates

Notes:

- The above calculations will not be considered for Milestones.
- For manually scheduled task effort driven will not be considered while adding or removing resources.
- For manually scheduled task the taskType and effortDriven fields are non-editable.
- When assigning a first resource for the task the effortDriven and taskType fields are not considered, the work field alone will be calculated.

The following screen shot depicts the work, task type and effort driven fields in Gantt.



Stripline

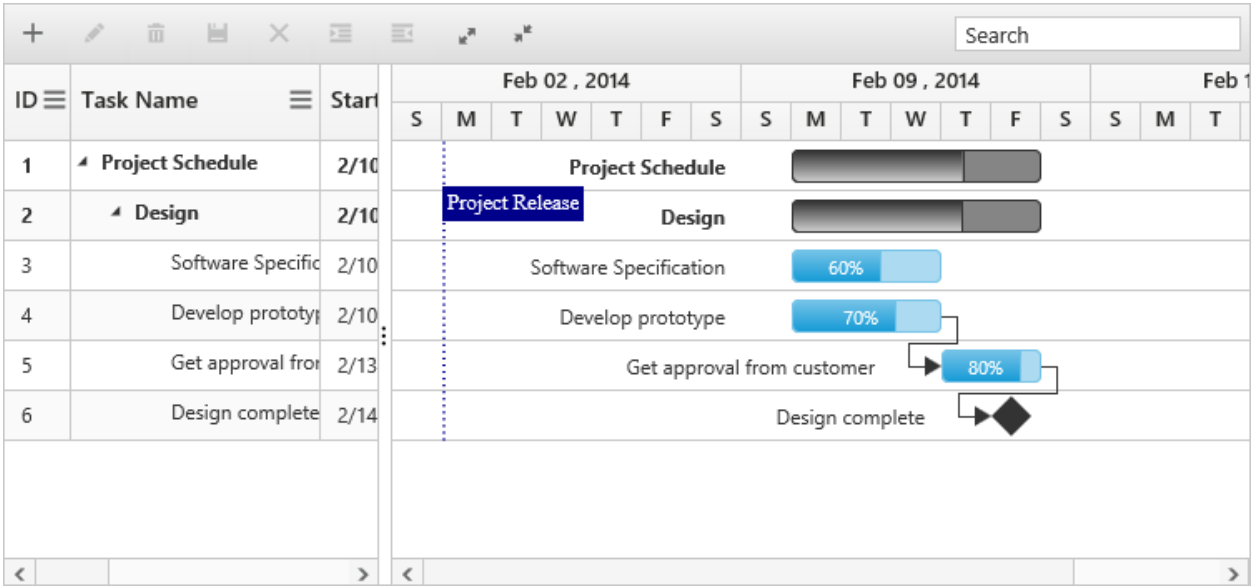
Stripline in Gantt control is used to highlight the important event in Gantt chart part. By using this feature, you can add the Striplines to highlight important days in your project. The following code example shows you how to add the Stripline in Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.StripLines(new    List<Syncfusion.JavaScript.Models.StripLine>
{
```

```
new Syncfusion.JavaScript.Models.StripLine()
{
Day="03/02/2014",
Label="Project Release",
LineStyle="dotted",
LineColor="blue",
LineWidth=2 },
})
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows stripline in Gantt control.



Holidays

The Holidays in Gantt control is used to highlight the non-working days in Gantt control and it can be initialized by using Holidays property.

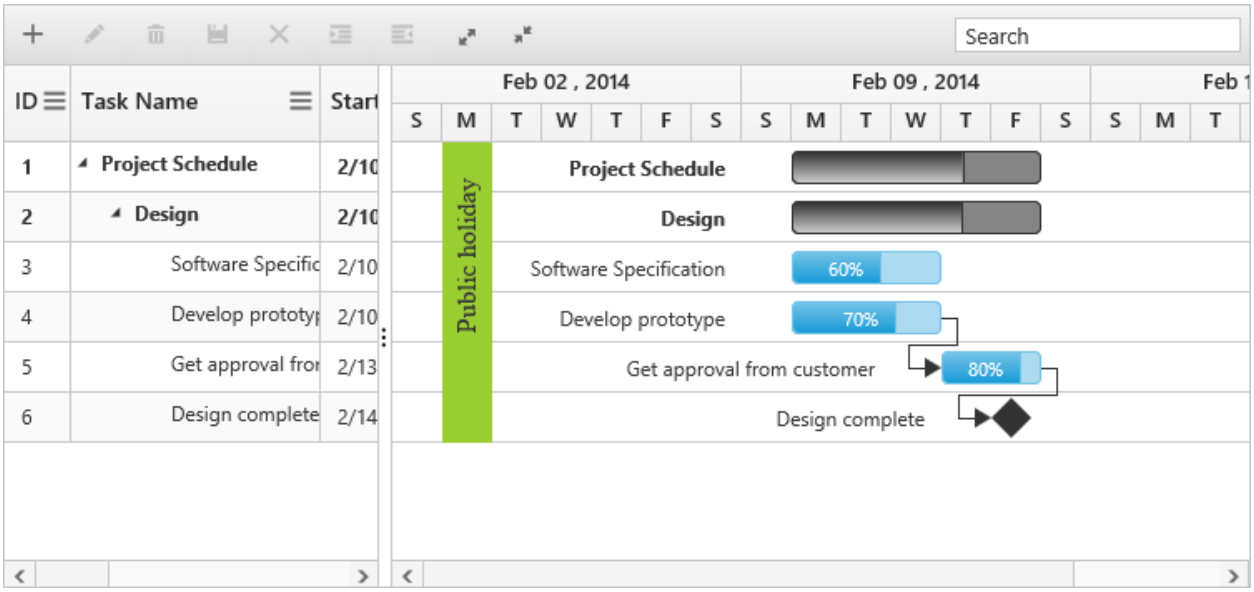
Each holiday can be defined with Day, Label, Background properties. The following code example shows how to initialize the Holidays in Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.Holidays(new List<Syncfusion.JavaScript.Models.Holiday>
{
new Syncfusion.JavaScript.Models.Holiday()
{
Day="2/03/2014",
Background="YellowGreen",
Label="Public holiday"
},
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot shows the output of Holidays in Gantt control.



We can also load holidays from SQL database into Gantt. Click here to view our knowledge base for this.

Localization

Localization is the process of customizing the User Interface (UI) based on a culture, specific to a particular country or region, in order to display regional data. The culture is represented by a unique string like en-US for US English and fr-FR for French.

Localization is the key feature that provides solutions to global customers with the help of localized control. It is necessary to include the specific culture script files (ej.culture.fr-FR.min.js file for French culture) in the reference section, which is available in the following location.

(installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n

Also it is possible to localize all the texts in the Gantt control with specific culture by referring the ej.localetexts.fr-FR.min.js file which is available in the following location.

(installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i10n

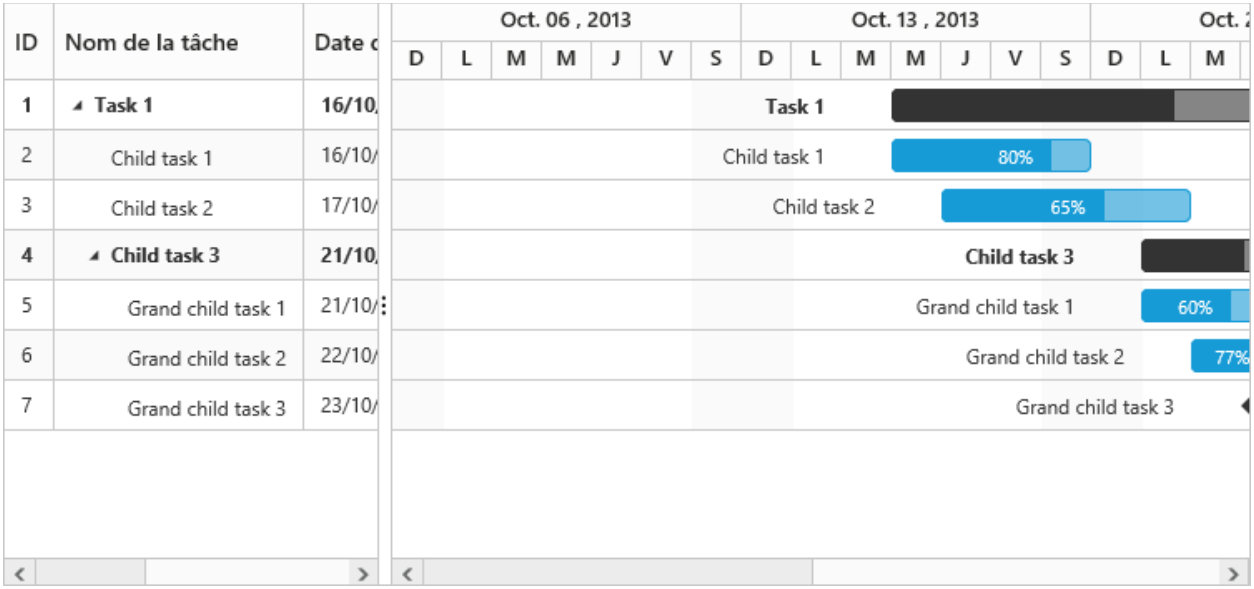
Culture of the Gantt control can be defined by using Locale property.The following code example explains on how to localize the control in French culture

JAVASCRIPT

```
<head>
//…
<script src="Scripts/ej.culture.fr-FR.min.js"></script>
<script src="Scripts/ej.localetexts.fr-FR.js"></script>
</head>
@(Html.EJ().Gantt("Gantt")
//…
.Locale("fr-FR")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
@(Html.EJ().ScriptManager())
```



Which will localize all the text and date formats to French culture. If we still need to customize the localized text, we can define them locally in the sample as explained below.

JAVASCRIPT

```
@(Html.EJ().Gantt("Gantt")
//…
.Locale("fr-FR")
)
@(Html.EJ().ScriptManager())
<script type = "text/javascript">
ej.Gantt.Locale["fr-FR"] = {
emptyRecord: "Aucun enregistrement à afficher",
alertTexts: {
indentAlert: "Il n'y a aucune trace de Gantt est sélectionné pour effectuer
le retrait",

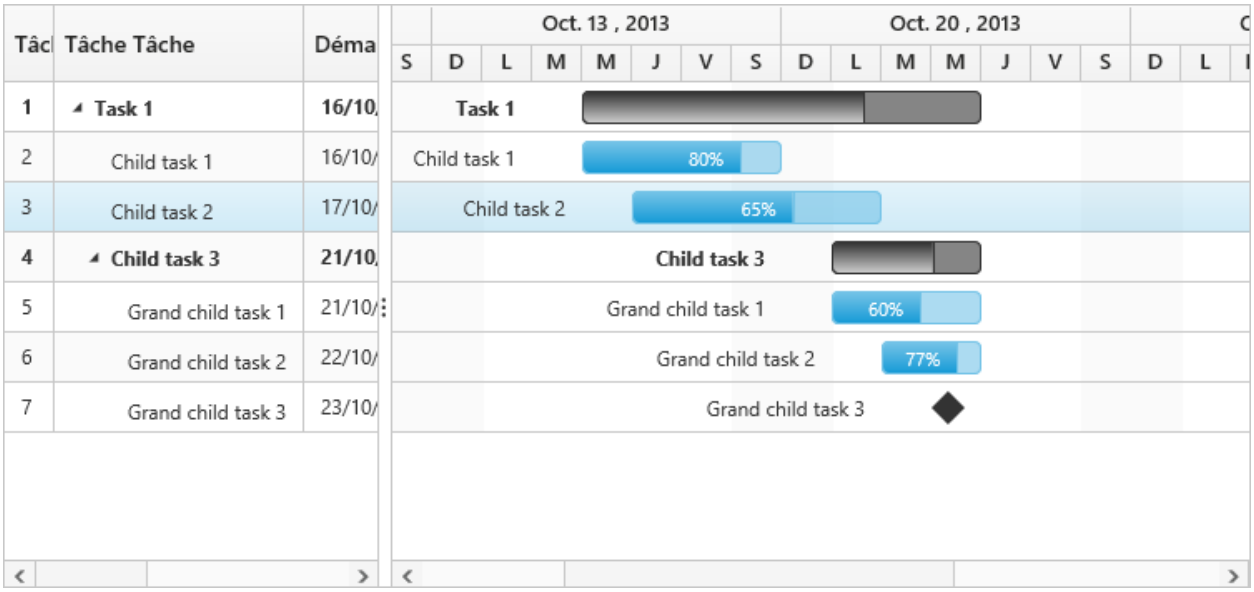
}
],
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.



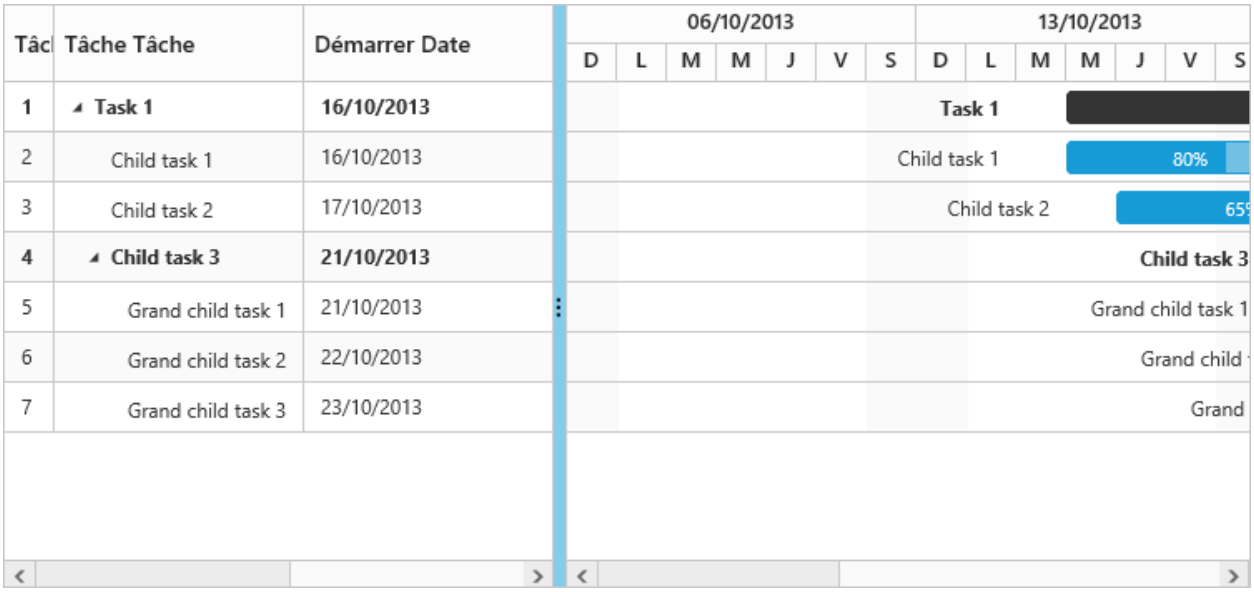
Date format

The default date format used in the Gantt control is “MM/dd/yyyy”. Date formats will be changed based on the culture referred in the control. But if you still need to change the date format we can define the desired format using the dateFormat property. The same have been explained in the following code example.

JAVASCRIPT

```
@(Html.EJ().Gantt("Gantt")
//…
.DateFormat("dd/MM/yyyy")
.ScheduleHeaderSettings(ScheduleHeader =>
ScheduleHeader.WeekHeaderFormat("dd/MM/yyyy"))
.Locale("fr-FR")
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



Keyboard navigation

Gantt control supports the following keyboard shortcuts for performing various actions and keyboard navigation can be enabled/disabled by AllowKeyboardNavigation property

Alt + j : To focus the Gantt control.

Home : To select the first row.

End : To select the last row.

F2 : For editing the focused cell of the selected row.

Enter : To save the edited cell.

Delete : To delete the selected row.

Ctrl + Down Arrow : To expand all the parent tasks.

Ctrl + Up Arrow : To collapse all the parent tasks.

Left Arrow : To collapse the selected parent task.

Right Arrow : To expand the selected parent task.

Click here to view the sample for keyboard navigation.

Tooltip

The Gantt has support to display tooltip for both taskbars and for column cells.

Taskbar and dependency line tooltip

In Gantt, you can enable or disable taskbar and dependency line mouse hover tooltip by using the EnableTaskbarTooltip property. The default value of this property is true. The following code example shows, how to enable the taskbar and dependency line tooltip in Gantt.

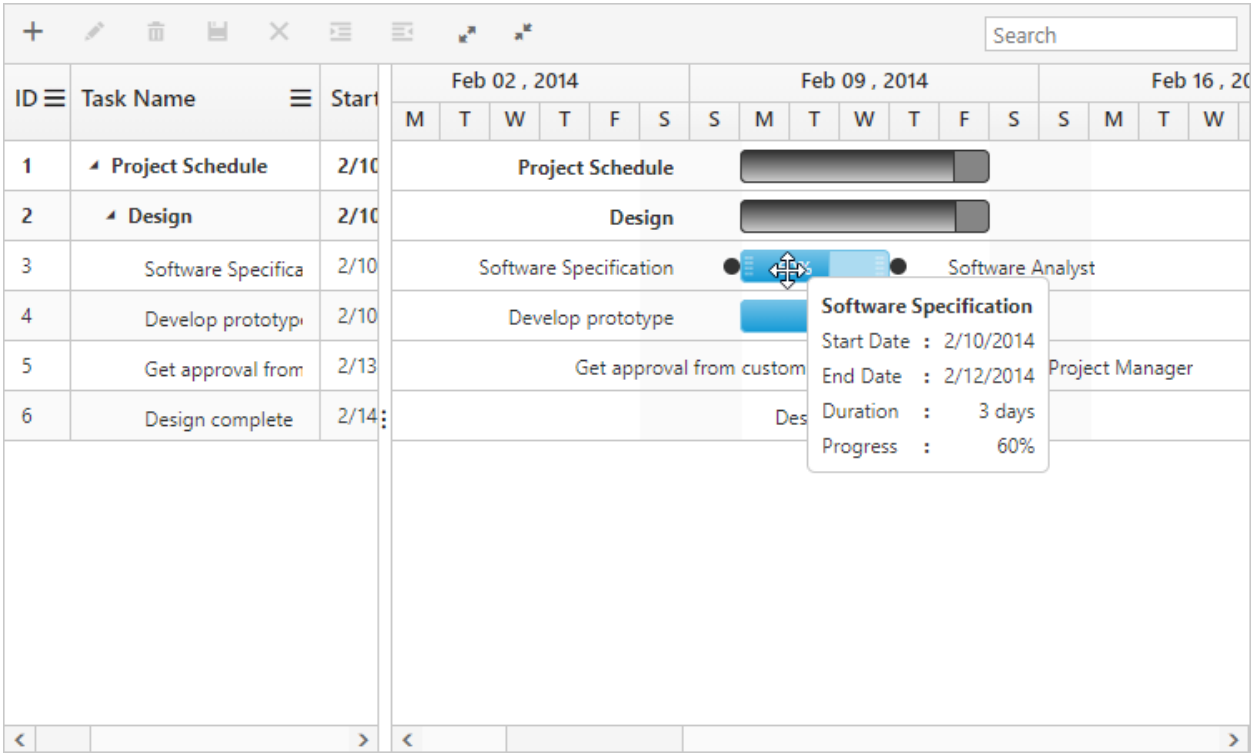
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EnableTaskbarTooltip(true)
```

Copyright © 2001 - 2020 Syncfusion Inc.

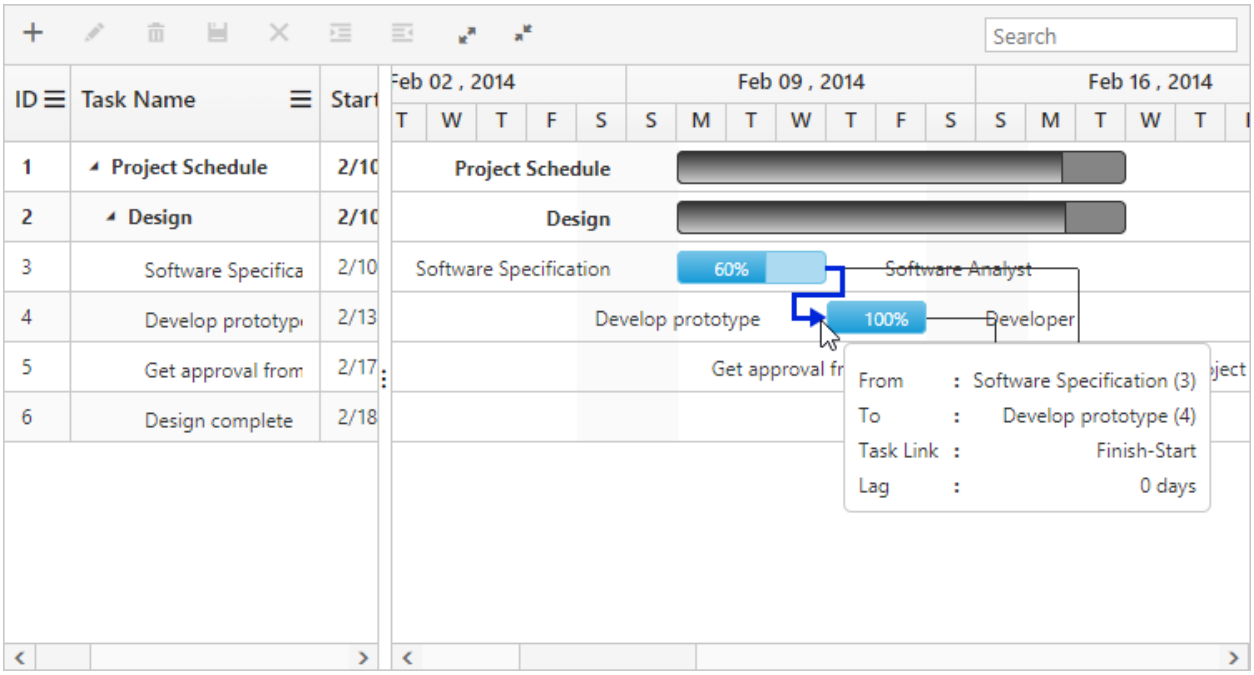
```
.PredecessorMapping("Predecessors")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Taskbar tooltip can be customized by using the TaskbarTooltipTemplate property and dependency line tooltip can be customized by using the PredecessorTooltipTemplate property, these properties are described briefly in the customization section.



Taskbar Tooltip

Copyright © 2001 - 2020 Syncfusion Inc.



Dependency Tooltip

Taskbar drag tooltip

It is possible to enable or disable the tooltip while performing editing actions on taskbar (left resizing, right resizing, dragging and progress resizing) by using the `EnableTaskbarDragTooltip` property. By default, this property is set to `true`. The following code example explains this behavior.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.EnableTaskbarDragTooltip(true)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Cell tooltip

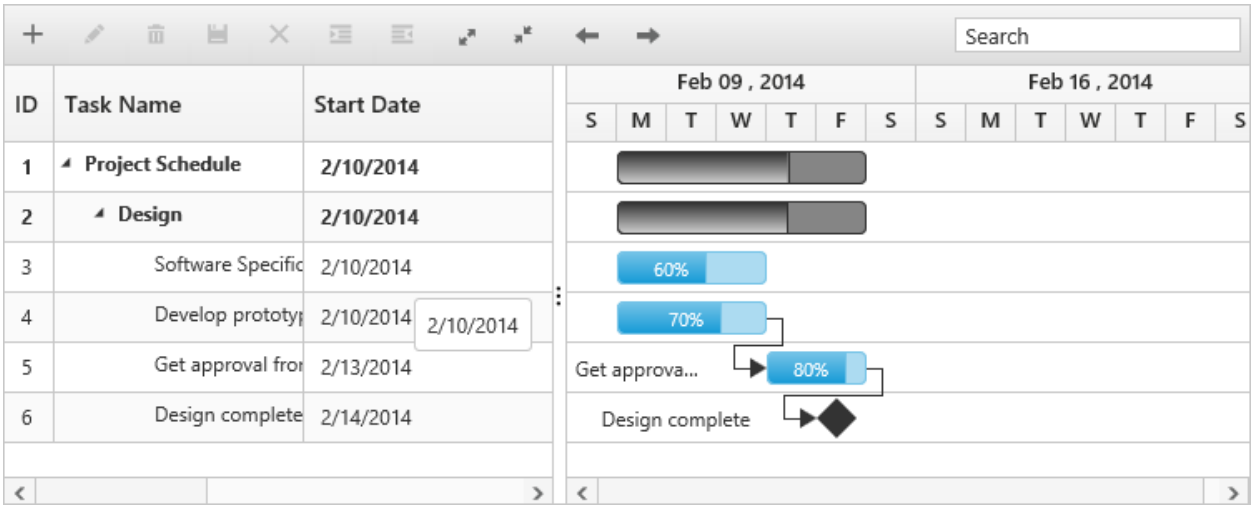
It is possible to enable or disable the TreeGrid cell tooltip in mouse hover by using the `ShowGridCellTooltip` property. By default, this property is set to `true`. The following code example explains how to enable disable this property.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.ShowGridCellTooltip(true)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

This tooltip can be customized using the `CellTooltipTemplate` property, which is described briefly in the customization section.

Copyright © 2001 - 2020 Syncfusion Inc.

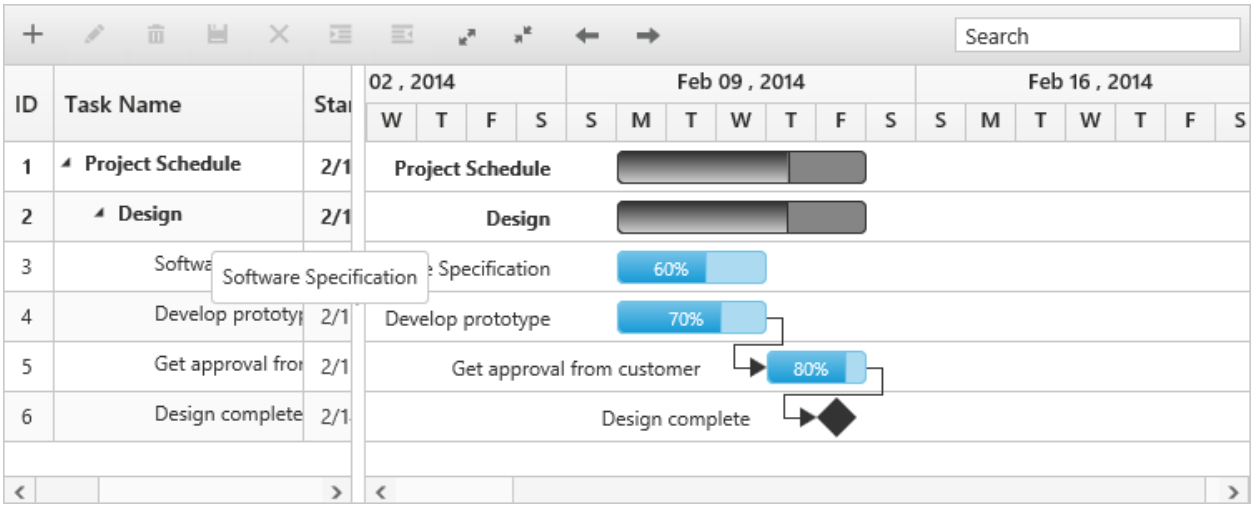


Tree column (Expander column) tooltip

It is also possible to display tooltip only for expander column by setting the ShowGridExpandCellTooltip property. The following code example shows you to enable expander column tooltip in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//...
.ShowGridExpandCellTooltip(true)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```



Duration Units

In Gantt, the task's duration value can be measured by the following duration units,

- Day
- Hour
- Minute

Copyright © 2001 - 2020 Syncfusion Inc.

Each task in the project can be defined with different duration units and the duration unit of a task can be defined by the following ways,

1. Using DurationUnitMapping property, to map the duration unit data source field.
2. Defining the duration unit value along with the duration field in the data source.

Mapping the Duration Unit field

The below code snippet explains the mapping of duration unit data source field to the Gantt control using the DurationUnitMapping property.

ASPX-CS

```
@(Html.EJ().Gantt("ganttsample1")
//..
.DurationMapping("Duration")
.DurationUnitMapping("DurationUnit")
)
@(Html.EJ().ScriptManager())
```

C#

```
public class GanttController : Controller
{
//
// GET: /DurationUnits/
public ActionResult GanttDurationUnits()
{
ViewBag.DataSource = GetData();
return View();
}
public static List<GanttDuratioUnitData> GetData()
{
List<GanttDuratioUnitData> list = new List<GanttDuratioUnitData>();
list.Add(new GanttDurationUnitData()
{
TaskID = 1,
TaskName = "Parent Task 1",
StartDate = "02/27/2017",
Duration = "5day",
Progress = 40,
Children = (new List<GanttDurationUnitData>()
{
new GanttDurationUnitData()
{
TaskID = 2,
TaskName = "Child Task 1",
StartDate = "02/27/2017",
Duration = "5d",
Progress = 40
},
new GanttDurationUnitData()
{
TaskID = 3,
TaskName = "Child Task 2",
StartDate = "02/27/2017",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Duration = "40",
DurationUnit="hour",
Progress = 40,
},
new GanttDurationUnitData()
{
TaskID = 4,
TaskName = "Child Task 3",
StartDate = "02/27/2017",
Duration = "2400",
DurationUnit = "minute",
Progress = 40
}
})
//..
});
return list;
}
public class GanttDurationUnitData
{
//..
public string Duration { get; set; }
public string DurationUnit { get; set; }
}
}
```

Note: 1. The default value of the DurationUnit property is GanttDurationUnit.Day.

Defining duration unit along with duration field

Duration units for the tasks can also be defined along with the duration values, the below code snippet explains the duration unit for a task along with duration value,

ASPX-CS

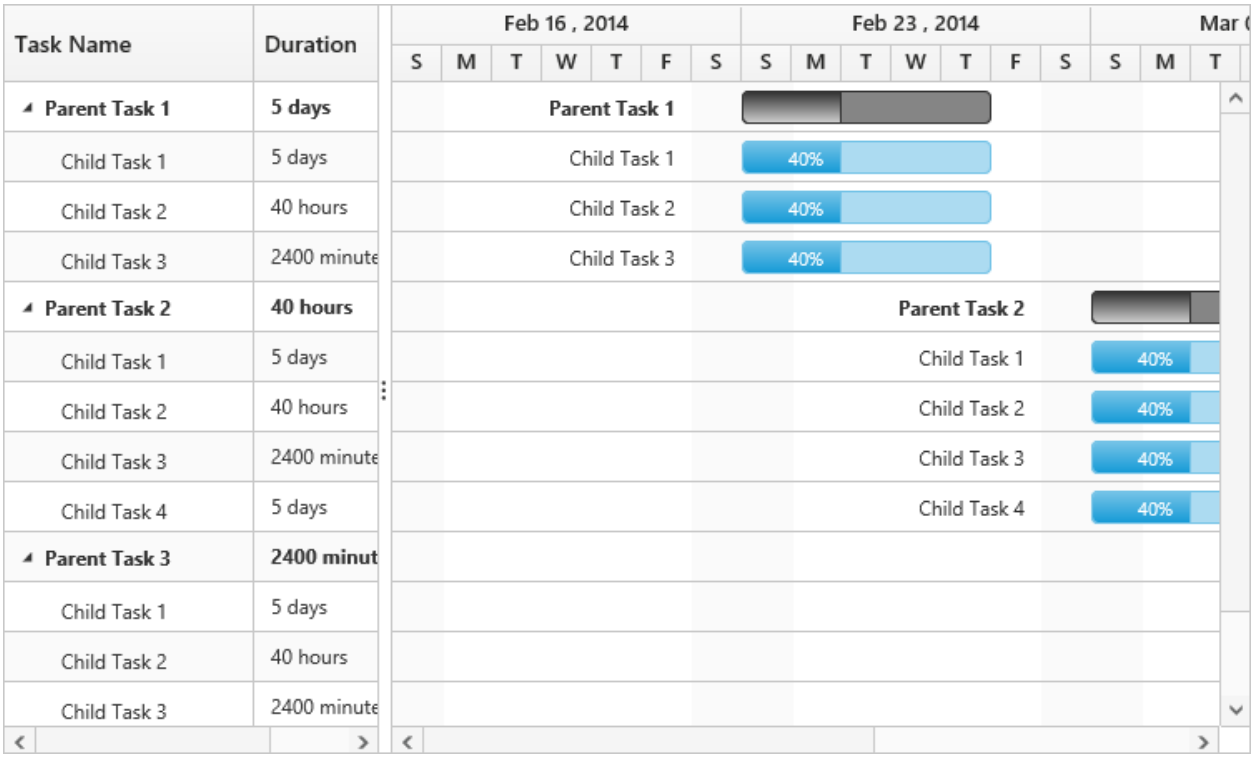
```
@(Html.EJ().Gantt("ganttsample1")
//..
.DurationMapping("Duration")
)
@(Html.EJ().ScriptManager())
```

The below sample explains the task's duration unit in Gantt.

[Duration Unit]

The below screen shot shows different duration unit support in Gantt control.

Copyright © 2001 - 2020 Syncfusion Inc.



Note: 1. The edit type of the duration column in Gantt is string, to support editing the duration field along with duration units.

Localizing the duration unit

We can localize the duration unit texts like below,

ASPX-CS

```
ej.Gantt.Locale["en-US"] = {
//...
durationUnitTexts: {
days: "days",
hours: "hours",
minutes: "minutes",
day: "day",
hour: "hour",
minute: "minute"
},
durationUnitEditText: {
minute: ["m", "min", "minute", "minutes"],
hour: ["h", "hr", "hour", "hours"],
day: ["d", "dy", "day", "days"]
}
};
```

Note: **durationUnitTexts** property is used to display the unit of duration in columns and taskbar tooltips.

durationUnitEditText property is used to save the edited duration unit value on editing action.

Click here to view the online demo sample for mapping the duration units.

Copyright © 2001 - 2020 Syncfusion Inc.

Working Time Range

In Gantt control, working hours in a day for a project can be defined by using the DayWorkingTime property. Based on the working hours, automatic date scheduling and duration validations for a task are performed.

The below code snippet explains on how to define the working time range for the project in Gantt,

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
// ...
.DayWorkingTime(dt=>
{
dt.From("08:00 AM").To("12:00 PM").Add();
dt.From("01:00 PM").To("05:00 PM").Add();
})
)
@(Html.EJ().ScriptManager())
```

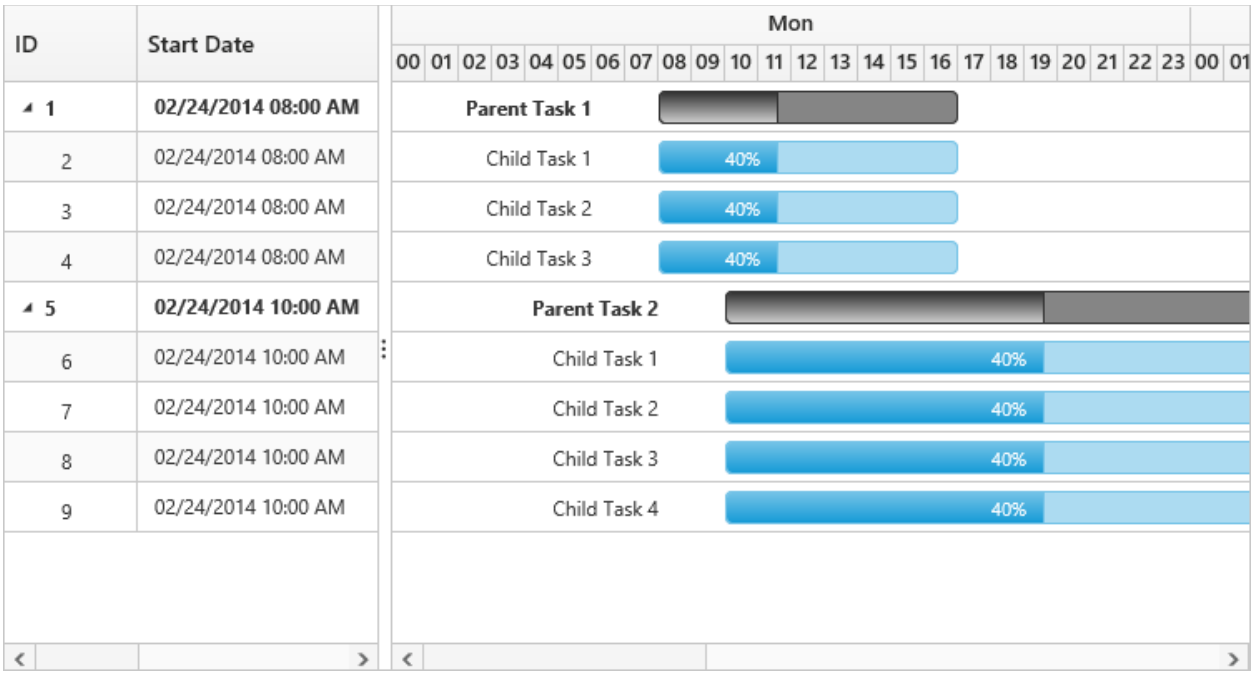
Note: 1. Individual tasks can lie between any time within the defined working time range of the project.

Note: 2. DayWorkingTime property is used to define the working time for the whole project.

The below demo explains the working time range in Gantt.

Working Time Range

The following screen shot shows working time range in Gantt control.



Highlight working time range

Highlight the working time range with a background color by using the DayWorkingTime.Background property. You can highlight the non-working time ranges in a day. To do this, set the

Copyright © 2001 - 2020 Syncfusion Inc.

HighlightNonWorkingTime property to true. To customize the non-working time background, use the NonWorkingBackground property.

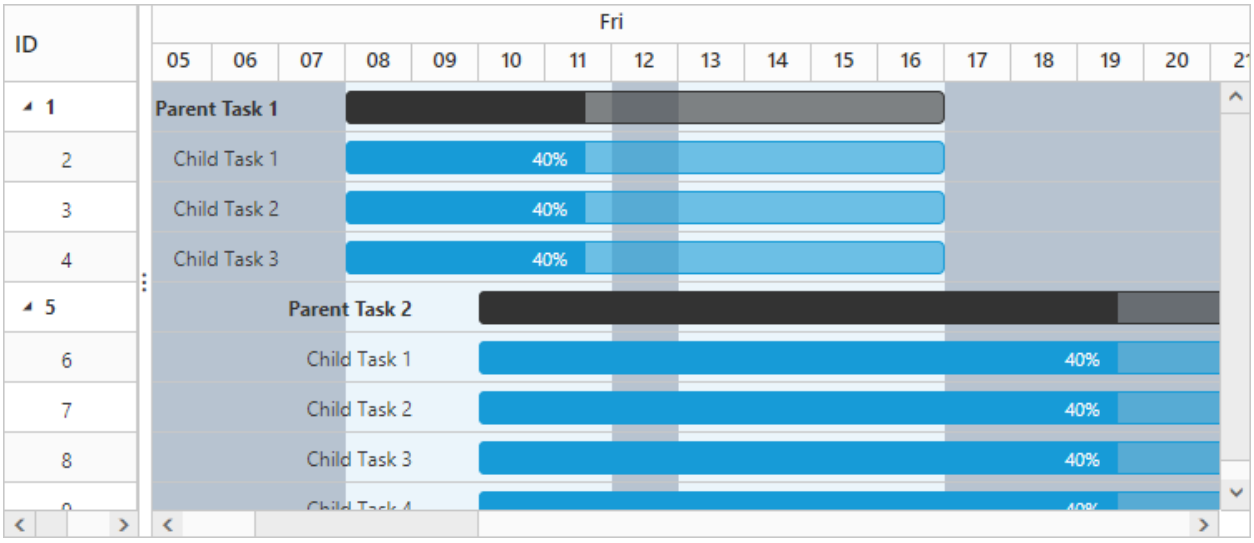
The following code snippet explains how to define the working time range with background in Gantt.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
// ...
.HighlightNonWorkingTime(true)
.NonWorkingBackground("#B7C3D0")
.DayWorkingTime(dt => {
dt.From("08:00 AM").To("12:00 PM").Background("#EBF5FB").Add();
dt.From("01:00 PM").To("05:00 PM").Background("#EBF5FB").Add();
})
)
@(Html.EJ().ScriptManager())
```

Note: The background colors of working time range are highlighted only when the ScheduleHeaderSettings.ScheduleHeaderType value as day.

The following screenshot shows the working time range with background colors.



Appearance and Styling

The look and feel of the Gantt control can be customized by applying themes and formatting the schedule header.

Schedule Header Customization

Schedule Header Unit Format

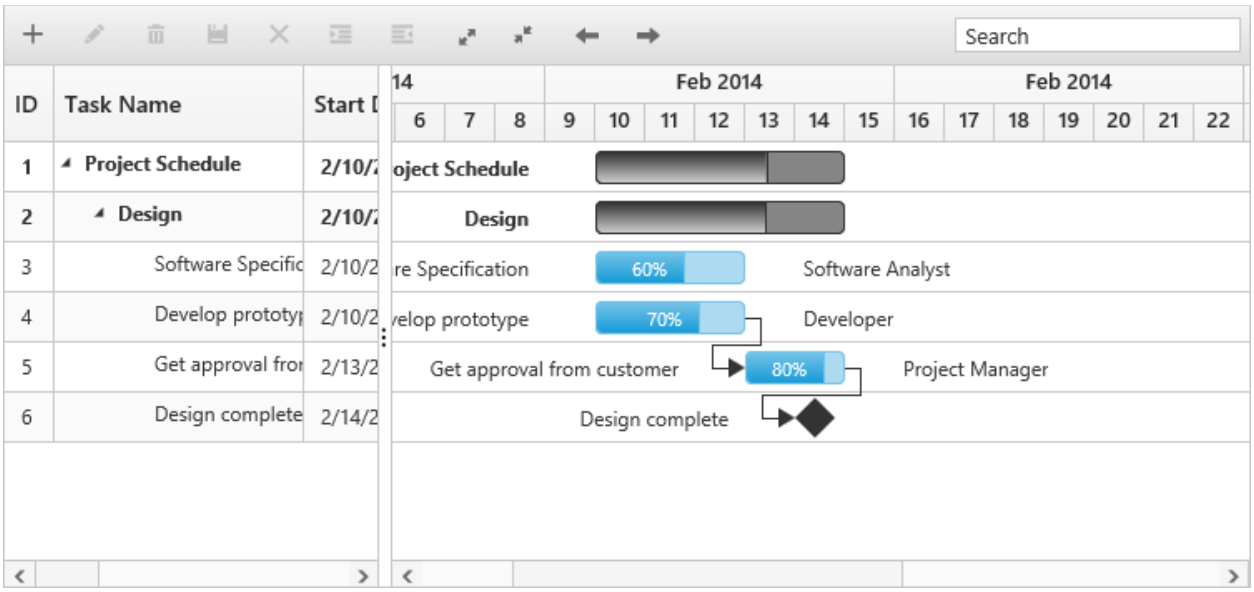
You can change the format of schedule headers in various timescale modes by using DayHeaderFormat, HourHeaderFormat, WeekHeaderFormat, MonthHeaderFormat and YearHeaderFormat properties available in ScheduleHeaderSettings property.

And you can change the background of weekends available in timescale by using WeekendBackground property, please refer the following code example.

ASPX-CS

```
@(Html.EJ().Gantt("GanttContainer")
//...
.ScheduleHeaderSettings(sh=>
{
sh.WeekHeaderFormat("MMM yyyy");
sh.DayHeaderFormat("d");
sh.HourHeaderFormat("HH");
sh.MonthHeaderFormat("MMM");
sh.YearHeaderFormat("yyyy");
sh.WeekendBackground("#F2F2F2");
})
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the customized format schedule header in Gantt control.



Schedule Header Unit Width

Schedule header units width value can be customized by using ScheduleHeaderSettings.TimescaleUnitSize property. The default value of this property was 100%, we can set value for this property from 50% to 500%.

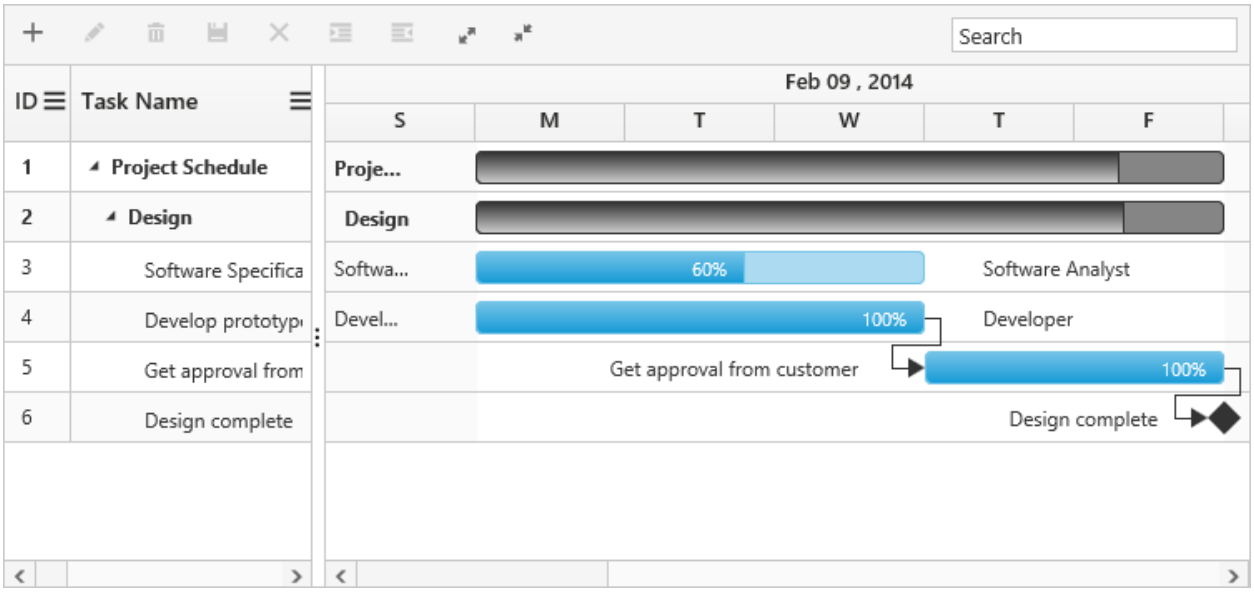
The following code example shows how to use this properties.

ASPX-CS

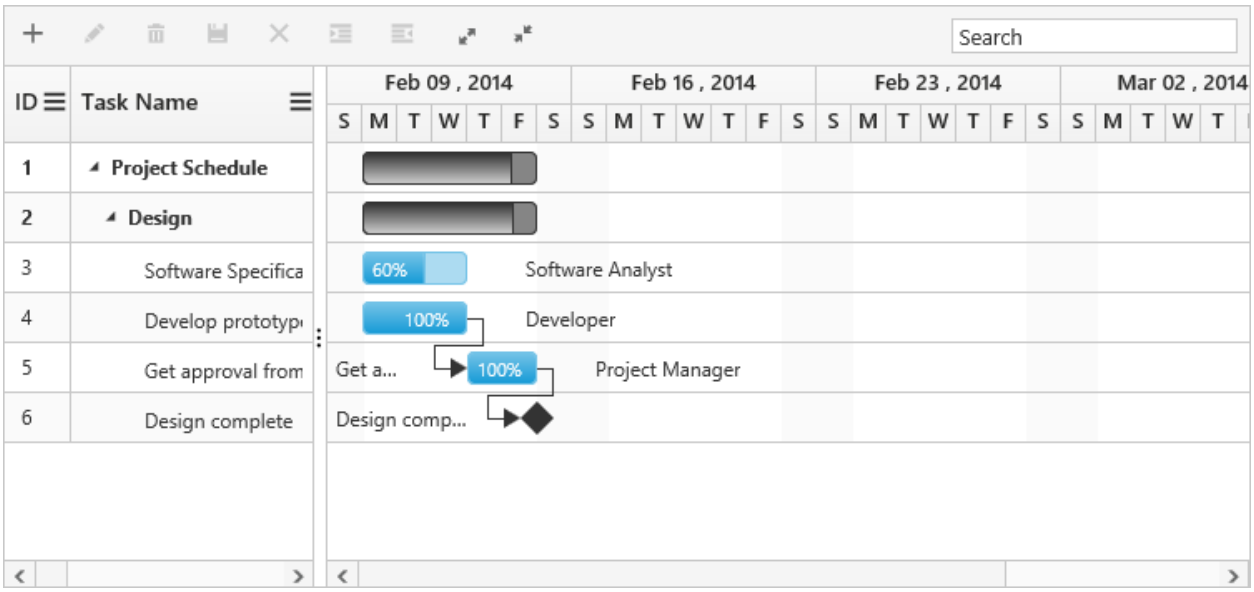
```
@(Html.EJ().Gantt("Gantt")
//..
.ScheduleHeaderSettings(sh=>
{
sh.TimescaleUnitSize("70%");
})
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Schedule header units with 300% width value



Schedule header units with 70% width value

Taskbar Customization

Taskbar Background

Background color of child taskbars and parent taskbars can be customized by using TaskbarBackground and ParentTaskbarBackground properties. The following code example shows how to use this properties.

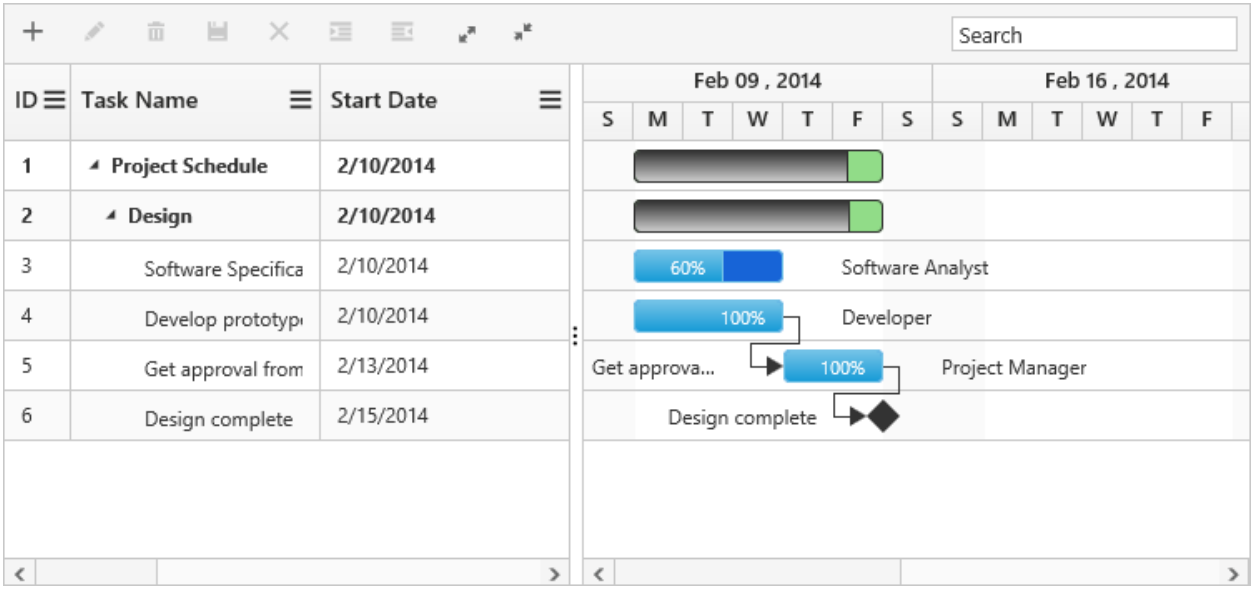
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//..
.TaskbarBackground("#1764d7")
.ParentTaskbarBackground("#91dc88")
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().ScriptManager())
```

The following screenshot shows the customized parent and child taskbars in Gantt.



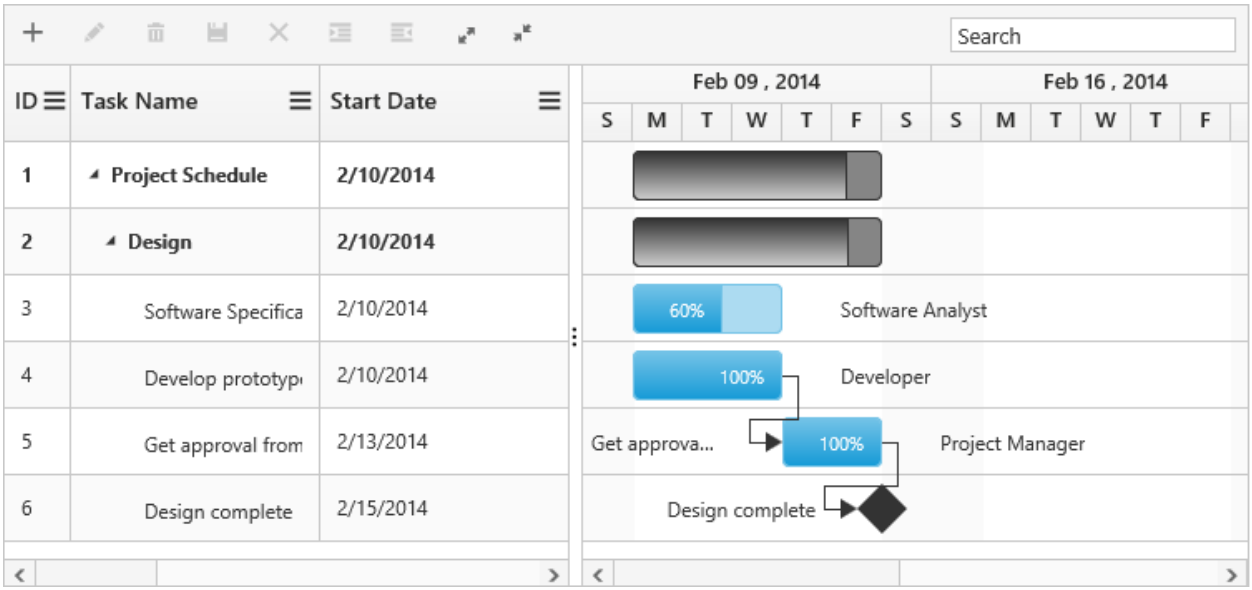
Taskbar Height

Height of child taskbars and parent taskbars can be customized by using TaskbarHeight property. The following code example shows how to use the property.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//..
.TaskbarHeight(30)
.RowHeight(40)
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the output of above code example.



Note: TaskbarHeight value should be lower than RowHeight property value.

Progressbar Customization

Background color of child task's progress bar and parent task's progress bar can be customized by using ProgressbarBackground and ParentProgressbarBackground properties. Progress bars height can be changed by using ProgressbarHeight property. The visibility of progress status label inside the taskbars can be changed by using ShowProgressStatus property.

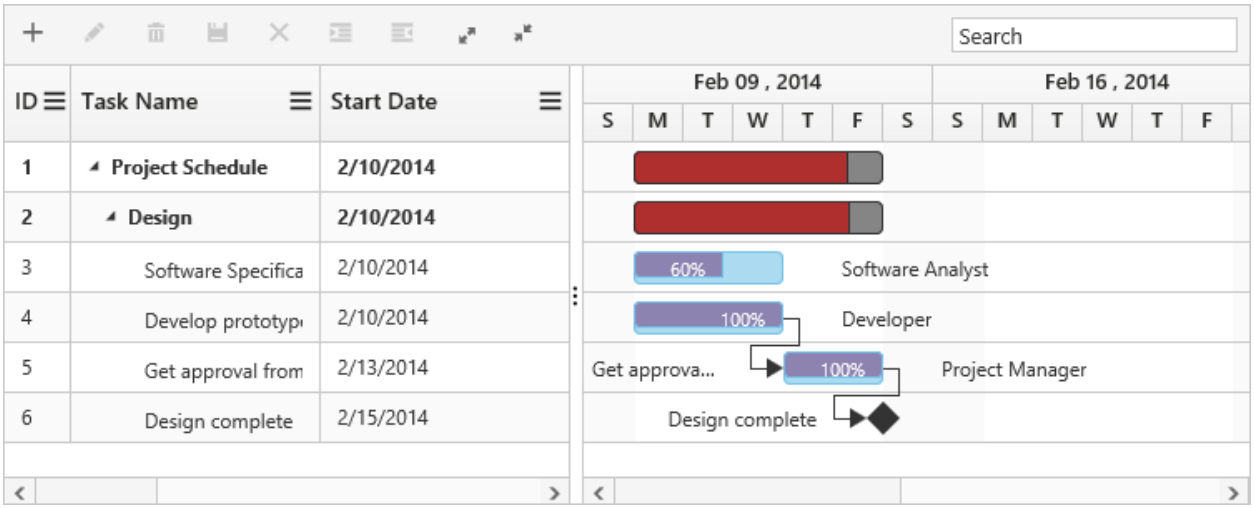
The following code example shows how to use this properties.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//..
.ProgressbarBackground("#8c83b1")
.ParentProgressbarBackground("#af2f2f")
.ProgressbarHeight(80)
.ShowProgressStatus(true)
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the customized progress bar of parent and child tasks in Gantt.

Copyright © 2001 - 2020 Syncfusion Inc.



Note: ProgressbarHeight property value should be in 0 to 100, because this value was considered as percentage value of taskbar height value.

Conditional Formatting

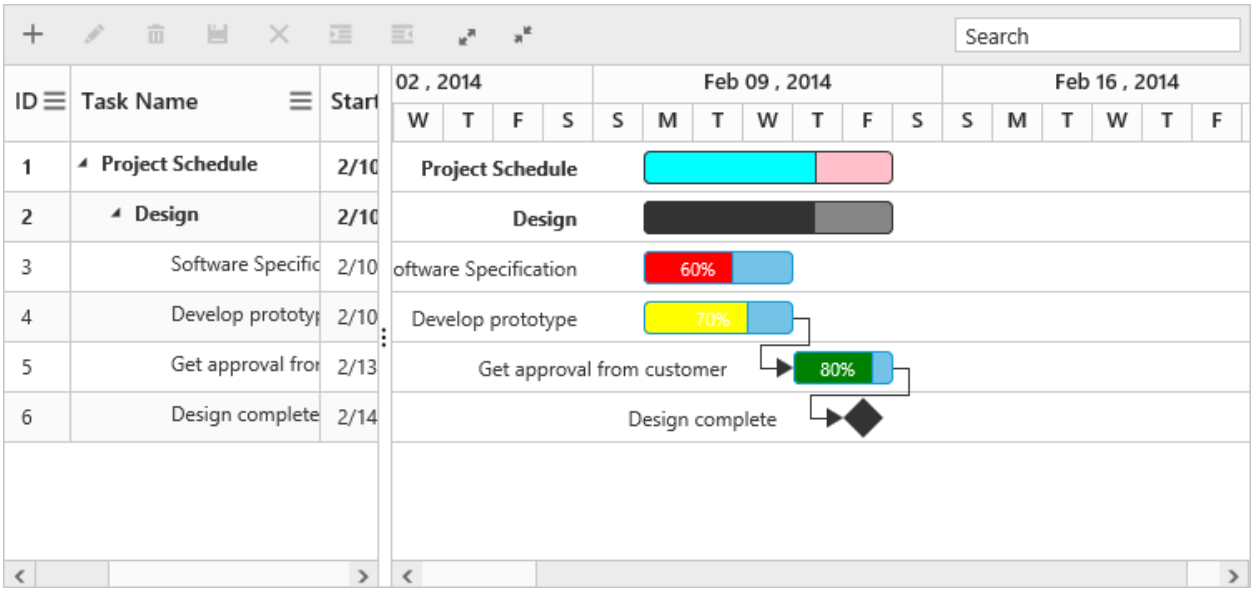
The Taskbar can be customized based on the task information in Gantt control by using QueryTaskbarInfo event. The following code example shows how to customize the Taskbar in Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.ClientSideEvents(eve =>
{
eve.QueryTaskbarInfo("queryTaskbarInfo");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function queryTaskbarInfo(args){
//queryTaskbarInfo will be triggered when a taskbar is rendered
if (args.data.level === 0) {
args.parentTaskbarBackground = "pink";
args.parentProgressbarBackground = "cyan";
} else {
if (args.data.status == "60") {
args.progressbarBackground = "red";
} else if (args.data.status == "70") {
args.progressbarBackground = "yellow";
} else if (args.data.status == "80") {
args.progressbarBackground = "green";
}
}
}
</script>
```

The following screenshot shows the customized taskbar in Gantt control.

Copyright © 2001 - 2020 Syncfusion Inc.



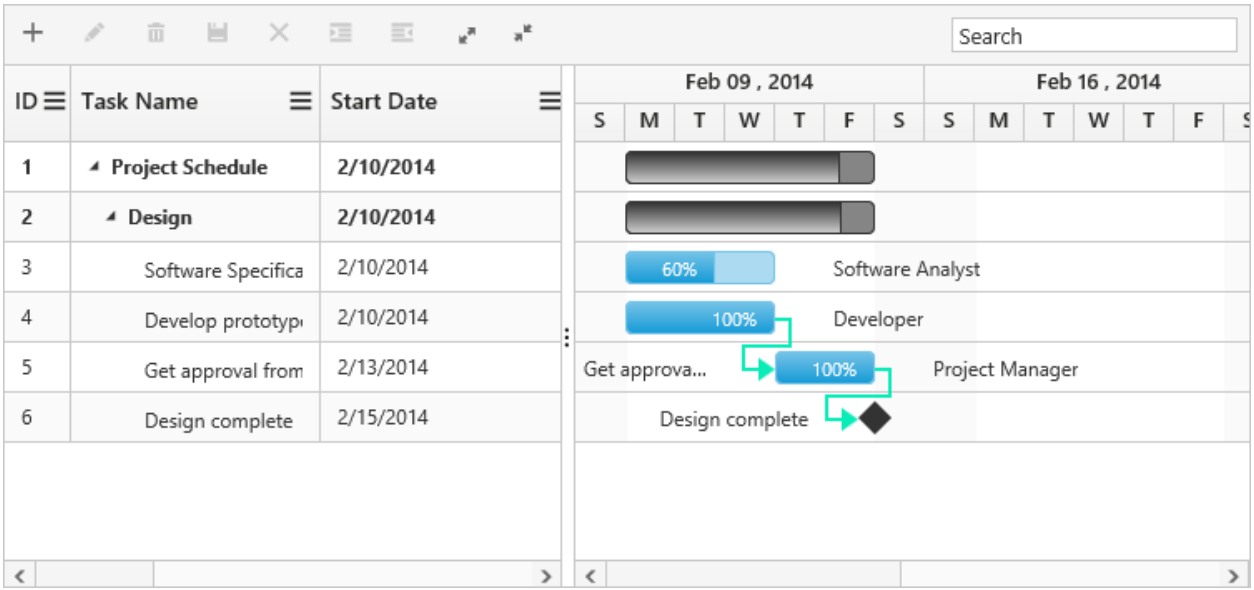
Dependency line customization

Width and background color of dependency line in Gantt can be customized by using `ConnectorlineWidth` and `ConnectorLineBackground` properties. The following code example shows how to use this properties.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.ConnectorlineWidth(2)
.ConnectorLineBackground("#0aecb8")
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the customized dependency lines in Gantt.



Copyright © 2001 - 2020 Syncfusion Inc.

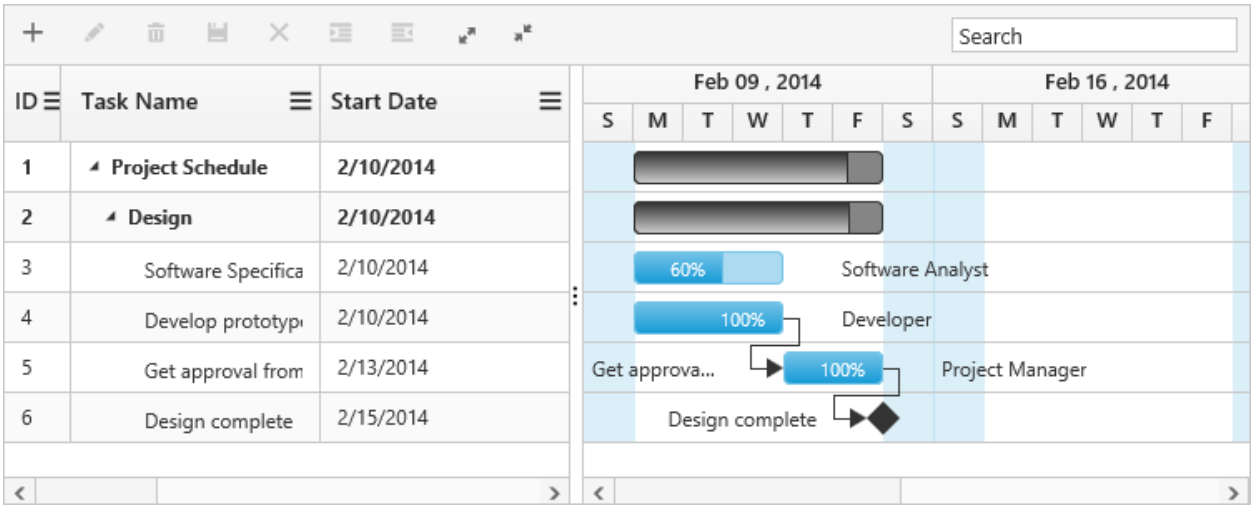
Weekend background

Background color of weekends in Gantt can be changed by using weekendBackground property. The following code example shows how to use this properties.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
//..
.WeekendBackground("rgba(116, 195, 231, 0.26)")
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the customized dependency lines in Gantt.



Themes

The following are the types of themes available in Gantt control.

1.Flat Azure 2.Flat Azure Dark 3.Flat Lime 4.Flat Lime Dark 5.Flat Saffron 6.Flat Saffron Dark 7.Gradient Azure 8.Gradient Azure Dark 9.Gradient Lime 10.Gradient Lime Dark 11.Gradient Saffron 12.Gradient Saffron Dark 13.Bootstrap 14.High Contrast 01 15.High Contrast 02 16.Material 17.Office-365

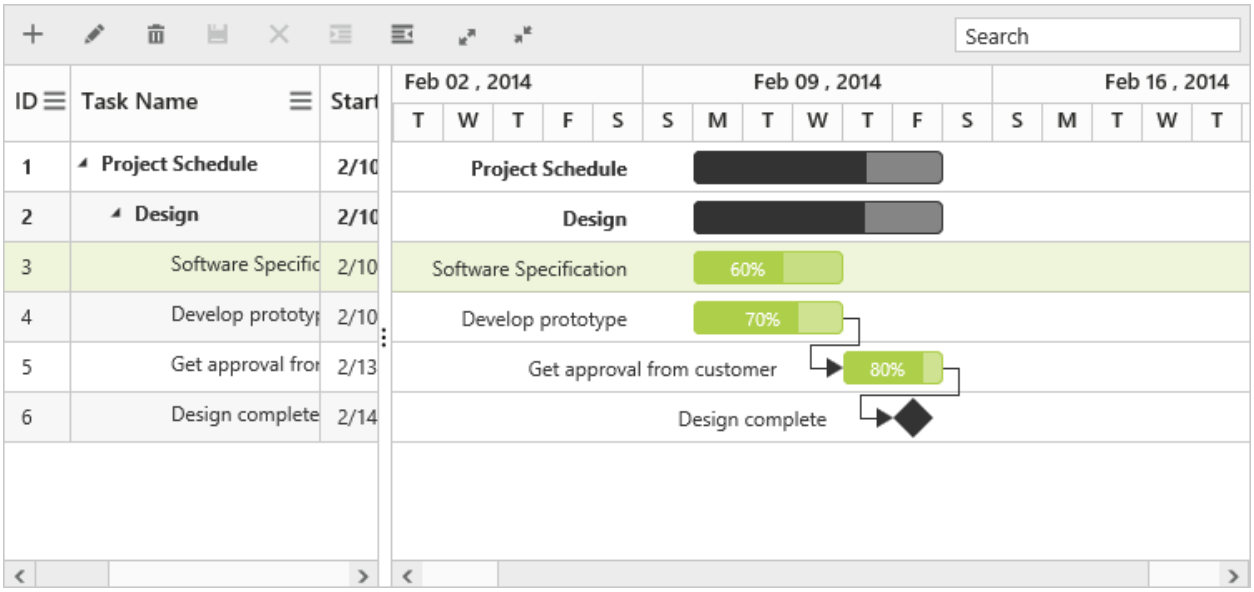
The theme (Gradient lime) can be applied to the Gantt control by using the style sheet from the online link as follows.

HTML

```
<!DOCTYPE html>
<html xmlns="http://www.w3.org/1999/xhtml">
<head>
<title>Getting Started with Gantt Control for JavaScript</title>
<!-- style sheet for default theme(gradient lime) -->
<link href="http://cdn.syncfusion.com/{{ site.releaseversion }}/js/web/flat-azure/ej.web.all.min.css" rel="stylesheet" />
//...
</html>
```

The following screenshot shows the Gantt control with Gradient-lime theme.

Copyright © 2001 - 2020 Syncfusion Inc.



Configuring CSS Class

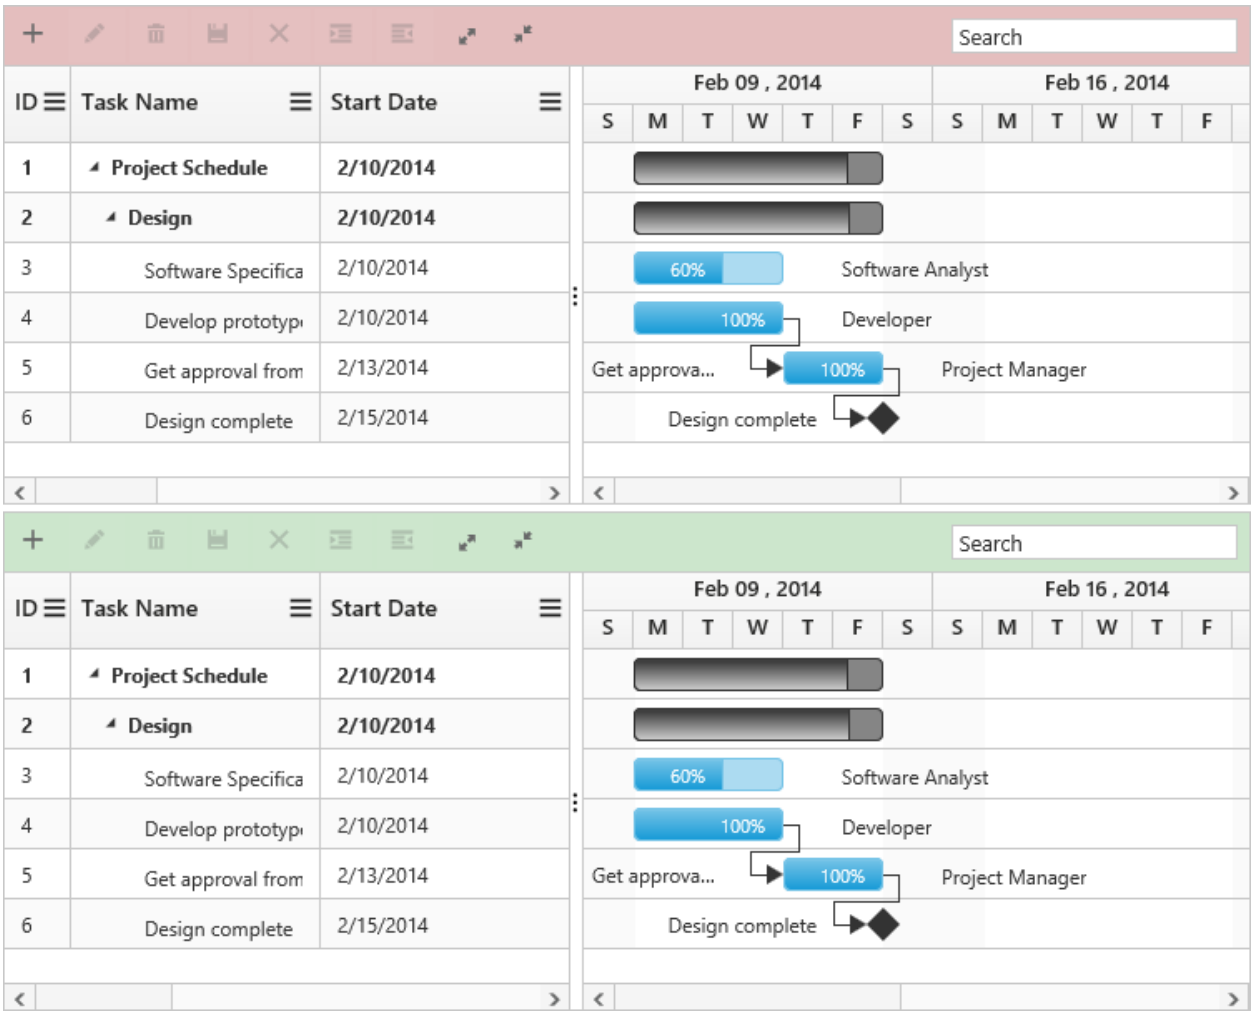
In Gantt CssClass property was used to apply different customized styles to multiple Gantt controls available in same page. The following code example shows how to apply different background color for each Gantt control's toolbar element.

HTML

```
<style>
.c-class1.e-gantt .e-toolbar {
background-color: rgba(169, 45, 45, 0.31);
}
.c-class2.e-gantt .e-toolbar {
background-color: rgba(0, 128, 0, 0.2);
}
</style>
@(Html.EJ().Gantt("GanttContainer")
.CssClass("c-class1")
)
@(Html.EJ().Gantt("GanttContainer1")
.CssClass("c-class2")
)
@(Html.EJ().ScriptManager())
```

The below screenshot shows the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Customize rows and cells

While rendering the rows in Grid part of Gantt RowDataBound event and QueryCellInfo event will be triggered for each rows and cells. Using this event we can customize the rows and cells. The below code example shows how to customize the cell and row element using this events.

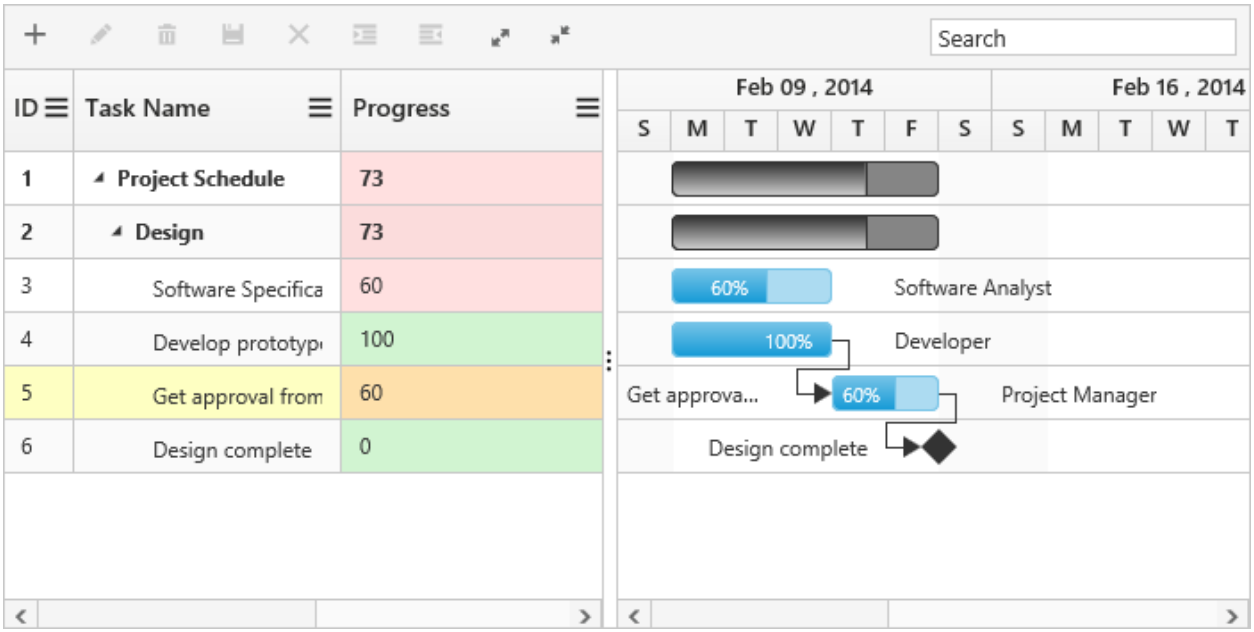
ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.ClientSideEvents(eve =>
{
eve.QueryCellInfo("queryCellInfo");
eve.RowDataBound("rowDataBound");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function queryCellInfo(args) {
if (args.column.mappingName == "progress") {
if (args.data.item["progress"] < 80)
$(args.cellElement).css("background-color", "rgba(255, 0, 0, 0.12)");
else
$(args.cellElement).css("background-color", "rgba(86, 226, 86, 0.25)");
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
function rowDataBound(args) {
if (args.data.item["taskID"] == 5)
$(args.rowElement).css("background-color", "rgba(251, 255, 0, 0.24)");
}
</script>
```

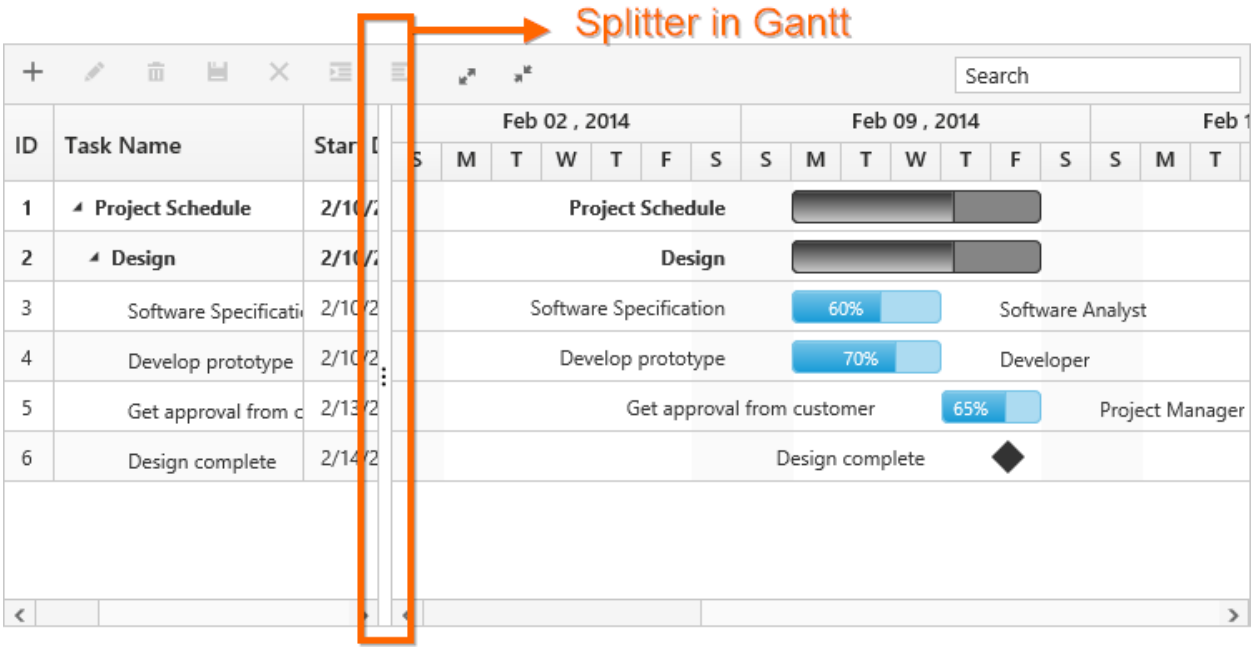
The below screenshot shows the output of above code example.



How to

Change Splitter position

In Gantt control, Splitter separates the TreeGrid section from the Chart section.



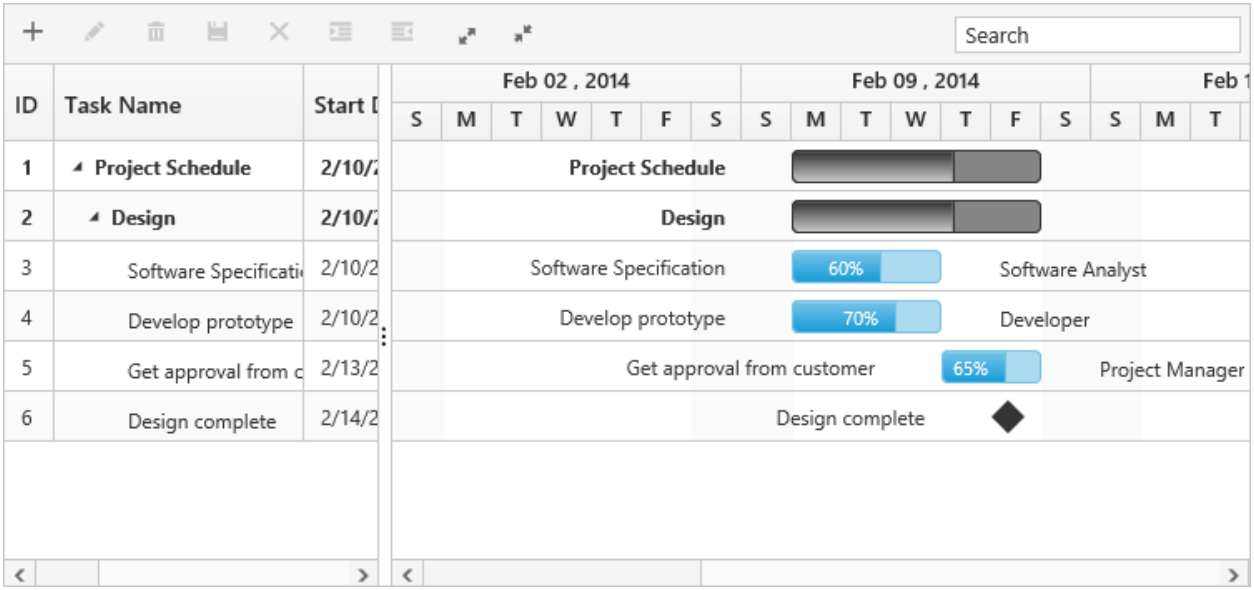
Copyright © 2001 - 2020 Syncfusion Inc.

It is possible to change the position of the Splitter while loading the Gantt by using the SplitterPosition property, thereby varying the width of the TreeGrid and Chart sections in the control. SplitterPosition property denotes the percentage of the TreeGrid section's width to be rendered and this property supports both pixels and percentage values.

The following code example explains how to define the SplitterPosition property in the Gantt.

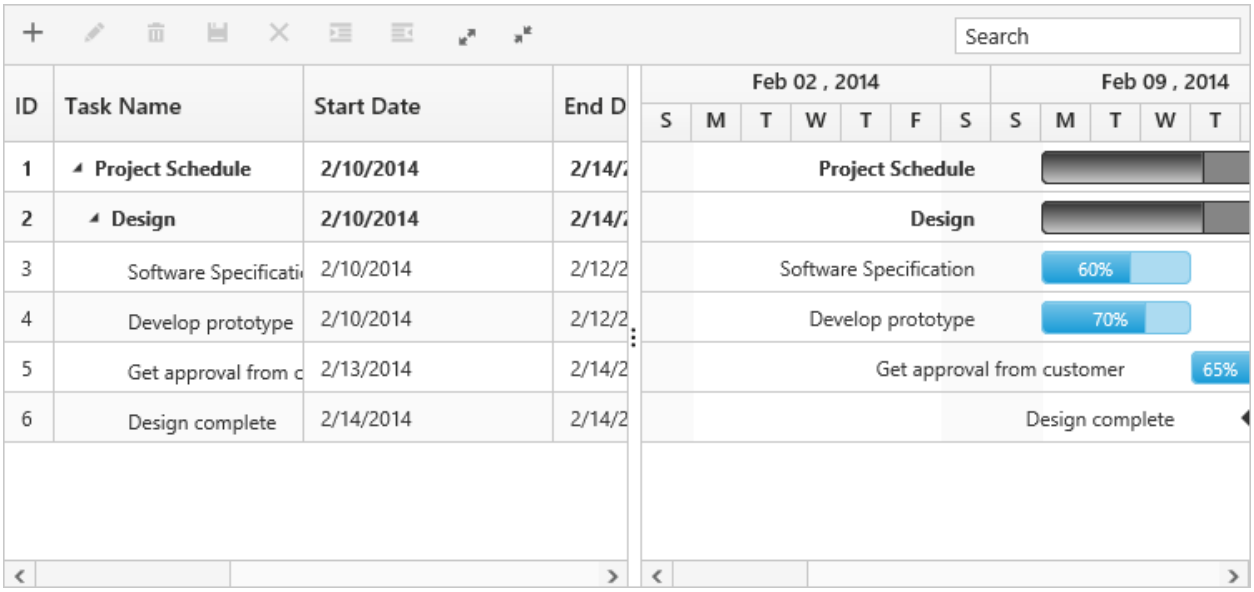
ASPX-CS

```
@(Html.EJ().Gantt("gantt")
.SplitterPosition("50%")
//also you can define with pixel value as
//.SplitterPosition(”650”) (or) .SplitterPosition(”650px”)
)
@(Html.EJ().ScriptManager())
```

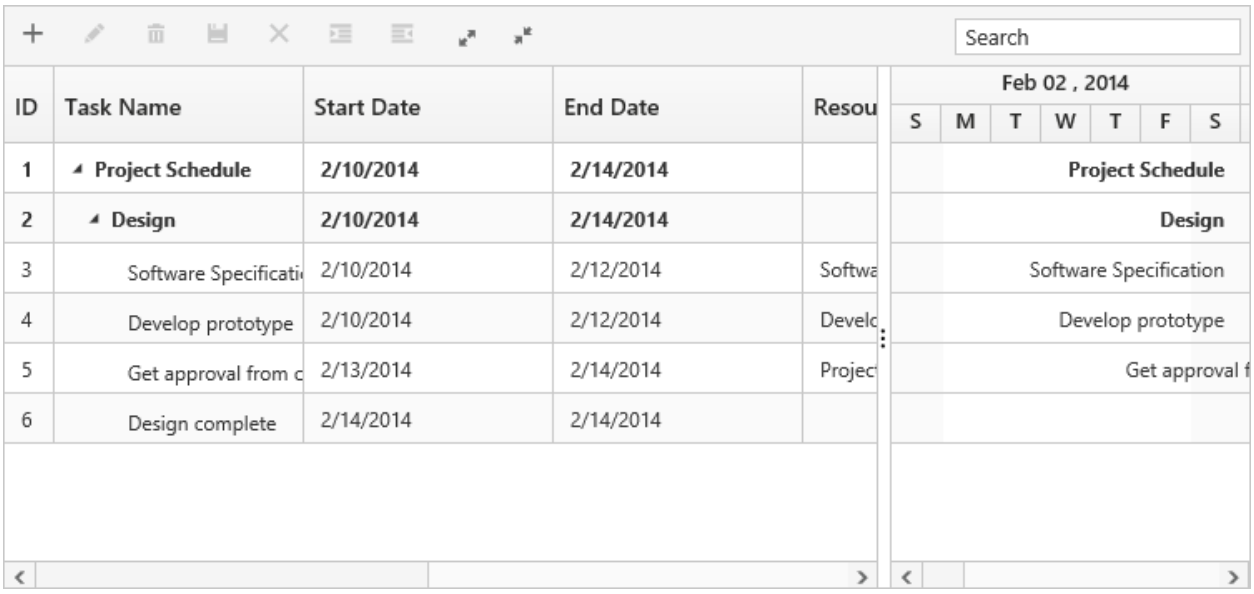


Gantt with 30 % splitter position

Copyright © 2001 - 2020 Syncfusion Inc.



Gantt with 50% splitter position



Gantt with 600px splitter position

Change workweek/working days in a week

Non-working days/weekend are used to represent the non-productive days in a project. It is possible to change the non-working days in a week using the `WorkWeek` property in Gantt.

By default, Saturdays and Sundays are considered as non-working days/weekend in a project.

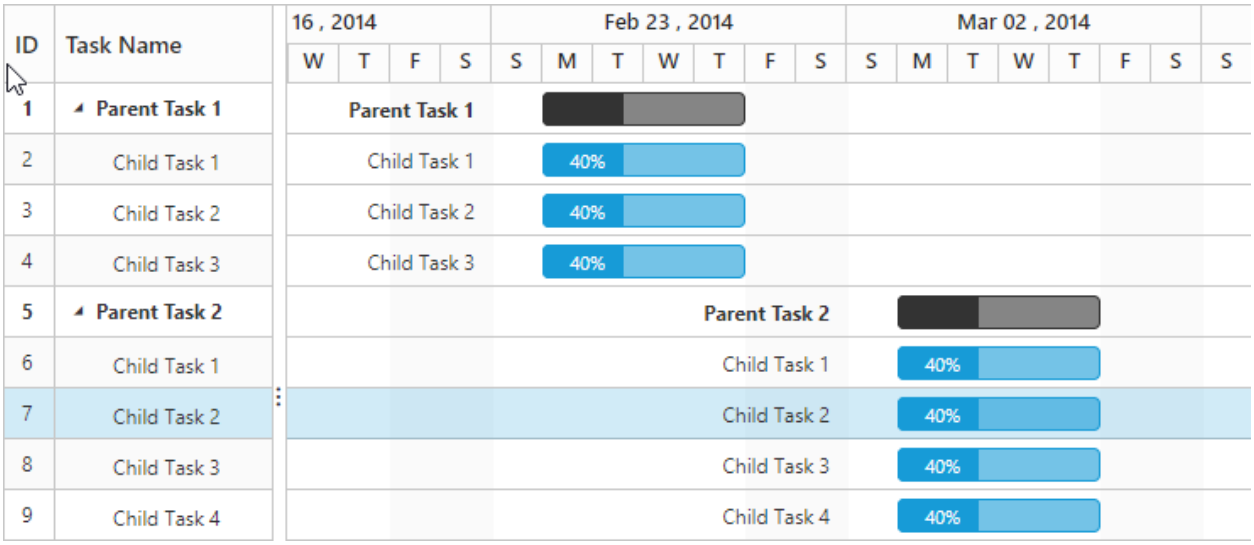
The following code example explains how to change weekend/non-working days

ASPX-CS

```
@(Html.EJ().Gantt("gantt")
.WorkWeek(new List<string>() {
"Sunday","Monday","Tuesday","Wednesday","Thursday" })
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().ScriptManager())
```



The above screen shot will be displayed after changing the non-working days in Gantt.

Destroy Gantt Control

Gantt control is composed with more sub-controls like TreeGrid, Splitter, Dialog etc. So while destroying the Gantt control we need to

remove all sub-control elements and unbind all events bound by this control. By using destroy public method, we can properly remove the Gantt control from DOM.

The following code example explains how to destroy Gantt control.

ASPX-CS

```
@(Html.EJ().Gantt("gantt")
//..
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#gantt").ejGantt("destroy");
<script>
```

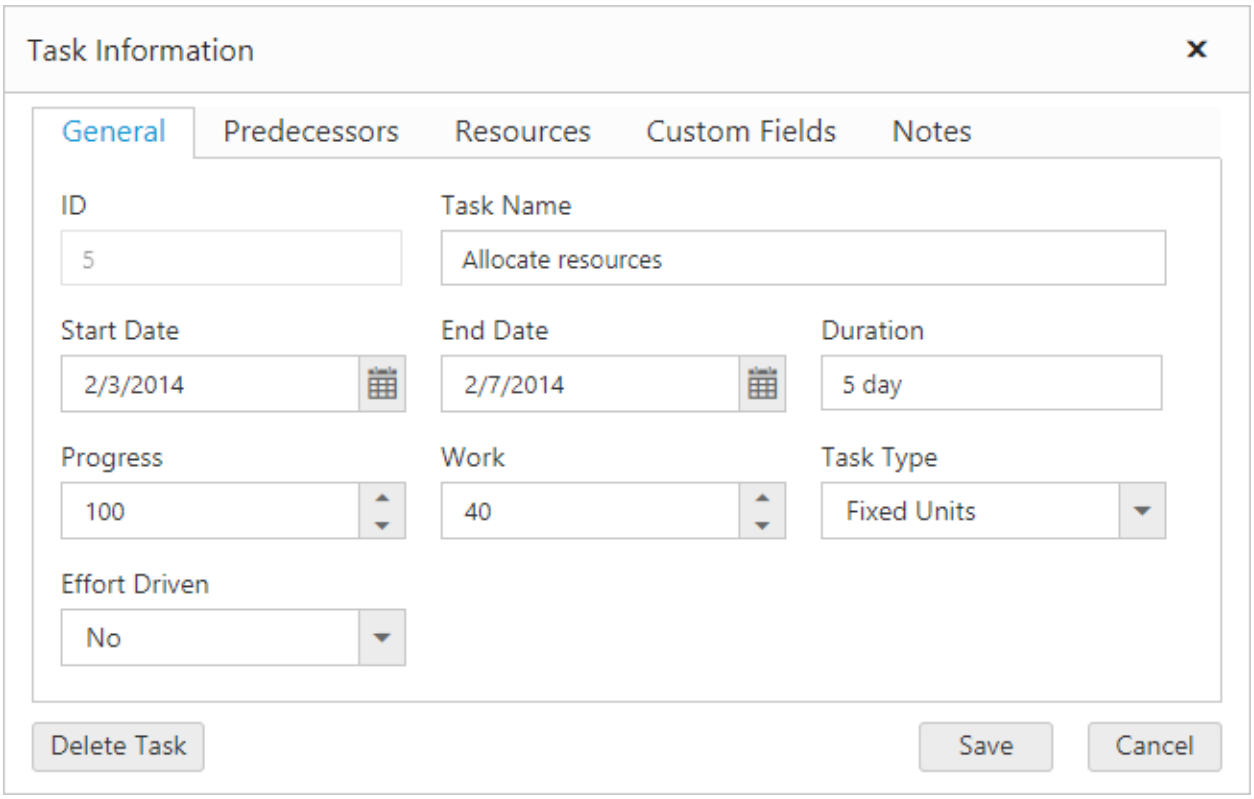
Note: If you want to re-initialize Gantt control on same div element,

we need to perform destroy action before re-initialize the Gantt.

Display custom fields in general tab

Gantt add and edit dialogs groups the data sources fields in five different tabs such as General, Predecessors, Resources, Custom Fields and Notes.

Copyright © 2001 - 2020 Syncfusion Inc.



The custom fields are usually displayed in Custom Fields tab, but it is also possible to display the custom fields in general tab using DisplayInGeneralTab property in Gantt. By default, its value is false.

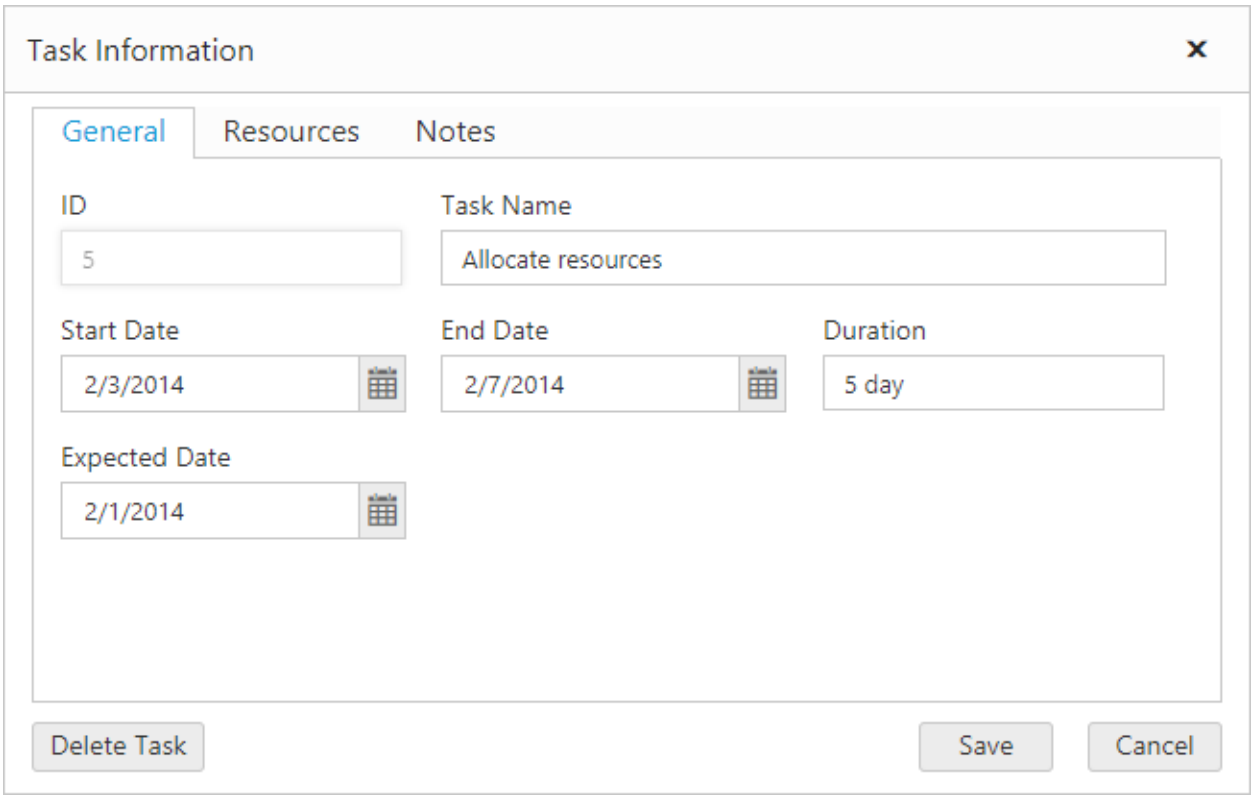
The following code example explains how to display custom fields in general tab

ASPX-CS

```
@(Html.EJ().Gantt("gantt")
.AddDialogFields(ads =>
{
ads.Field("TaskID").Add();
ads.Field("TaskName").Add();
ads.Field("EndDate").Add();
ads.Field("Duration").Add();
ads.Field("Notes").Add();
ads.Field("ExpectedDate").DisplayInGeneralTab(true).Add();
})
.EditDialogFields(eds =>
{
eds.Field("TaskID").Add();
eds.Field("TaskName").Add();
eds.Field("EndDate").Add();
eds.Field("Duration").Add();
eds.Field("Notes").Add();
eds.Field("ExpectedDate").DisplayInGeneralTab(true).Add();
})
)
@(Html.EJ().ScriptManager())
```

The above code example makes Fridays and Saturdays as non-working days in a week.

Copyright © 2001 - 2020 Syncfusion Inc.



The above screen shot shows custom column field “Expected Date” displayed in General tab.

Change week start day in month timescale mode

Using start date mode as Month

When setting the timescaleStartDateMode property as month, the project will start from the first date of the same month of the first task in a project. Using below code example we can change the week start day of the project start date in month timescale mode.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.ScheduleHeaderSettings(sh =>
{
sh.ScheduleHeaderType(GanttScheduleHeaderType.Month);
sh.TimescaleStartDateMode(GanttTimescaleRoundMode.Month);
sh.MonthHeaderFormat("MMM yyyy");
sh.WeekHeaderFormat("M/dd");
sh.WeekStartDay(1);
})
.ClientSideEvents(cs =>
{
cs.Load("load");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function load(args) {
var ganttObj = $("#Gantt").data("ejGantt");
ganttObj._enableMonthStart = false;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script>
```

Using start date mode as Year

When setting the timescaleStartDateMode property as Year, the project will start from the first date of the same year to which the first task in a project starts. Using below code example we can change the week start day of the project start date in year timescale mode.

ASPX-CS

```
@(Html.EJ().Gantt("Gantt")
.ScheduleHeaderSettings(sh =>
{
sh.ScheduleHeaderType(GanttScheduleHeaderType.Month);
sh.TimescaleStartDateMode(GanttTimescaleRoundMode.Year);
sh.WeekHeaderFormat("M/dd");
sh.WeekStartDay(1);
})
.ClientSideEvents(cs =>
{
cs.Load("load");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function load(args) {
var ganttObj = $("#Gantt").data("ejGantt");
ganttObj._enableMonthStart = false;
}
<script>
```

By default *enableMonthStart property will be true. Week header in month schedule mode will be rendered with month/year start day. To customize the week start day in month mode we need to set* enableMonthStart as false.

Round-off start date, end date and duration value on taskbar editing

In Gantt start date, end date and duration values can be round-off as per current ScheduleHeaderSettings.ScheduleHeaderType value on taskbar resizing and dragging actions. This can be achieved by setting roundOffDuration argument value as true in TaskbarEditing event.

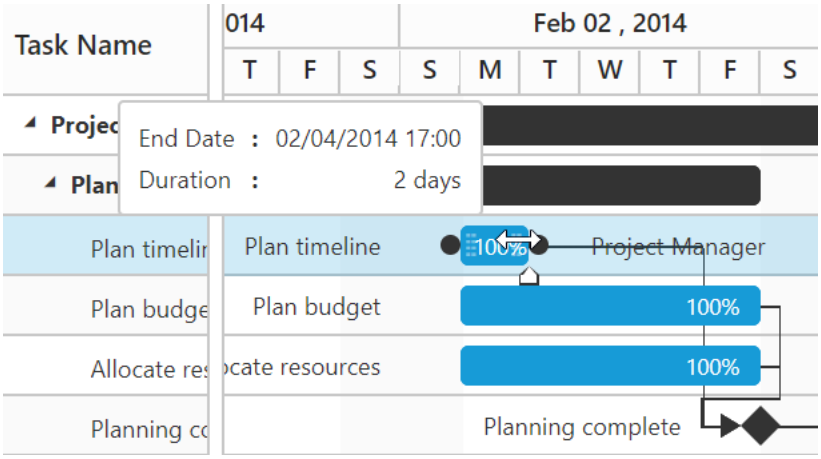
The below code example explains how to achieve this requirement.

ASPX-CS

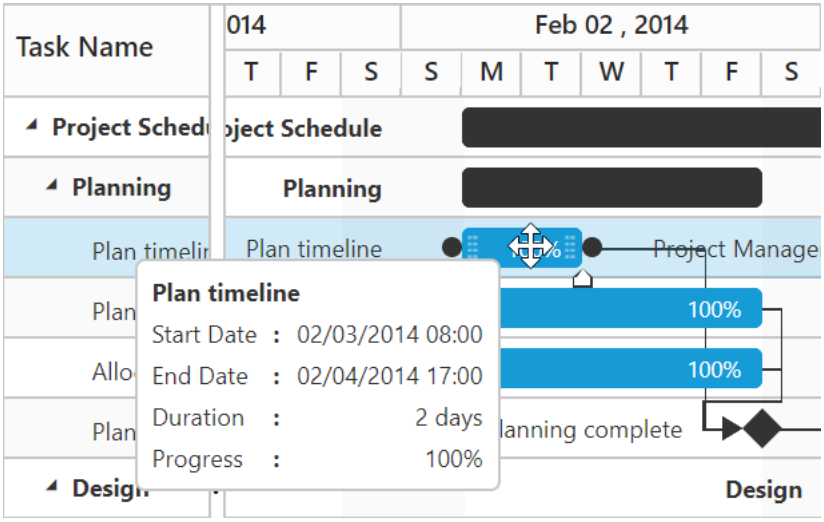
```
@(Html.EJ().Gantt("gantt")
.ClientSideEvents(eve =>
{
eve.TaskbarEditing("taskbarEditing");
})
)
<script type="text/javascript">
function taskbarEditing(args) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
args.roundOffDuration = true;
}
<script>
```



Before resizing



After resizing

Rendering the Gantt control using GanttProperties in server-side

The GanttProperties helps to render the Gantt control in server-side.

The following code example explains how to render the Gantt control in server-side.

RAZOR

```
@(Html.EJ().Gantt("GanttControl", ViewBag.GanttModel))
```

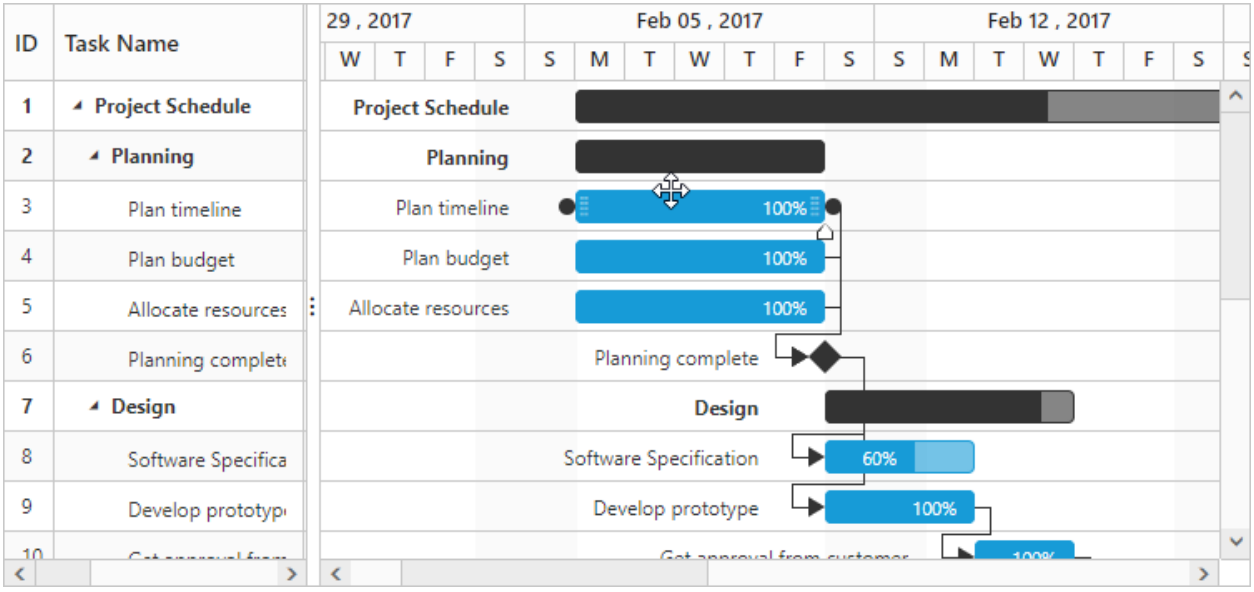
C#

```
namespace Gantt_MVC.Controllers
{
public class GanttController : Controller
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult Gantt()
{
GanttProperties gantt = new GanttProperties();
gantt.TaskIdMapping = "TaskID";
gantt.TaskNameMapping = "TaskName";
gantt.StartDateMapping = "StartDate";
gantt.DurationMapping = "Duration";
gantt.ProgressMapping = "Progress";
gantt.ScheduleStartDate = "02/01/2017";
gantt.ScheduleEndDate = "03/14/2017";
gantt.ChildMapping = "SubTasks";
gantt.PredecessorMapping = "Predecessors";
gantt.TreeColumnIndex = 1;
gantt.SizeSettings.Width = "750px";
gantt.SizeSettings.Height = "350px";
gantt.DataSource = GetTaskData();
ViewBag.GanttModel = gantt;
return View();
}
}
}
```

The below screenshot shows the output of above code example.



Update task id value

Id value of Gantt tasks can be changed dynamically by using updateTaskId method. The below code example shows how to invoke this method on button click action.

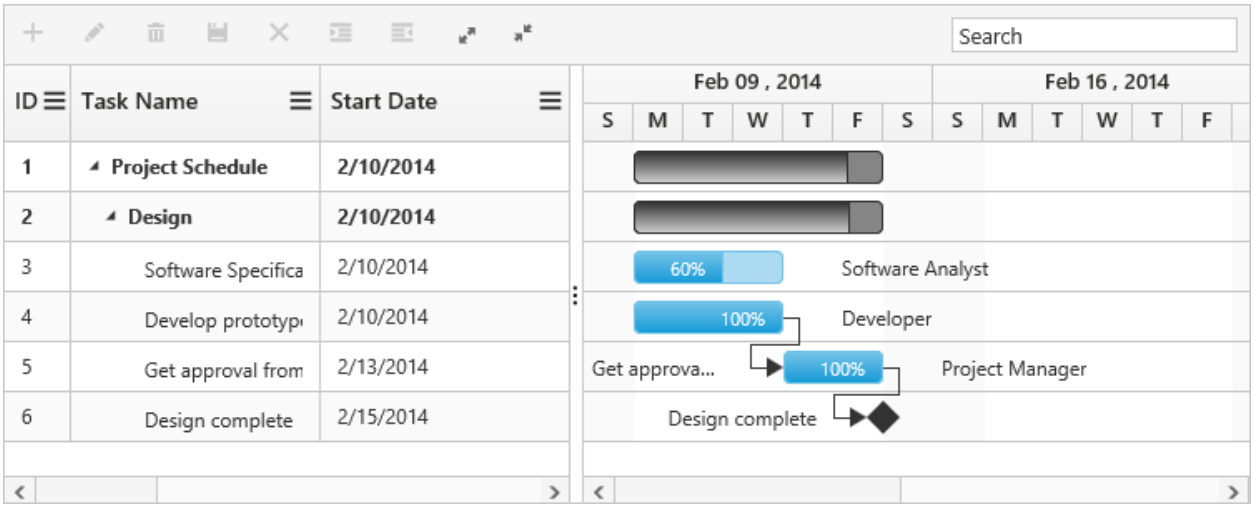
ASPX-CS

```
@(Html.EJ().Gantt("gantt")
//..
)
@(Html.EJ().ScriptManager())
$("#update_task_id").click(function () {
var ganttObj = $("#gantt").ejGantt("instance");
```

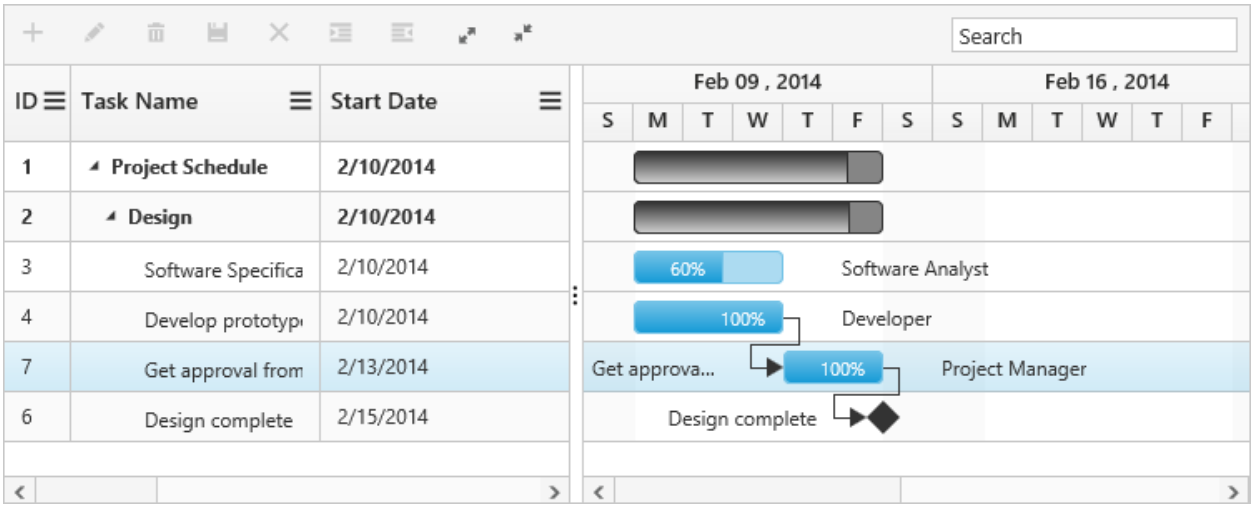
Copyright © 2001 - 2020 Syncfusion Inc.

```
ganttObj.updateTaskId(5, 7);
});
```

The below screen shows the output of above code example.



Before id update



After id update

Get taskbar information on click action

When we click on the taskbar, TaskbarClick event will be triggered, using this event and it's arguments, we can do any action related to taskbar. The following code example shows how to use this event.

ASPX-CS

```
@(Html.EJ().Gantt("gantt")
.ClientSideEvents(eve =>
{
eve.TaskbarClick("taskbarClick");
})
)
<script type="text/javascript">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
function taskbarClick(args) {
var taskbarElement = args.taskbarElement,
taskData = args.data,
target = args.target;
//...
}
<script>
```

Grid

Grid

The grid control for ASP.NET MVC is an efficient display engine for tabular data. It will pull from a datasource, such as List of collections, OData web services, or DataManager, binding data fields to columns and displaying a column header to identify the field. It is a feature-rich control that provides extensive appearance customization options with support for grouped records. This grid is very useful for generating complex grid-based reports with rich formatting. The most important features available in the grid control for ASP.NET MVC are paging, sorting, filtering, searching, grouping, and editing.

Key features

Some important features of the grid control for JavaScript are:

- Data sources—Bind the grid control with a List of collections or ej.DataManager.
- Sorting and grouping—Supports *n* levels of sorting and grouping.
- Filtering—Offers Excel-like filtering for filter data.
- Editing—Offers two editing modes for inserting, editing, and deleting records in a grid.
- Paging—Provides the option to easily switch between pages using the pager bar.
- Reordering—Allows you to drag any column and drop it at any position in the grid, allowing columns to be repositioned at the required place.
- Resize columns—grid provides option for resizing the columns.
- Summary support—Offers options for specifying summary rows and columns.
- Detail template—Offers to render the detail row for the corresponding expanded master row.
- Unbound columns—Offers the option to specify unbound columns.
- RTL support—Provides a full-fledged right-to-left mode which aligns content in the Grid control from right to left.
- Localization—Provides inherent support to localize the UI.

Getting Started

This section explains briefly about how to create a Grid in your application with ASP.NET MVC, and also explains about how to enable basic grid operations like paging, filtering, grouping and summary. The following screenshot illustrates the grid control.

Copyright © 2001 - 2020 Syncfusion Inc.

ItemID	ItemName	ItemType	Price	Stock
1	Apple Pie	Veg	15	3
2	Bread	Veg	10	5
3	Chocolate cake	Veg	20	2
4	Cream cookies	Veg	12	7
5	Doughnut	Veg	16	12
6	Green pepper	Veg	18	5
7	Nuggets	Veg	14	3
8	Chicken soup	Non-Veg	20	8
9	Pancake	Veg	17	6
10	Pomegranate	Veg	20	1
11	Sugar cookie	Veg	22	9
12	Wheat	Veg	12	13

Create your first grid in MVC

The following steps explain creating first grid with an empty datasource:

1. Create Syncfusion ASP.NET MVC application. You can refer to MVC Getting Started documentation to create a new project and add necessary dll's and script files.
2. Add a grid control in view file with an empty datasource as like as follows. In Columns definition, the TextAlign property allows you to align text of the columns, the Width property is used to define width of the columns and Format property allows you to format the particular columns value.

RAZOR

```
@(Html.EJ().Grid<object>("FlatGrid")
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("ShipName").HeaderText("Ship Name").Width(100).Add();
col.Field("ShipCity").HeaderText("Ship City").Width(100).Add();
col.Field("Freight").Format("{0:c3}").HeaderText("Freight").Width(80).TextAl
ign(TextAlign.Right).Add();
})
)
```

You can execute the above code sample to render an empty grid is rendered with specified column headers.

Copyright © 2001 - 2020 Syncfusion Inc.

Order ID	Customer ID	Ship Name	Ship City	Freight
No records to display				

Data binding

You can bind the data to grid control using the DataSource property.

RAZOR

```
@(Html.EJ().Grid<object>("FlatGrid")
.Datasource((IEnumerable<object>)ViewBag.datasource)
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("ShipName").HeaderText("Ship Name").Width(100).Add();
col.Field("ShipCity").HeaderText("Ship City").Width(100).Add();
col.Field("Freight").Format("{0:c3}").HeaderText("Freight").Width(80).TextAl
ign(TextAlign.Right).Add();
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public class GridController : Controller
{
public ActionResult Paging()
{
var DataSource = new NorthwindDataContext().OrdersViews.ToList();
ViewBag.datasource = DataSource;
return View();
}
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Order ID	Customer ID	Ship Name	Ship City	Freight
10248	VINET	Vins et alcools Chevalier	Reims	$32.380
10249	TOMSP	Toms Spezialitäten	Münster	$11.610
10250	HANAR	Hanari Carnes	Rio de Janeiro	$65.830
10251	VICTE	Victuailles en stock	Lyon	$41.340
10252	SUPRD	Suprêmes délices	Charleroi	$51.300
10253	HANAR	Hanari Carnes	Rio de Janeiro	$58.170
10254	CHOPS	Chop-suey Chinese	Bern	$22.980
10255	RICSU	Richter Supermarkt	Genève	$148.330
10256	WELLI	Wellington Importadora	Resende	$13.970
10257	HILAA	HILARION-Abastos	San Cristóbal	$81.910
10258	ERNSH	Ernst Handel	Graz	$140.510
10259	CENTC	Centro comercial Moctez	México D.F.	$3.250
10260	OTTIK	Ottilies Käseladen	Köln	$55.090
10261	QUEDE	Que Delícia	Rio de Janeiro	$3.050
10262	RATTC	Rattlesnake Canyon Groc	Albuquerque	$48.290
10263	ERNSH	Ernst Handel	Graz	$146.060
10264	FOLKO	Folk och fä HB	Bräcke	$3.670
10265	BLONP	Blondel père et fils	Strasbourg	$55.280
10266	WARTH	Wartian Herkku	Oulu	$25.730
10267	FRANK	Frankenversand	München	$208.580
10268	GROSR	GROSELLA-Restaurante	Caracas	$66.290
10269	WHITC	White Clover Markets	Seattle	$4.560
10270	WARTH	Wartian Herkku	Oulu	$136.540

Enable paging

The Paging feature can be enabled by the AllowPaging property of grid control. This adds the pager in the bottom of the grid, using that pager you can display the grid records in paged view. The page size can be customized using the PageSize

and PageSettings property.

RAZOR

```
@(Html.EJ().Grid<object>("FlatGrid")
.Datasource((IEnumerable<object>)ViewBag.datasource)
.AllowPaging()
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").TextAlign(TextAlign.Right).Width(75).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("ShipName").HeaderText("Ship Name").Width(100).Add();
col.Field("ShipCity").HeaderText("Ship City").Width(100).Add();
col.Field("Freight").Format("{0:c3}").HeaderText("Freight").Width(80).TextAl
ign(TextAlign.Right).Add();
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public class GridController : Controller
{
public ActionResult Paging()
{
var DataSource = new NorthwindDataContext().OrdersViews.ToList();
ViewBag.datasource = DataSource;
return View();
}
}
}
```

Note: *Pager settings can be customized by using the 'PageSize' and 'PageCount' properties. When it is not given the default values for PageSize and PageCount are 12 and 8 respectively.*

Order ID	Customer ID	Ship Name	Ship City	Freight
10248	VINET	Vins et alcools Chevalier	Reims	$32.380
10249	TOMSP	Toms Spezialitäten	Münster	$11.610
10250	HANAR	Hanari Carnes	Rio de Janeiro	$65.830
10251	VICTE	Victuailles en stock	Lyon	$41.340
10252	SUPRD	Suprêmes délices	Charleroi	$51.300
10253	HANAR	Hanari Carnes	Rio de Janeiro	$58.170
10254	CHOPS	Chop-suey Chinese	Bern	$22.980
10255	RICSU	Richter Supermarkt	Genève	$148.330
10256	WELLI	Wellington Importadora	Resende	$13.970
10257	HILAA	HILARION-Abastos	San Cristóbal	$81.910
10258	ERNSH	Ernst Handel	Graz	$140.510
10259	CENTC	Centro comercial Moctez	México D.F.	$3.250

1 of 17 pages (200 items)

Copyright © 2001 - 2020 Syncfusion Inc.

Enable filtering

The Filtering feature in the grid is used to facilitate the extraction of a subset of records that meets certain criteria. You can apply Filter to one or more columns. Filtering feature can be enabled by the AllowFiltering property. By default, the filter bar row is displayed to perform filtering, you can change the filter type by using the FilterType property of FilterSettings.

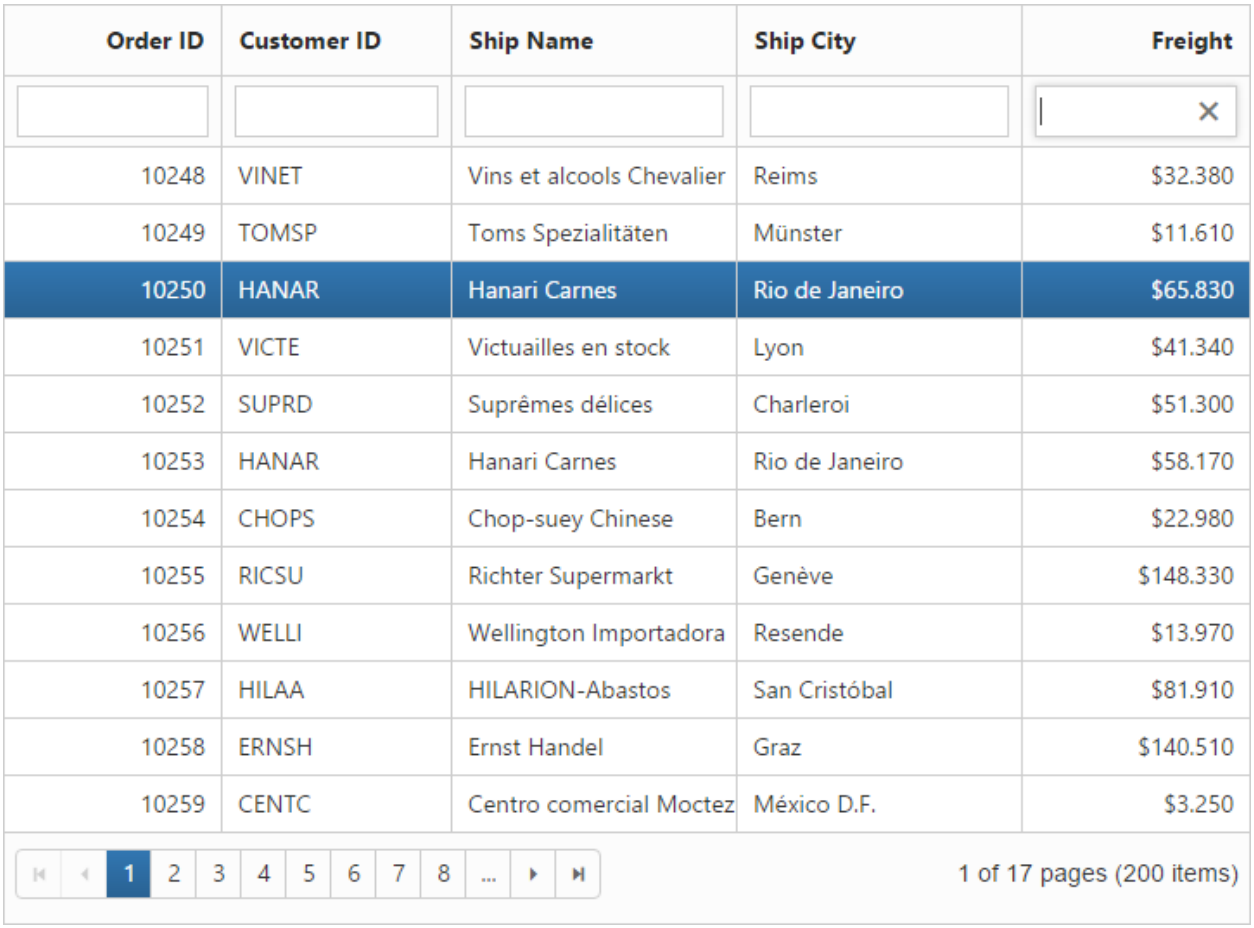
RAZOR

```
@(Html.EJ().Grid<object>("FlatGrid")
.Datasource((IEnumerable<object>)ViewBag.datasource)
.AllowPaging()
.AllowFiltering()
.FilterSettings(d => d.FilterType(FilterType.FilterBar))
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("ShipName").HeaderText("Ship Name").Width(100).Add();
col.Field("ShipCity").HeaderText("Ship City").Width(100).Add();
col.Field("Freight").Format("{0:c3}").HeaderText("Freight").Width(80).TextAl
ign(TextAlign.Right).Add();
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public class GridController : Controller
{
public ActionResult Paging()
{
var DataSource = new NorthwindDataContext().OrdersViews.ToList();
ViewBag.datasource = DataSource;
return View();
}
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Order ID	Customer ID	Ship Name	Ship City	Freight
10248	VINET	Vins et alcools Chevalier	Reims	$32.380
10249	TOMSP	Toms Spezialitäten	Münster	$11.610
10250	HANAR	Hanari Carnes	Rio de Janeiro	$65.830
10251	VICTE	Victuailles en stock	Lyon	$41.340
10252	SUPRD	Suprêmes délices	Charleroi	$51.300
10253	HANAR	Hanari Carnes	Rio de Janeiro	$58.170
10254	CHOPS	Chop-suey Chinese	Bern	$22.980
10255	RICSU	Richter Supermarkt	Genève	$148.330

10258	ERNSH	Ernst Handel	Graz	$140.510
10259	CENTC	Centro comercial Moctez	México D.F.	$3.250

Enable grouping

The 'Grouping' feature in the grid is used to consolidate grid data into groups. Grouping allows the categorization of records based on specified columns. You can enable grouping feature by the AllowGrouping property. Columns can be grouped dynamically by drag and drop of the grid column header to the group drop area. The initial grouping can be done by adding required column names in the GroupedColumns property of GroupSettings property.

RAZOR

```
@(Html.EJ().Grid<object>("FlatGrid")
.Datasource((IEnumerable<object>)ViewBag.datasource)
.AllowPaging()
.AllowGrouping()
.GroupSettings(group => group.GroupedColumns(col=>col.Add("ShipName") ))
.AllowFiltering()
.FilterSettings(d => d.FilterType(FilterType.FilterBar))
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("ShipName").HeaderText("Ship Name").Width(100).Add();
col.Field("ShipCity").HeaderText("Ship City").Width(100).Add();
col.Field("Freight").Format("{0:c3}").HeaderText("Freight").Width(80).TextAl
ign(TextAlign.Right).Add();
```

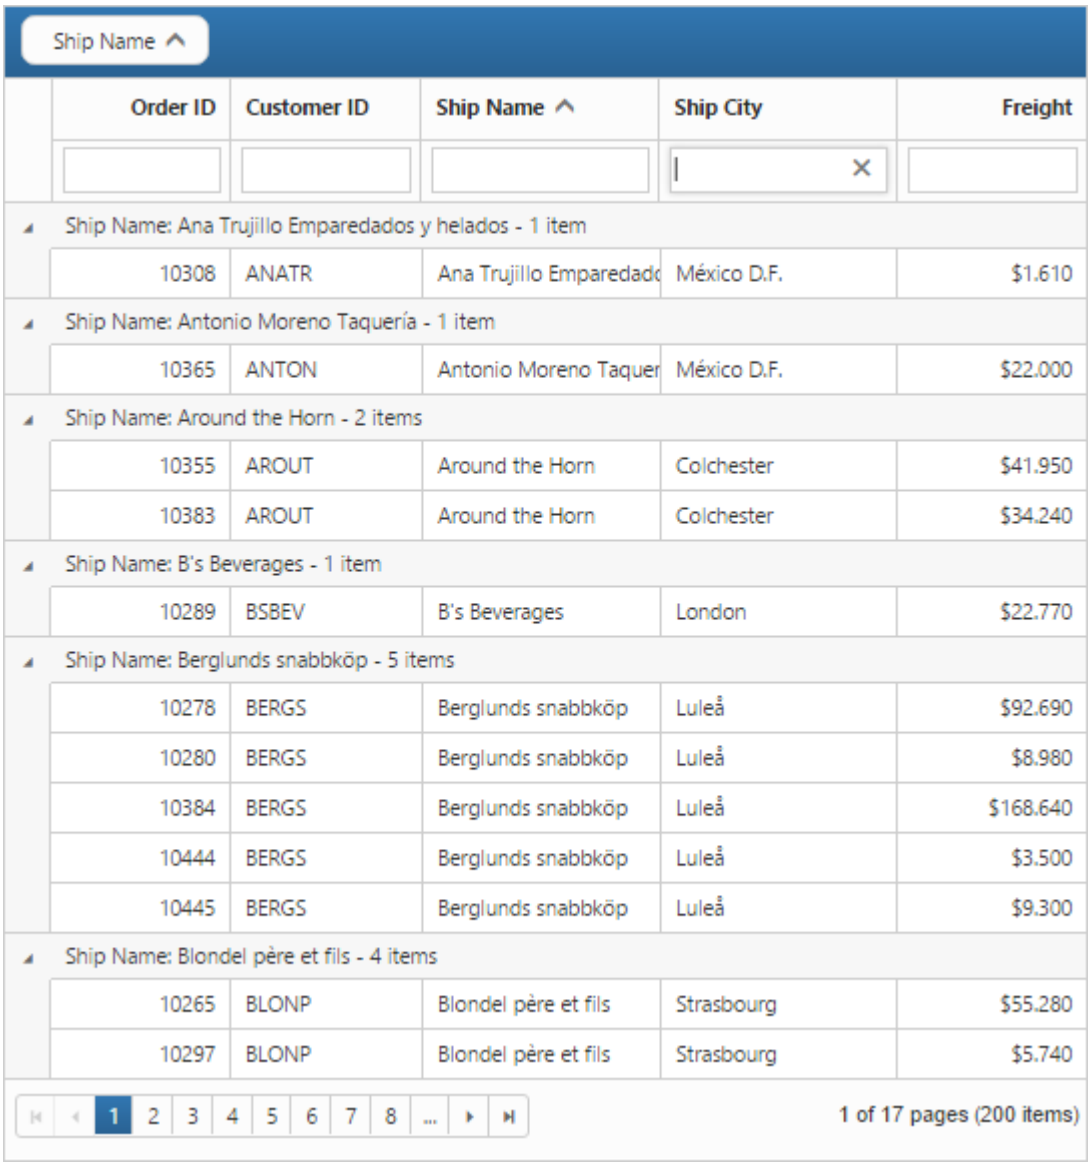
Copyright © 2001 - 2020 Syncfusion Inc.

```
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public class GridController : Controller
{
public ActionResult Paging()
{
var DataSource = new NorthwindDataContext().OrdersViews.ToList();
ViewBag.datasource = DataSource;
return View();
}
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Add summaries

The Summaries can be enabled by setting the ShowSummary to true and adding required summary rows and columns in the SummaryRows property.

The following code example shows the option to enable group summary.

RAZOR

```
@(Html.EJ().Grid<object>("FlatGrid")
.Datasource((IEnumerable<object>)ViewBag.datasource)
.AllowPaging()
.AllowGrouping()
.ShowSummary()
.GroupSettings(group => group.GroupedColumns(col=>col.Add("ShipName") ))
.AllowFiltering()
.FilterSettings(d => d.FilterType(FilterType.FilterBar))
.SummaryRow(row =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
row.ShowTotalSummary(false)
.SummaryColumns(col =>
{
col.SummaryType(SummaryType.Sum)
.DisplayColumn("Freight")
.DataMember("Freight")
.Prefix("Sum = ")
.Format("{0:c3}")
.Add();
}).Add();
})
.Columns(col =>
{
col.Field("OrderID").HeaderText("Order
ID").TextAlign(TextAlign.Right).Width(75).Add();
col.Field("CustomerID").HeaderText("Customer ID").Width(80).Add();
col.Field("ShipName").HeaderText("Ship Name").Width(100).Add();
col.Field("ShipCity").HeaderText("Ship City").Width(100).Add();
col.Field("Freight").Format("{0:c3}").HeaderText("Freight").Width(80).TextAl
ign(TextAlign.Right).Add();
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public class GridController : Controller
{
public ActionResult Paging()
{
var DataSource = new NorthwindDataContext().OrdersViews.ToList();
ViewBag.datasource = DataSource;
return View();
}
}
}
```

Grid Dependencies

ej.web.all.js is a bundle of all EssentialJavaScript controls. When you use ej.web.all.js in your application, you can leave this section or else you can try to render the grid in your application by using ej.grid.min.js file. You can refer to the following frameworks and controls in your project.

Grid Dependency

FileÂ Â	Description/Usage
ej.core.min.js	Must be referred always before using all the JS controls.
ej.data.min.js	Used to handle dataManager operation and should be used while binding data to JS controls.

ej.grid.min.js	Should be referred when using grid control.
ej.pager.min.js	Should be referred when using paging in grid. Â
ej.scroller.min.js	Should be referred when using scrolling in grid. Â
ej.waitingpopup.min.js	Should be referred when using the remote data binding in grid. The waiting popup will show while requesting the server for data.
ej.gridresize.min.js	Need to refer when using the resizing feature in grid.
ej.dropdownlist.min.js	These files are used while enable Editing and Filtering feature in grid.
ej.dialog.min.js	
ej.button.min.js	
ej.autocomplete.min.js	
ej.datepicker.min.js	
ej.timepicker.min.js	
ej.datetimepicker.min.js	
ej.checkbox.min.js	
ej.editor.min.js	

Note: _Please refers ej.unobtrusive.min.js while enable the UnobtrusiveJavaScriptEnabled in web.config file.

Data Binding

Grid DataSource property allows to bind datasource as the instance of one of the following types.

Collection that implements IEnumerable or IEnumerable<T>. DataTable. *ITypedList.* REST Service URL as string. *Table – Allows to bind HTML Table and it accepts table template script "ID".* ORM components such as Entity Framework/Linq to SQL.

We can also bind the above type of datasource by using lambda Expressions of Grid DataSource Property.

Note: 1. To update the dataSource after Grid rendered, use dataSource method of Grid. Refer to this link for more information.

Note: 2. DateTime values, retrieved from server-end or database, will be converted based on the local time zone. To avoid the local time zone conversion, refer this knowledge base link.

In the following section, let us see on how to bind various datasources to Grid using DataSource API.

IEnumerable

The Grid can be bound with either non-generic collection or generic collection that implements IEnumerable interface. It can be assigned to Grid's DataSource property.

Copyright © 2001 - 2020 Syncfusion Inc.

Note: When using DataSource builder, the IEnumerable datasource can be passed as parameter either directly to the DataSource builder or to the Json property of the DataSource builder.

The following code example describes the above behavior.

RAZOR

```
@(Html.EJ().Grid<Person>("Grid")
.Datasource((IEnumerable<Person>)ViewBag.datasource)
.Columns(col =>
{
col.Field(p => p.FirstName).HeaderText("First
Name").TextAlign(TextAlign.Left).Add();
col.Field(p => p.LastName).HeaderText("Last
Name").TextAlign(TextAlign.Left).Add();
col.Field(p => p.Email).HeaderText("Email").TextAlign(TextAlign.Left).Add();
}))
```

C#

```
namespace Grid.Controllers
{
public class HomeController : Controller
{
public ActionResult Index()
{
List<Person> Persons = new List<Person>();
Persons.Add(new Person() { FirstName = "John", LastName = "Beckett", Email =
"john@syncfusion.com" });
Persons.Add(new Person() { FirstName = "Ben", LastName = "Beckett", Email =
"ben@syncfusion.com" });
Persons.Add(new Person() { FirstName = "Andrew", LastName = "Beckett", Email
= "andrew@syncfusion.com" });
ViewBag.datasource = Persons;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

First Name	Last Name	Email
John	Beckett	john@syncfusion.com
Ben	Beckett	ben@syncfusion.com
Andrew	Beckett	andrew@syncfusion.com

DataTable

A DataTable, which represents one table of in-memory relational data that has in-built schema to work easily with data column and data row objects.

Copyright © 2001 - 2020 Syncfusion Inc.

Binding DataTable to Grid is a very simpler way that you only need to set DataTable model to Grid DataSource API.

The following code example describes the above behavior.

RAZOR

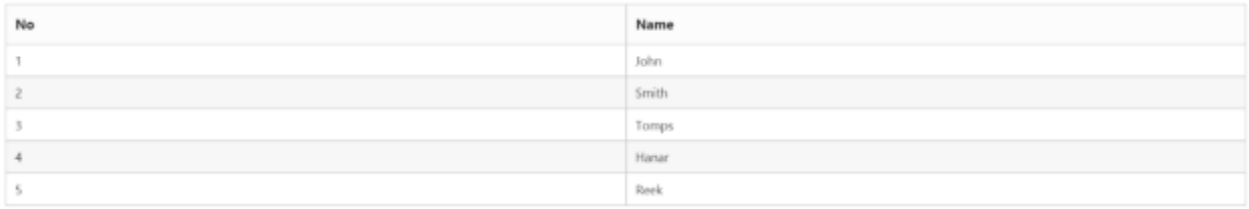
```
@(Html.EJ().Grid<object>("FlatGrid")
.Datasource((System.Data.DataTable)ViewBag.dataSource)
)
```

C#

```
namespace EJGrid.Controllers
{
public class HomeController : Controller
{
public ActionResult Index()
{
DataTable dt = new DataTable("Table1");
DataColumn cl = new DataColumn("No");
dt.Columns.Add(cl);
cl = new DataColumn("Name");
dt.Columns.Add(cl);
DataRow dataRow = dt.NewRow();
dataRow[0] = 1;
dataRow[1] = "John";
dt.Rows.Add(dataRow);
dataRow = dt.NewRow();
dataRow[0] = 2;
dataRow[1] = "Smith";
dt.Rows.Add(dataRow);
dataRow = dt.NewRow();
dataRow[0] = 3;
dataRow[1] = "Tomps";
dt.Rows.Add(dataRow);
dataRow = dt.NewRow();
dataRow[0] = 4;
dataRow[1] = "Hanar";
dt.Rows.Add(dataRow);
dataRow = dt.NewRow();
dataRow[0] = 5;
dataRow[1] = "Reek";
dt.Rows.Add(dataRow);
ViewBag.dataSource = dt;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



No	Name
1	John
2	Smith
3	Tomps
4	Hanar
5	Reek

Entity Framework

The collection of business objects generated from Entity Framework ORM can be used as Grid`s datasource. The Grid can be used with Entity Framework using either code first technique or Database first technique.

The following code example describes the above behavior.

RAZOR

```
@(Html.EJ().Grid<OrdersView>("Grid")
.Datasource((IEnumerable<OrdersView>)ViewBag.datasource)
.AllowPaging()
.Columns(col =>
{
col.Field(p => p.OrderID).HeaderText("Order
ID").TextAlign(TextAlign.Right).Add();
col.Field(p => p.CustomerID).HeaderText("Customer ID").Add();
col.Field(p => p.EmployeeID).HeaderText("Employee
ID").TextAlign(TextAlign.Right).Add();
col.Field(p =>
p.Freight).HeaderText("Freight").Format("{0:C2}").TextAlign(TextAlign.Right)
.Add();
})
)
```

C#

```
namespace Grid.Controllers
{
public class HomeController : Controller
{
public ActionResult Index()
{
ViewBag.datasource = new NORTHWNDEntities().OrdersView.ToList();
return View();
}
}
}
```

The following output is displayed as a result of the above code example.
