<div class="cols-sample-area">
<textarea id="rteSample1" rows="10" cols="70" style="height: 440px">
<p>Model-view-controller (MVC) is a software architecture pattern which
separates the representation of information from the user's interaction
with it.
The model consists of application data, business rules, logic, and
functions. A view can be any output representation of data, such as a
chart or a diagram.
Multiple views of the same data are possible, such as a bar chart for
management and a tabular view for accountants.
The controller mediates input, converting it to commands for the model or
view.The central ideas behind MVC are code reusable and in addition to
dividing the application into three kinds of components, the MVC design
defines the interactions between them.</p>
<p>A controller can send commands to its associated view to change the
view's presentation of the model (e.g., by scrolling through a document).
It can also send commands to the model to update the model's state (e.g.,
editing a document).</p>
```

```
<p>A model notifies its associated views and controllers when there has
been a change in its state. This notification allows the views to produce
updated output, and the controllers to change the available set of
commands. A passive implementation of MVC omits these notifications,
because the application does not require them or the software platform
does not support them.</p>
<p>A view requests from the model the information that it needs to
generate an output representation to the user.</p>
</textarea>
@{
Html.EJ().RTE("rteSample1").Width("100%").MinWidth("10px").ShowContextMen
u(false).ClientSideEvents(clientSideEvent =>
clientSideEvent.Create("rteCreate").Change("rteChange").Select("radialSho
w")).ShowToolbar(false).Render();
}
</div>

```
</script>
```

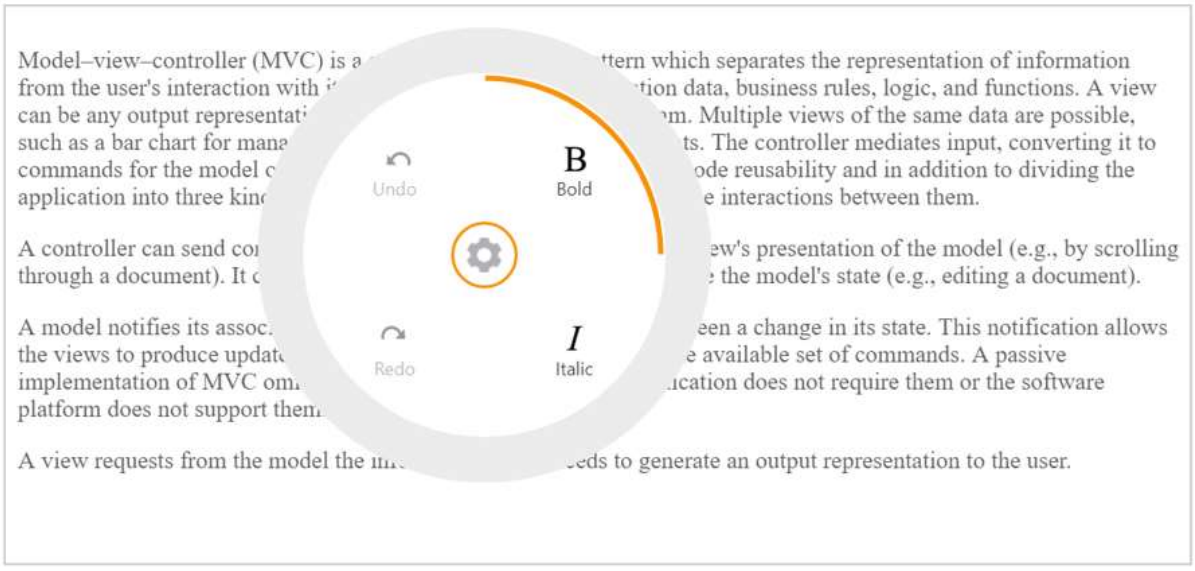
Add the following code in your style section,

CSS

```
<style type="text/css" class="cssStyles">
.e-radialmenu .e-radial {
background-image: url("../Images/RadialMenu/settings.png");
}
#rteSample1 {
width: 100%;
}
font-face {
font-family: 'ej-webfont';
font-weight: normal;
font-style: normal;
font-size: 20px;
}
.e-radialmenu .e-abs.e-radialshow, .e-radialmenu .e-abs.e-scaleshow {
/* use !important to prevent issues with browser extensions that change
fonts */
font-family: 'ej-webfont' !important;
speak: none;
font-size: 20px;
font-style: normal;
font-weight: normal;
font-variant: normal;
text-transform: none;
line-height: 1;
-webkit-font-smoothing: antialiased;
/* Better Font Rendering =========== */
-webkit-font-smoothing: antialiased;
-moz-osx-font-smoothing: grayscale;
}
</style>
```

The following screenshot illustrates the output,

Copyright © 2001 - 2020 Syncfusion Inc.



Note: This is the example sample for SVG icon support for Radial Menu.Like wise you can add any SVG element to it, but you need to customize and position the element individually.

How to

Render RadialMenu from Code behind

RadialMenu can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of RadialMenu properties in the controller.

C#

```
//Namespace to get the JavaScript (RadialMenu) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class RadialmenuController: Controller
{
public ActionResult RadialmenuFeatures()
{
//Initializing the RadialMenu model
RadialMenuProperties RadialmenuObj = new RadialMenuProperties();
//Initializing the items and other properties
List<RadialMenuBaseItem> obj = new List<RadialMenuBaseItem> ();
obj.Add(new RadialMenuBaseItem(){ Text = "Copy" , ImageURL =
"http://mvc.syncfusion.com/demos/web/Images/RadialMenu/copy.png"});
obj.Add(new RadialMenuBaseItem() { Text = "Paste", ImageURL =
"http://mvc.syncfusion.com/demos/web/Images/RadialMenu/paste.png" });
obj.Add(new RadialMenuBaseItem() { Text = "Undo", ImageURL =
"http://mvc.syncfusion.com/demos/web/Images/RadialMenu/undo.png" });
obj.Add(new RadialMenuBaseItem() { Text = "Redo", ImageURL =
"http://mvc.syncfusion.com/demos/web/Images/RadialMenu/redo.png" });
RadialmenuObj.Items = obj;
RadialmenuObj.ImageClass = "e-radial";
RadialmenuObj.TargetElementId = "radialtarget1";
//Passing Radialmenu properties using the ViewData
ViewData["RadialMenuModel"] = RadialmenuObj;
```

```
return View();
}
}
```

Binding the RadialMenu properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
<div id="radialtarget11" class="content-container-fluid">
</div>
@{
Html.EJ().RadialMenu("RadialMenu1",
(Syncfusion.JavaScript.Models.RadialMenuProperties)ViewData["RadialMenuMo
del"]).Render();
}
<style type="text/css" class="cssStyles">
.e-radialmenu .e-radial {
background-image:
url("http://mvc.syncfusion.com/demos/web/Images/RadialMenu/settings.png")
;
}
.e-radialmenu.e-displaynone {
display: block;
}
</style>
```

RadialSlider

Overview

The RadialSlider control that provides an optimized interface for selecting a numeric value using touch interface.This allows the user to select a value or range of values in a circular motion.

Key Features

- Angle Support: Provides start and end angle level view of RadialSlider.
- Animation: Offers animation effect for the RadialSlider handle.
- Image Customization: Supports customize the images of inner circle in Radial Slider.
- Dimension: Allows to change the radius and Stroke width of RadialSlider .
- Accuracy: Provides way to select accurate numeric value and customize the display values

Getting Started

Creating your first RadialSlider in MVC application

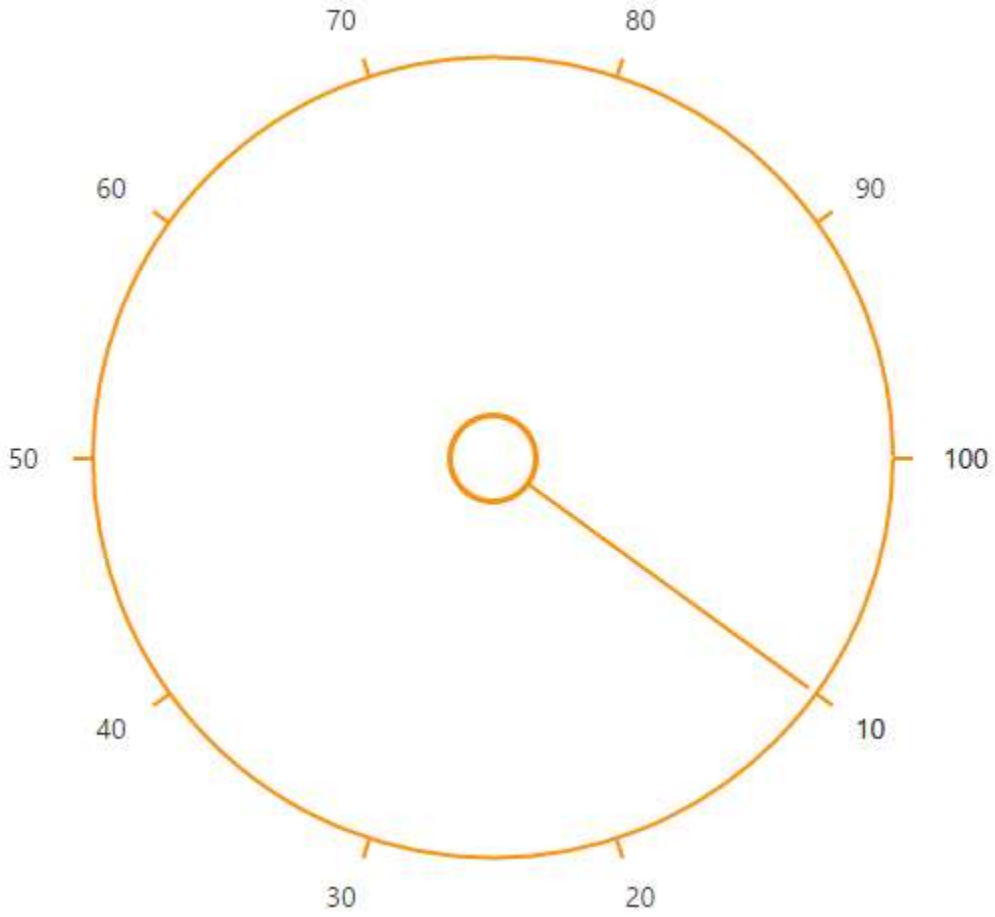
1. Create an MVC Project and add necessary assemblies, scripts and CSS files given in MVC-Getting Started Documentation.
2. Add RadialSlider control using the helper from EJ namespace.

HTML

```
@Html.EJ().RadialSlider("RadialSlider1")
```

Copyright © 2001 - 2020 Syncfusion Inc.

3. Execute the code and get a Default RadialSlider control as below



RadialSlider Dependencies

The external script dependencies of the RadialSlider component are,

- jQuery 1.7.1 and later versions.

And the internal script dependencies of the RadialSlider widget are:

FileÂ	Description / Usage
ej.core.min.js	Must be referred always before using all the JS controls.
ej.touch.min.js	For providing touch support
ej.radialslider.min.js	This is main source file specific for rendering RadialSlider

Dimension

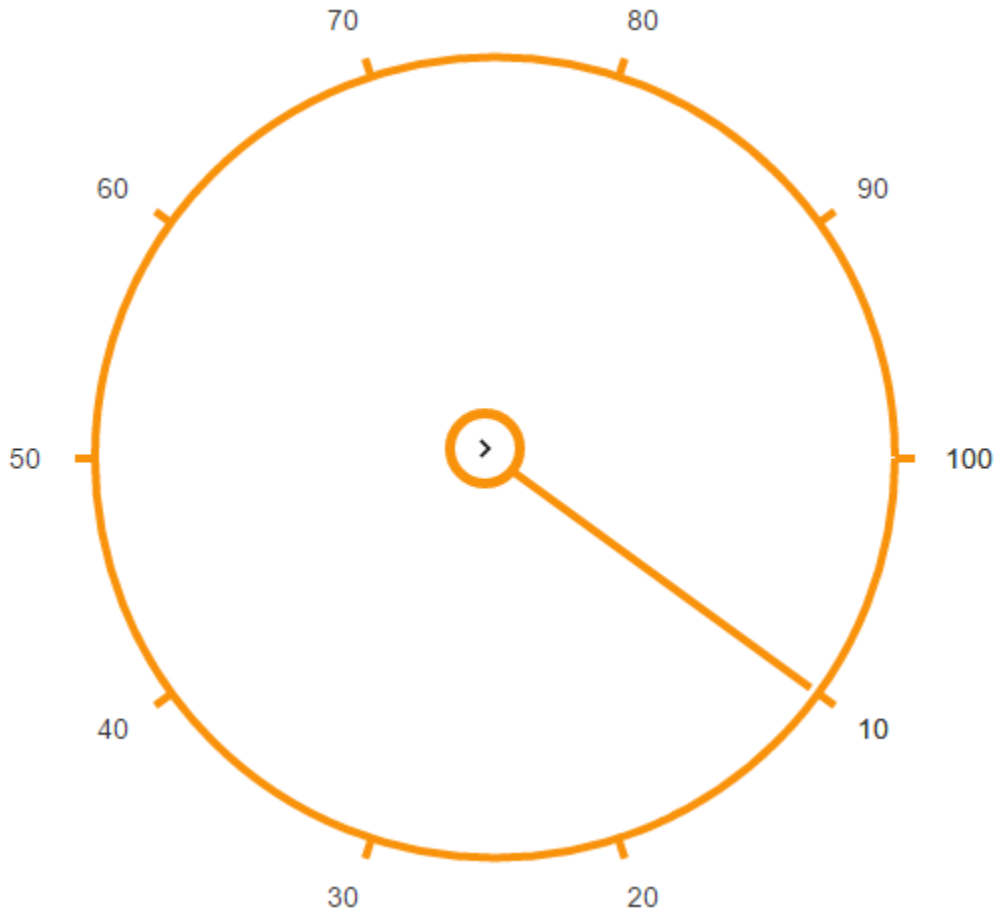
Stroke Width

Radial Slider StrokeWidth property specifies the width of the outline . By default, the **Radial slider** StrokeWidth is set as 2. Refer to the following code example.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").StrokeWidth(4).InnerCircleImageUrl("../
images/radialslider/chevron-right.png")
```

The following screenshot illustrates the output of the above code.



Setting radius

The **RadialSlider** property **Radius** indicates the radius of the RadialSlider's circle ant its allow to change radius value. By default, the **Radial Slider** Radius is set to 200. Refer to the following code example.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").Radius(250)
```

Behavior settings

The following are some properties that enables you to an option to enhance the behavior of **RadialSlider** control.

Show/hide RadialSlider on initial rendering

The **RadialSlider** property **AutoOpen** allow to enable or disable RadialSlider visibility. By default,Value of the property is set as **true** and type of the property is **Boolean**.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").AutoOpen(false)
```

Value Accuracy

The **RadialSlider** property **EnableRoundOff** allow to show the rounded off value when user changes it. By default, value of the property is set as **true**. For accurate values you can set this as false.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").EnableRoundOff(true)
```

Display inline

The **RadialSlider** property **Inline** is used to show the control values inline of the slider. By default, value of the property is set as **false**.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").Inline(true)
```

Modifying Label Space

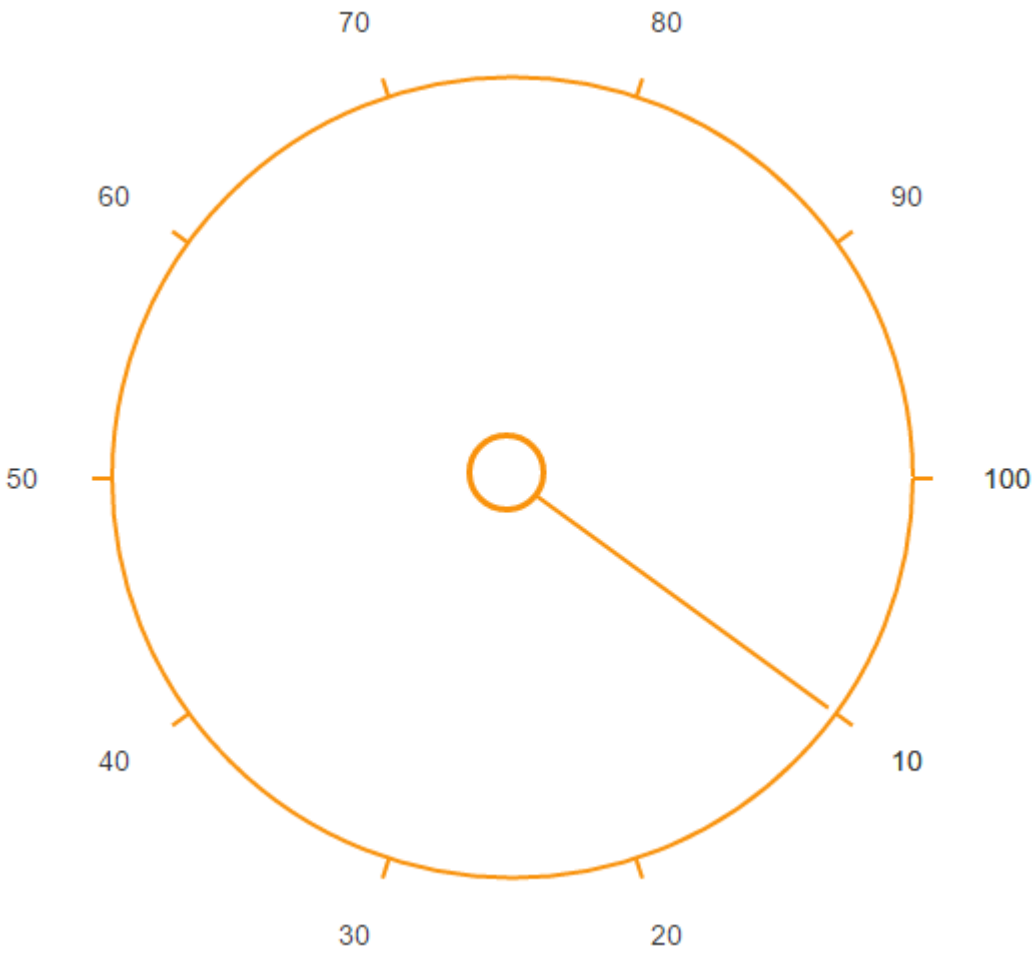
The **RadialSlider** property **LabelSpace** allow to define the space of label in it. By default, the **RadialSlider** labelSpace is set as 30. Refer to the following code example.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").LableSpace(40)
```

The following screenshot shows the output for the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Show/Hide inner circle

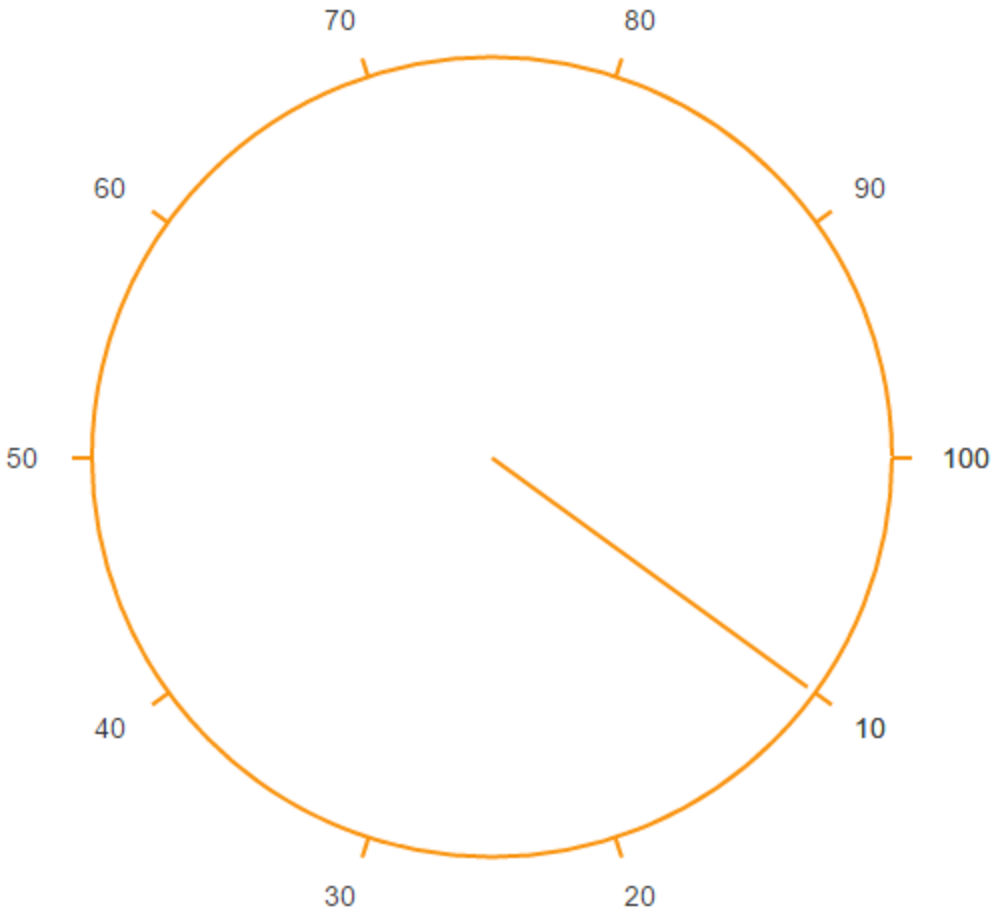
The **RadialSlider** property **ShowInnerCircle** allow to show or hide the inner circle of the **RadialSlider**.By default,Value of the property is set as **true** and type of the property is **Boolean**.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").ShowInnerCircle(false).InnerCircleImage
Url("../images/radialslider/chevron-right.png")
```

The following screenshot shows the output for the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Values customization

The **RadialSlider** property **Ticks** allow to set an array of numeric value which will be displayed in it. By Default **RadialSlider** ticks value is a set to an array of length 11 as following,

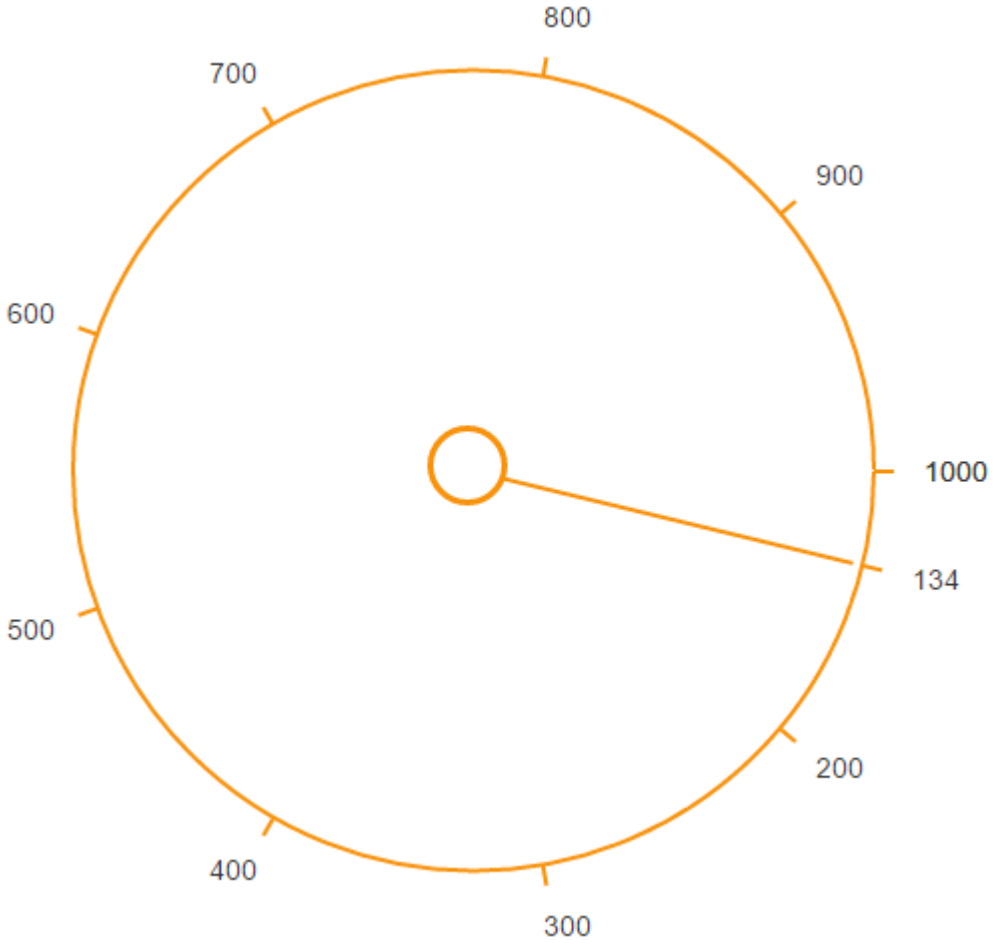
Ticks = new List<double>{ 0, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100 }. You can refer the below code for reference.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").Ticks(new List<double>{ 100, 200, 300,
400, 500, 600, 700, 800, 900, 1000 })
```

The following screenshot shows the output for the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Animation Effect

The animation effect for the **RadialSlider** can be enabled or disabled using the **EnableAnimation** property.By default, it is set as **true**, so that the handle movement will be animated.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").EnableAnimation(true).InnerCircleImageU
rl("../images/radialslider/chevron-right.png")
```

Display Angle Settings

Start Angle

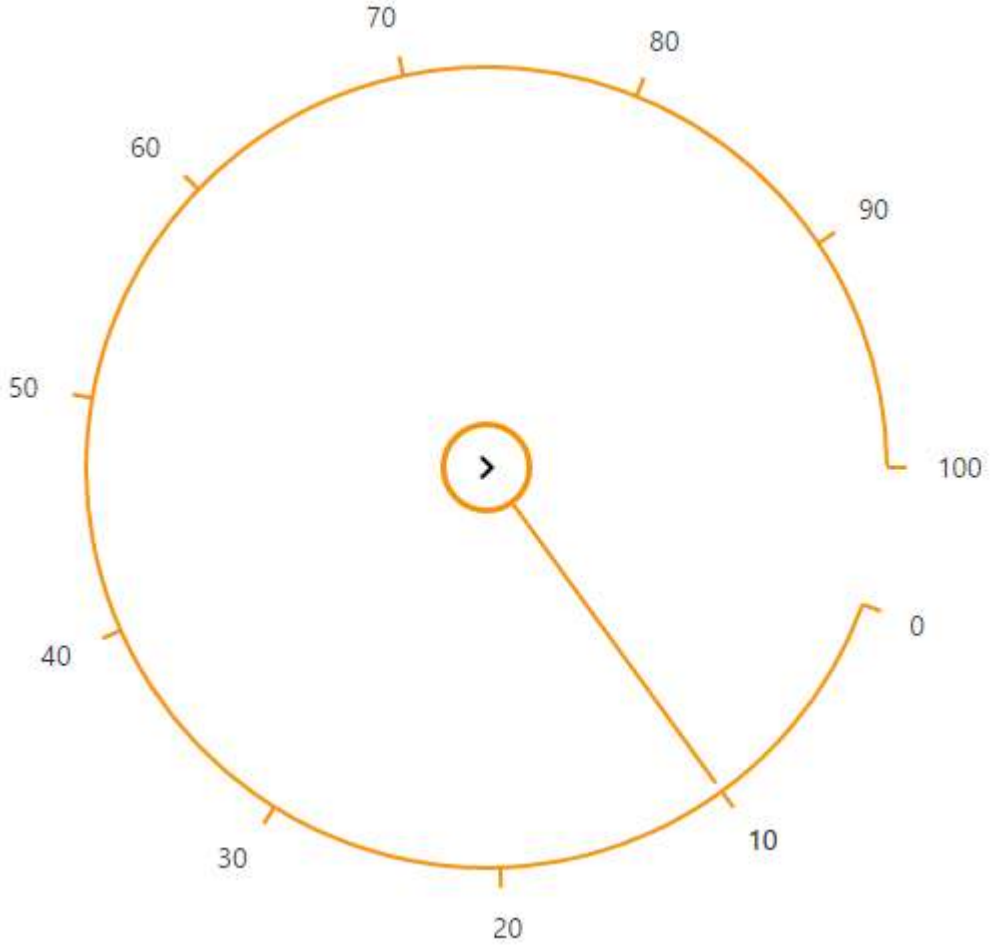
The **RadialSlider** property **StartAngle** allows you to change the startAngle level of the **RadialSlider**. By default, the **Radial Slider** StartAngle is set as 0. Refer to the following code example.

ASPX-CS

```
@Html.EJ().RadialSlider("radialSlider").InnerCircleImageUrl("../images/ra
dialslider/chevron-right.png").StartAngle(20)
```

The following screenshot illustrates the output of the above code.

Copyright © 2001 - 2020 Syncfusion Inc.



End Angle

The **RadialSlider** property **EndAngle** allows you to change the endAngle level of the **RadialSlider**. By default, the **Radial Slider** endAngle is set as 360. Refer to the following code example.

ASPX-CS

```
@Html.EJ().RadialSlider("radialSlider").InnerCircleImageUrl("../images/ra
dialslider/chevron-right.png").EndAngle(300)
```

The following screenshot illustrates the output of the above code.

Copyright © 2001 - 2020 Syncfusion Inc.

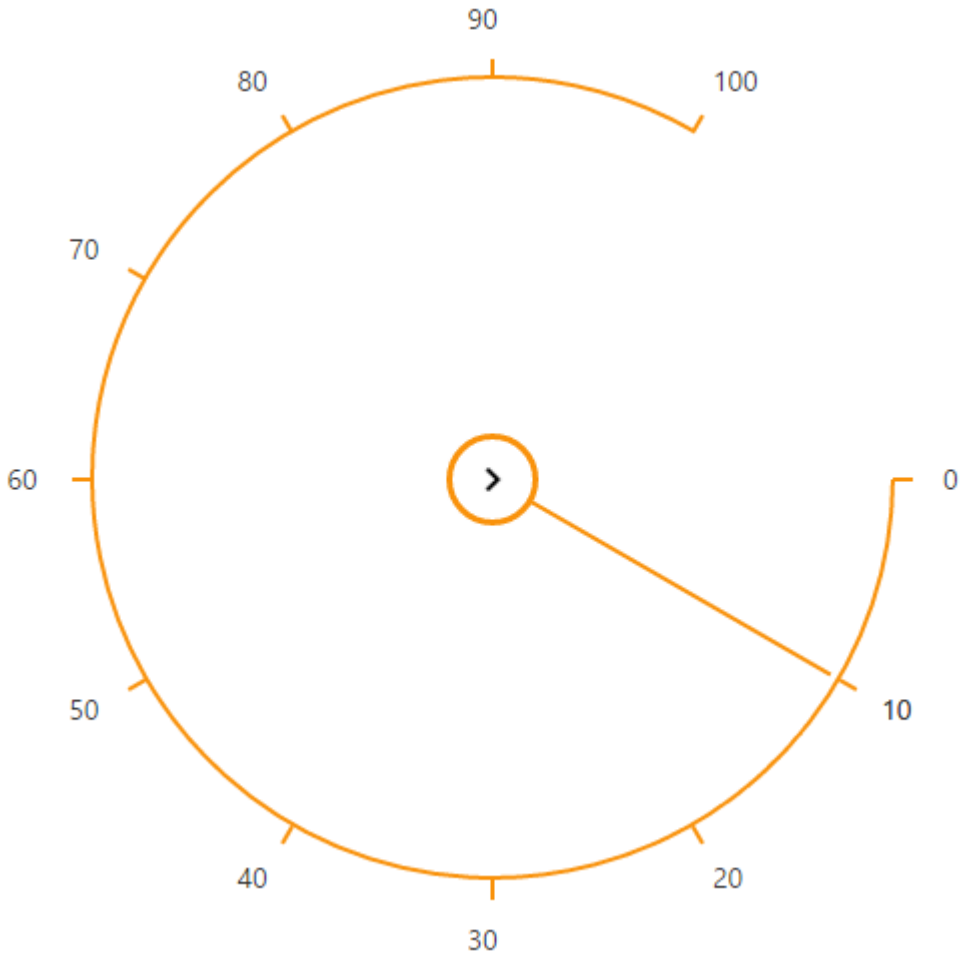


Image customization

Customizing inner circle

Using Class

The **RadialSlider** property **InnerCircleImageClass** allow to set image for the inner circle of the **RadialSlider**. By default, the **Radial Slider** innerCircleImageClass is set as "null". Refer to the following code example.

ASPX-CS

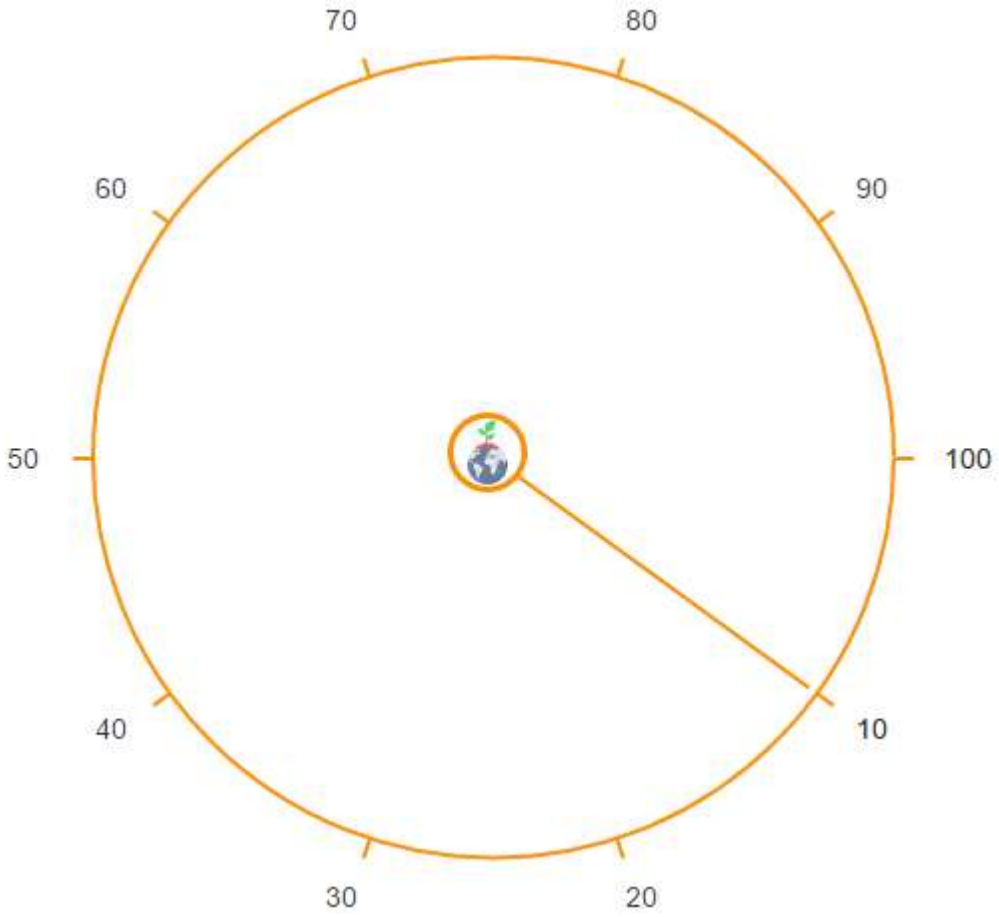
```
@Html.EJ().RadialSlider("slider").InnerCircleImageClass("custom-circle")
```

CSS

```
<style>
.e-custom-circle {
background-image: url("../images/radialslider/diagram.png");
}
</style>
```

The following screenshot illustrates the output of above code.

Copyright © 2001 - 2020 Syncfusion Inc.



Using image URL

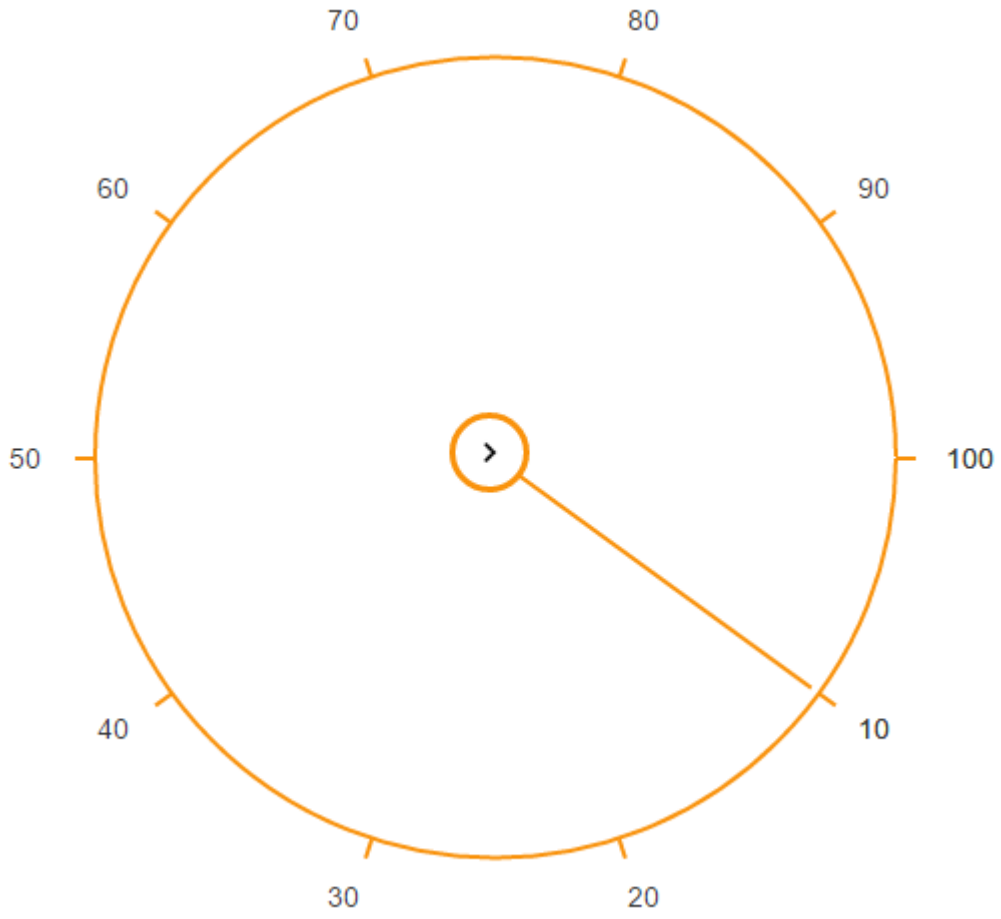
The **RadialSlider** property **InnerCircleImageUrl** allow to set URL image to the inner circle of the **RadialSlider**. By default, the **Radial Slider** InnerCircleImageUrl is set as "null". Refer to the following code example.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").InnerCircleImageUrl("../images/radialsl
ider/chevron-right.png")
```

The following screenshot illustrates the output of above code.

Copyright © 2001 - 2020 Syncfusion Inc.



Appearance and Styling

You can customize RadialSlider control style and appearance by using available themes or cssClass property.

Theme

In order to apply styles to the RadialSlider control, refer to 2 files namely, ej.widgets.core.min.css and ej.theme.min.css. When you refer ej.web.all.min.css file, it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.web.all.min.css is the combination of these two.

By default, there are 13 theme support available for RadialSlider component, namely:

- flat-azure
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark

Copyright © 2001 - 2020 Syncfusion Inc.

- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark
- bootstrap

CssClass

RadialSlider control also allows you to customize its appearance using user-defined CSS. To apply custom themes you can use **CssClass** property, which sets the root class for **RadialSlider** theme.

Using this **CssClass** you can override the existing styles under the theme style sheet. In the following example, the value of **CssClass** property is set as "**Purple-dark**". **Purple-dark** is added as root class to **RadialSlider** control at the runtime. From this root class you can customize the **RadialSlider** appearance.

Add the following code example to the corresponding CSHTML page to render the RadialSlider with the customized style.

ASPX-CS

```
@Html.EJ().RadialSlider("slider").CssClass("Purple-dark")
```

Using below style sheet,exiting theme style sheet file has been over-ridden using root class "**Purple-dark**".

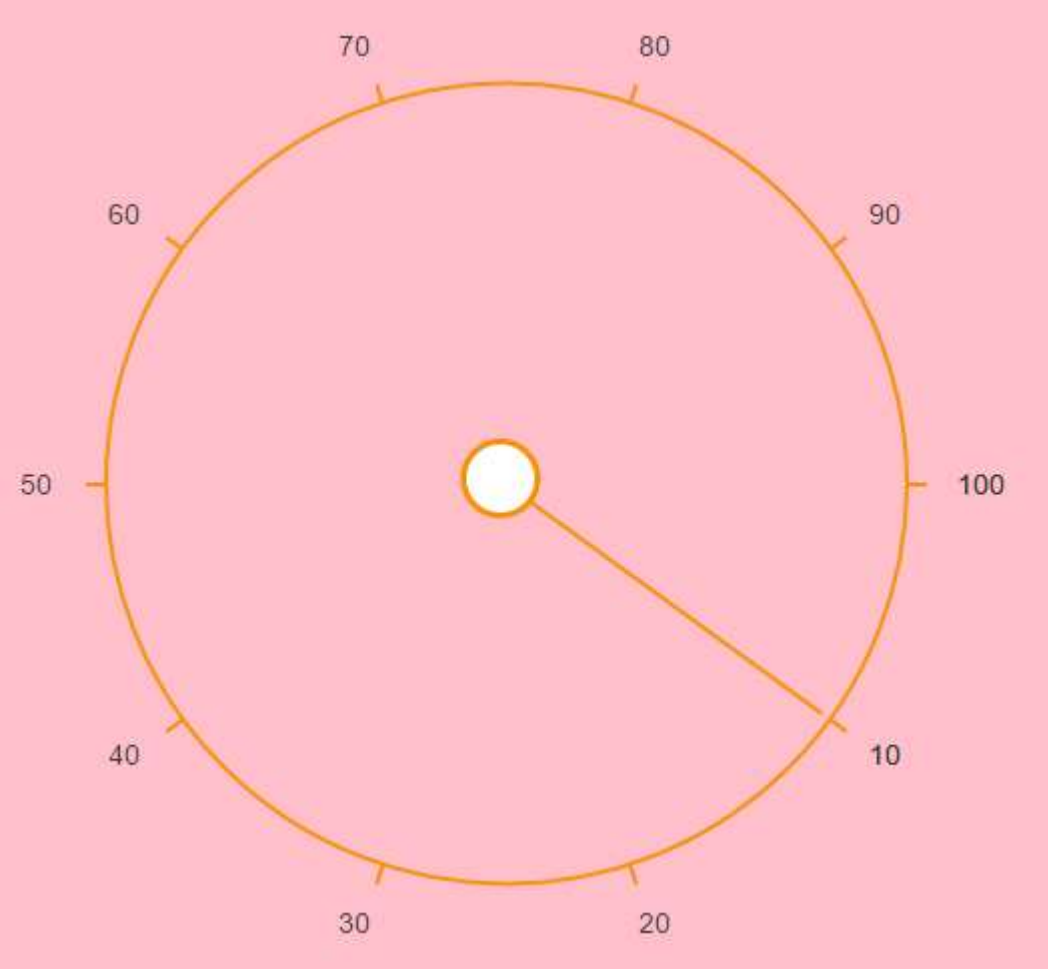
Add the following code in your style section.

CSS

```
.Purple-dark{
background-color:pink;
}
```

The following screenshot illustrates the output of the above code.

Copyright © 2001 - 2020 Syncfusion Inc.



How to

Render RadialSlider from Code behind

RadialSlider can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of RadialSlider properties in the controller.

C#

```
//Namespace to get the JavaScript (RadialSlider) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class RadialsliderController: Controller
{
public ActionResult RadialSliderFeatures()
{
//Initializing the RadialSlider model
RadialSliderProperties sliderObj = new RadialSliderProperties();
//Initializing the other properties
sliderObj.StrokeWidth = 4;
sliderObj.ShowInnerCircle = true;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
sliderObj.InnerCircleImageUrl =
"http://js.syncfusion.com/demos/web/content/images/radialslider/chevron-
right.png";
//Passing RadialSlider properties using the ViewData
ViewData["RSliserModel"] = sliderObj;
return View();
}
}
}
```

Binding the RadialSlider properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().RadialSlider("Radialslider1",
(Syncfusion.JavaScript.Models.RadialSliderProperties)ViewData["RSliserMod
el"]).Render();
}
```

RadioButton

RadioButton

The Essential ASP.NET MVCRadioButton control allows you to choose an option to perform an action. This control allows you to select true/false. These RadioButtons are supported with themes.

Key Features

- Trendy Look : Rich Appearance with Theme Support
- RTL : Supports for Right to Left alignment
- Easy Customization: The customization of RadioButton is made simple

Getting Started

This section briefly describes you on how to create a QuizApp and RegistrationApp using ASP.NET MVC RadioButton control and use the features available in it.

Create your first RadioButton in MVC

ASP.NET MVC RadioButton provides support to display the RadioButton within your web page, and allows you to pick your choice. Using the following guidelines, you can customize RadioButton for a real-time QuizApp and RegistrationApp scenarios. This allows you to select the corresponding choice for each question.

Copyright © 2001 - 2020 Syncfusion Inc.

Create your QuizApp

Essential Studio ASP.NET MVCRadioButton widget has a built-in feature to select a single option from the QuizApp. You can create the RadioButton widget using the following steps.

1. Create an MVC Project and add necessary assemblies and scripts to it.
2. Refer MVC-Getting Started.
3. Add the following code example to the corresponding view page to render RadioButton.

ASPX-CS

```
<div class="frame">
<div>
<div >
<br />
1. What is the Expansion for MVC<br />
<table>
<tr>
<td >
@Html.EJ().RadioButton("Radio1").Name("rad1").Size(RadioButtonSize.Small)
.Checked(false).Enabled(true)<!--Creates a small Radio Button-->
<label for="Radio1" class="clslab">
Model View Controller
</label>
</td>
<td  >
@Html.EJ().RadioButton("Radio2").Name("rad1").Size(RadioButtonSize.Small)
.Checked(false).Enabled(true)
<label for="Radio2" class="clslab">
Model Virtual Container
</label>
</td>
<td >
@Html.EJ().RadioButton("Radio3").Name("rad1").Size(RadioButtonSize.Small)
.Checked(false).Enabled(true)
<label for="Radio3" class="clslab">
Model Visual Controller
</label>
</td>
</tr>
</table>
```

```
<br />
<br />
2.What is the Expansion for USB<br />
<table>
<tr>
<td >
@Html.EJ().RadioButton("Radio4").Name("rad2").Size(RadioButtonSize.Medium
).Checked(false).Enabled(true)<!--Creates a Medium size Radio Button-->
<label for="Radio4" class="clslab">
Universal Serial Bus
</label>
</td>
<td >
@Html.EJ().RadioButton("Radio5").Name("rad2").Size(RadioButtonSize.Medium
).Checked(false).Enabled(true)
<label for="Radio5" class="clslab">
Universal Serial Buffer
</label>
</td>
<td>
@Html.EJ().RadioButton("Radio6").Name("rad2").Size(RadioButtonSize.Medium
).Checked(false).Enabled(true)
<label for="Radio6" class="clslab">
Universal Serialized Buffer
</label>
</td>
</tr>
</table>
<br/>
<br />
3.What is the Expansion for JS<br />
<table>
<tr>
<td >
@Html.EJ().RadioButton("Radio7").Name("rad3").Size(RadioButtonSize.Medium
).Checked(false).Enabled(true)
<label for="Radio7" class="clslab">
Jquery Script
</label>
</td>
<td >
@Html.EJ().RadioButton("Radio8").Name("rad3").Size(RadioButtonSize.Medium
).Checked(false).Enabled(true)
<label for="Radio8" class="clslab">
Java Script
</label>
</td>
<td>
@Html.EJ().RadioButton("Radio9").Name("rad3").Size(RadioButtonSize.Medium
).Checked(false).Enabled(true)
<label for="Radio9" class="clslab">
Json Script
</label>
</td>
</tr>
</table>
<center>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<table>
@Html.EJ().Button("Submit").Width("100px").Size(ButtonSize.Large).Text("S
ubmit").ClientSideEvents(s => s.Click("button"))
</center>
</table>
<br />
</div>
</div>
</div>
```

Add Script

JS

```
<script type="text/javascript">
function button()
{
var checkedItem = [];
$(".e-radiobtn:checked").each(function (index, Element) {
//if ($(this).ejRadioButton('isChecked')) {
checkedItem.push($(this).parent().siblings().html());
//}
});
alert(checkedItem);
}
</script>
```

Configure Style

Add the following code example in the index page.

CSS

```
<style>
.frame
{
width: 80%;
}
</style>
```

Execute the above code example to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Create RegistrationApp

ASPX-CS

```
<div class="frame">
<div>
<div >
<br />
1. Are you a Fresher ?<br />
<table>
<tr>
<td >
@Html.EJ().RadioButton("Radio1").Name("rad1").Size(RadioButtonSize.Small)
.Checked(false).Enabled(true)<!--Creates a small Radio Button-->
<label for="Radio1" class="clslab">
Yes
</label>
</td>
<td  >
@Html.EJ().RadioButton("Radio2").Name("rad1").Size(RadioButtonSize.Small)
.Checked(false).Enabled(true)
<label for="Radio2" class="clslab">
No
</label>
</td>
</tr>
</table>
<br />
<br />
2. Do you complete any .NET certification courses ?<br />
<table>
<tr>
<td>
@Html.EJ().RadioButton("Radio3").Name("rad2").Size(RadioButtonSize.Small)
.Checked(false).Enabled(true)<!--Creates a small Radio Button-->
<label for="Radio1" class="clslab">
Yes
</label>
</td>
<td>
```

```
@Html.EJ().RadioButton("Radio4").Name("rad2").Size(RadioButtonSize.Small)
.Checked(false).Enabled(true)
<label for="Radio2" class="clslab">
No
</label>
</td>
</tr>
</table>
<br />
<br />
3. Are you interested to work in .NET platform ?<br />
<table>
<tr>
<td>
@Html.EJ().RadioButton("Radio5").Name("rad3").Size(RadioButtonSize.Small)
.Checked(false).Enabled(true)<!--Creates a small Radio Button-->
<label for="Radio1" class="clslab">
Yes
</label>
</td>
<td>
@Html.EJ().RadioButton("Radio6").Name("rad3").Size(RadioButtonSize.Small)
.Checked(false).Enabled(true)
<label for="Radio2" class="clslab">
No
</label>
</td>
</tr>
</table>
<br />
<br />
<center>
<table>
@Html.EJ().Button("Submit").Width("100px").Size(ButtonSize.Large).Text("S
ubmit").ClientSideEvents(s => s.Click("button"))
</center>
</table>
<br />
</div>
</div>
</div>
```

Add Script

JS

```
<script type="text/javascript">
function button()
{
var checkedItem = [];
var result = "";
$(".e-radiobtn:checked").each(function (index, Element)
{
quest = index + 1;
checkedItem.push("Question" + quest + ":" +
$(this).parent().siblings().html().trim()+" ");
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

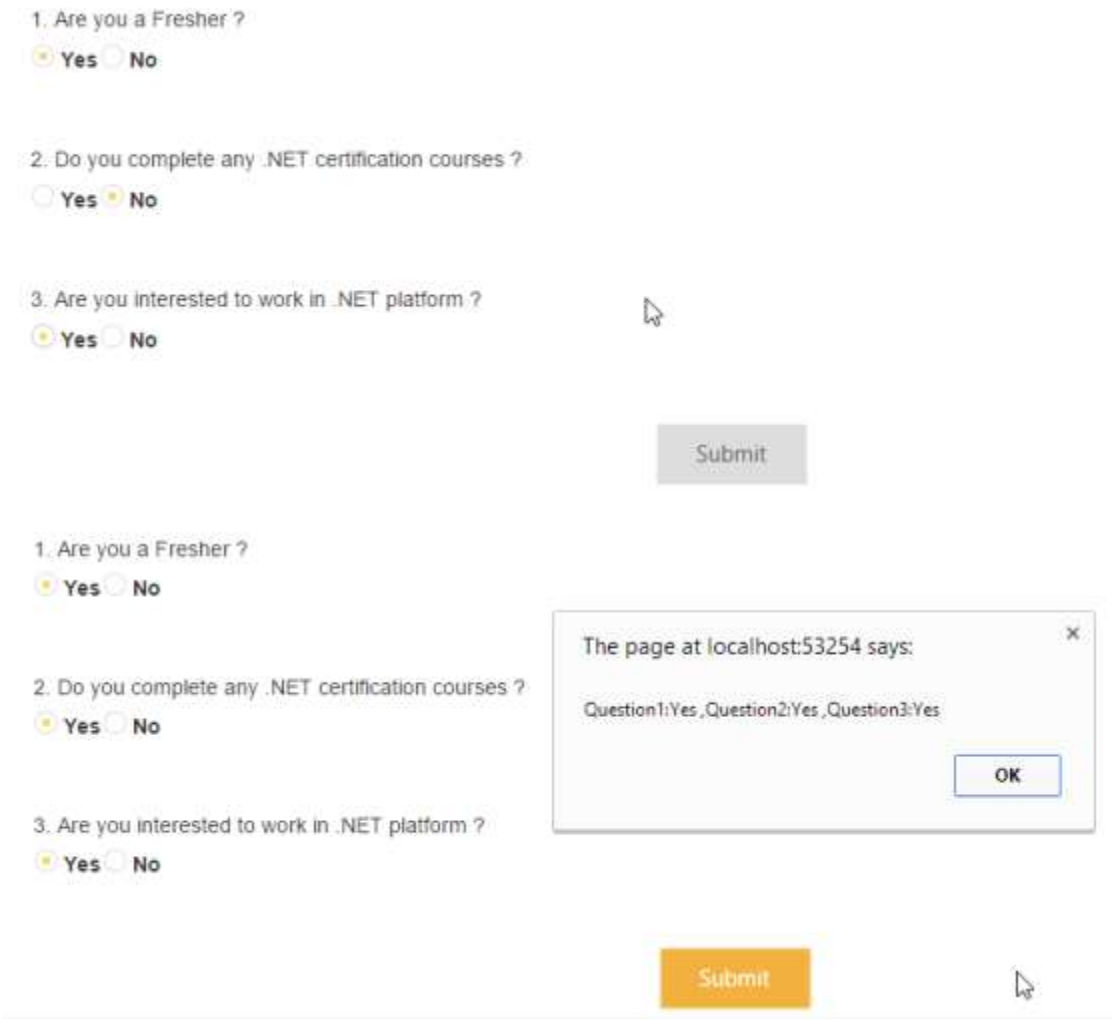
```
alert(checkedItem);
}
</script>
```

Add Style

CSS

```
<style>
.frame
{
width: 80%;
}
</style>
```

Execute the above code example to render the following outputs.



The whole purpose of Radio Button is to enable you to make one selection, only one, from a list. When you want to make multiple selections, you do not require a Radio Button, you need to use a CheckBox.

Copyright © 2001 - 2020 Syncfusion Inc.

You can make only one selection from the group of radio buttons. All radio buttons in that group need to share the same name. This tells the form handler, the name of the group, and the value of the selected Radio Button.

Radio Button is mutually exclusive; that is, when you select a radio button, any previously selected radio buttons in the same group become deselected.

For example, when you want to choose between a groups of colors, you can create Radio Buttons for each color. You can give all the radio buttons the same name, for example, "preferred_color", but you must give each radio button a different value, for example, "red".

1. All radio buttons within a group must share the same name. That is, the value of the name attribute has to be the same. For example, all three radio buttons in the "Preferred Color" group have the name "preferred_color".
2. All radio buttons within a group must have a different value for the value attribute. For example, when one radio button has value as "red", none of the others in that group can have a value of red, as this would defeat the purpose of having the extra radio button.
3. The label for each radio button is determined by the text next to the radio button and not by the value attribute. The value attribute is used by the form handler.

Easy Customization

Checked status

You have options to set the state of the radio button as either checked or unchecked. When you select any option from the group of radio buttons, a dot mark appears inside the circle. This is called the checked state. Previously selected radio buttons in this group are unselected that is they go to the unchecked state. The Checked property is used to set the state of the radio button.

The following steps explain the details about rendering the Radio Button with the checked option

In the CSHTML page, add the following input elements to configure Radio Button widget.

ASPX-CS

```
// Add the code in CSHTML page to configure Radio Button
@* Here checked and unchecked type of radio buttons are rendered in same
group
set checked state of radio button as follows*@
@Html.EJ().RadioButton("Radio_checked").Name("Gender").Size(RadioButtonSi
ze.Small).Checked(true)
<label for="Radio_checked" class="clslab">Male</label>
<br />
@Html.EJ().RadioButton("Radio_unchecked").Name("Gender").Size(RadioButton
Size.Small).Checked(false)
<label for="Radio_unchecked" class="clslab">Female</label>
```

Configure the CSS styles to align the radio buttons.

CSS

```
<style>
.page-align
{
margin: 100px;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</style>
```

The following image is displayed as the output for the above steps.

Text

Specifies the text content for the radio button. In previous programs, separate labels were created for each radio button. But now you have the option to set the text for radio button using the Text property. So here you do not have to add a label tag for each radio button in the HTML code.

The following steps explain the details about rendering the Radio Button with Text and without using the label tag options.

In the CSHTML page, add the following input elements to configure the Radio Button widget.

ASPX-CS

```
// Add the code in CSHTML page to configure Radio Button
@*radio button with text property*@
@Html.EJ().RadioButton("RadBtn_male").Name("Gender").Size(RadioButtonSize
.Small).Checked(true).Text("Male")
<br />
@Html.EJ().RadioButton("RadBtn_female").Name("Gender").Size(RadioButtonSi
ze.Small).Checked(false).Text("Female")
```

Configure the CSS styles to align the radio buttons.

CSS

```
<style>
.page-align
{
margin: 100px;
}
</style>
```

The following image is displayed as the output for the above steps.

Size

You can render the Radio Button in different sizes. There are some predefined size options available for rendering a Radio Button in an easy way. Each size option has different height and width. It mainly avoids the complexity in rendering Radio Button with complex CSS class.

Copyright © 2001 - 2020 Syncfusion Inc.

Size

Property	Description
Small	Creates radio button with Built-in small size height, width specified.
Medium	Creates radio button with Built-in medium size height, width specified.

The following steps explain the details about rendering Radio Button with different size options.

In the CSHTML page, add the following input elements to configure Radio Button widget.

ASPX-CS

```
// Add the code in CSHTML page to configure Radio Button
@* small and medium size of radio buttons in same group
By default, here no one radio button is checked*@
Small size radio buttons
<br />
@Html.EJ().RadioButton("Radio_Male").Name("Gender").Size(RadioButtonSize.
Small).Checked(true)
<label for="Radio_Male" >Male</label>
<br />
@Html.EJ().RadioButton("Radio_Female").Name("Gender").Size(RadioButtonSiz
e.Small).Checked(false)
<label for="Radio_Female" >Female</label>
<br />
Medium size radio buttons
<br />
@Html.EJ().RadioButton("Radio1_Male").Name("Gender1").Size(RadioButtonSiz
e.Medium).Checked(true)
<label for="Radio1_Male">Male</label>
<br />
@Html.EJ().RadioButton("Radio1_Female").Name("Gender1").Size(RadioButtonS
ize.Medium).Checked(false)
<label for="Radio1_Female" >Female</label>
```

Configure the CSS styles to align the radio buttons.

CSS

```
<style>
.page-align
{
margin: 100px;
}
</style>
```

The following image is displayed as the output for the above steps.

Copyright © 2001 - 2020 Syncfusion Inc.

RTL Support

In some cases you need to use right-to-left alignment. You can give RTL support by using EnableRTL property. RTL mode works when you use the Text property in Radio Button. The Radio Buttons and text are aligned in the right-to-left format. For example, when text is right-aligned and Radio Button is left-aligned, after you apply right-to-left alignment, these positions are interchanged.

The following steps explain the details about rendering the Radio Button with right-to-left alignment support. Here the text property is necessary.

In the CSHTML page, add the following button elements to configure Radio Button widget.

ASPX-CS

```
// Add the code in CSHTML page to configure Radio Button
@*set radio button with right to left format*@
<div class="page-align">
<table class="rightAlign">
<tr>
<td>
@Html.EJ().RadioButton("RadBtn_male").Name("Gender").Size(RadioButtonSize
.Small).Checked(true).Text("Male").EnableRTL(true)
</td>
</tr>
<tr>
<td>
@Html.EJ().RadioButton("RadBtn_female").Name("Gender").Size(RadioButtonSi
ze.Small).Checked(false).Text("Female").EnableRTL(true)
</td>
</tr>
</table>
</div>
```

In the above mentioned code, the text property has been used. In LTR format, the Radio Button is on the left side. In RTL format, the Radio Button appears on the right side. Here the Text property is used and the EnableRTL property is set as “true”. It changes the alignment to right-to-left.

Configure the CSS styles to align the Radio Buttons.

CSS

```
<style>
.page-align
{
margin: 100px;
}
.rightAlign
{
text-align: right;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
</style>
```

The following image is displayed as the output for the above steps.

Styles Customization

RadioButton allows you to customize its appearance by using user-defined CSS and custom skin options such as colors and backgrounds. To apply custom themes, use **CssClass** property. CssClass property sets the root class for RadioButton theme.

By using this CssClass, you can override the existing styles under the theme style sheet. The theme style sheet applies theme-specific styles like colors and backgrounds. From the root class, you can customize the RadioButton control theme.

In the following example, the border color and border width of the active RadioButton is customized through the custom classes to create the success, and danger indication with RadioButton.

HTML

```
<span><b>Agree terms & conditions:</b></span>
<span style="margin-left: 15px">
@Html.EJ().RadioButton("Radio_checked").Text("Yes").Name("radio1").CssCla
ss("success").Size(Syncfusion.JavaScript.RadioButtonSize.Medium)
@Html.EJ().RadioButton("Radio_unchecked").Text("No").Name("radio1").CssCl
ass("warning").Size(Syncfusion.JavaScript.RadioButtonSize.Medium)
</span>
<br>
<br>
<span><b>Confirm:</b></span>
<span style="margin-left: 15px">
@Html.EJ().RadioButton("RadioButton3").Text("Yes").Name("radio2").CssClas
s("success").Size(Syncfusion.JavaScript.RadioButtonSize.Medium)
@Html.EJ().RadioButton("RadioButton4").Text("No").Name("radio2").CssClass
("warning").Size(Syncfusion.JavaScript.RadioButtonSize.Medium)
</span>
```

CSS

```
<style>
.success .e-spanicon.e-rad-active,
.success .e-spanicon.e-rad-active:hover {
border-color: #17ad37;
border-width: 2px;
}
.warning .e-spanicon.e-rad-active,
.warning .e-spanicon.e-rad-active:hover {
border-color: #ff6e40;
border-width: 2px;
}
</style>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Miscellaneous

Radio Button ID

Radio Button id is not shown in the user interface. Here Id denotes the Id attribute of the root element of Radio Button control. This Id value is unique. You can give Id through element and through the Id property. When you use two ids for a single radio button at initialization, the element Id is considered.

Set Id for Radio Button control as follows.

ASPX-CS

```
@*set new id value as follows*@
@Html.EJ().RadioButton("RadioButton_Male").Id("male_type").Name("Gender")
<br />
@Html.EJ().RadioButton("RadioButton_female").Id("female_type").Name("Gend
er")
```

Radio Button Prefix id

Id prefix value is appended to the element id value. It is used to mention the prefix for the wrapper's id attribute. When you assign a value for IdPrefix property, the older prefix id gets replaced by the new prefix id.

Setting a new prefix id for Radio Button control is as follows.

ASPX-CS

```
@*set new idPrefix  value as follows*@
@Html.EJ().RadioButton("Radio_Male").IdPrefix("sync_").Name("Gender")
<br />
@Html.EJ().RadioButton("Radio_Female").IdPrefix("sync_").Name("Gender")
```

Radio Button Name

The Name setting tells you where a Radio Button belongs. When you select one button, all other buttons in the same group are unselected. You can have only one group of Radio Buttons on each page.

The Name attribute is also used to identify form data after it has been submitted to the server, or for reference of form data using JavaScript on the client's side. Only form elements with a Name attribute have their values passed, when submitting a form.

Radio Button Value

The Value setting defines what can be submitted when checked.

For Radio Buttons, the contents of the value property do not appear in the user interface. The Value property only has meaning when submitting a form. If a radio button is in the checked state when the form is submitted, the name of the Radio Button is sent along with the value of the value property, if the radio button is not checked, no information is sent.

Copyright © 2001 - 2020 Syncfusion Inc.

To identify, on the server side, which one was checked, give different values for radio buttons in the same group,

Set name and value for each radio button control as follows.

ASPX-CS

```
@*set name and value for each radio button as follows*@
@Html.EJ().RadioButton("Radio_Male").Name("Gender").Value("male")
<br />
@Html.EJ().RadioButton("Radio_Female").Name("Gender").Value("female")
```

How to?

Render RadioButton from Code behind

RadioButton can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of RadioButton properties in the controller.

C#

```
//Namespace to get the JavaScript (RadioButton) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class RadioButtonController : Controller
{
// GET: RadioButton
public ActionResult RadioButtonFeatures()
{
//Initializing the RadioButton model
RadioButtonProperties BtnObj = new RadioButtonProperties();
//Initializing the datasource and other properties
BtnObj.Checked = true;
BtnObj.Size = RadioButtonSize.Medium;
BtnObj.Text = "Computer";
//Passing RadioButton properties using the ViewData
ViewData["BtnModel"] = BtnObj;
return View();
}
}
}
```

Binding the RadioButton properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().RadioButton("searchCustomer",(Syncfusion.JavaScript.Models.Radi
oButtonProperties)ViewData["BtnModel"]).Render();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

RangeNavigator

RangeNavigator

RangeNavigator is a data visualization control. It allows you to scroll and navigate through the data. This control easily combines with other controls such as Chart, GridView, etc., to create rich and powerful dashboards.

Key Features

The **RangeNavigator** is composed of the following features:

- **Higher level label:** Contains a time span format one level higher than the lower level **DateTime** values. For example, if the higher level label contains the year format (yyyy), the lower level label contains the Quarter format.
- **Lower level label:** Contains a time span format one level lower than the higher level **DateTime** values. For example, if the lower level label contains the Quarter format, the higher level label contains the year format (yyyy).
- **Chart:** To represent the data in RangeNavigator.
- **Slider:** To handle the selected data in RangeNavigator.

Getting Started

This section explains briefly about how to create a **RangeNavigator** in your ASP.NET MVC application.

Create your first RangeNavigator in MVC

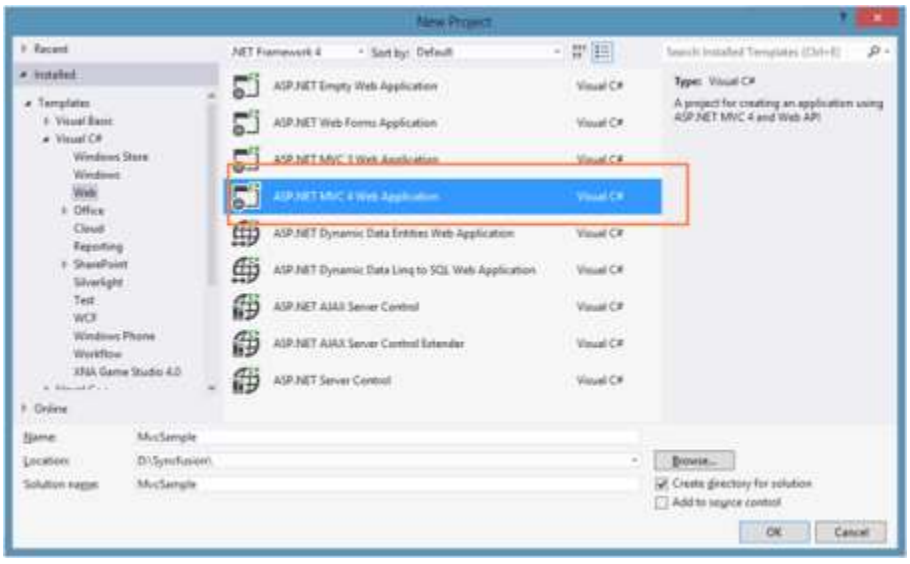
This section encompasses the details on how to configure the **RangeNavigator** and update the **chart** control for **RangeNavigator's** selected range. It also helps you to learn how to pass the required data to **RangeNavigator** and customize the scale and selected range for your requirements. In this example, you will learn how to configure the RangeNavigator to analyze sales of a product for a particular quarter in a year.

Copyright © 2001 - 2020 Syncfusion Inc.

Create a simple MVC Application for RangeNavigator

You can create a new ASP.NET MVC project Razor Application.

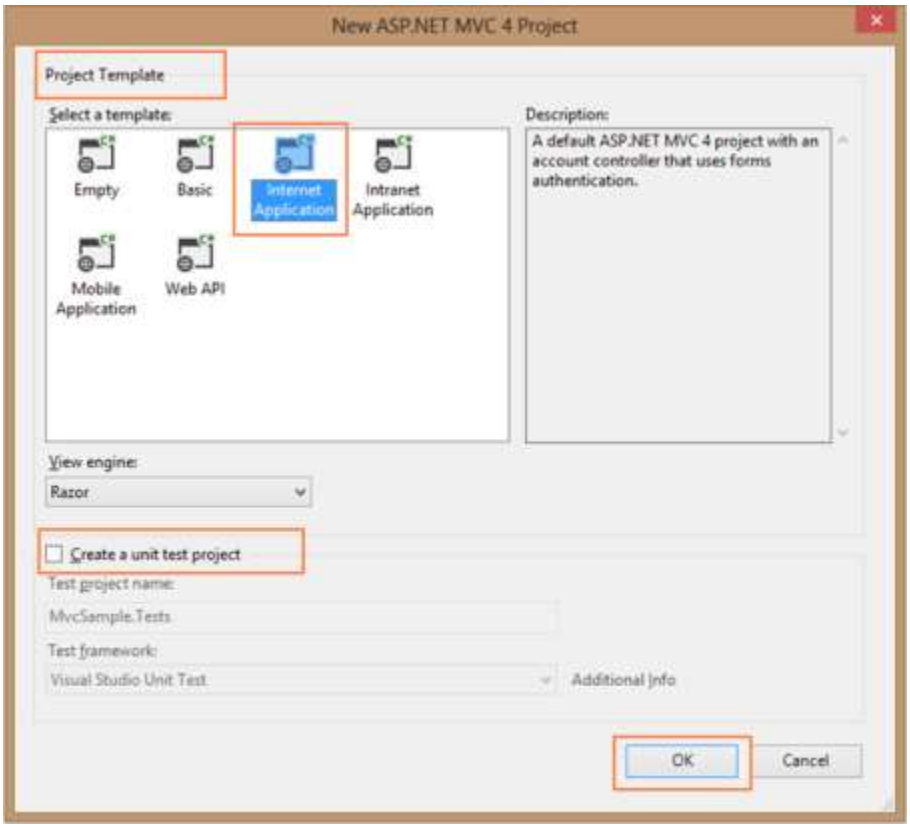
1. On the File menu, click New Project. The New Project dialog box opens.



2. On the upper-right corner, select .NET Framework 4.0.
3. In the Installed Templates pane, expand either Visual Basic or Visual C# and then click Web.
4. In the Visual Studio Installed Templates pane, select ASP.NET MVC 4 Web Application.
5. In the Name box, enter MvcSample

Copyright © 2001 - 2020 Syncfusion Inc.

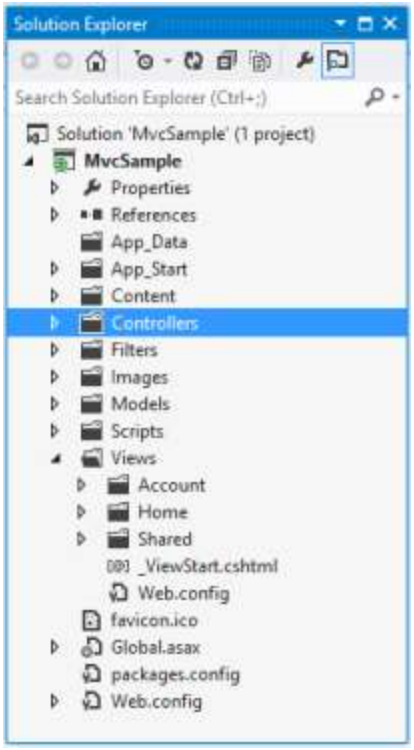
6. In the Location box, enter a name for the project folder.
7. If you want the name of the solution to differ from the project name, then enter a name in the Solution name box.
8. Select the Create directory for solution checkbox.
9. Click OK.
10. The New ASP.NET MVC4Project dialog box opens.



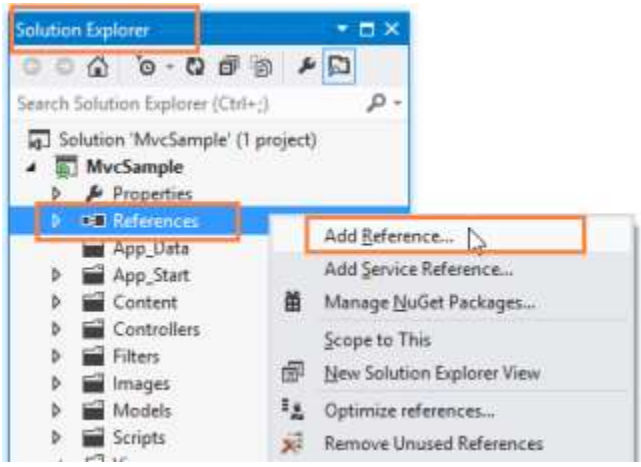
11. In the Project Template group, select the Internet Application template for MVC4 project.
12. Check the Create a unit test project checkbox, if you want to create a unit test project.
13. Click OK. The new MVC application project is generated.

The following screenshot shows the folder structure of the newly created MVC project.

Copyright © 2001 - 2020 Syncfusion Inc.



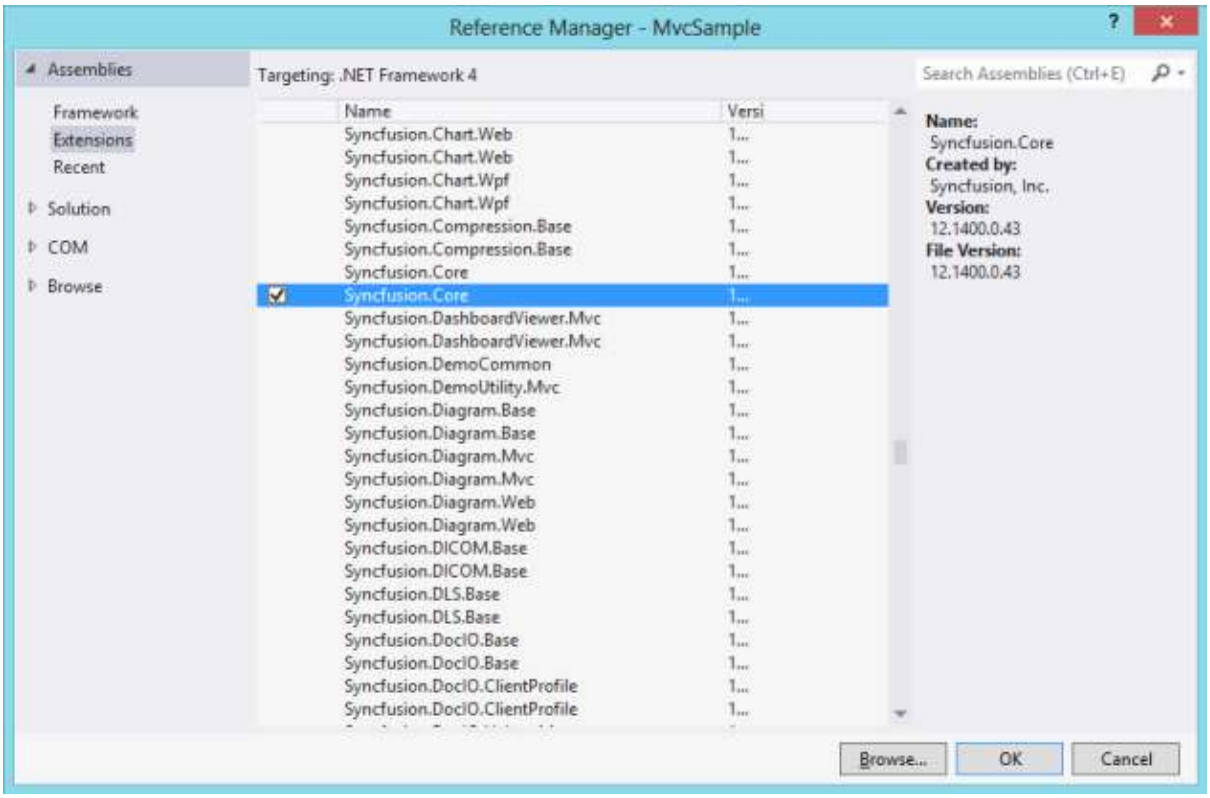
14. Adding Reference Assemblies
    - On the Solution Explorer, right-click the References folder and then click Add Reference. The Add Reference dialog box appears.

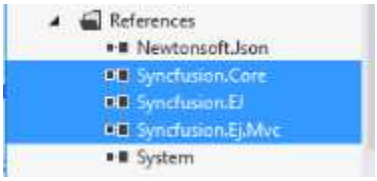


Adding Reference Assemblies

- Add the following Syncfusion assemblies :
    1. Syncfusion.Core
    2. Syncfusion.EJ
    3. Syncfusion.EJ.MVC

Copyright © 2001 - 2020 Syncfusion Inc.





15. You can add required Scripts and ScriptManger in _Layout page
    - Add the script references of the required libraries in the _Layout page as shown in the following code sample

ASPX-CS

```
<!DOCTYPE html>
<html xmlns="http://www.w3.org/1999/xhtml">
<head>
<script src="@Url.Content("~/Scripts/jquery-1.10.2.min.js")"
type="text/javascript"></script>
<script src="@Url.Content("~/Scripts/jquery.globalize.min.js")"
type="text/javascript" ></script>
<script src="@Url.Content("~/Scripts/ej.web.all.min.js")"
type="text/javascript"></script>
<script src="@Url.Content("~/Scripts/ej.unobtrusive.min.js")"
type="text/javascript"></script>
</head>
```

- Add the ScriptManager() at the end of tag in _Layout page.

ASPX-CS

```
<!DOCTYPE html>
<html xmlns="http://www.w3.org/1999/xhtml">
<head>
</head>
<body>
@(Html.EJ().ScriptManager())
</body>
</html>
```

16. Configure web.config files for assemblies
    - The following assemblies references are added properly in web.config file (There will be two web.config files. Refer to the one in the root folder.).

ASPX-CS

```
<compilation debug="true" targetFramework="4.0" >
<assemblies>
<add assembly="Syncfusion.Core, Version=XX.XXXX.X.X, Culture=neutral,
PublicKeyToken=632609B4D040F6B4" />
<add assembly="Syncfusion.EJ, Version= XX.XXXX.X.X, Culture=neutral,
PublicKeyToken=3d67ed1f87d44c89" />
<add assembly="Syncfusion.EJ.Mvc, Version= XX.XXXX.X.X, Culture=neutral,
PublicKeyToken=3d67ed1f87d44c89" />
</assemblies>
</compilation>
```

Note: Add the following namespaces in web.config file within the Views folder.

ASPX-CS

```
<namespaces>
<add namespace="System.Web.Mvc" />
<add namespace="System.Web.Mvc.Ajax" />
<add namespace="Syncfusion.JavaScript" />
<add namespace="Syncfusion.JavaScript.DataVisualization" />
<add namespace="Syncfusion.MVC.EJ" />
<add namespace="Syncfusion.EJ" />
</namespaces>
```

The above steps are done automatically, if you create your project with the help of MVC Project creation template, which is available once the MVC Extension is installed on your machine.

Configure RangeNavigator

Getting started with your MVC **RangeNavigator** is simple; all you need to do is initialize the **RangeNavigator** by setting range values.

1. Create a simple

   tag.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
<div>
</div>
```

2. Add the following code in the SimpleRangeNavigator.cshtml file, to create the RangeNavigator control in the View page.

The following code example renders a **RangeNavigator** with a range from 2010 January 1st to December 31st.

ASPX-CS

```
<div>
@(Html.EJ().RangeNavigator("container")
.RangeSettings(range=>range.Start("2010/1/1").End("2010/12/31"))
)
</div>
```

3. Open ~/Controllers/HomeController.cs.
4. Add the SimpleRangeNavigator() action as illustrated in the following code example.

C#

```
public ActionResult SimpleRangeNavigator()
{
return View();
}
```

The following Screen shot displays the **RangeNavigator** with a range from 2010 January 1st to December 31st.

Add series

To add a series to **RangeNavigator**, you need to set DataSource property, as given in the following code example.

You can add JSON data to the RangeNavigator using the Datasource property.

In Controllers/HomeController.cs specify the data for data source.

C#

```
public ArrayList GetData()
{
ArrayList dataTable = new ArrayList();
dataTable.Add(new NavigatorData (new DateTime(2011, 01, 01), 10));
dataTable.Add(new NavigatorData (new DateTime(2011, 02, 01), 5));
```

Copyright © 2001 - 2020 Syncfusion Inc.

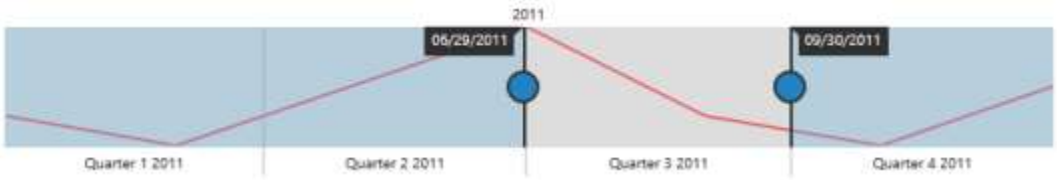
```
dataTable.Add(new NavigatorData (new DateTime(2011, 04, 01), 15));
dataTable.Add(new NavigatorData (new DateTime(2011, 06, 01), 25));
dataTable.Add(new NavigatorData (new DateTime(2011, 08, 01), 10));
dataTable.Add(new NavigatorData (new DateTime(2011, 10, 01), 5));
dataTable.Add(new NavigatorData (new DateTime(2011, 12, 31), 15));
return dataTable;
}
class NavigatorData
{
private DateTime date;
public DateTime xDate
{
get { return date; }
set { date = value; }
}
private double value;
public double yValue
{
get { return value; }
set { value = value; }
}
public NavigatorData(DateTime date, double value)
{
this.xDate = date;
this.yValue = value;
}
}
public ActionResult SimpleRangeNavigator()
{
var DataSource = GetData();
ViewBag.datasource = DataSource;
return View();
}
```

In SimpleRangeNavigator.cshtml specify the type of series you want to render using Type property. And specify the Datasource to the Series of RangeNavigator.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.DataSource((System.Collections.IEnumerable)ViewBag.datasource)
.XName("xDate")
.YName("yValue")
)
```

The following screenshot displays the RangeNavigator with the type series as “line”.



Copyright © 2001 - 2020 Syncfusion Inc.

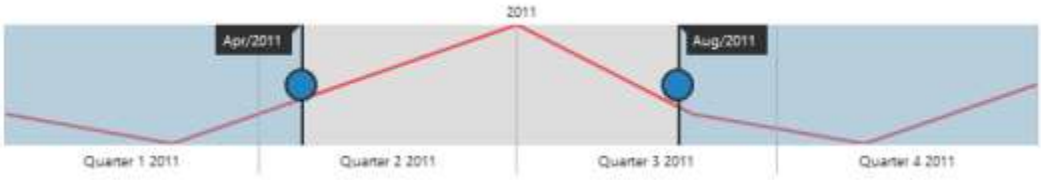
Enable tooltip

Tooltip can be customized for RangeNavigator using TooltipSettings option. You can also use TooltipDisplayMode option in tooltip to display the tooltip “always” or “ondemand” (displays tooltip only while dragging the sliders). You can also specify label format for tooltip using LabelFormat.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.TooltipSettings(tooltip=>tooltip.Visible(true).LabelFormat("MMM/yyyy").T
ooltipDisplayMode("always"))
)
```

The following screen shot displays the label format Tooltip in RangeNavigator:



Update Chart

RangeNavigator is used along with the controls like **chart** and **grid** to view the range of data selected in RangeNavigator.

In order to update **chart**, whenever the selected range changes in **RangeNavigator**, you need to use RangeChanged event of **RangeNavigator** and then update the **chart** with the selected data in this event.

Now, add the DataSource to the series and provide the field name to get the values from the DataSource in XName and YName options and also trigger the RangeChanged event for updating the chart.

ASPX-CS

```
@(Html.EJ().Chart("container")
.Title(title => title.Text("Sales Analysis"))
.Legend(legend => legend.Visible(true).Position(LegendPosition.Top))
.PrimaryYAxis(axis => axis.Title(axisTitle =>
axisTitle.Text("Sales(Million)")))
.Series(series =>
{
series.Name("Product A").Type(SeriesType.Line)
.DataSource((System.Collections.IEnumerable)ViewBag.datasource)
.XName("xDate")
.YName("yValue")
.Add();
}))
@(Html.EJ().RangeNavigator("container")
.DataSource((System.Collections.IEnumerable)ViewBag.datasource)
.XName("xDate")
.YName("yValue")
.RangeChanged("onRangeChanged")
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example illustrates how to use the RangeChanged event of RangeNavigator for updating the chart with the selected data.

ASPX-CS

```
<script type="text/javascript" language="javascript">
function onRangeChanged(sender)
{
var chart = $("#container").data("ejChart");
if (chart != null)
{
chart.model.series[0].dataSource = sender.selectedData;
$("#container").ejChart("redraw");
}
}
</script>
```

The following screenshot displays how the RangeNavigator is updated when the selected range is changed.

Set value type

RangeNavigator can also be used with numerical values. You can specify the data type using ValueType option.

First let's create a DataSource for Chart Series with integer Values.

In Controllers/HomeController.cs specify the data for data source.

C#

```
public ArrayList GetData()
```

```
{
ArrayList dataTable = new ArrayList();
dataTable.Add(new NavigatorData (0, 10));
dataTable.Add(new NavigatorData (50, 5));
dataTable.Add(new NavigatorData (100, 15));
dataTable.Add(new NavigatorData (150, 25));
dataTable.Add(new NavigatorData (200, 10));
dataTable.Add(new NavigatorData (250, 5));
dataTable.Add(new NavigatorData (300, 15));
return dataTable;
}
class NavigatorData
{
private double xValue;
public double xValue
{
get { return xValue; }
set { xValue = value; }
}
private double yValue;
public double yValue
{
get { return yValue; }
set { yValue = value; }
}
public NavigatorData(double xValue, double yValue)
{
this.xValue = xValue;
this.yValue = yValue;
}
}
public ActionResult SimpleRangeNavigator()
{
var DataSource = GetData();
ViewBag.datasource = DataSource;
return View();
}
```

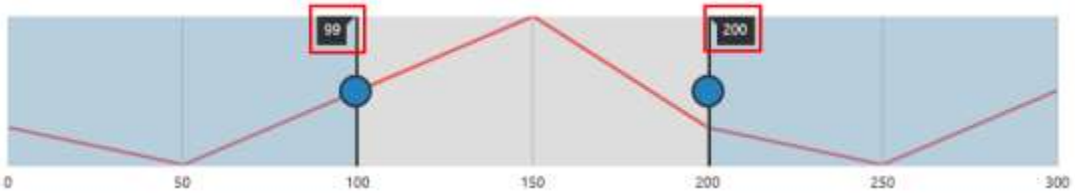
In SimpleRangeNavigator.cshtml, specify the DataSource to the Series and provide the field name to get the values from the DataSource in XName and YName options series and also set the ValueType property to “numeric” as given in the following code example.

ASPX-CS

```
@(Html.EJ().RangeNavigator ("container")
.Series(sr =>
{
sr.Type(SeriesType.Line)
.DataSource((System.Collections.IEnumerable)ViewBag.datasource)
.XName("xDate")
.YName("yValue")
.Add();
})
.ValueType("numeric"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot displays the RangeNavigator with numerical values:



Range Types

RangeNavigator control is designed to visualize large number of data and navigate to particular data from the large collection at ease. The data for the RangeNavigator is either **Numeric** values or **DateTime** values and the ValueType property in RangeNavigator indicates the type of the data that should be passed for the control. By default the ValueType of RangeNavigator is DateTime

- Numeric
- DateTime

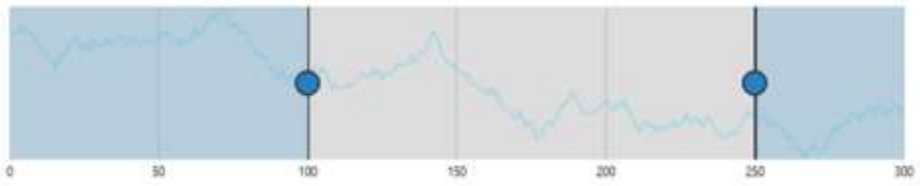
Numeric Type

RangeNavigator is also used with numeric data and the ValueType for this data is **"numeric"**

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.ValueType("numeric")
)
```

The following screenshot displays the RangeNavigator with numeric data.



DateTime

By default the ValueType of the RangeNavigator is **"datetime"** and represents the **DateTime** values.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.ValueType("datetime")
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

DateTime Intervals

The **DateTime** range type contains an IntervalType property that sets the DateTime interval to one of the following:

- Years
- Quarters
- Months
- Weeks
- Days
- Hours

By default IntervalType for higher level labels are **Years** and for lower level labels its **Quarters**.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.LabelSettings(ls=>ls
.HigherLevel(higher=>higher.IntervalType(NavigatorIntervalType.Years))
.LowerLevel(li=>li.IntervalType(NavigatorIntervalType.Quarters))
))
```

Range Padding

Range Padding adds padding for range in **RangeNavigator**. It allows you to space the grid lines in the RangeNavigator. By default, this property is set to none.

Numeric

The RangePadding property allows you to customize the automatic range calculation using the default auto range calculation for **RangeNavigator**.

ASPX-CS

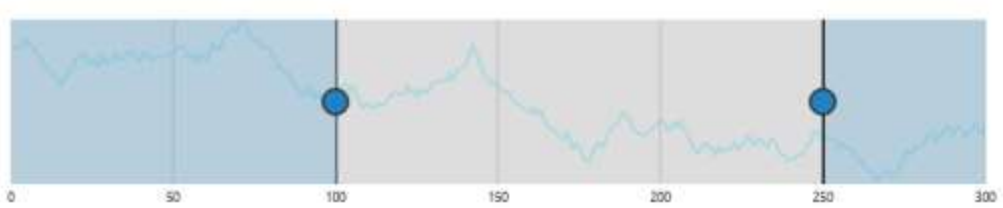
```
@(Html.EJ().RangeNavigator("container")
.RangePadding("none")
.ValueType("numeric")
)
```

None:

By default, the RangePadding for numerical range is none. The range is calculated from the minimum value to the maximum value of data in the RangeNavigator.

The following screenshot illustrates a **RangeNavigator** with RangePadding set to none.

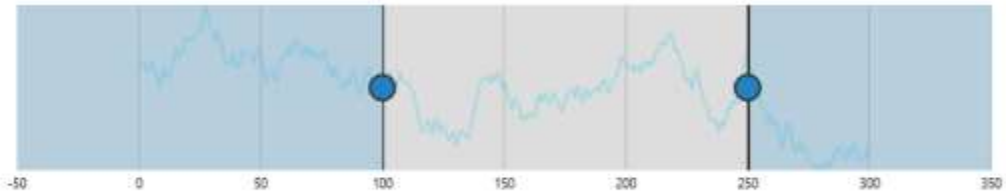
Copyright © 2001 - 2020 Syncfusion Inc.



Additional:

When you set the RangePadding for numerical range to **Additional**, range is padded with an interval.

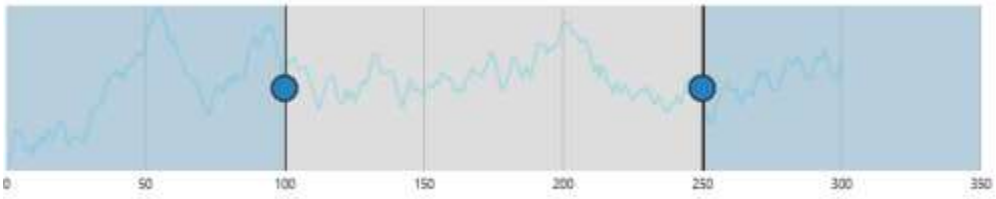
The following screenshot illustrates a **RangeNavigator** with RangePadding set to additional.



Normal:

In normal RangePadding, automatic range calculation differs based on the data.

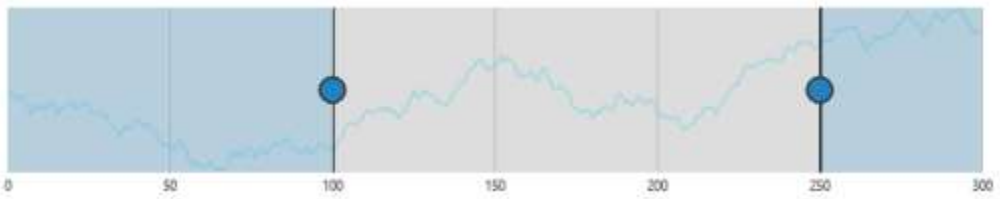
The following screenshot illustrates **RangeNavigator** with RangePadding set to **normal**



Round:

Round RangePadding for a numerical range rounds the range of the control to the nearest possible value that is divisible by the interval.

The following screenshot illustrates a **RangeNavigator** with RangePadding set to **Round**.



DateTime

Using the default range calculation for **RangeNavigator**, the RangePadding property allows you to customize the range.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().RangeNavigator("container")
.RangePadding("none")
)
```

None:

By default, the RangePadding for **DateTime** range is none. The range is calculated from the minimum value to the maximum value of data in the RangeNavigator

The following screenshot illustrates a **RangeNavigator** with RangePadding set to none.

Round:

Round RangePadding for a **DateTime** range rounds the range of the control to the nearest possible value.

The following screenshot illustrates a **RangeNavigator** with RangePadding set to Round.

Padding

The gap between the container and the **RangeNavigator** can be specified using Padding property.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.Padding(15)
)
```

AllowSnapping

An AllowSnapping property toggles the placement of slider exactly on the place it left or on the nearest interval.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.AllowSnapping(true)
)
```

Responsive

Set IsResponsive value to make the **RangeNavigator** responsive on resize.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().RangeNavigator("container")
.IsResponsive(true)
)
```

Auto Resizing

Enable EnableAutoResizing option to resize the **RangeNavigator**.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.EnableAutoResizing(true)
)
```

Customize range Navigator border

RangeNavigator provides options to customize the Color, Opacity and Width of range navigator Border.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.Border(border=>border.Color("green").Opacity(0.5).Width(2))
)
```

Customize size of range navigator

The Height and Width of **RangeNavigator** can be customized using SizeSettings property.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.SizeSettings(size=>size.Height("130").Width("900"))
)
```

Customize axis range of navigator

RangeNavigator calculates the range automatically based on the values of series data points. However you can explicitly specify the range using the Start, End properties in RangeSettings that is not possible when data is provided.

The following code example renders a RangeNavigator with a range from 2010 January 1st to 2013 January 1st.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
. RangeSettings(range=>range.Start("2010/1/1").End("2012/13/1"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Populate Data

When you provide data to **RangeNavigator**, it produces limited set of data. You can populate the RangeNavigator with data using the DataSource and Series properties.

Add series to the RangeNavigator

The Series property provides access to a collection of all series that are defined explicitly within a **RangeNavigator** control. Each series is assigned with Type and Name. It contains collection of data point, each point contains x value and y values. You can add data points to the series through DataSource property field name to get the values from the dataSource in XName and YName options.

Animation can be enabled by setting EnableAnimation property as true and the series color and opacity can be customized by using Fill and Opacity property in series.

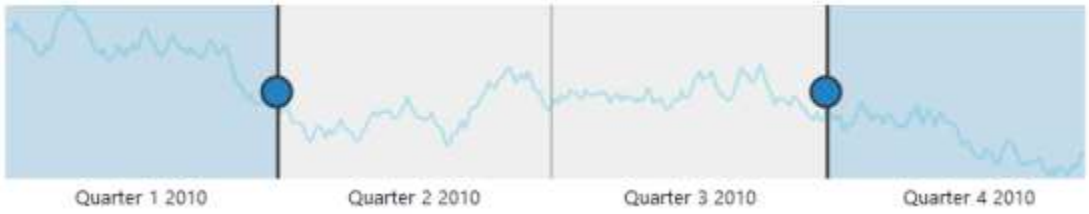
ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
// Adding Series
.Series(sr =>
{
sr.Name("ProductA")
.EnableAnimation(false)
.Type(SeriesType.Line)
.Opacity(0.5)
.Fill("#69D2E7").Add();
})
.Load("loadingData"))
<script type="text/javascript">
function loadingData(sender)
{
data = GetData();
sender.model.series[0].dataSource = data.Open;
sender.model.series[0].xName =  "XValue",
sender.model.series[0].yName = "YValue";
}
// Method to get data in JSON format
function GetData()
{
var series1 = [];
var series2 = [];
var value = 100;
var value1 = 120;
for (var i = 1; i < 730; i++)
{
if (Math.random() > .5)
{
value += Math.random();
value1 += Math.random();
}
else
{
value -= Math.random();
value1 -= Math.random();
}
var point1 = { XValue: new Date(2010, 0, i), YValue: value };
var point2 = { XValue: new Date(2010, 0, i), YValue: value1 };
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
series1.push(point1);
series2.push(point2);
}
data = { Open: series1, Close: series2 };
return data;
}
</script>
```

The following screenshot illustrates the RangeNavigator that is populated with data using DataSource property in series.



Behavior Customization

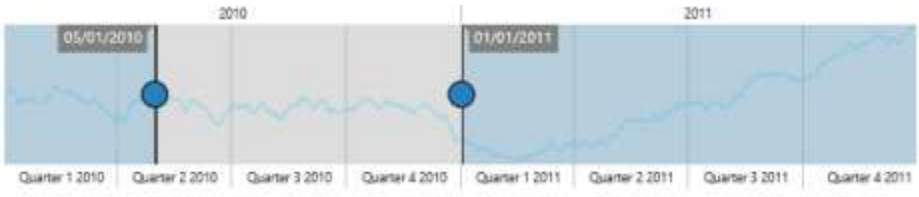
RangeNavigator allows you to customize the control using events. You can change the range for selected data of the **RangeNavigator** using events.

Deferred update

If you set EnableDeferredUpdate to true, the RangeChanged event gets fired after dragging and dropping the slider. By default the EnableDeferredUpdate is true. If EnableDeferredUpdate is false then the RangeChanged event gets fired while dragging the slider.

ASPX-CS

```
[
@(Html.EJ().RangeNavigator("container")
. EnableDeferredUpdate (true)
)
```



Deferred update

Methods

Destroy

This method is used to destroy the **RangeNavigator** widget.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
)
<script type="text/javascript">
var obj = $("#container").data("ejRangeNavigator");
```

```
obj.destroy(); // destroy the range navigator
</script>
```

Handle Events

Load

This event is fired when **RangeNavigator** is loading. A parameter **sender** is passed to the handler. Using **sender.model**, you can access the RangeNavigator properties.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.Load("loadingData")
)
<script type="text/javascript">
function loadingData(sender)
{
sender.model.allowSnapping = false;
}
</script>
```

Loaded

This event is handled when the **RangeNavigator** gets loaded. A parameter **sender** is passed to the handler. Using **sender.model**, you can access the RangeNavigator properties.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.Loaded("loadingData")
)
<script type="text/javascript">
function loadingData(sender)
{
sender.model.isResponsive = false;
}
</script>
```

RangeChanged

This event gets fired whenever the selected range changes in **RangeNavigator**. A parameter **sender** is passed to the handler. Using **sender.selectedRangeSettings**, you can access the start and end value of range for the selected region.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.RangeChanged("loadingData")
)
<script type="text/javascript">
function loadingData(sender)
{
console.log(sender.selectedRangeSettings.start);
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

SelectedRangeStart

This event is fired when starting to change the slider position in **RangeNavigator**. A parameter **sender** is passed to the handler. Using **sender.selectedRangeSettings**, you can access the start value of range for the selected region.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.SelectedRangeStart("loadingData")
)
<script type="text/javascript">
function loadingData(sender)
{
console.log(sender.selectedRangeSettings.start);
}
</script>
```

SelectedRangeEnd

This event is fired when selection ends in **RangeNavigator**. A parameter **sender** is passed to the handler. Using sender.selectedRangeSettings, you can access the end value of range for the selected region.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.SelectedRangeEnd("loadingData")
)
<script type="text/javascript">
function loadingData(sender)
{
console.log(sender.selectedRangeSettings.end);
}
</script>
```

ScrollStart

This event is fired when starting to change the scrollbar position of **RangeNavigator**. A parameter **sender** is passed to the handler. Using sender.data startRange and sender.data endRange, you can access the scrollbar position starting and ending range value on changed scrollbar.

JAVASCRIPT

```
@(Html.EJ().RangeNavigator("container")
.ScrollStart(loadingData)
)
<script type="text/javascript">
function loadingData(sender)
{
console.log(sender.type);
}
</script>
```

ScrollEnd

This event is fired while ending the change in scrollbar position of **RangeNavigator**. A parameter **sender** is passed to the handler. Using data oldRange and data newRange, you can access the scrollbar position old and new range values on changing scrollbar.

Copyright © 2001 - 2020 Syncfusion Inc.

JAVASCRIPT

```
@(Html.EJ().RangeNavigator("container")
.ScrollEnd(loadingData)
)
<script type="text/javascript">
function loadingData(sender)
{
console.log(sender.type);
}
</script>
```

ScrollChanged

This event is fired when changing the scrollbar position of **RangeNavigator**. A parameter **sender** is passed to the handler. Using data oldRange and data newRange, you can access the old and new range values of changed scrollbar position.

JAVASCRIPT

```
@(Html.EJ().RangeNavigator("container")
.ScrollChanged(loadingData)
)
<script type="text/javascript">
function loadingData(sender)
{
console.log(sender.type);
}
</script>
```

Click

Click event is handled when the **RangeNavigator** gets clicked. A parameter **sender** is passed to the handler. Using **sender.model**, you can access the RangeNavigator properties.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.Click(loadingData)
)
<script type="text/javascript">
function loadingData(sender)
{
console.log(sender.type);
}
</script>
```

DoubleClick

DoubleClick event is handled when the **RangeNavigator** gets clicked. A parameter **sender** is passed to the handler. Using **sender.model**, you can access the RangeNavigator properties.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.DoubleClick(loadingData)
)
<script type="text/javascript">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
function loadingData(sender)
{
console.log(sender.type);
}
</script>
```

RightClick

RightClick event is handled when the **RangeNavigator** gets clicked. A parameter **sender** is passed to the handler. Using **sender.model**, you can access the RangeNavigator properties.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.RightClick(loadingData)
)
<script type="text/javascript">
function loadingData(sender)
{
console.log(sender.type);
}
</script>
```

Use of ZoomCoordinates

RangeNavigator is used along with the controls like chart and grid to view the selected data. To update chart/grid, whenever the selected range changes in **RangeNavigator**, you can use RangeChanged event of RangeNavigator and then update the chart/grid with the selected data in this event.

You can easily update the data for chart by assigning the ZoomFactor and ZoomPosition of the RangeNavigator to the chart axis.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.RangeChanged("loadingData")
)
<script type="text/javascript">
// setting zoom factor and position for chart axis in rangeChanged event.
function loadingData(sender)
{
var chart = $("#container").data("ejChart");
if (chart != null)
{
chart.model.axes[0].zoomPosition = sender. zoomPosition;
chart.model.axes[0].zoomFactor = sender. zoomFactor;
}
$("#container").ejChart("redraw");
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Thumb Template

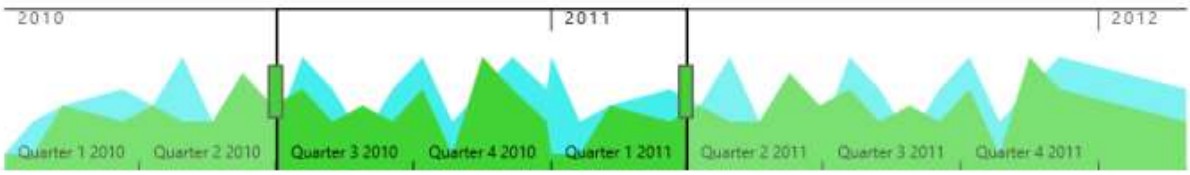
You can customize Thumb template by using `LeftThumbTemplate` and `RightThumbTemplate` property. You can add the required template as a “div” element with an “id” to the web page and assign the id or assign the HTML string to this property under `NavigatorStyleSettings`.

ASPX-CS

```
<script type="text/x-jsrender" id="left" >
<svg height="24" width="32" style="fill:#DD4A4A;stroke:black;">
<path d="M2 2 L2 22 L22 22 L32 12 L22 2 Z" />
</svg>
</script>
<script type="text/x-jsrender" id="right">
<svg height="24" width="32" style="fill:#DD4A4A;stroke:black; ">
<path d="M2 12 L12 22 L32 22 L32 2 L12 2 Z" />
</svg>
</script>
@(Html.EJ().RangeNavigator("container")
// ...
.NavigatorStyleSettings(navigator=>navigator.LeftThumbTemplate("left")
.RightThumbTemplate("right"))
// ...
)
```

The following screenshot displays the **RangeNavigator** using thumb template.

Copyright © 2001 - 2020 Syncfusion Inc.



Value Axis Settings

You can customize the line, Font Size, gridline, tickline, range, RangePadding and visibility of **RangeNavigator** axis.

To enable the visibility of axis line, you need to set Visible property of AxisLine in ValueAxisSettings.

You can customize the axis range by specifying Min, Max and Interval for Range property.

The MajorGridLines can be enabled by specifying Visible property. The Size, Width and Visible property of MajorTickLines is used to customize the axis tick lines.

The visibility of ValueAxisSettings is enabled by setting Visible property as true.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
// ...
.ValueAxisSettings(value=>value
.AxisLine(axis=>axis.Visible(true))
.Font(f=>f.Size('12px'))
.MajorGridLines(grid=>grid.Visible(true))
.MajorTickLines(tick=>tick.Size(3).Visible(false).Width(3))
.Range(range=>range.Min(0).Max(100).Interval(10))
.RangePadding(RangePadding.Normal),
.Visible(true)
)
// ...
)
```

Selected Range Settings

The start and end range values of selected range can be customized using Start and End property of SelectedRangeSettings.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
// ...
.SelectedRangeSettings(range=>range.Start("01/05/1992").End("01/05/1993")
)
// ...
)
```

Appearance and Styling

RangeNavigator is enriched with lots of customization options for labels, gridlines and slider to develop high quality graphic rich control.

Copyright © 2001 - 2020 Syncfusion Inc.

Customize labels

The labels are found along the range, displaying the value of the data it correspond, both on (higher level label) and below (lower level label) the RangeNavigator. **RangeNavigator** labels are further customized using higher level label Style property of Font and lower level label Style property of Font property in LabelSettings.

The higher level labels font Color, FontFamily, FontStyle, FontWeight, Opacity and Size can be customized using HigherLevel property.

The lower level labels font Color, FontFamily, FontStyle, FontWeight, Opacity and Size can be customized using LowerLevel property.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.LabelSettings(ls=>ls
// customizing higher level labels.
.HigherLevel(higher =>higher
.Style(style => style
.Font(f =>f
.Color("#ff0000")
.Opacity(1)
.Size("12px")
.Style(RangeNavigatorFontStyle.Normal)
.Weight(RangeNavigatorFontWeight.Regular)
)
)
)
// customizing lower level labels.
.LowerLevel(ll => ll
. Style(style => style
.Font(f => f
.Color("#ff0000")
.Opacity(1)
.Size("12px")
.Style(RangeNavigatorFontStyle.Normal)
.Weight(RangeNavigatorFontWeight.Regular)
)
)
)
))
```

Customize labels

Label Placement:

Labels in **RangeNavigator** are placed inside or outside of the control. You can customize both the higher and lower level labels using LabelPlacement property in label setting of RangeNavigator. By default LabelPlacement is “outside” for the both higher and lower level labels.

The following screen shot illustrates both the lower and higher level labels that are placed outside the control with LabelPlacement specified as outside.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.LabelSettings(ls=>ls
.HigherLevel(higher =>higher.LabelPlacement("inside"))
.LowerLevel(ll => ll.LabelPlacement("inside"))
)
)
```

The following screenshot illustrates a **RangeNavigator** with labels inside the control after specifying the LabelPlacement as inside.

Customize RangeNavigator

Customize NavigatorStyleSettings

RangeNavigator is customized using NavigatorStyleSettings properties. You can customize the selected and unselected region color using SelectedRegionColor and UnselectedRegionColor, SelectedRegionOpacity and UnselectedRegionOpacity in **NavigatorStyleSettings** and the thumb of the slider using ThumbColor, ThumbRadius and ThumbStroke in NavigatorStyleSettings. MajorGridLineStyle and MinorGridLineStyle are used to customize the major grid line Color, Visible property and minor gridline Color and Visible. You can customize the Background, Opacity and Border Color, DashArray and Width of navigatorStyleSettings.

Customize Labels

The visibility of labels are enabled by setting Visible in higher level and Visible in lower level. The labels can be aligned by specifying HorizontalAlignment of higher level style and HorizontalAlignment of lower level style.

You can customize the Border Color and Width, Fill, GridLineStyle Color, DashArray and Width, Position property of higher level labels in labelSettings.

You can also customize the Border Color and Width, Fill, GridLineStyle Color, DashArray and Width, Position property for lower level labels of labelSettings.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
//  To customize the navigator element
.NavigatorStyleSettings (navigator=>navigator
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Border(br=>br.Color("black").Width(3))
.Background("transparent")
.UnselectedRegionColor("white")
.SelectedRegionColor("#5EABDE")
.ThumbRadius(10)
.ThumbColor("white")
.MajorGridLineStyle(mr=>mr.Color("transparent").Visible(true))
.MinorGridLineStyle(mi=>mi.Color("transparent").Visible(true))
)
//  To customize the labels
.LabelSettings(ls=>ls
.HigherLevel(higher =>higher
.LabelPlacement("inside")
.IntervalType(NavigatorIntervalType.Years)
.Style(style => style
.HorizontalAlignment(HorizontalAlignment.Left)
.Font(f =>f
.Color("black")
.Opacity(1)
.Size("13px")
)
)
)
.LowerLevel(ll => ll
.LabelPlacement("inside")
.IntervalType(NavigatorIntervalType.Quarters)
.Style(style => style
.HorizontalAlignment(HorizontalAlignment.Center)
.Font(f => f
.Color("black")
.Opacity(1)
.Size("12px")
)
)
)
))
```

Themes

RangeNavigator Theme is a set of pre-defined options that are applied to the control before each RangeNavigator is instantiated. Following predefined themes are available in ASP.NET MVC RangeNavigator.

1. flatlight
2. flatdark
3. gradientlight

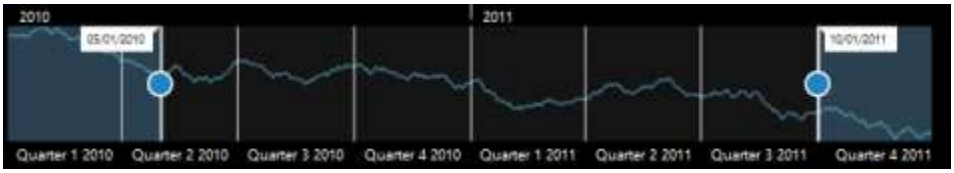
Copyright © 2001 - 2020 Syncfusion Inc.

4. gradientdark
5. azure
6. azuredark
7. lime
8. limedark
9. saffron
10. saffrondark
11. gradientazure
12. gradientazuredark
13. gradientlime
14. gradientlimedark
15. gradientsaffron

gradientsaffrondark

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.Theme("azuredark")
)
```



Tooltip

RangeNavigator provides **Tooltip** support for sliders. Sliders are used to select data at particular range in the RangeNavigator control. Tooltips for sliders display the selected start and end **DateTime** values.

Customization

RangeNavigator provides support for you to customize the text display in the tooltip and background using TooltipSettings property. You can change font family, font color, font style, font weight. By default “Segoe UI” font family is set to tooltip text.

- Tooltip visibility can be enabled or disabled using Visible property.
- You can change background color of tooltip using BackgroundColor property.
- You can customize the Color, Family, FontStyle, Opacity, Size and Weight of tooltip text in Font property.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.TooltipSettings(tooltip=>tooltip
.Visible(true)
.BackgroundColor("Black")
//  To customize the tooltip text
.Font(font=>font
.Color("red")
. Family("Segoe UI")
.Style(RangeNavigatorFontStyle.Normal)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Size("12px")
.Opacity(1)
.Weight(RangeNavigatorFontWeight.Regular)
)
))
```

Label Format

By default, the **tooltip** texts are automatically determined based on the data points. To make it readable and understandable you can format the tooltip text. For **DateTime** data, all globalized format are supported. By default the LabelFormat is "MM/dd/yyyy".

Some of the LabelFormat for **DateTime** data are as follows:

- 'MMM, yyyy'
- 'dd, MMM'
- 'dd/MM/yyyy'
- 'dd, hh:mm'
- 'hh:mm:ss'

'hh:mm:ss:tt'

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.TooltipSettings(tooltip=>tooltip.LabelFormat("MMM, yyyy"))
)
```

Tooltip display mode

By default the **tooltip** for RangeNavigator gets displayed. You can change this behavior using the TooltipDisplayMode property in the TooltipSettings and it takes the following values.

Tooltip values

Value	Description
always	Tooltip get displayed for RangeNavigator always.

Copyright © 2001 - 2020 Syncfusion Inc.

onDemand	Tooltip get displayed only when we move the slider.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.TooltipSettings(tooltip=>tooltip.TooltipDisplayMode("onDemand"))
)
```

Globalization & Localization

RangeNavigator supports Localization and Globalization to customize the labels based on a culture specific to a country. The culture defines specific information for the number formats, week and month names, date and time formats etc.

Localization

The Locale property is used to specify the **Localization** of RangeNavigator. Localization is the process of customizing the user interface based on a culture specific to a particular country or region in order to display regional data. The culture is represented by a unique string, for example, —en-US‖ for U.S. English and —fr-FR‖ for French (common), this is achieved by creating a JavaScript file **"rangeNavigatorSource.fr-FR.js"** and setting the equivalent word as illustrated in the following code sample.

ASPX-CS

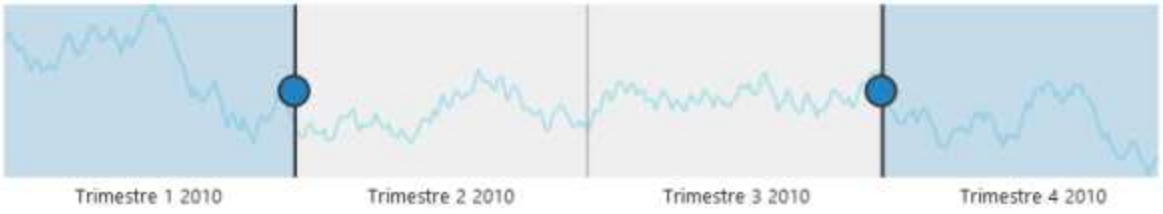
```
ej.datavisualization.RangeNavigator.locale["fr-FR"] =
{
intervals:
{
//string to display the intervals on RangeNavigator
quarter: {longQuarters: "Trimestre", shortQuarters: "T"},
week: { longWeeks: "Semaine", shortWeeks: "S" }
}
}
```

Localization is the key feature that provides solutions globally with the help of localized control.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.Locale("fr-FR")
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

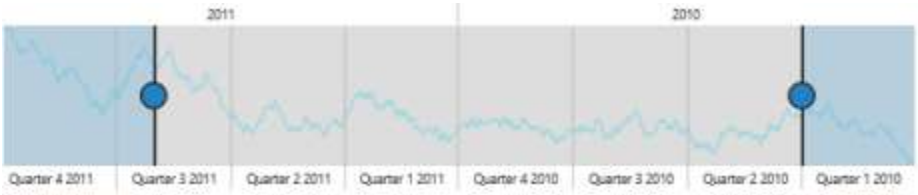


RTL

Right-to-Left or **RTL** describes the ability of application to handle and responds you to communicate with a right-to-left language, like Arabic or Japanese. EnableRTL property is used to change the rendering format to **"Right to Left"**, by default it renders from **"Left to Right"** in RangeNavigator.

ASPX-CS

```
@(Html.EJ().RangeNavigator("container")
.EnableRTL(true)
)
```



User Interactions

Highlight

EjRangeNavigator provides highlighting supports to the intervals on mouse hover. To enable the highlighting option, set the Enable property to true in the HighlightSettings of NavigatorStyleSettings.

ASPX-CS

```
@(Html.EJ().RangeNavigator("rangeContainer")
//...
.NavigatorStyleSettings(navigator=>
navigator.HighlightSettings(highlight=>
// enable the highlight settings
highlight.Enable(true))
)
)
```

Click here to view the highlight and selections online demo sample.

Customize the highlight style

To customize the highlighted intervals, use Color, Border and Opacity options in the HighlightSettings.To customize border of highlighted interval, use Color and Width options in Border.

ASPX-CS

```
@(Html.EJ().RangeNavigator("rangeContainer")
//...
.NavigatorStyleSettings(navigator=>
navigator.HighlightSettings(highlight=>
// enable the highlight settings
highlight.Enable(true)
// customizing style
.Color("#006fa0")
.Border(br=>br.Color("red").Width(2))
)
)
)
```

Selection

EjRangeNavigator provides selection supports to the intervals by, clicking and dragging the highlighted intervals. To enable the selection option, set the Enable property to true in the SelectionSettings.

ASPX-CS

```
@(Html.EJ().RangeNavigator("rangeContainer")
//...
.NavigatorStyleSettings(navigator=>
navigator.SelectionSettings(selection=>
// enable the selection settings
selection.Enable(true)
)
)
)
```

Click here to view the highlight and selections online demo sample.

Customize the selection style

To customize the selected intervals, use Color, Border and Opacity options in the SelectionSettings. To customize border of selected interval, useColor and Width options in Border.

ASPX-CS

```
@(Html.EJ().RangeNavigator("rangeContainer")
//...
.NavigatorStyleSettings(navigator=>
navigator.SelectionSettings(selection=>
```

```
// enable the selection settings
selection.Enable(true)
// customizing style
.Color("#27e8e5’")
.Border(br=>br.Color("red").Width(2))
)
)
)
```

Scrollbar

- To render the Scrollbar in RangeNavigator, you need to enable EnableScrollbar option.
- ScrollRangeSettings of rangenavigator Start and End value is used to set the minimum and maximum datasource value to be added in the rangenavigator.
- Based on the ScrollRangeSettings *Start, End* value and dataSource *Start, End* value scrollbar will be adjust.
- When you change the scrollbar position, ScrollEnd event returns the current position of start and end range value.

ASPX-CS

```
@(Html.EJ().RangeNavigator("rangeContainer")
//...
//Enable scrollbar option in the rangenavigator
.EnableScrollbar(true)
//Maximum data to be displayed in the rangenavigator control
.ScrollRangeSettings(range=>
range.Start("2010/1/1").End("2011/11/31")
)
//Subscribe the event on scrollbar position changed
.ScrollEnd("onScrollbarChange")
)
```

JS

```
function onScrollbarChange(sender) {
var start  = sender.data.newRange.start;
var end  = sender.data.newRange.end;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Click here to view scrollbar online demo sample.

Rating

Rating

Essential Studio ASP.NET MVC Rating control provides an intuitive Rating experience that enables you to select a number of stars representing a Rating. You can configure the item size, orientation and the number of displayed items in the Rating control. You can also customize the Rating star image by using custom CSS.

Key Features

Some important features of the Rating control are as follows:

- Precision support— You can set three different precisions like full, half, and exact.
- Orientation support—Rating control can be displayed in horizontal or vertical direction.
- Read-only mode—Rating control can be rendered in the read-only mode to enable or disable user interaction.
- Reset—You can reset the Rating value by using the Reset button.
- Tooltip—You can set a tooltip to display the currently selected Rating value.
- Theme—Rating control consists of 12 built-in themes (6 – metro and 6 – gradient effects), and also supports custom skins to set user-defined themes.

Getting Started

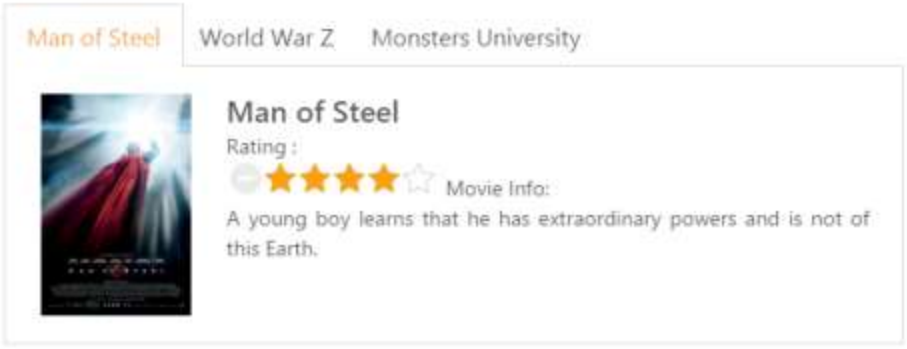
This section explains briefly how to create a Rating control in the ASP.NET MVC.

Create your first Rating control in MVC

Essential Studio ASP.NET MVCRating control provides support to display Rating bar within your web page, and allows you to rate the products. Refer to the following guidelines to customize the Rating control for a real-time movie download application. You can use Rating control to rate a movie. In this real-time application, Essential Studio ASP.NET MVCTab control is used to display the movies information with rating star.To know more about Tab control, refer to the Getting Started of the Tab control.

The following screenshot demonstrates the functionality of a Rating control with a Rating range of 0 to 5.

Copyright © 2001 - 2020 Syncfusion Inc.



In the above screenshot, you can rate the movie by selecting a corresponding movie.

Create a Rating

The Essential Studio ASP.NET MVCRating widget renders with built-in features like Precision, Orientation and flexible APIs. You can easily create the Rating widget by using HTML helper class as follows.

You can create an MVC Project and add the necessary assemblies, styles and scripts to it.

Refer to MVC-Getting Started.

Add the following code example to the corresponding view page to render Rating inside the Tab control.

ASPX-CS

```
<div class="frame">
@{Html.EJ().Tab("moviesTab").Items(event=>
{
event.Add().ID("steel").Text("Man of Steel").ContentTemplate(
@<div>
<table>
<tr>
<td class="movies-img" valign="top">
<img src="@Url.Content("~/Images/rating/mos.png")" alt="mos" />
</td>
<td valign="top">
<div>
<span class="movie-header">Man of Steel</span><br />
Rating :
<br />
@Html.EJ().Rating("univRating").Value(4)
<span>Movie Info:</span>
<p>
A young boy learns that he has extraordinary powers and is not of this
Earth.
</p>
</div>
</td>
</tr>
</table>
</div>);
event.Add().ID("war").Text("World War Z").ContentTemplate(
@<div>
<table>
<tr>
```

```
<td class="movies-img" valign="top">
<img src="@Url.Content("~/Images/rating/wwz.png")" alt="mos" />
</td>
<td valign="top">
<div>
<span class="movie-header">World War Z</span><br />
Rating :
<br />
@Html.EJ().Rating("wwzRating"). Value(4)
<span>Movie Info:</span>
<p>
The story revolves around United Nations employee Gerry Lane (Pitt).
</p>
</div>
</td>
</tr>
</table>
</div>);
event.Add().ID("university").Text("Monsters University").ContentTemplate(
@<div>
<table>
<tr>
<td class="movies-img" valign="top">
<img src="@Url.Content("~/Images/rating/mu.png")" alt="mos" />
</td>
<td valign="top">
<div>
<span class="movie-header">Monsters University</span><br />
Rating :
<br />
@Html.EJ().Rating("mosRating").Value(3)
<span>Movie Info:</span>
<p>
Mike Wazowski and James P. Sullivan are an inseparable pair, but that
wasn't always the case.
</p>
</div>
</td>
</tr>
</table>
</div>);
}).Render();
}
</div>
```

Add the following styles to the corresponding view page to show the Rating in a horizontal order.

CSS

```
<style type="text/css" class="cssStyles">
.movies-img
{
width: 125px;
}
.movie-header
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
font-size: 20px;
font-weight: 600;
}
.frame
{
width: 600px;
height: 250px;
}
</style>
```

Execute the above code to render the following output.

Note: Add necessary images to the mentioned directory. <project directory>/Images/rating/yourimage.png

Rating Customization

Setting Value

The Value property sets the display value of the Rating. For example, when the Value property is set to 4, the Rating control renders 4 ratings. By default, Value property's value is one.

The following code example is used to render the Rating control with the customized value.

Add the following code in your view page to render the Rating with the customized value.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating with customized value.
<div id="container" style="border: 1px solid black; width: 300px;
padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").Value(4)
</td>
</tr>
</table>
</div>
```

The following screenshot illustrates the Rating with custom defined value.

Copyright © 2001 - 2020 Syncfusion Inc.

Min Value

Rating control provides support for setting the MinimumValue. This is achieved by adding the MinValue property. When the MinValue property is set, the Rating value starts with MinValue+1.

The following code example is used to render the Rating control with minimum rating value specified.

Add the following code in your view page to render the Rating with Minimum value.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating with customized minimum value.
<div id="container" style="width: 300px; padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").MinValue(3)
</td>
</tr>
</table>
</div>
```

The following screenshot Rating value starts with 4 since MinValue value is set as 3.

Rating with minimum value as 4

Max Value

Rating control provides support for setting Maximum value. This is achieved by adding the MaxValue property. By default, MaxValue is five.

The following code example is used to render the Rating control with maximum rating value specified

Add the following code in your view page to render the Rating with maximum value.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating with customized maximum value.
<div id="container" style="border: 1px solid black; width: 300px;
padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").MaxValue(10)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</td>
</tr>
</table>
</div>
```

The following screenshot illustrates the Rating with maximum value.

Set Precision

You can set Precision in Rating value between two whole numbers such as 2.5 or 3.7 and it is done by using the property Precision by changing the value to Precision.Half or Precision.Exact. By default, value of Precision is Full.

The following code example is used to render the Rating control with Precision.

Add the following code in your view page to render the Rating with Precision.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating with Precision.
<div id="container" style="border: 1px solid black; width: 300px;
padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("FullRating").Precision(Precision.Full).Value(4)
</td>
</tr>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("HalfRating").Precision(Precision.Half).Value(3.5)
</td>
</tr>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("ExactRating").Precision(Precision.Exact).Value(4.7)
</td>
</tr>
</table>
</div>
```

The following screenshot illustrates the Rating with Precision.

Copyright © 2001 - 2020 Syncfusion Inc.

Increment Step

Rating control supports customized increment value for Rating. This is achieved by adding the IncrementStep property.

The following code example is used to render the Rating control with customized increment.

Add the following code in your view page to render the Rating with customized increment.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating with customized increment.
<div id="container" style="border: 1px solid black; width: 300px;
padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").IncrementStep(2).MaxValue(10)
</td>
</tr>
</table>
</div>
```

The following screenshot illustrates the Rating with customized increment.

Resetting values

Rating control provides support for value reset at runtime. This is achieved by enabling the AllowReset property to true. By default, the property value is set to true.

The following code example is used to render the Rating control with AllowReset.

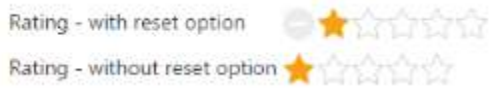
Add the following code in your view page to render the Rating with AllowReset.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
// Add the following code example to the corresponding CSHTML page to
render Rating with allowReset.
<div id="container" style="border: 1px solid black; width: 300px;
padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("ResetRating").AllowReset(true)
</td>
</tr>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").AllowReset(false)
</td>
</tr>
</table>
</div>
```

The following illustrates the Rating with allowReset.



Read only

Rating control provides support for changeable or unchangeable values for Rating control. This is achieved by the ReadOnly property. When this property is set to true, the Rating value becomes unchangeable. By default, this property value is set to false.

The following code example is used to render the Rating control with ReadOnly.

Add the following code in your view page to render Rating with readOnly.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating with readOnly.
<div id="container" style="width: 300px; padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").ReadOnly(true).Value(2).MaxValue(10)
</td>
</tr>
</table>
</div>
```

The following screenshot illustrates the Rating with ReadOnly.

Copyright © 2001 - 2020 Syncfusion Inc.

Enable or Disable

Rating control provides support to Enable or Disable the control. This is achieved by the Enabled property. By default the property value is true.

The following code example is used to render the Rating control with Enable or Disable support.

Add the following code in your view page to render the Rating with enable or disable support.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating with Enable/Disable support.
<div id="container" style="border: 1px solid black; width: 300px;
padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").Enabled(false)
</td>
</tr>
</table>
</div>
```

The following screenshot illustrates the Rating in a disabled form.

Appearance and Styling

Show ToolTip

Rating control provides support for Tooltip values. This is achieved by enabling the ShowTooltip property to true. When you move the mouse over the Rating control, it displays the Tooltip value as rating value. By default, this property value is set to true.

The following code example is used to render the Rating control without tooltip.

1. Add the following code in your view page to render Rating with Tooltip.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating without Tooltip
<div id="container" style="width: 300px; padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").ShowTooltip(false)
</td>
</tr>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</table>
</div>
```

The following screenshot illustrates Rating without Tooltip.

Adjusting Rating Size

Adjust Shape Width and Shape Height

You can customize the width and height of the Rating by ShapeWidth and ShapeHeight properties. These properties completely depend on rating image's size. The ShapeWidth and ShapeHeight are adjusted within the rating image size.

The following code example is used to render the Rating control with customized ShapeWidth and ShapeHeight.

In this sample, the default rating star is replaced by crystal-stars.png local image by overriding the Rating control CSS.

Add the following code in your view page to render the Rating with customized ShapeWidth and ShapeHeight.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating with customized ShapeWidth and ShapeHeight.
<div id="container" style="border: 1px solid black; width: 300px;
padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").Value(4).ShapeWidth(29).ShapeHeight(29)
</td>
</tr>
</table>
</div>
```

Add the following styles.

CSS

```
<style type="text/css">
.e-rating
{
margin-top: -7px;
}
.e-rating.e-horizontal .e-shape-list, .e-rating.e-vertical .e-shape-list,
.e-rating.e-horizontal .e-shape, .e-rating.e-vertical .e-shape, .e-
rating.e-horizontal .e-ul,.e-rating.e-vertical .e-ul,.e-rating.e-
horizontal .e-reset, .e-rating.e-vertical .e-reset
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
height:28px;width:28px;
background:url(images/crystal-stars.png) no-repeat;
}
.e-rating.e-horizontal .e-reset, .e-rating.e-vertical .e-reset
{
background-position: 0 42px;
margin-left: 2px;
}
.e-rating.e-horizontal .e-shape-list
{
background-position: 0 -56px;
}
.e-rating .e-shape.inactive
{
background-position: 0 -56px;
}
.e-rating .e-shape.active
{
background-position: 0 -112px;
}
.e-rating .e-shape.selected
{
background-position: 0 -84px;
}
</style>
```

The following screenshot illustrates Rating with customized ShapeWidth and ShapeHeight.

Theme

Rating control's style and appearance are controlled based on CSS classes. In order to apply styles to the Rating control, refer to 2 files namely, ej.widgets.core.min.css and ej.theme.min.css. When the file ej.widgets.all.min.css is referred, then it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these both.

By default, there are 12 themes support available for Rating control namely:

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron

Copyright © 2001 - 2020 Syncfusion Inc.

- gradient-saffron-dark

Custom styles

The style of the Rating control is customized by CssClass property.

The following code example is used to render the Rating control with customized style.

Add the following HTML to render the Rating with customized style. In this, hovering behaviors, tooltip position and display have been customized by using custom CSS class.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating with customized styles.
<div id="container" style="border: 1px solid black; width: 300px;
padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").CssClass("custom")
</td>
</tr>
</table>
</div>
```

Add the following styles.

CSS

```
<style type="text/css">
.customCss
{
margin-top: -7px;
}
.customCss.e-horizontal .e-shape-list, .e-rating.e-vertical .e-shape-
list,
.customCss.e-horizontal .e-shape, .e-rating.e-vertical .e-shape, .e-
rating.e-horizontal .e-ul, .customCss.e-vertical .e-ul, .e-rating.e-
horizontal .e-reset, .e-rating.e-vertical .e-reset
{
height: 28px;
width: 28px;
background: url(../../Content/ej/default-theme/images/crystal-stars.png)
no-repeat repeat;
}
.customCss.e-horizontal .e-reset, .customCss.e-vertical .e-reset
{
background-position: -2px 113px;
margin-left: 2px;
}
.customCss.e-horizontal .e-shape-list
{
background-position: 0 -56px;
}
.customCss.e-horizontal .e-reset:hover
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
background-position: 0 42px;
}
.customCss .e-shape.inactive
{
background-position: 0 -84px;
}
.customCss .e-shape.active
{
background-position: 0 -112px;
}
.customCss .e-shape.selected
{
background-position: 0 -84px;
}
.customCss.e-tooltip
{
background-color: white;
border: 2px solid #b0c4de;
color: black;
}
</style>
```

The following screenshot illustrates the Rating with customized style.

Orientation

Rating provides support for Vertical orientation. By default Rating renders with Horizontal orientation. You can change the orientation by the Orientation property.

The following code example is used to render the Rating control with Vertical orientation.

Add the following code in your view page to render the Rating with customizedOrientation.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Rating with customized orientation.
<div id="container" style="border: 1px solid black; width: 300px;
padding: 2px">
<table>
<tr>
<td valign="top">Rating:
</td>
<td>
@Html.EJ().Rating("Rating").Orientation(Orientation.Vertical)
</td>
</tr>
</table>
</div>
```

The following screenshot illustrates the Rating with Vertical orientation.

Copyright © 2001 - 2020 Syncfusion Inc.

How To

Render Rating from code behind

Rating can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of Rating using Rating properties from code behind.

RAZOR

```
@{Html.EJ().Rating("univRating", Model).Render();}
```

C#

```
public ActionResult Index()
{
RatingProperties Obj = new RatingProperties();
Obj.Value = 4;
Obj.Orientation = Syncfusion.JavaScript.Orientation.Vertical;
return View(Obj);
}
```

ReportViewer

ReportViewer

The ReportViewer is a visualization control to view Microsoft SSRS RDL/RDLC files on a web page and it is powered by HTML5/JavaScript. It has support to bind DataSources/Parameters to the Reports and also supports exporting, paging, zooming and printing the report.

Key Features

The ReportViewer supports the following features.

- DataSources (SQL Server, Oracle, MS Azure, XML, Business Object and SQL Server Compact Data Sources)
- Filters and Parameters
- Built-in Fields and Expressions
- Grouping and Sorting
- Report Items
- Table
- Matrix
- List
- Chart
- Sparkline
- DataBar

Copyright © 2001 - 2020 Syncfusion Inc.

- Map
- Gauge
- Indicator
- Image
- Textbox
- Line
- Rectangle
- Subreport
- Actions: Drilldown, Drill through, Toggle and Document Map
- Printing, Exporting, Paging, FitToPage and Zooming
- Report Processing Events
- KnockOut/AngularJS Support
- Toolbar Customization

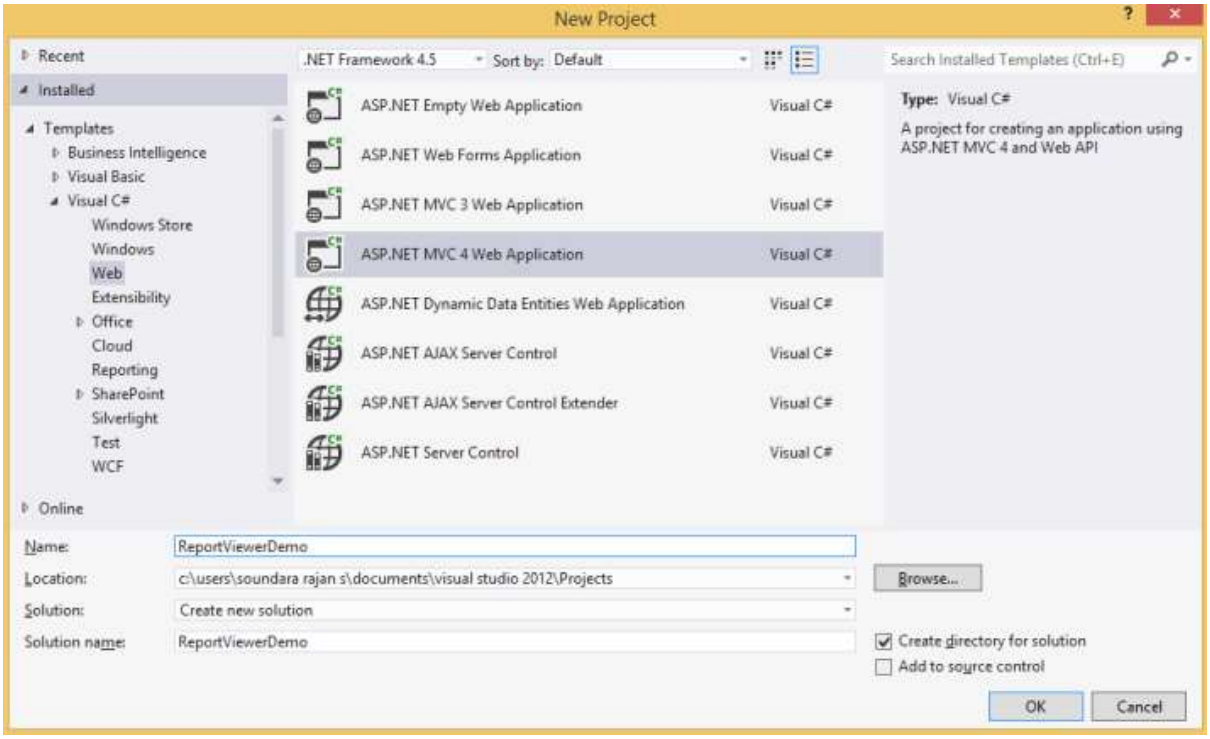
Getting Started

This section explains briefly about how to create a ReportViewer in your web application with MVC.

Create your first ReportViewer in MVC

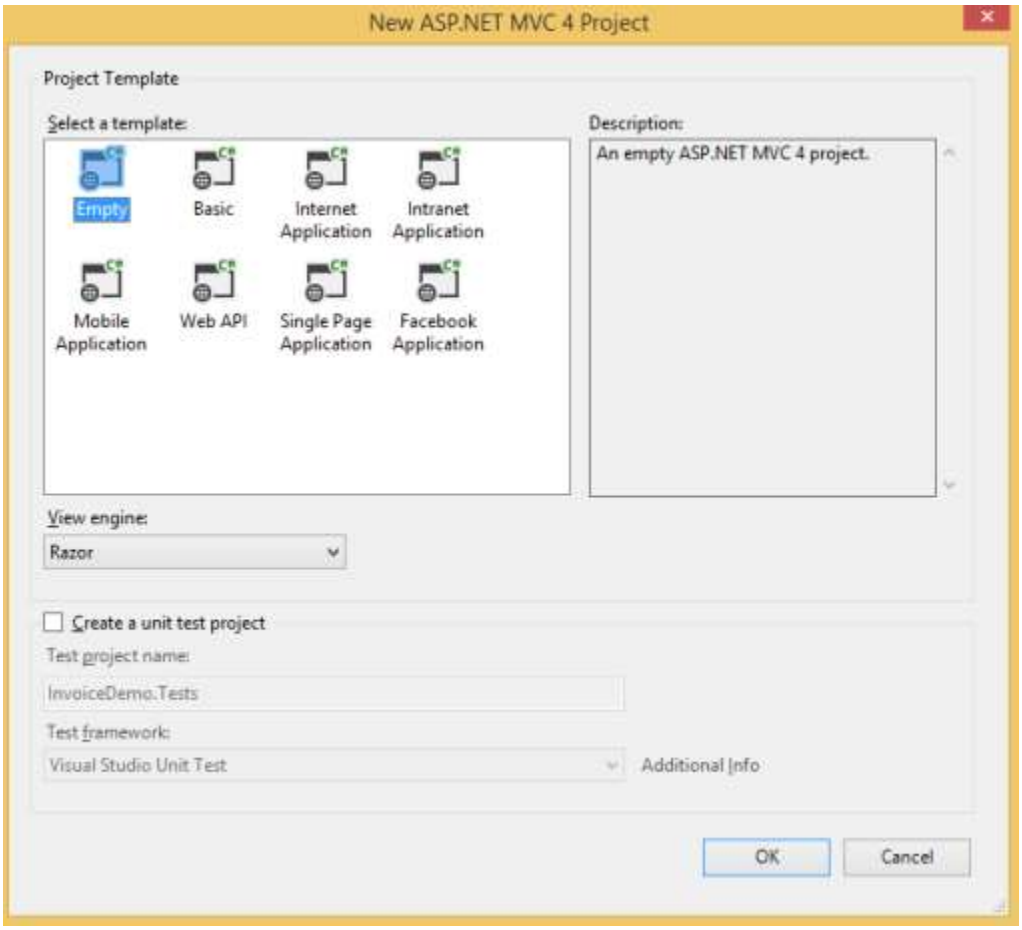
This section explains how to configure a ReportViewer component in web application. As ReportViewer uses WebApi to process the report file, you can also learn how to create WebApi Service to process the report for ReportViewer. In the following example, the ReportViewer component displays the Sales Dashboard Report.

Open Visual Studio and create a new project by clicking New Project. Select the Web category, select the ASP.NET MVC4 Web Application template, and then click OK. The following screenshot displays the Project Creation Wizard.



Project Creation Wizard

The following screenshot displays how to select Internet application template with razor view engine.

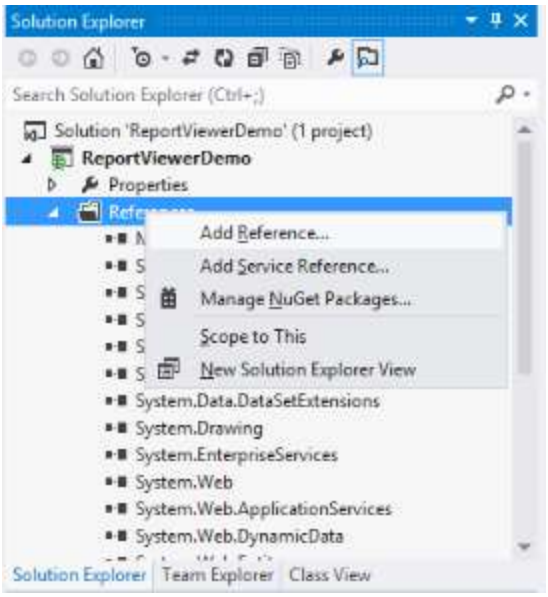


Add References, Scripts, Styles and Control in CSHTML Page

Add References

1. In the Solution Explorer, right-click the References folder and then click Add Reference

Copyright © 2001 - 2020 Syncfusion Inc.



Adding Reference

2. Add the following assemblies
    - System.Web.Routing
    - System.Web.Http
    - System.Web.WebHost
    - System.Net.Http
    - System.Net.Http.WebRequest
    - System.Net.Http.Formatting
    - Syncfusion.Linq.Base
    - Syncfusion.EJ
    - Syncfusion.EJ.MVC
    - Syncfusion.EJ.ReportViewer
    - Syncfusion.Pdf.Base
    - Syncfusion.XlsIO.Base
    - Syncfusion.DocIO.Base
    - Syncfusion.Shared.Wpf
    - Syncfusion.Chart.Wpf
    - Syncfusion.Gauge.Wpf
    - Syncfusion.SfMaps.Wpf

Note: Refer the above assemblies from the installed location, C:\Program Files (x86)\Syncfusion\Essential Studio\ASP.NET MVC\{{ site.releaseversion }}\Assemblies

Note:

Note: Refer System.Web.Http, System.Web.WebHost, System.Net.Http.WebRequest and System.Net.Http.Formatting assemblies from ASP.NET WebApi NuGet package.

3. Click OK

Copyright © 2001 - 2020 Syncfusion Inc.

Add Scripts and Styles

Add the script files and CSS files in the <title> tag of the _Layout.cshtml page.

Note: Use the following code example while adding scripts and styles.

ASPX-CS

```
<link rel="stylesheet" href="https://cdn.syncfusion.com/{{
site.releaseversion }}/js/web/flat-azure/ej.web.all.min.css" />
<script src="https://code.jquery.com/jquery-1.10.2.min.js"
type="text/javascript"></script>
<script src="https://cdnjs.cloudflare.com/ajax/libs/jquery-
easing/1.3/jquery.easing.min.js" type="text/javascript"></script>
<script src="https://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/ej.web.all.min.js"> </script>
<script src="https://cdn.syncfusion.com/{{ site.releaseversion
}}/js/common/ej.unobtrusive.min.js"></script>
```

Add Control in View page

Add the following code example in the Index.cshtml page that is already created. Set the desired ReportPath and ReportServiceUrl to ReportViewer.

ASPX-CS

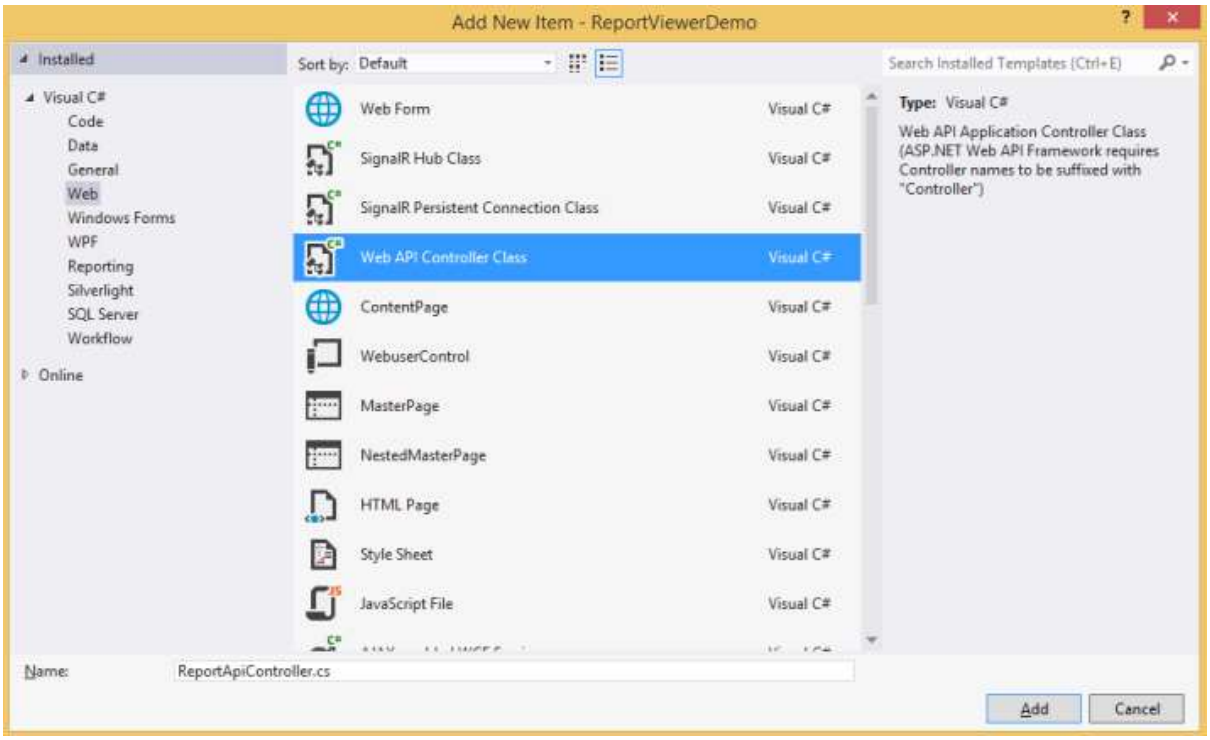
```
@using Syncfusion.MVC.EJ
@using Syncfusion.JavaScript.Models
@using Syncfusion.JavaScript
@using Syncfusion.JavaScript.ReportViewer
@{
ViewBag.Title = "Index";
}
<h2>Index</h2>
<div>
@{Html.EJ().ReportViewer("viewer").ReportPath("~/App_Data/Sales
Dashboard.rdl").ReportServiceUrl("/api/ReportApi").Render();}
</div>
```

Note: Add your report files to your application's App_Data folder. You can obtain sample rdl/rdlc files from Syncfusion installed location(%userprofile%\AppData\Local\Syncfusion\EssentialStudio\{{ site.releaseversion }}\Common\Data\ejReportTemplate). {{ site.releaseversion }} is the Essential Studio Release Version.

Add WebAPI controller for ReportViewer

The MVC ReportViewer uses WebApi services to process the report file and process the request from control.

Copyright © 2001 - 2020 Syncfusion Inc.



Adding WebApi Controller

Inherit IReportController

The ApiController inherits the IReportController and you can add the following code example to its methods definition in order to process the report file. The interface IReportController contains the required actions and helper methods declaration to process the report. The ReportHelper class contains helper methods that helps to process Post/Get request from control and return the response to control.

C#

```
using Syncfusion.EJ.ReportViewer;
using System;
using System.Collections.Generic;
using System.Linq;
using System.Net;
using System.Net.Http;
using System.Web.Http;
namespace ReportViewerDemo.Api
{
public class ReportApiController : ApiController, IReportController
{
//Post action for processing the rdl/rdlc report
public object PostReportAction(Dictionary<string, object> jsonResult)
{
return ReportHelper.ProcessReport(jsonResult, this);
}
//Get action for getting resources from the report
[System.Web.Http.ActionName("GetResource")]
[AcceptVerbs("GET")]
public object GetResource(string key, string resourcetype, bool isPrint)
{
return ReportHelper.GetResource(key, resourcetype, isPrint);
```

```
}
//Method will be called when initialize the report options before start
processing the report
public void OnInitReportOptions(ReportViewerOptions reportOption)
{
//You can update report options here
}
//Method will be called when reported is loaded
public void OnReportLoaded(ReportViewerOptions reportOption)
{
//You can update report options here
}
}
}
```

WebAPI Routing

You can route the WebAPI in Application_Start event into Global.asax file as follows.

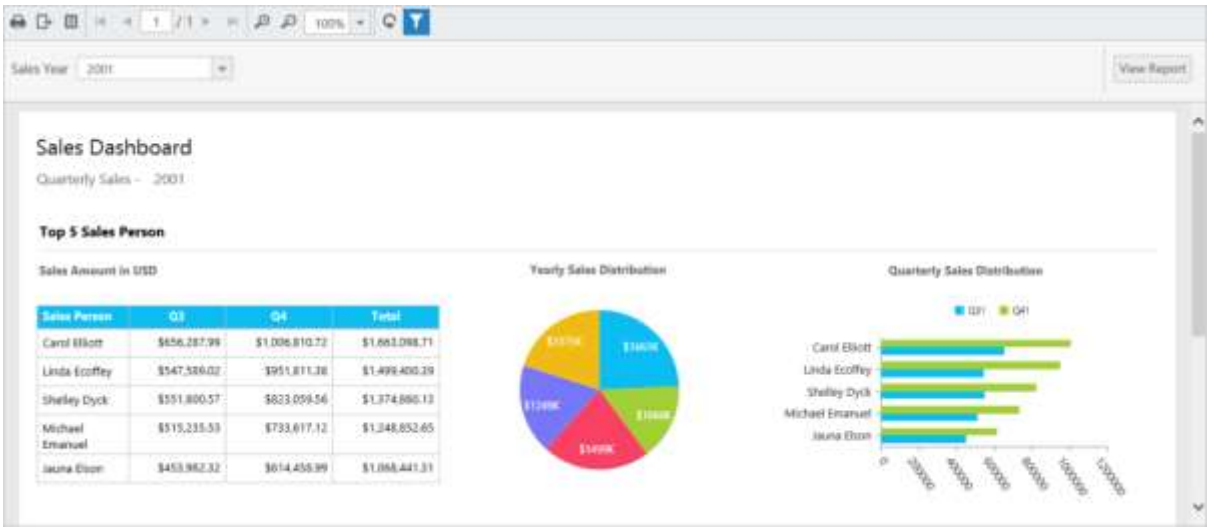
C#

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;
using System.Web.Security;
using System.Web.SessionState;
using System.Web.Http;
namespace ReportViewerDemo
{
public class Global : System.Web.HttpApplication
{
protected void Application_Start(object sender, EventArgs e)
{
System.Web.Http.GlobalConfiguration.Configuration.Routes.MapHttpRoute(
name: "DefaultApi",
routeTemplate: "api/{controller}/{action}/{id}",
defaults: new { id = RouteParameter.Optional });
}
}
}
```

Run the Application

Run the sample application and you can see the ReportViewer on the page as displayed in the following screenshot.

Copyright © 2001 - 2020 Syncfusion Inc.



ReportViewer with Sales Dashboard Report

Load SSRS Server Reports

ReportViewer supports to load RDL/RDLC files from SSRS Server. The following steps help you to load reports from SSRS Server.

1. Set the ReportPath from SSRS and SSRS ReportServerUrl in the ReportViewer properties.

ASPX-CS

```
@using Syncfusion.MVC.EJ
@using Syncfusion.JavaScript.Models
@using Syncfusion.JavaScript
@using Syncfusion.JavaScript.ReportViewer
@{
ViewBag.Title = "Index";
}
<h2>Index</h2>
<div>
@(Html.EJ().ReportViewer("viewer").ProcessingMode(Syncfusion.JavaScript.R
eportViewerEnums.ProcessingMode.Remote)
.ReportServiceUrl("/api/ReportApi")
.ReportServerUrl("http://mvc.syncfusion.com/reportserver")
.ReportPath("/SSRSSamples2/Territory Sales new"))
</div>
```

2. Add the credential information in ReportApiController'sOnInitReportOptions method that is inherited in IReportController.

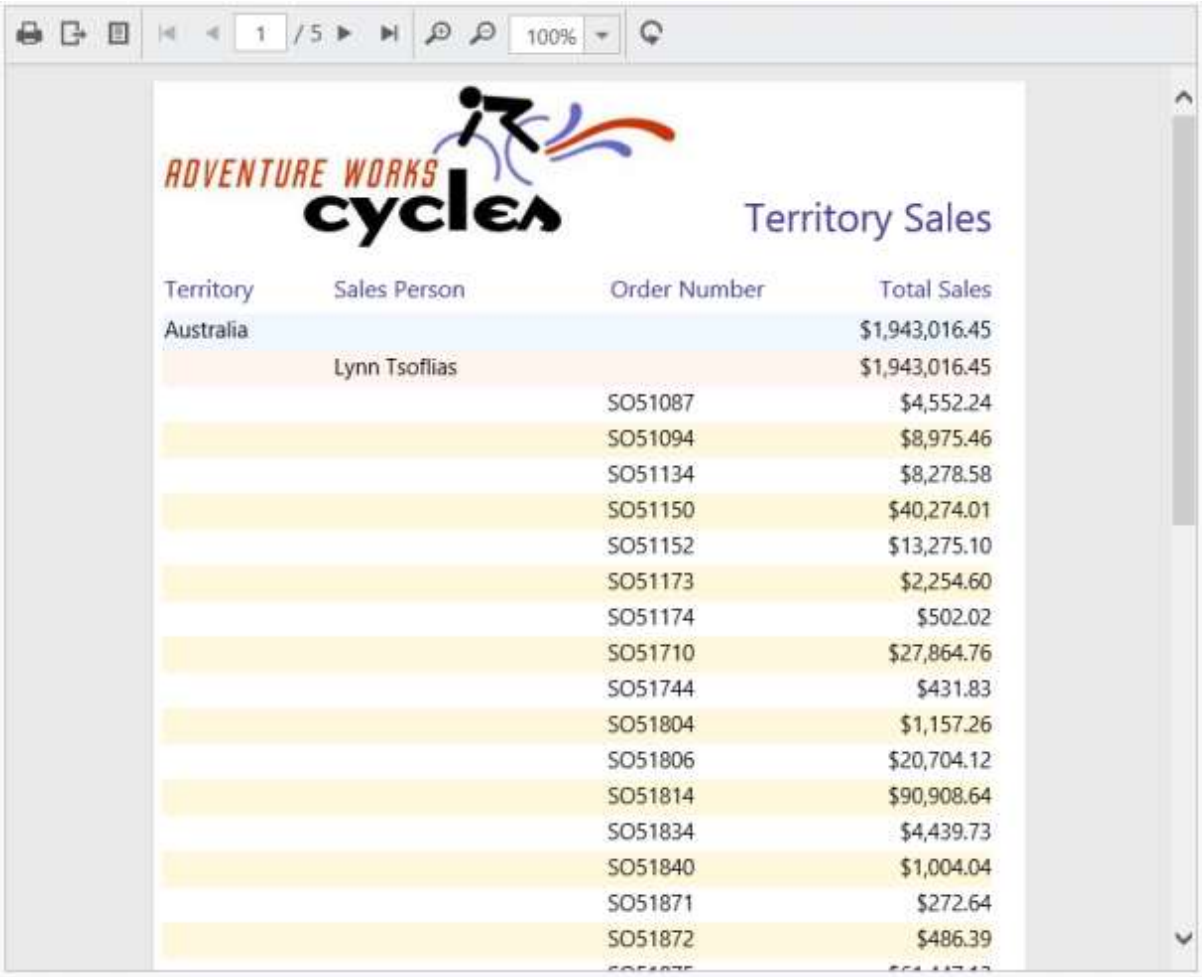
CSHARP

```
public void OnInitReportOptions(ReportViewerOptions reportOption)
{
//Add SSRS Server and database credentials here
reportOption.ReportModel.ReportServerCredential = new
System.Net.NetworkCredential("ssrs", "RDLReport1");
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
reportOption.ReportModel.DataSourceCredentials.Add(new
DataSourceCredentials("AdventureWorks", "ssrs1", "RDLReport1"));
}
```

3. Run the application and you can see the ReportViewer on the page as displayed in the following screenshot.



Report from SSRS

Load RDLC Reports

The ReportViewer has data binding support to visualize the RDLC reports. The following code example helps you to bind data to ReportViewer.

1. Assign the RDLC report path to ReportViewer'sReportPath property and set the data sources to the ReportViewer'sDataSources property.

ASPX-CS

```
@(Html.EJ().ReportViewer("viewer").ProcessingMode(Syncfusion.JavaScript.R
eportViewerEnums.ProcessingMode.Local)
.ReportPath("~/App_Data/Product List.rdlc")
```

```
.ReportServiceUrl("/api/ReportApi")
.DataSources(ds =>
ds.Name("list").Value(ViewData["reportDsource"]).Add()))
```

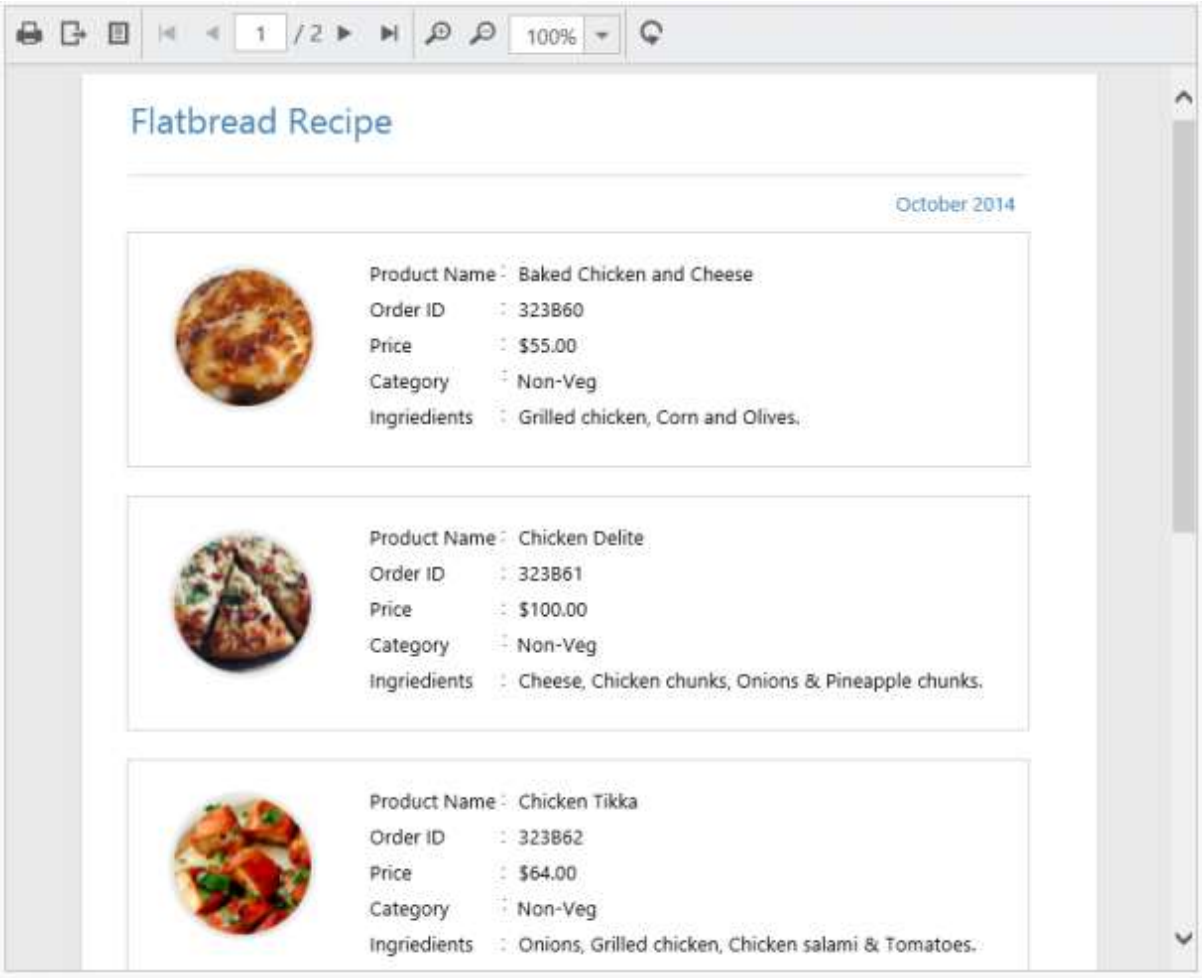
2. The following code example illustrates the creation of business object data source.

CSHARP

```
namespace ReportViewerDemo.Controllers
{
public partial class ReportViewerController : Controller
{
public ActionResult ProductList()
{
ProductList prodlist = new ProductList();
ViewData["reportDsource"] = prodlist.GetData();
return View();
}
}
public class ProductList
{
public string ProductName { get; set; }
public string OrderId { get; set; }
public double Price { get; set; }
public string Category { get; set; }
public string Ingredients { get; set; }
public string ProductImage { get; set; }
public IList GetData()
{
List<ProductList> datas = new List<ProductList>();
ProductList data = null;
data = new ProductList() {ProductName = "Baked Chicken and
Cheese",OrderId = "323B60",Price = 55,Category = "Non-Veg",Ingredients =
"grilled chicken, corn and olives.",ProductImage = "" };
datas.Add(data);
data = new ProductList() {ProductName = "Chicken Delite",OrderId =
"323B61",Price = 100,Category = "Non-Veg",Ingredients = "cheese, chicken
chunks, onions & pineapple chunks.",ProductImage = ""};
datas.Add(data);
data = new ProductList() {ProductName = "Chicken Tikka",OrderId =
"323B62",Price = 64,Category = "Non-Veg",Ingredients = "onions, grilled
chicken, chicken salami & tomatoes.",ProductImage = ""};
datas.Add(data);
return datas;
}
}
}
```

3. Run the application and you can see the ReportViewer on the page as displayed in the following screenshot.

Copyright © 2001 - 2020 Syncfusion Inc.



Product List RDLC Report

Report Controller

The ReportViewer uses Web API services to process the report file, process the request from control, and to return the processed data to control. The Syncfusion.EJ.ReportViewer assembly has helper APIs to define the service actions and process the service requests.

IReportController

The interface IReportController has the declaration of action methods that is defined in WebApi Controller for processing the RDL/RDLC files and for processing request from ReportViewer control. The IReportController has the following action methods declaration.

Methods	Description
GetResource	Action (HttpGet) method for getting resource for report.
PostReportAction	Action (HttpPost) method for posting the request for report process.
OnInitReportOptions	Report initialization method that is triggered when report begins to be processed.

Copyright © 2001 - 2020 Syncfusion Inc.

OnReportLoaded	Report loaded method that is triggered when report and sub report begin loading.

ReportHelper

The class ReportHelper contains helper methods that helps process Post/Get request from ReportViewer control and returns the response to ReportViewer control. The ReportHelper has the following methods.

Methods	Description
GetResource	Returns the report resource for the requested key.
ProcessReport	Processes the report request and returns the result.

C#

```
public class ReportsController : ApiController, IReportController
{
/// <summary>
/// Action (HttpGet) method for getting resource for report.
/// </summary>
/// <param name="key">The unique key to get the required
resource.</param>
/// <param name="resourceType">The type of the requested
resource.</param>
/// <param name="isPrinting">If set to <see langword="true"/>, then the
resource is generated for printing.</param>
/// <returns>The object data.</returns>
public object GetResource(string key, string resourceType, bool
isPrinting)
{
//Returns the report resource for the requested key.
return ReportHelper.GetResource(key, resourceType, isPrinting);
}
/// <summary>
/// Report Initialization method that is triggered when report begin
processed.
/// </summary>
/// <param name="reportOptions">The ReportViewer options.</param>
public void OnInitReportOptions(ReportViewerOptions reportOptions)
{
//You can update report options here
}
/// <summary>
/// Report loaded method that is triggered when report and sub report
begins to be loaded.
/// </summary>
/// <param name="reportOptions">The ReportViewer options.</param>
public void OnReportLoaded(ReportViewerOptions reportOptions)
{
//You can update report options here
}
/// <summary>
```

```
/// Action (HttpPost) method for posting the request for report process.
/// </summary>
/// <param name="jsonData">The JSON data posted for processing
report.</param>
/// <returns>The object data.</returns>
public object PostReportAction(Dictionary<string, object> jsonData)
{
//Processes the report request and returns the result.
return ReportHelper.ProcessReport(jsonData, this);
}
}
```

SSRS Configuration

The ReportViewer has support to load RDL/RDLC reports from SSRS server. You have to set your SSRS server URL to ReportViewer's ReportServerUrl property and set the relative path of RDL/RDLC file in SSRS to ReportViewer's ReportPath property.

ASPX-CS

```
@(Html.EJ().ReportViewer("viewer").ProcessingMode(Syncfusion.JavaScript.R
eportViewerEnums.ProcessingMode.Remote)
.ReportServiceUrl("/api/SSRSReport")
.ReportServerUrl("http://mvc.syncfusion.com/ReportServer")
.ReportPath("/SSRSSamples2/Territory Sales new"))
```

Network Credentials for SSRS

The Network credentials can be given at WebAPI Controller to connect the SSRS server.

C#

```
/// <summary>
/// Report Initialization method that is triggered when report begins to
process.
/// </summary>
/// <param name="reportOptions">The ReportViewer options.</param>
public void OnInitReportOptions(ReportViewerOptions reportOptions)
{
//Adds SSRS Server and Database Credentials here.
reportOptions.ReportModel.ReportServerCredential = new
System.Net.NetworkCredential("ssrs", "RDLReport1");
reportOptions.ReportModel.DataSourceCredentials.Add(new
DataSourceCredentials("AdventureWorks", "ssrs1", "RDLReport1"));
}
```

Note: DataSource credentials must be added to the ReportViewer for Shared DataSources that do not have credentials in the connection string and used in the SSRS Reports.

Report DataSources

The ReportViewer has support to add data sources to ReportViewer for RDLC reports at runtime. You can add SQL Server, Oracle, MS Azure, XML, Business Object, and SQL Server Compact DataSources to ReportViewer. The ReportViewer has DataSources property that is the list of ReportDataSource type to add collection of DataSources to it. You can add DataSources either through ReportViewer model when creating ReportViewer control or through Web API.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example illustrates how to add DataSource at control creation.

ASPX-CS

```
@(Html.EJ().ReportViewer("viewer").ProcessingMode(Syncfusion.JavaScript.R
eportViewerEnums.ProcessingMode.Local)
.ReportPath("~/App_Data/Product List.rdlc")
.ReportServiceUrl("/api/ReportApi").DataSources(ds => ds.Name("list")
.Value(ViewData["DataSource"]).Add()))
```

C#

```
public partial class ReportViewerController : Controller
{
public ActionResult ProductList()
{
ProductList productList = new ProductList();
ViewData["DataSource"] = productList.GetData();
return View();
}
}
public class ProductList
{
public string ProductName { get; set; }
public string OrderId { get; set; }
public double Price { get; set; }
public string Category { get; set; }
public string Ingredients { get; set; }
public string ProductImage { get; set; }
public IList GetData()
{
List<ProductList> dataList = new List<ProductList>();
ProductList data = null;
data = new ProductList() {ProductName = "Baked Chicken and
Cheese",OrderId = "323B60",Price = 55,Category = "Non-Veg",Ingredients =
"grilled chicken, corn and olives.",ProductImage = "" };
dataList.Add(data);
data = new ProductList() {ProductName = "Chicken Delite",OrderId =
"323B61",Price = 100,Category = "Non-Veg",Ingredients = "cheese, chicken
chunks, onions & pineapple chunks.",ProductImage = ""};
dataList.Add(data);
data = new ProductList() {ProductName = "Chicken Tikka",OrderId =
"323B62",Price = 64,Category = "Non-Veg",Ingredients = "onions, grilled
chicken, chicken salami & tomatoes.",ProductImage = ""};
dataList.Add(data);
return dataList;
}
}
```

The following code example illustrates how to add DataSource in Web API.

C#

```
public class ReportsController : ApiController, IReportController
{
/// <summary>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
/// Report loaded method that is triggered when report and sub report are
loaded.
/// </summary>
/// <param name="reportOptions">The ReportViewer options.</param>
public void OnReportLoaded(ReportViewerOptions reportOptions)
{
//Adds data sources to report model.
reportOptions.ReportModel.DataSources.Clear();
ProductList productList = new ProductList();
reportOptions.ReportModel.DataSources.Add(new ReportDataSource { Name =
"list", Value = productList.GetData() });
}
}
public class ProductList
{
public string ProductName { get; set; }
public string OrderId { get; set; }
public double Price { get; set; }
public string Category { get; set; }
public string Ingredients { get; set; }
public string ProductImage { get; set; }
public IList GetData()
{
List<ProductList> dataList = new List<ProductList>();
ProductList data = null;
data = new ProductList() { ProductName = "Baked Chicken and Cheese",
OrderId = "323B60", Price = 55, Category = "Non-Veg", Ingredients =
"grilled chicken, corn and olives.", ProductImage = "" };
dataList.Add(data);
data = new ProductList() { ProductName = "Chicken Delite", OrderId =
"323B61", Price = 100, Category = "Non-Veg", Ingredients = "cheese,
chicken chunks, onions & pineapple chunks.", ProductImage = "" };
dataList.Add(data);
data = new ProductList() { ProductName = "Chicken Tikka", OrderId =
"323B62", Price = 64, Category = "Non-Veg", Ingredients = "onions,
grilled chicken, chicken salami & tomatoes.", ProductImage = "" };
dataList.Add(data);
return dataList;
}
}
```

DataSource Credentials

The DataSource credentials can be given at Web API Controller to connect data source.

C#

```
/// <summary>
/// Report Initialization method that is triggered when report begins to
process.
/// </summary>
/// <param name="reportOptions">The ReportViewer options.</param>
public void OnInitReportOptions(ReportViewerOptions reportOptions)
{
//Adds SSRS Server and Database Credentials here.
reportOptions.ReportModel.ReportServerCredential = new
System.Net.NetworkCredential("ssrs", "RDLReport1");
```

```
reportOptions.ReportModel.DataSourceCredentials.Add(new
DataSourceCredentials("AdventureWorks", "ssrs1", "RDLReport1"));
}
```

Report Parameters

The ReportViewer has support to add report parameters to ReportViewer at runtime. The ReportViewer has Parameters property that is the list of ReportParameter type to add collection of report parameters to it. You can add report parameters either through ReportViewer model when creating ReportViewer control or through Web API.

The following code example illustrates how to add ReportParameter at control creation.

ASPX-CS

```
@(Html.EJ().ReportViewer("viewer").ProcessingMode(Syncfusion.JavaScript.R
eportViewerEnums.ProcessingMode.Remote)
.ReportPath("InvoiceTemplate.rdl")
.ReportServiceUrl("/api/ReportApi")
.Parameters(param => {param.Name("InvoiceID").Labels(new List<string>() {
"InvoiceID" }).Values(new List<string>() { "10250" }).Add();}))
```

The following code example illustrates how to add ReportParameter in Web API.

C#

```
public class ReportsController : ApiController, IReportController
{
/// <summary>
/// Report Initialization method that is triggered when report begins to
be processed.
/// </summary>
/// <param name="reportOptions">The ReportViewer options.</param>
public void OnInitReportOptions(ReportViewerOptions reportOptions)
{
List<ReportParameter> parameters = new List<ReportParameter>();
parameters.Add(new ReportParameter() { Name = "InvoiceID", Labels = new
List<string>() { "InvoiceID" }, Values = new List<string>() { "10250" }
});
reportOptions.ReportModel.Parameters = parameters;
}
}
```

Toolbar Customization

The ReportViewer has an option to show or hide items in the toolbar. To customize the toolbar items, use the ReportViewer's ToolbarSettings property. The toolbar template can also be customized by specifying custom template to ReportViewer toolbar.

ASPX-CS

```
@(Html.EJ().ReportViewer("viewer")
.ToolbarSettings(tb=>tb.Items(Syncfusion.JavaScript.ReportViewerEnums.Too
lbarItems.All &
~Syncfusion.JavaScript.ReportViewerEnums.ToolbarItems.Parameters)))
```

Copyright © 2001 - 2020 Syncfusion Inc.

Events

The ReportViewer has the following client-side events support to listen to the control action.

Events	Description
destroy	Fires when the ReportViewer is destroyed.
drillThrough	Fires during drill through action done in report and event can be canceled.
renderingBegin	Fires before report rendering is completed.
renderingComplete	Report loaded method that is triggered when report and sub report begin loading.
reportError	Fires when any error occurs while rendering the report and event can be canceled.
reportLoaded	Fires when the report is loaded.

HTML

```
@(Html.EJ().ReportViewer("viewer")
.ProcessingMode(Syncfusion.JavaScript.ReportViewerEnums.ProcessingMode.Lo
cal)
.ReportPath("DatabindingRemote.rdlc")
.ReportServiceUrl(VirtualPathUtility.ToAbsolute("~/api/RDLCReport")).Repo
rtLoaded("reportLoaded") )
<script type="text/javascript">
function reportLoaded(senderObj) {
$.ajax({
type: "POST",
contentType: "application/json; charset=utf-8",
url: '../wcf/Reportservice.svc/GetOrderDetails',
dataType: "json",
processData: false,
crossDomain: true,
async: false,
timeout: 5000,
success: function (result) {
reportdata = result.d;
var dataManger = ej.DataManager(reportdata);
var query = ej.Query().select("OrderID", "CustomerID", "EmployeeID",
"Freight", "ShipCity", "ShipCountry");
reportResult = dataManger.executeLocal(query);
var reportModel = $("#viewer").data('ejReportViewer');
reportModel.model.dataSources = [{ value: reportResult, name: "remote"
}];
},
error: function (result) {
alert(result);
}
});
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Limitations

RDL Specification support

- The ReportViewer control does not support RDL Specification for SQL Server 2000 and SQL Server 2005.

Layout process

- The Syncfusion ReportViewer control has some limitations in the Tablix cell split layout process in comparison with MS ReportViewer. When the table cell width value exceeds the page width, the entire cell moves to the next page to display the complete cell items.
- The Syncfusion ReportViewer control does not support vertical alignment in the text box report item.

Unsupported expression

- The object function and VB function do not have complete support in the ReportViewer.

ReportDesigner

Overview

Report Designer helps to create and modify the RDL 2008/2008R2 specification standard reports. By using Report Designer, the data can be transformed into meaningful information and quickly build the reports using both table and visualization formats with the help of following features.

Key features

Data Sources --- All the commonly used data sources like Microsoft SQL Server, Oracle, OLEDB and ODBC are supported.

Business user friendly --- The drag-and-drop friendly report designer application makes it possible for business users to compose reports without any help from IT.

Report items --- All interactive report items that are commonly used in business reports like a variety of charts, pivot, grouping and grid have been included.

Report Parameter --- Parameters are used to specify the data to use in a report, connect related reports together and vary report presentation.

Expression --- Expressions are used throughout the report definition to specify or calculate values for parameters, queries, filters, report item properties, group and sort definitions, textbox properties, dynamic page header and footer content and images.

Getting Started

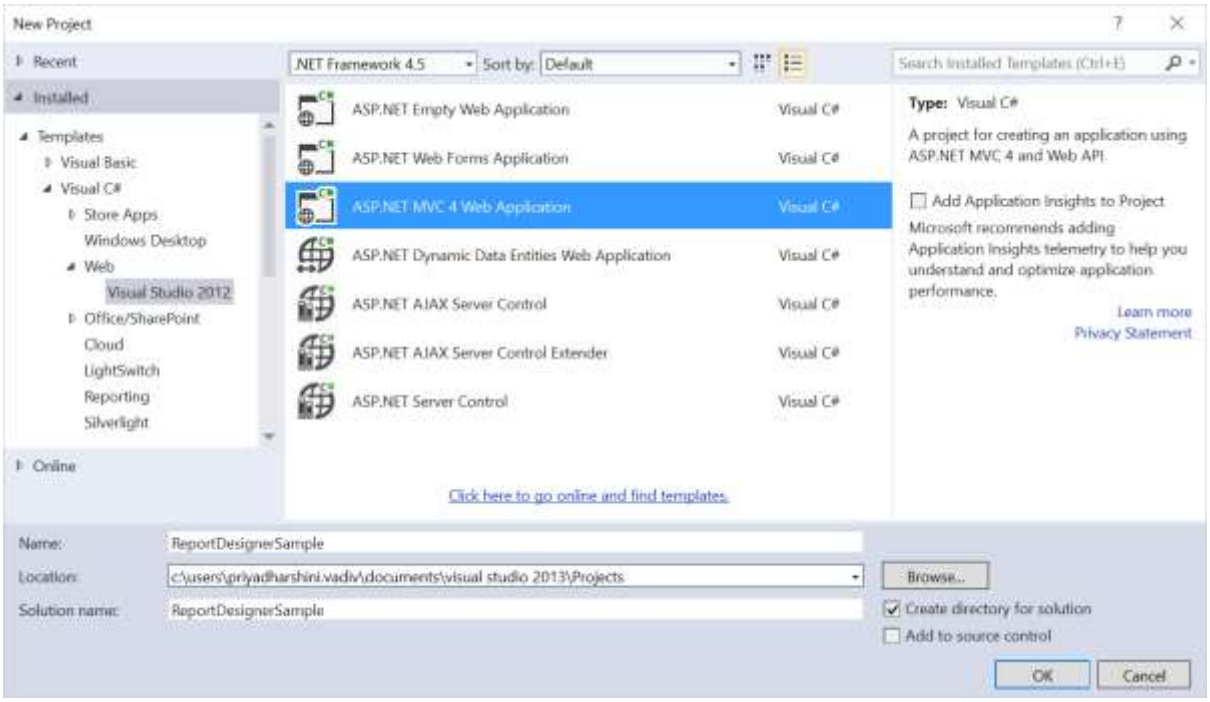
This section explains briefly about how to create a **ReportDesigner** in your ASP.NET MVC application.

Create your first ReportDesigner application in ASP.NET MVC

The following screenshots displays the Project Creation Wizard in Visual Studio 2013

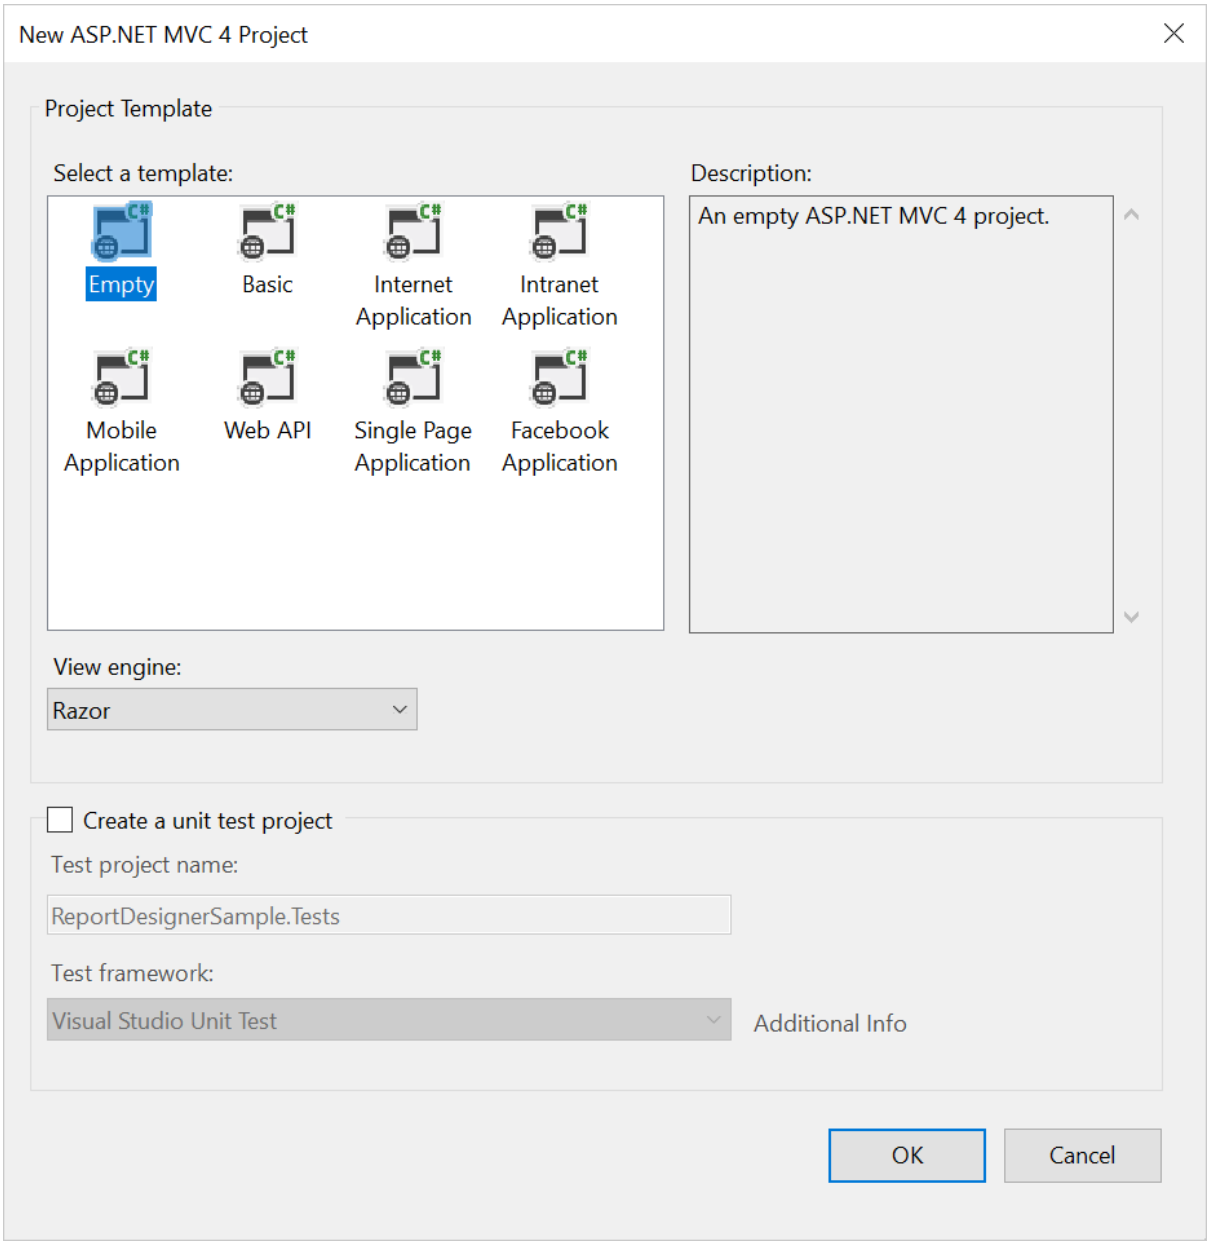
Create a new ASP.NET MVC4 Web Application project by selecting the **WEB** category from the listed project template in Microsoft Visual Studio IDE.

Copyright © 2001 - 2020 Syncfusion Inc.



Project Creation Wizard

The following screenshot displays how to select the project template with razor view engine:

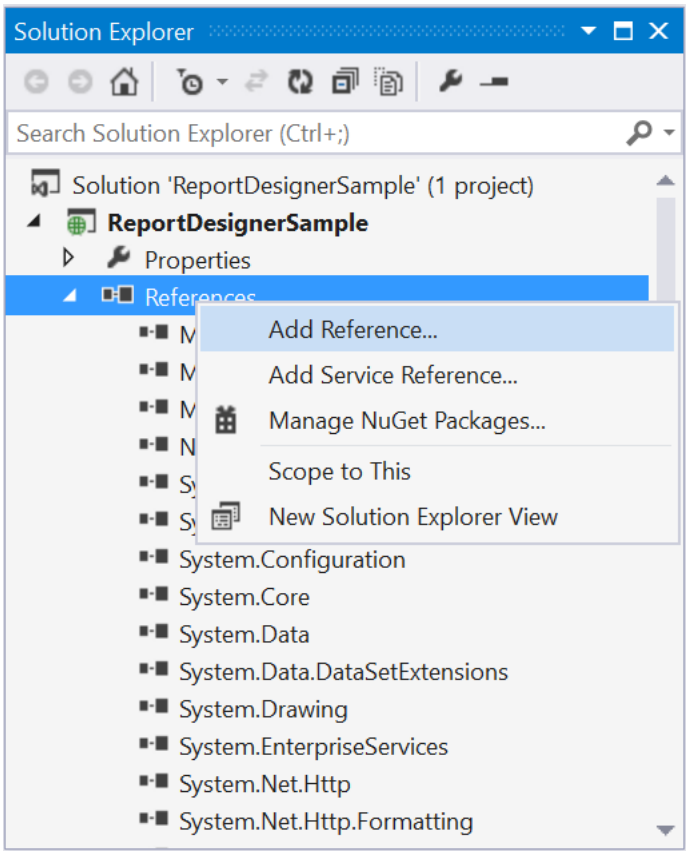


Select an empty template and click OK.

Add Assembly References

1. In the Solution Explorer, right-click the References folder and then click Add Reference.

Copyright © 2001 - 2020 Syncfusion Inc.



2. Add the following Syncfusion assemblies to the project that are necessary for using the report designer control.
    - Syncfusion.Chart.Wpf
    - Syncfusion.Compression.Base
    - Syncfusion.DocIO.Base
    - Syncfusion.EJ.ReportDesigner
    - Syncfusion.EJ.ReportViewer
    - Syncfusion.Gauge.Wpf
    - Syncfusion.Pdf.Base
    - Syncfusion.Presentation.Base
    - Syncfusion.Shared.Wpf
    - Syncfusion.SfMaps.Wpf
    - Syncfusion.XlsIO.Base
    - Syncfusion.EJ
    - Syncfusion.EJ.MVC

Refer the Syncfusion.EJ.MVC assembly from the installed location, [Installed Location]:\Program Files (x86)\Syncfusion\Essential Studio\ASP.NET MVC\{{ site.releaseversion }}\Assemblies\MVC\MVC4

Refer the other assemblies from the installed location, [Installed Location]:\Program Files (x86)\Syncfusion\Essential Studio\ASP.NET MVC\{{ site.releaseversion }}\Assemblies

3. Add the following WebAPI assemblies from NuGet package.

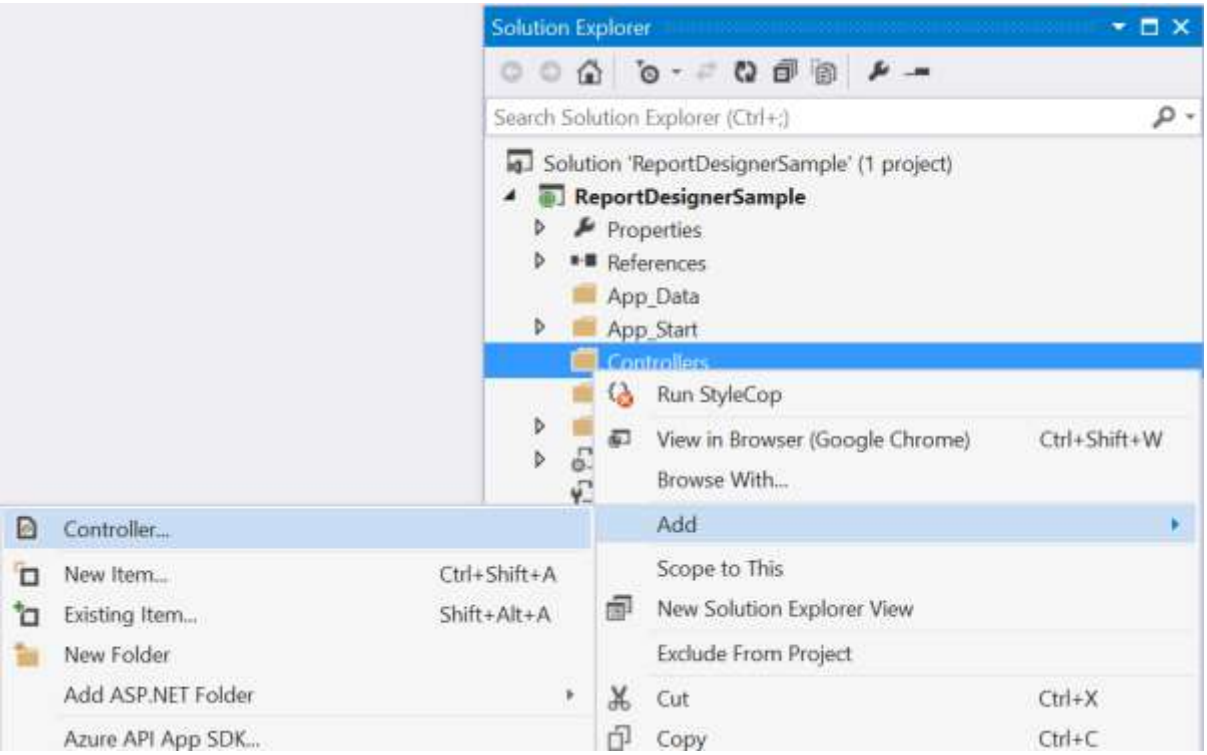
Copyright © 2001 - 2020 Syncfusion Inc.

- System.Web.Http
- System.Web.Http.WebHost
- System.Net.Http.WebRequest
- System.Net.Http.Formatting

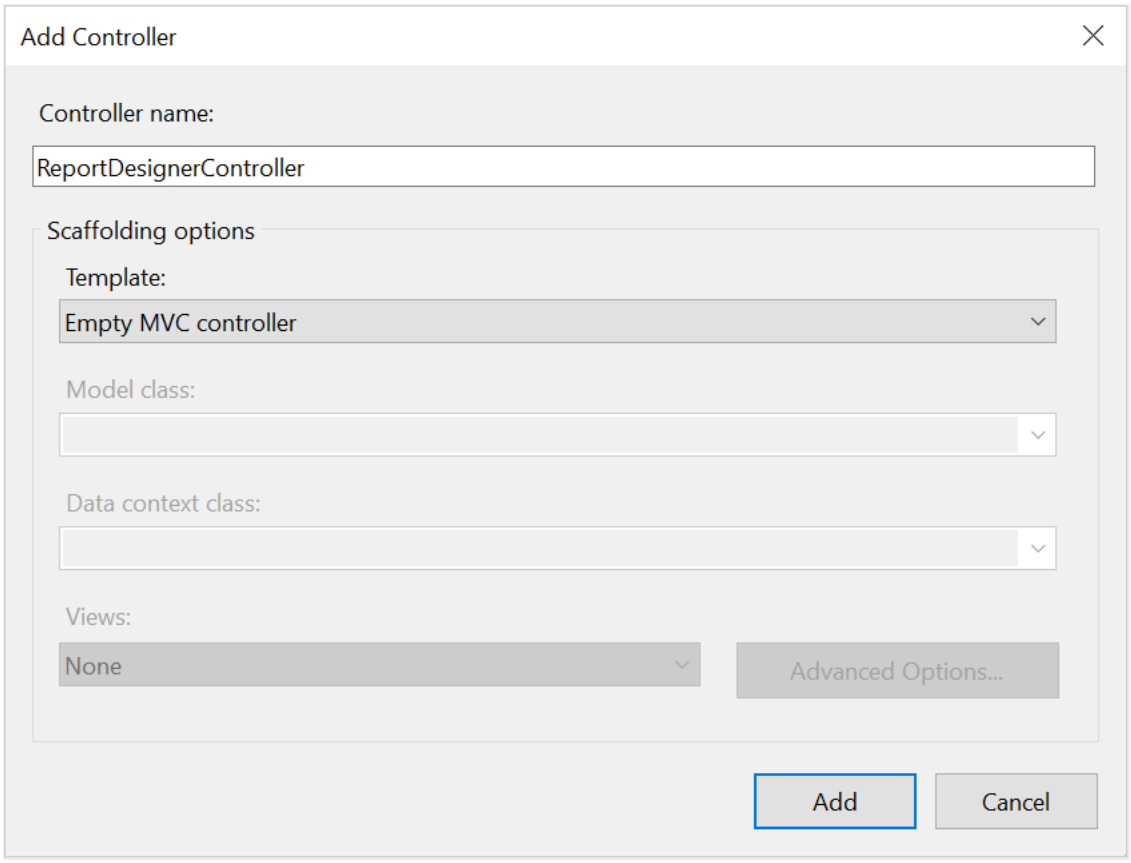
The System.Web.Routing and System.Net.Http assemblies are also required, which are referred by default when creating the project.

Add Controller

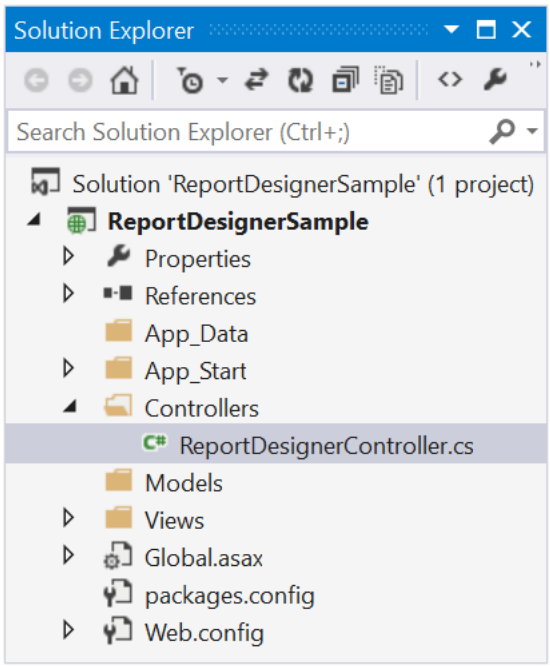
1. Right-Click on the **Controllers** folder in the project and select Add then select Controller.



2. Name the controller as **ReportDesignerController**.

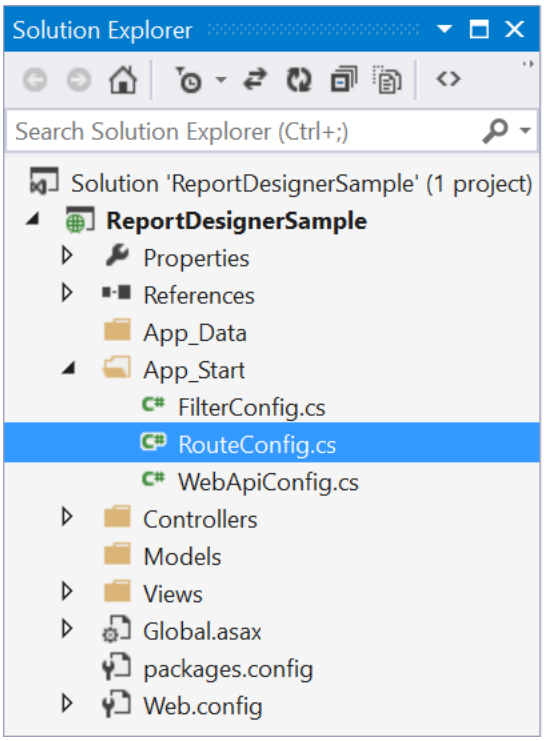


3. Click Add.



Modify RouteConfig.cs

1.Open the RouteConfig.cs file from App_Start folder of your application.



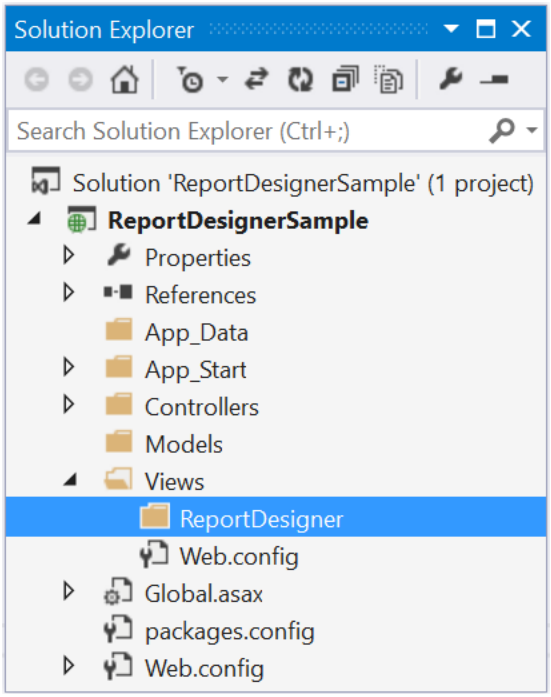
2.Modify the controller name to map to the **ReportDesigner** controller as follows.

C#

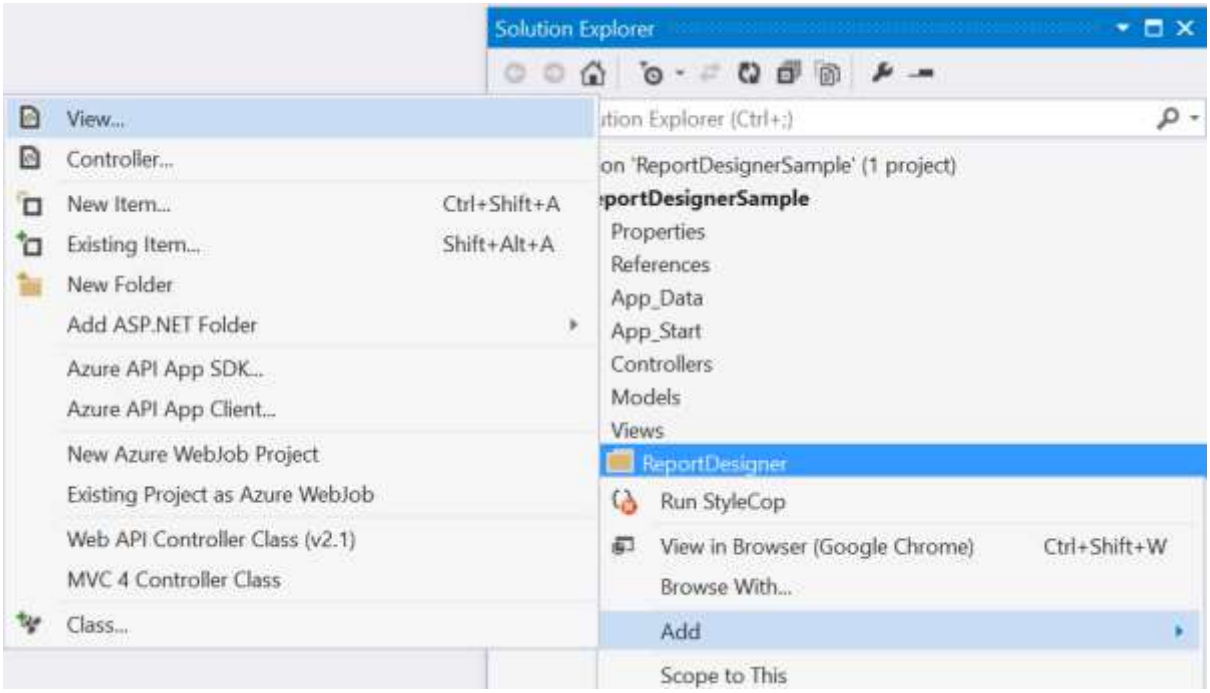
```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;
using System.Web.Mvc;
using System.Web.Routing;
namespace ReportDesignerSample
{
public class RouteConfig
{
public static void RegisterRoutes(RouteCollection routes)
{
routes.IgnoreRoute("{resource}.axd/{*pathInfo}");
routes.MapRoute(
name: "Default",
url: "{controller}/{action}/{id}",
defaults: new { controller = "ReportDesigner", action = "Index", id =
UrlParameter.Optional }
);
}
}
}
```

Add View page

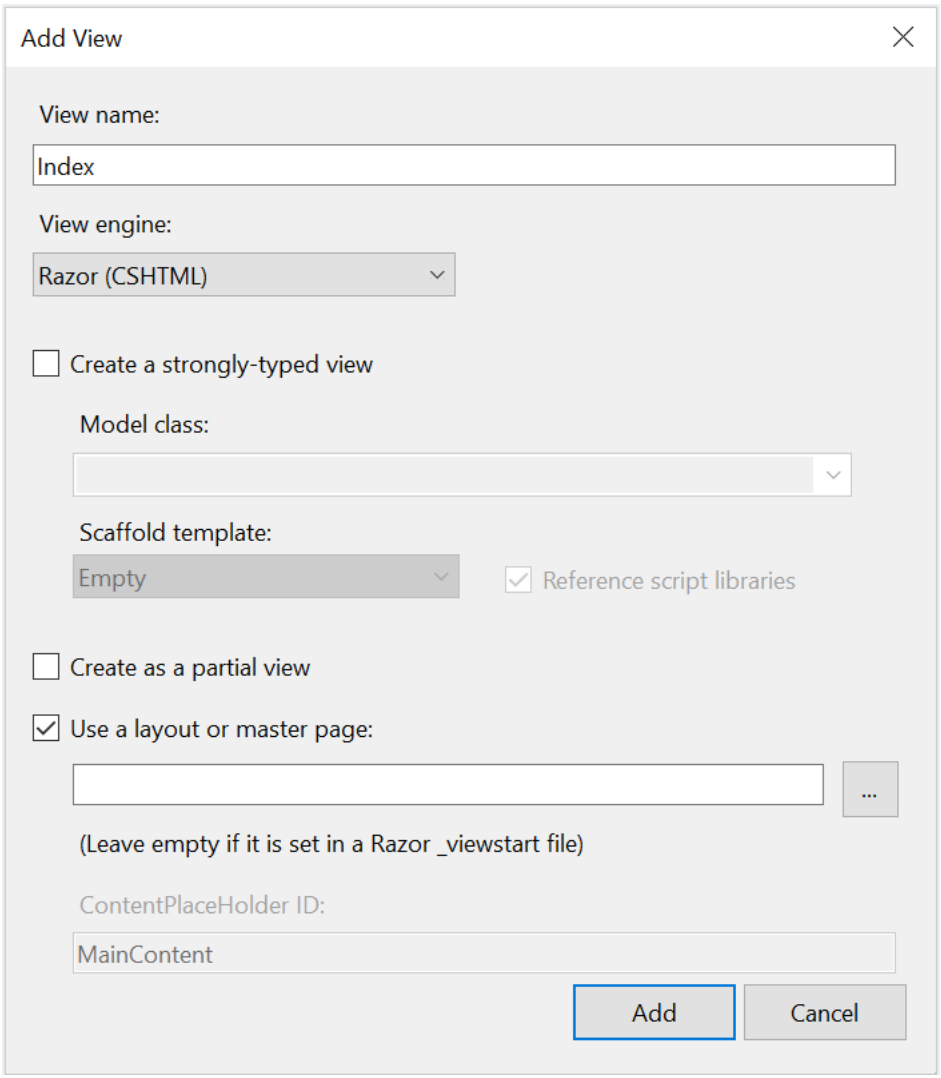
1. Create a new folder **ReportDesigner** in Views folder.



2. Right-Click on the **ReportDesigner** folder in the Views folder and select Add then select View.

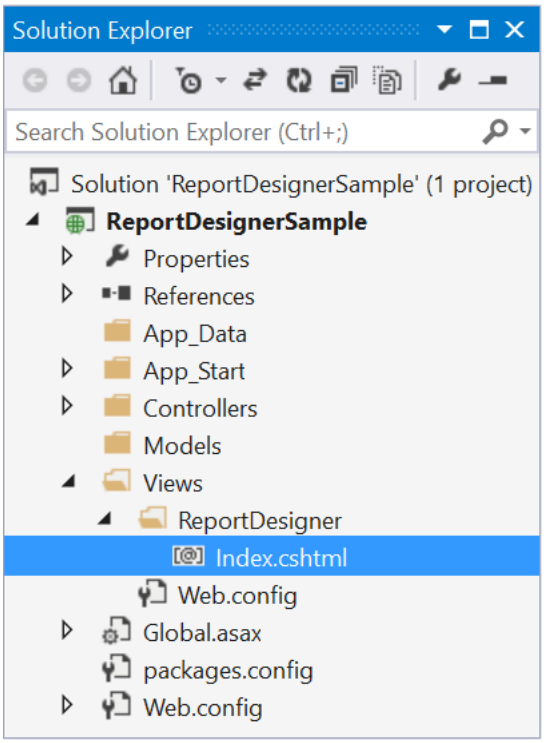


3. Name the view page as **Index**.



Add View
View name:
Index
View engine:
Razor (CSHTML)
Create a strongly-typed view
Model class:
Scaffold template:
Empty
Reference script libraries
Create as a partial view
Use a layout or master page:
...
(Leave empty if it is set in a Razor _viewstart file)
ContentPlaceHolder ID:
MainContent
Add
Cancel

4. Click Add.



Add Scripts and Styles

For complete dependencies list of report designer control Click here.

Add the below code snippet in the Index.cshtml page.

ASPX-CS

```
@using Syncfusion.JavaScript
@using Syncfusion.MVC.EJ
<!DOCTYPE html>
<html lang="en">
<head>
<meta charset="utf-8" />
<title>@ViewBag.Title</title>
</head>
<body>
</body>
</html>
```

Themes

ASPX-CS

```
<link href="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/flat-azure/ej.web.all.min.css" rel="stylesheet" />
<link href="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/flat-azure/ej.reportdesigner.min.css" rel="stylesheet" />
```

Scripts

External dependencies

ASPX-CS

```
<script src="http://code.jquery.com/jquery-1.10.2.min.js"
type="text/javascript"></script>
<script src="http://cdnjs.cloudflare.com/ajax/libs/jquery-
easing/1.3/jquery.easing.min.js" type="text/javascript"></script>
<script
src="https://cdnjs.cloudflare.com/ajax/libs/jsrender/0.9.90/jsrender.min.
js" type="text/javascript"></script>
```

Internal dependencies

Refer the below scripts to render report designer control.

ASPX-CS

```
<script src="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/ej.web.all.min.js" type="text/javascript"></script>
<script src="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/ej.reportdesigner.min.js" type="text/javascript"></script>
```

Code Mirror

To edit the SQL queries with syntax highlighter need to refer the below code mirror scripts and themes.

ASPX-CS

```
<link
href="https://cdnjs.cloudflare.com/ajax/libs/codemirror/5.37.0/codemirror
.min.css" rel="stylesheet" />
<link
href="https://cdnjs.cloudflare.com/ajax/libs/codemirror/5.37.0/addon/hint
/show-hint.min.css" rel="stylesheet" />
<script
src="https://cdnjs.cloudflare.com/ajax/libs/codemirror/5.37.0/codemirror.
min.js" type="text/javascript"></script>
<script
src="https://cdnjs.cloudflare.com/ajax/libs/codemirror/5.37.0/addon/hint/
show-hint.min.js" type="text/javascript"></script>
<script
src="https://cdnjs.cloudflare.com/ajax/libs/codemirror/5.37.0/addon/hint/
sql-hint.min.js" type="text/javascript"></script>
<script
src="https://cdnjs.cloudflare.com/ajax/libs/codemirror/5.37.0/mode/sql/sq
l.min.js" type="text/javascript"></script>
```

Add the script files and theme file references in the <head> tag of the Index.cshtml page.

Also the scripts and styles can be referred from the installed location, [Installed Location]:\Program Files (x86)\Syncfusion\Essential Studio\ASP.NET MVC\{{ site.releaseversion }}\JavaScript\assets

Unobtrusive Mode

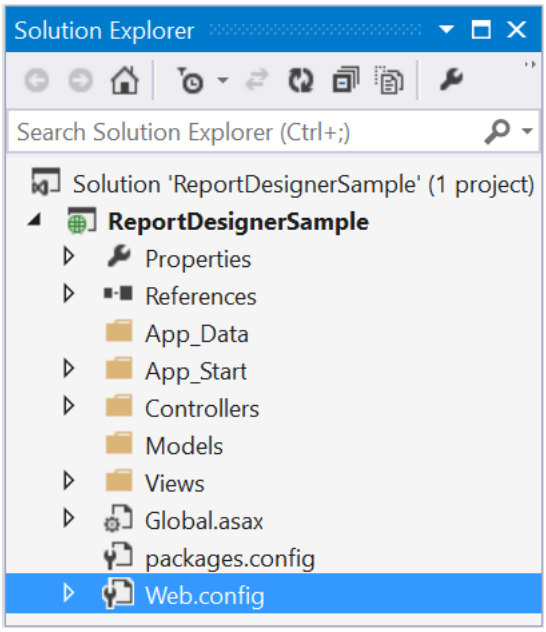
Enable unobtrusive mode

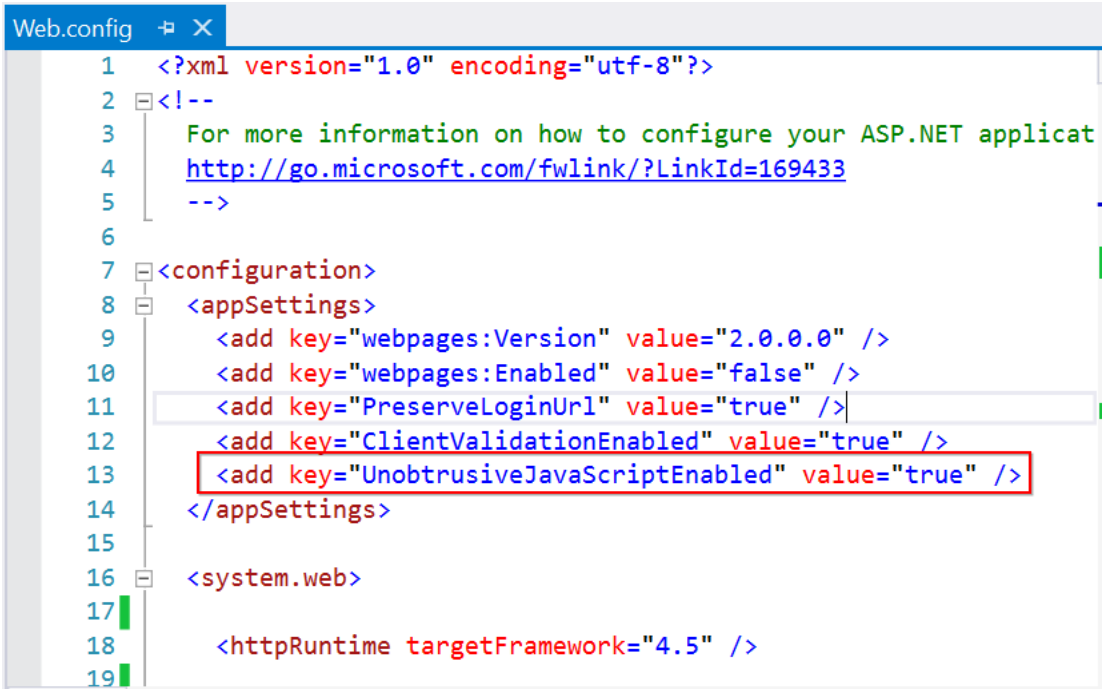
1.To render the Report Designer in unobtrusive mode, refer to the **ej.unobtrusive.js** script file in <head> of Index.cshtml page.

ASPX-CS

```
<script src="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/common/ej.unobtrusive.min.js"></script>
```

2.Set **UnobtrusiveJavaScriptEnabled** to true in Web.config file of your application.





Disable unobtrusive mode

Set **UnobtrusiveJavaScriptEnabled** to false in Web.config file of your application.

Web.config

```
<?xml version="1.0" encoding="utf-8"?>
<!--
  For more information on how to configure your ASP.NET applicat
  http://go.microsoft.com/fwlink/?LinkId=169433
  -->

<configuration>
  <appSettings>
    <add key="webpages:Version" value="2.0.0.0" />
    <add key="webpages:Enabled" value="false" />
    <add key="PreserveLoginUrl" value="true" />
    <add key="ClientValidationEnabled" value="true" />
    <add key="UnobtrusiveJavaScriptEnabled" value="false" />
  </appSettings>

  <system.web>

    <httpRuntime targetFramework="4.5" />
```

Refer to the unobtrusive section for more details.

Registering namespaces within Web.config

Register the following namespaces in the web.config file present within the Views folder as well as the root directory of your application.

XML

```
<namespaces>
<add namespace="Syncfusion.EJ.ReportViewer"/>
<add namespace="Syncfusion.EJ.ReportDesigner"/>
<add namespace="Syncfusion.EJ"/>
<add namespace="Syncfusion.MVC.EJ"/>
</namespaces>
```

Add Control in View page

Add the following code example in the <body> tag of the Index.cshtml page that is already created. Set the desired ServiceUrl to ReportDesigner.

ASPX-CS

```
<div>
@{Html.EJ().ReportDesigner("designer").ServiceUrl("/api/DesignerAPI").Ren
der();}
</div>
@(Html.EJ().ScriptManager())
```

The main reason for referring the **Script manager** in Index.cshtml is that, it can be referred as common by all the View files present within your application. If **unobtrusive** is set to true in the application, the script manager can be excluded, as the control is initialized using HTML5 attributes. Also for control

Copyright © 2001 - 2020 Syncfusion Inc.

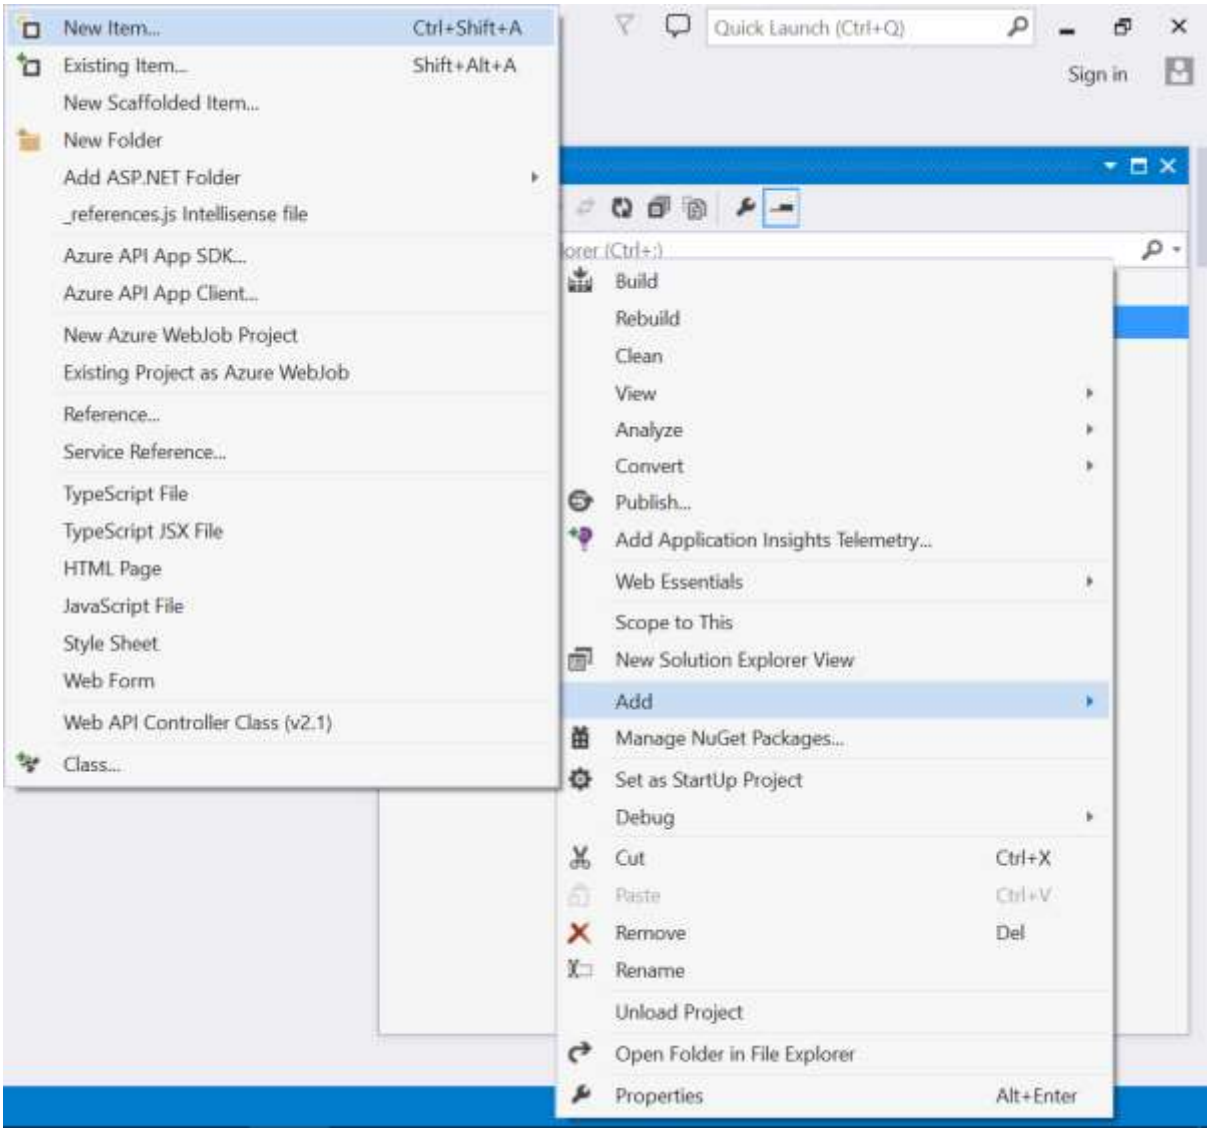
rendering, you need to include **ej.unobtrusive.min.js** file along with ej.web.all.min.js in **Index.cshtml** page.

Add WebAPI controller for ReportDesigner

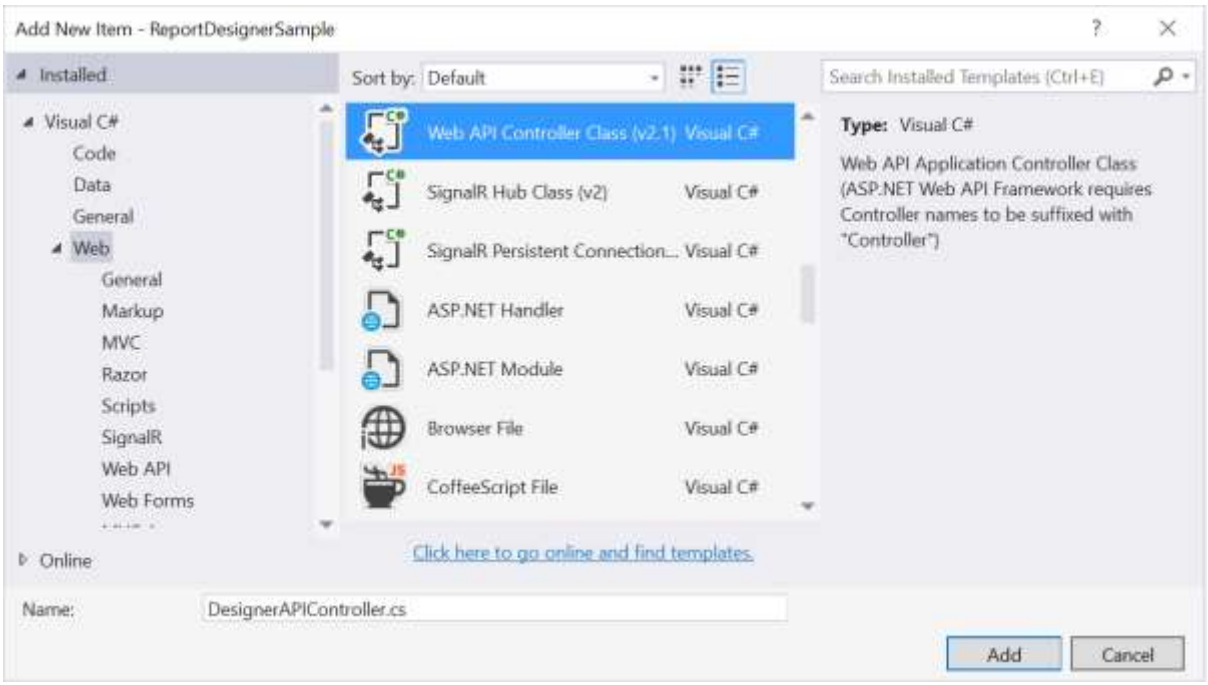
The MVC ReportDesigner uses WebApi services to process the report file and process the request from control.

Add Controller

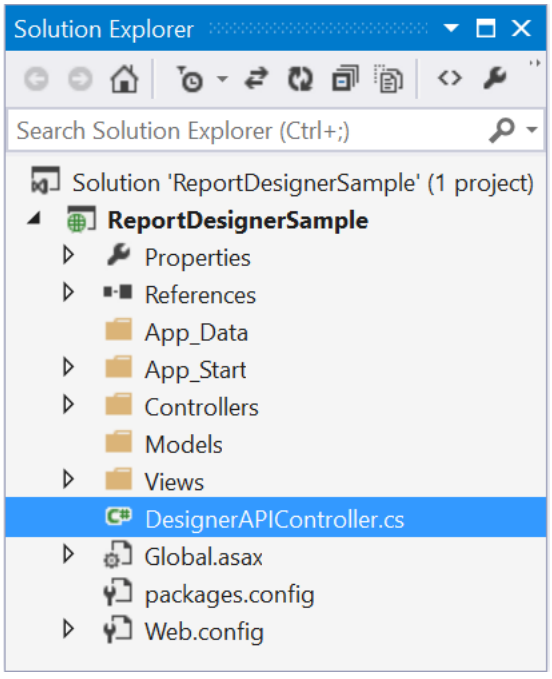
1. Right-Click on the project and select Add then click New Item.



2. Select Web API Controller Class from the listed templates and name the controller as **DesignerAPIController.cs**.



3. Click Add.



Inherit IReportDesignerController

The ApiController should inherit the `IReportDesignerController` and to process the report file. The interface `IReportDesignerController` contains the required actions and helper methods declaration to process the report. The `ReportDesignerHelper` and `ReportHelper` class contains helper methods that helps to process Post/Get request from control and return the response to control.

Please add the following code example in `DesignerAPIController.cs`.

C#

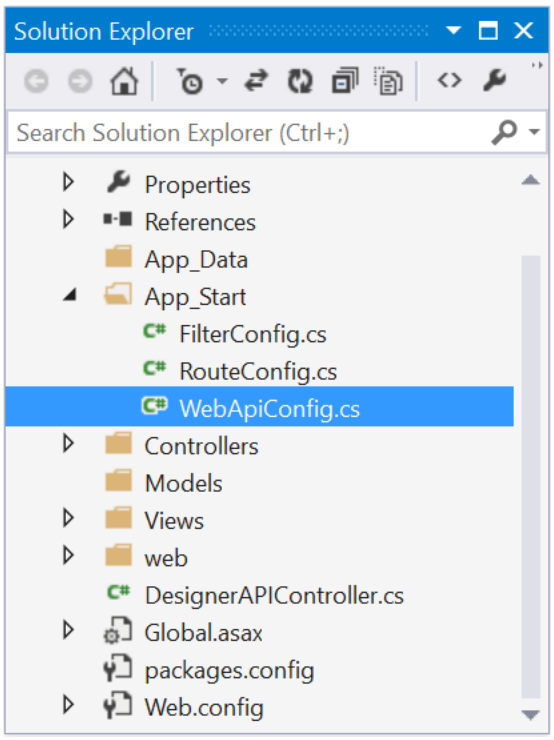
```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Net;
using System.Net.Http;
using System.Web.Http;
using System.IO;
using System.Web;
using Syncfusion.EJ.ReportViewer;
using Syncfusion.Reports.EJ;
using Syncfusion.EJ.ReportDesigner;
namespace ReportDesignerSample
{
public class DesignerAPIController : ApiController,
Syncfusion.EJ.ReportDesigner.IReportDesignerController
{
public string GetFilePath(string fileName)
{
string targetFolder = HttpContext.Current.Server.MapPath("~/");
targetFolder += "Cache";
if (!Directory.Exists(targetFolder))
{
Directory.CreateDirectory(targetFolder);
}
if (!Directory.Exists(targetFolder + "\\" +
ReportDesignerHelper.EJReportDesignerToken))
{
Directory.CreateDirectory(targetFolder + "\\" +
ReportDesignerHelper.EJReportDesignerToken);
}
var folderPath = HttpContext.Current.Server.MapPath("~/") + "Cache\\" +
ReportDesignerHelper.EJReportDesignerToken + "\\";
return folderPath + fileName;
}
[HttpGet]
public object GetImage(string key, string image)
{
return ReportDesignerHelper.GetImage(key, image, this);
}
[HttpPost]
public object PostDesignerAction(Dictionary<string, object> jsonResult)
{
return ReportDesignerHelper.ProcessDesigner(jsonResult, this, null);
}
public bool UploadFile(System.Web.HttpPostedFile httpPostedFile)
{
string targetFolder = HttpContext.Current.Server.MapPath("~/");
string fileName =
!string.IsNullOrEmpty(ReportDesignerHelper.SaveFileName) ?
ReportDesignerHelper.SaveFileName :
Path.GetFileName(httpPostedFile.FileName);
targetFolder += "Cache";
if (!Directory.Exists(targetFolder))
{
Directory.CreateDirectory(targetFolder);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
if (!Directory.Exists(targetFolder + "\\" +
ReportDesignerHelper.EJReportDesignerToken))
{
Directory.CreateDirectory(targetFolder + "\\" +
ReportDesignerHelper.EJReportDesignerToken);
}
httpPostedFile.SaveAs(targetFolder + "\\" +
ReportDesignerHelper.EJReportDesignerToken + "\\" + fileName);
return true;
}
public void UploadReportAction()
{
ReportDesignerHelper.ProcessDesigner(null, this,
HttpContext.Current.Request.Files[0]);
}
public object GetResource(string key, string resourcetype, bool isPrint)
{
return ReportHelper.GetResource(key, resourcetype, isPrint);
}
public void OnInitReportOptions(ReportViewerOptions reportOption)
{
//You can update report options here
}
public void OnReportLoaded(ReportViewerOptions reportOption)
{
//You can update report options here
}
public object PostReportAction(Dictionary<string, object> jsonResult)
{
return ReportHelper.ProcessReport(jsonResult, this as IReportController);
}
public FileModel GetFile(string filename, bool isOverride)
{
throw new NotImplementedException();
}
public List<FileModel> GetFiles(FileType fileType)
{
throw new NotImplementedException();
}
}
}
```

Modify WebApiConfig.cs

1. Open the WebApiConfig.cs file from App_Start folder of your application.



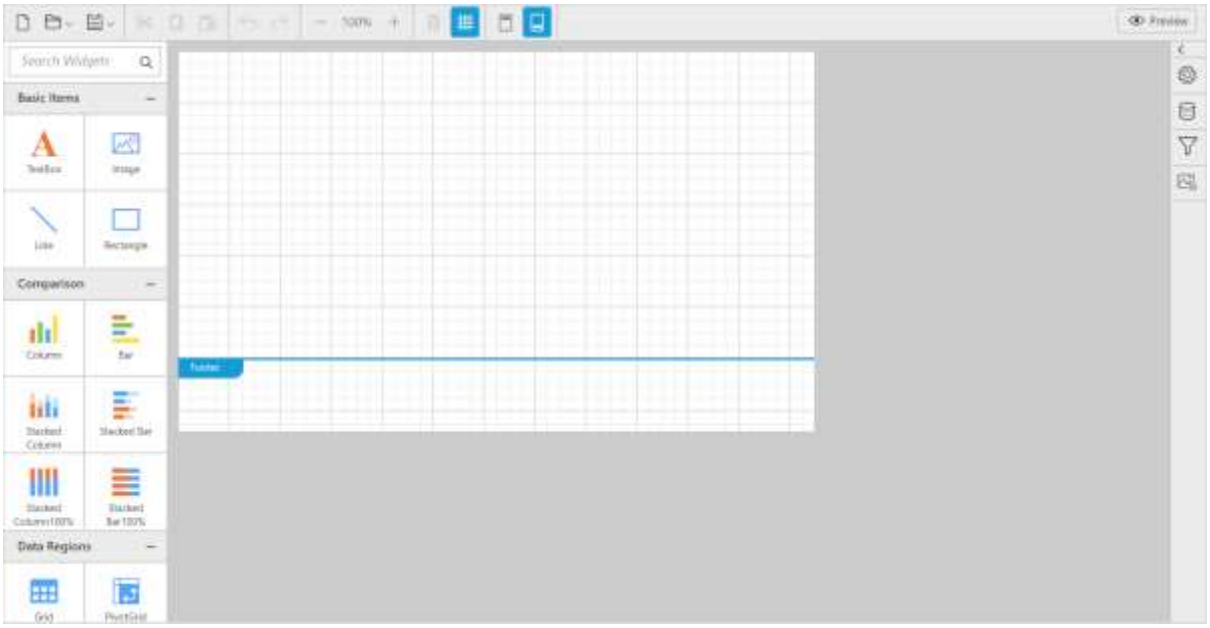
2. Modify the **routeTemplate** to map to the API controller of **ReportDesignerSample** project as follows.

C#

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web.Http;
namespace ReportDesignerSample
{
public static class WebApiConfig
{
public static void Register(HttpConfiguration config)
{
config.Routes.MapHttpRoute(
name: "DefaultApi",
routeTemplate: "api/{controller}/{action}/{id}",
defaults: new { id = RouteParameter.Optional }
);
}
}
}
```

Run the Application

On running the application, Report Designer will be rendered like below.



ReportDesigner Dependencies

The ReportDesigner have the following list of external dependencies.

- jQuery 1.7.1 and later versions.
- jsRender - to render the templates.
- CodeMirror - to edit the SQL queries with syntax highlighter.

And the internal dependencies are tabulated below.

File	Description/Usage
ej.core.min.js	Must be referred always before using all the *ASP.NET MVC* controls.
ej.data.js	Used to handle data operation and should be used while binding data to *ASP.NET MVC* controls.
ej.draggable.js	Used to handle drag on drop operation in all *ASP.NET MVC* controls.
ej.scroller.js	Used to handle scrolling operation in all *ASP.NET MVC* controls.
ej.globalize.js	It is referred when using localization in ReportDesigner.
ej.waitingpopup.js	These files are used to handle the internal UI and actions of ReportDesigner.
ej.button.js	
ej.checkbox.js	
ej.radiobutton.js	
ej.autocomplete.js	
ej.datepicker.js	

Copyright © 2001 - 2020 Syncfusion Inc.

ej.timepicker.js	
ej.datetimepicker.js	
ej.daterangepicker.js	
ej.dialog.js	
ej.dropdownlist.js	
ej.tooltip.js	
ej.listbox.js	
ej.map.js	
ej.editor.js	
ej.maskedit.js	
ej.menu.js	
ej.pager.js	
ej.slider.js	
ej.splitter.js	
ej.splitbutton.js	
ej.toolbar.js	
ej.tab.js	
ej.treeview.js	
ej.uploadbox.js	
ej.colorpicker.js	
ej.grid.js	
ej.reportViewer.js	
ej.chart.js	
ej.circulargauge.js	
ej.lineargauge.js	
ej.bulletgraph.js	

API Service

External assemblies needed for ReportDesigner service are tabulated below.

Assemblies	Description/Usage

Copyright © 2001 - 2020 Syncfusion Inc.

System.Web.Http	Must be referred these assemblies for WebAPI.
System.Web.Http.WebHost	
System.Net.Http.WebRequest	
System.Net.Http.Formatting	
System.Net.Http	
System.Web.Routing	

And the internal assemblies are tabulated below.

Assemblies	Description/Usage
Syncfusion.Shared.Wpf	It's common dependencies for our WPF components which will be used to handle the report export related actions in ReportViewer.
Syncfusion.Pdf.Base	Must be referred to handle pdf export.
Syncfusion.DocIO.Base	Must be referred to handle word export.
Syncfusion.XlsIO.Base	Must be referred to handle excel export.
Syncfusion.Presentation.Base	Must be referred to handle ppt export.
Syncfusion.Chart.Wpf	Must be referred to export the chart item from ReportViewer.
Syncfusion.Gauge.Wpf	Must be referred to export the Gauge item from ReportViewer.
Syncfusion.SfMaps.Wpf	Must be referred to export the Map item from ReportViewer.
Syncfusion.EJ.ReportViewer	It's used to preview the report.
Syncfusion.EJ.MVC	Must be referred to use Web Report Designer control from Syncfusion ASP.NET MVC controls.
Syncfusion.EJ	It's used as base class for Syncfusion ASP.NET MVC controls.

ReportWriter

Overview

ReportWriter is a class library that enables the user to render reports defined in Microsoft's RDL format (2008 or 2008 R2) as PDF, Word, Excel, PPT and HTML documents.

The important features of ASP MVC ReportWriter are listed as follows:

- RDL Specification - Supports RDL Specification for the SQL Server 2008 and RDL Specification for the SQL Server 2008 R2 only. List of available report definition formats msdn.microsoft.com/library/dd297486
- Data sources - You can use advanced database servers DataSources in ReportWriter (SQL and Oracle).

Copyright © 2001 - 2020 Syncfusion Inc.

- Charts - Show all basic types of Charts that are available in Microsoft RDL reports.
- Tablix - Shows the summaries and simple tables.
- Gauge - Shows measurement values by using expression values.
- Textbox - Shows textbox data with expression support.
- Export - Export report as PDF, Word, Excel, PPT and HTML.
- Report Parameter - Views the report based on the report parameter value.

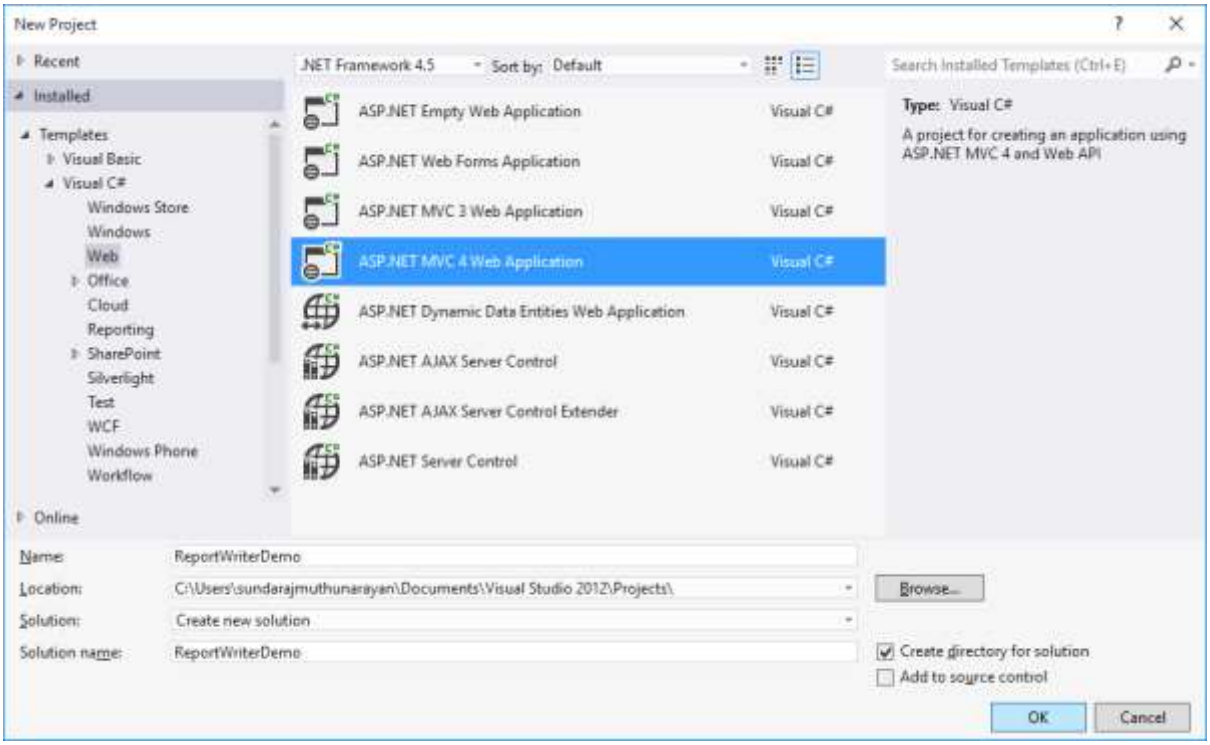
Getting Started with ASP.NET MVC Application

This section describes how to export the Report Server report as PDF, Word, Excel, PPT and HTML formats in ASP.NET MVC application using ReportWriter.

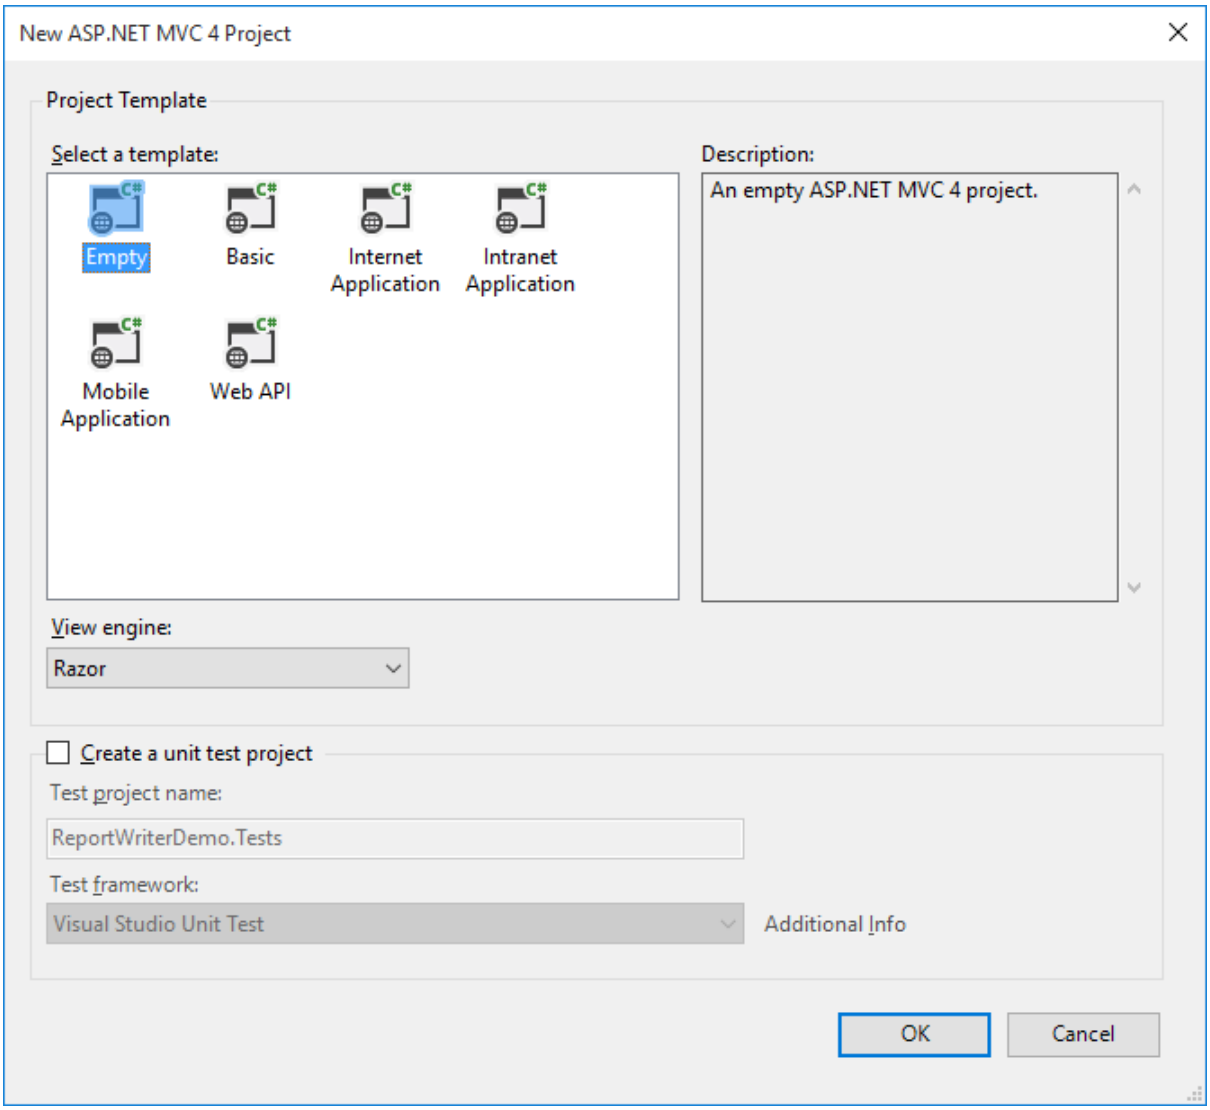
Project Creation

This section illustrates how to add ReportWriter to the ASP.NET MVC application. It includes the following steps.

1. Create a new ASP.NET MVC project by selecting the WEB category from the listed project template in Microsoft Visual Studio IDE.



2. The following screenshot displays how to select empty application template with razor view engine.

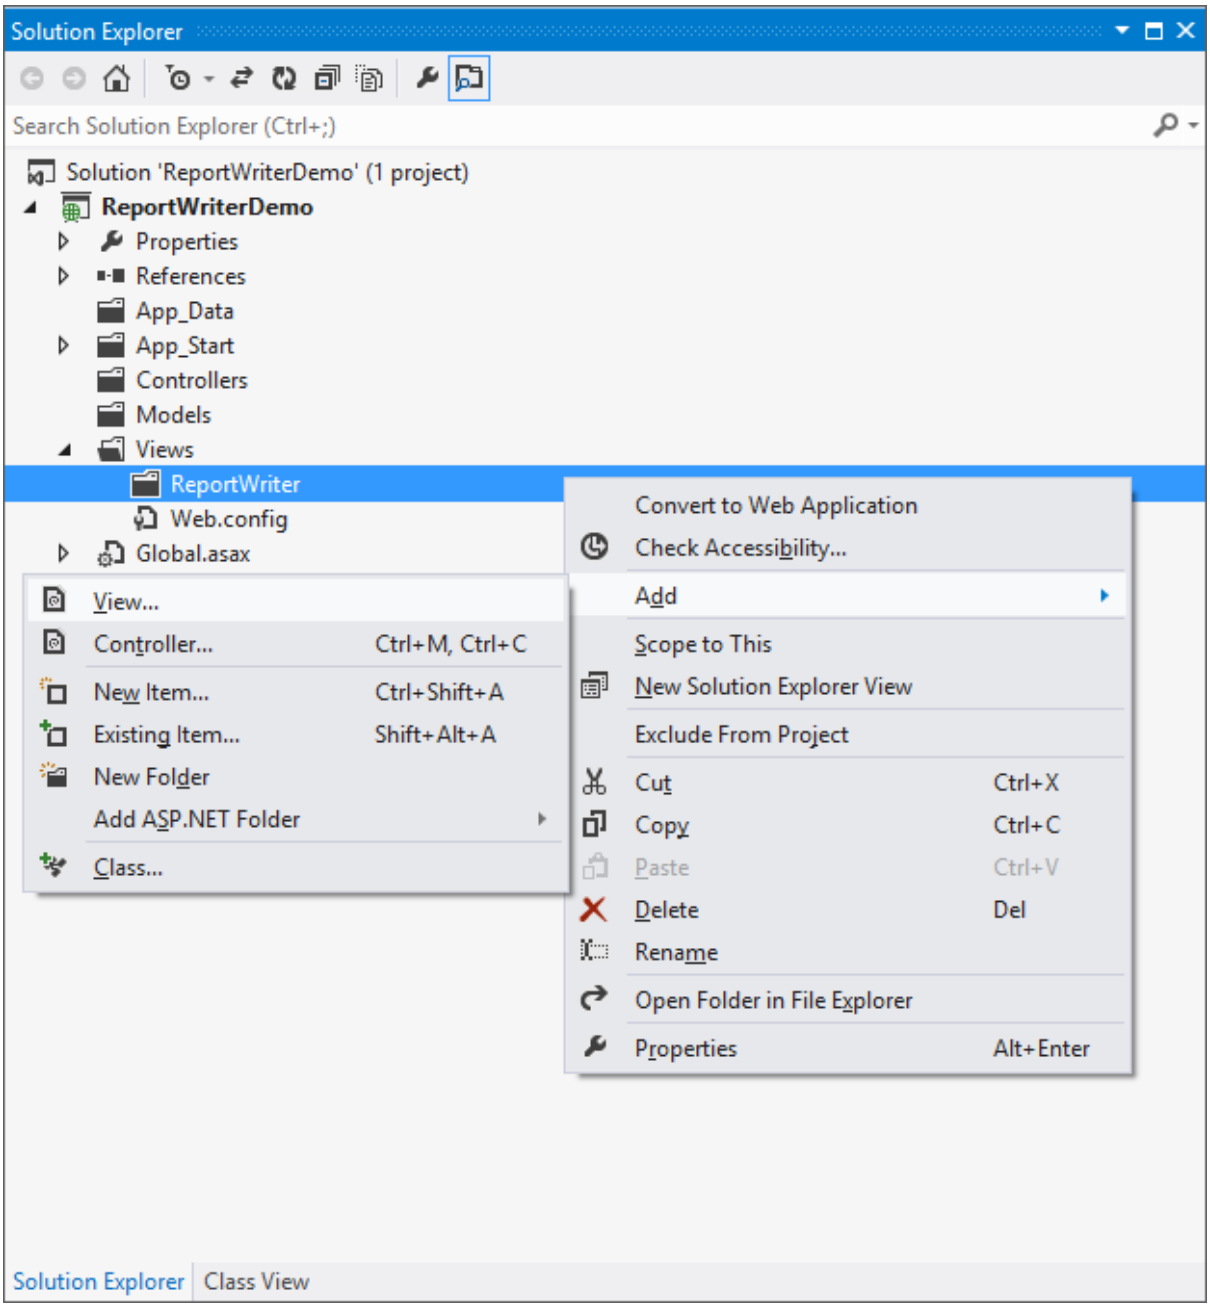


Create CSHTML Page

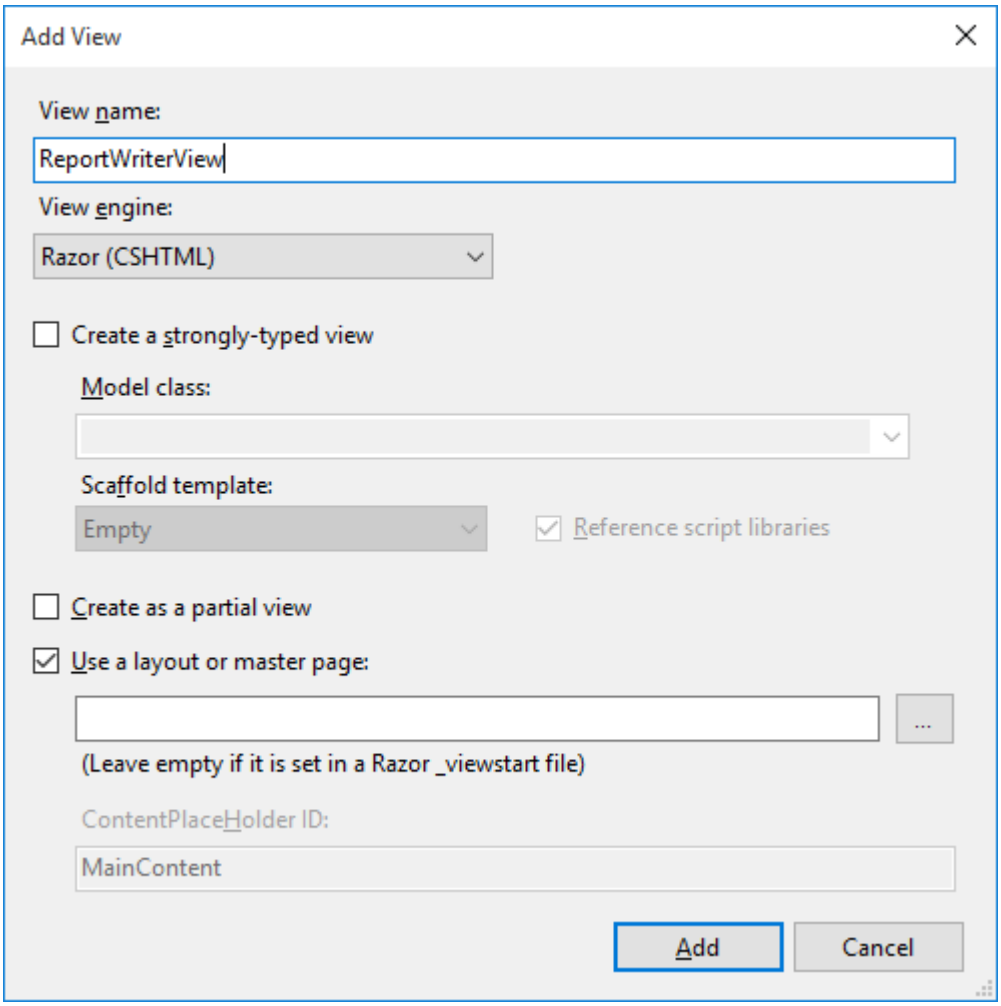
To create a new CSHTML view page in the application follow the below steps.

1. Right click on the ReportWriter folder from Views followed by Add and then click View.

Copyright © 2001 - 2020 Syncfusion Inc.

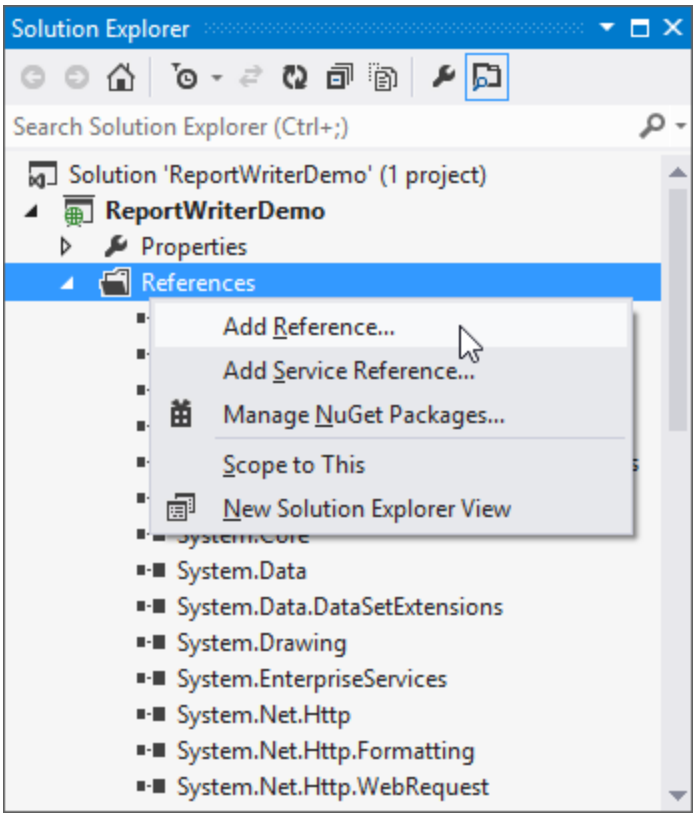


2. Specify the name and then click on OK.



Add References

1. In the Solution Explorer, Right-click the References folder and then click Add Reference.



2. Add the following references
    - Syncfusion.Chart.Wpf
    - Syncfusion.Compression.Base
    - Syncfusion.DocIO.Base
    - Syncfusion.EJ.ReportViewer
    - Syncfusion.Gauge.Wpf
    - Syncfusion.Linq.Base
    - Syncfusion.Pdf.Base
    - Syncfusion.SfMaps.Wpf
    - Syncfusion.Shared.Wpf
    - Syncfusion.XlsIO.Base

Note: Refer the above assemblies from the installed location, C:\Program Files (x86)\Syncfusion\Essential Studio\ASP.NET MVC\{{ site.releaseversion }}\Assemblies

Registering Assemblies within the Web.config file

In your application's root web.config file, add the below assembly information within the <assemblies> tag.

HTML

```
<system.web>
<compilation debug="true" targetFramework="4.5">
<assemblies>
<add assembly="Syncfusion.Chart.WPF, Version=14.1400.0.42,
Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
```

```
<add assembly="Syncfusion.Compression.Base, Version=14.1400.0.42,
Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
<add assembly="Syncfusion.DocIO.Base, Version=14.1400.0.42,
Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
<add assembly="Syncfusion.EJ.ReportViewer, Version=14.1400.0.42,
Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
<add assembly="Syncfusion.Gauge.WPF, Version=14.1400.0.42,
Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
<add assembly="Syncfusion.Linq.Base, Version=14.1400.0.42,
Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
<add assembly="Syncfusion.Pdf.Base, Version=14.1400.0.42,
Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
<add assembly="Syncfusion.SfMaps.WPF, Version=14.1400.0.42,
Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
<add assembly="Syncfusion.Shared.WPF, Version=14.1400.0.42,
Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
<add assembly="Syncfusion.XlsIO.Base, Version=14.1400.0.42,
Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
</assemblies>
</compilation>
</system.web>
```

Registering namespaces within Web.config

Now you need to register the below mentioned two namespaces in the web.config file present within the Views folder as well as the Root directory of your application.

- Syncfusion.EJ.ReportViewer

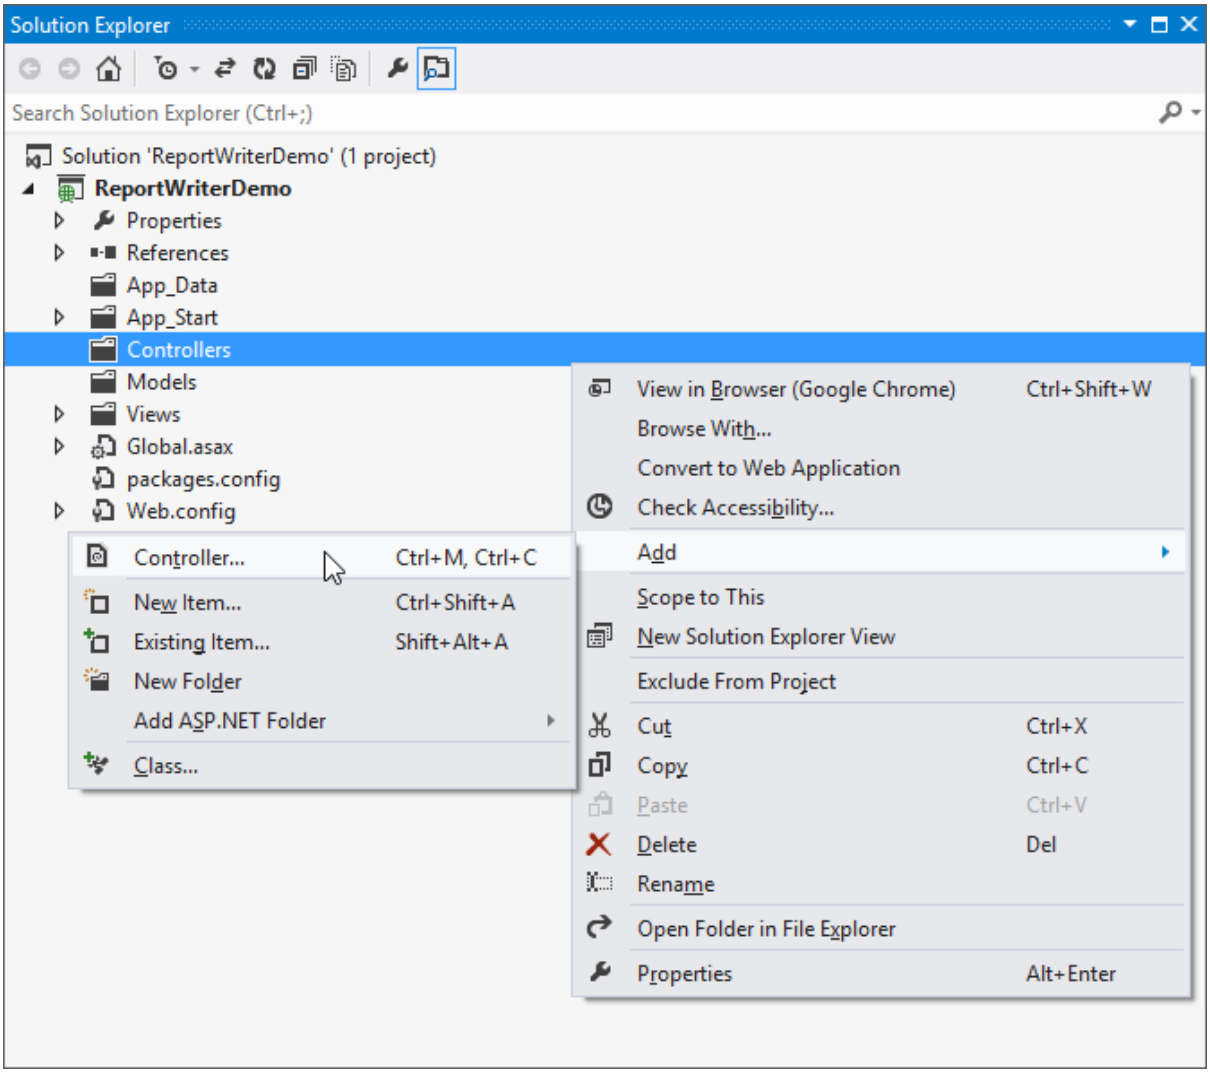
HTML

```
<namespaces>
<add namespace="System.Web.Mvc"/>
<add namespace="System.Web.Mvc.Ajax"/>
<add namespace="System.Web.Mvc.Html"/>
<add namespace="System.Web.Routing"/>
<add namespace="System.Web.WebPages"/>
<add namespace="Syncfusion.EJ.ReportViewer"/>
</namespaces>
```

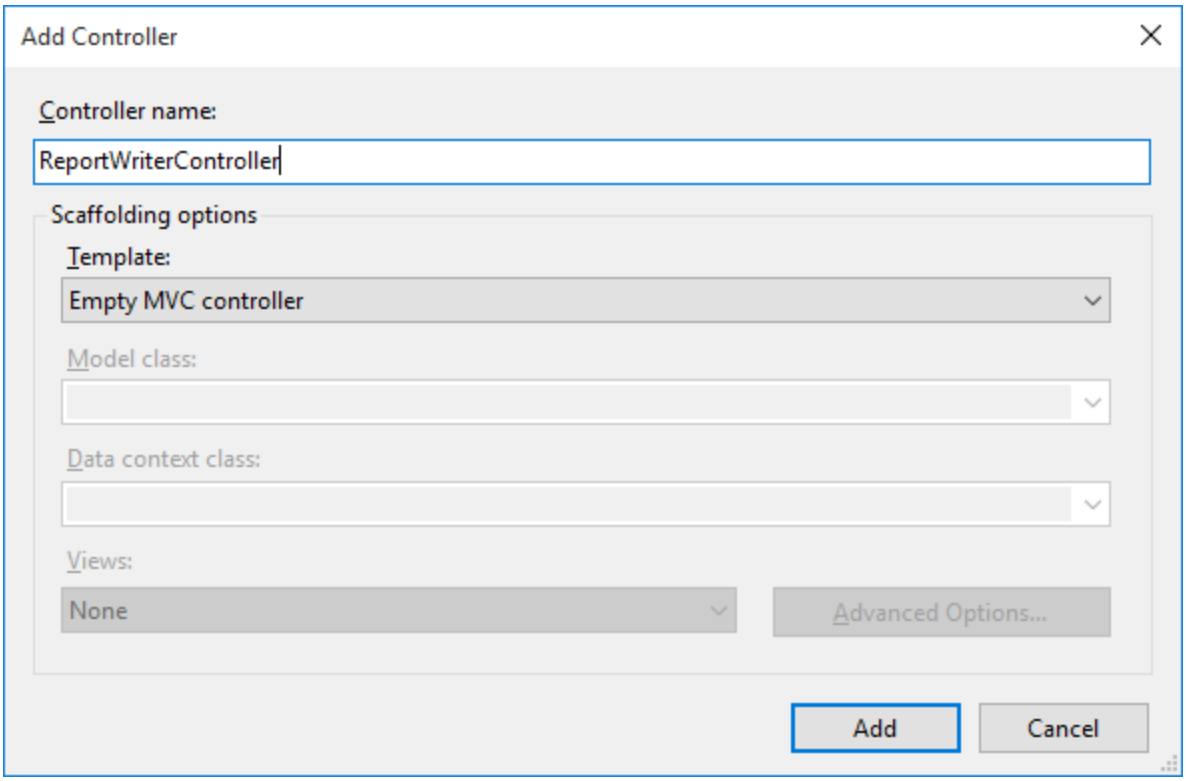
ReportWriter Initialization

1. Initialize ReportWriter by using the controller in the Application. To create a controller in the Application, please follow the below steps.

Copyright © 2001 - 2020 Syncfusion Inc.



2. Specify the name to the controller and then click on OK.



4. Set the following properties to ReportWriter.
    - ReportPath - Set the local file system or Report Server path of report.
    - ReportProcessingMode - Set ProcessingMode as Remote for RDL and Report Server report also Local for RDLC report.
    - WriterFormat - Set WriterFormat as PDF, Excel, Word and HTML.
5. Add the following code to the ReportWriter in the controller class.

CSHARP

```
public ActionResult Index(string writerFormat)
{
try
{
string fileName = null;
WriterFormat format;
HttpContext httpContext = System.Web.HttpContext.Current;
ReportWriter reportWriter = new ReportWriter();
reportWriter.ReportPath = Server.MapPath("~/App_Data/GroupingAgg.rdl");
reportWriter.ReportProcessingMode = ProcessingMode.Remote;
if (writerFormat == "PDF")
{
fileName = "GroupingAgg.pdf";
format = WriterFormat.PDF;
}
else if (writerFormat == "Word")
{
fileName = "GroupingAgg.doc";
format = WriterFormat.Word;
}
```

```
else if (writerFormat == "Html")
{
fileName = "GroupingAgg.Html";
format = WriterFormat.HTML;
}
else if (writerFormat == "PPT")
{
fileName = "GroupingAgg.ppt";
format = WriterFormat.PPT;
}
else
{
fileName = "GroupingAgg.xls";
format = WriterFormat.Excel;
}
reportWriter.Save(fileName, format, httpContext.Response);
}
catch
{
}
return View();
}
```

6. Add the following code example in the <body> tag of the CSHTML page to view ReportWriter export options.

HTML

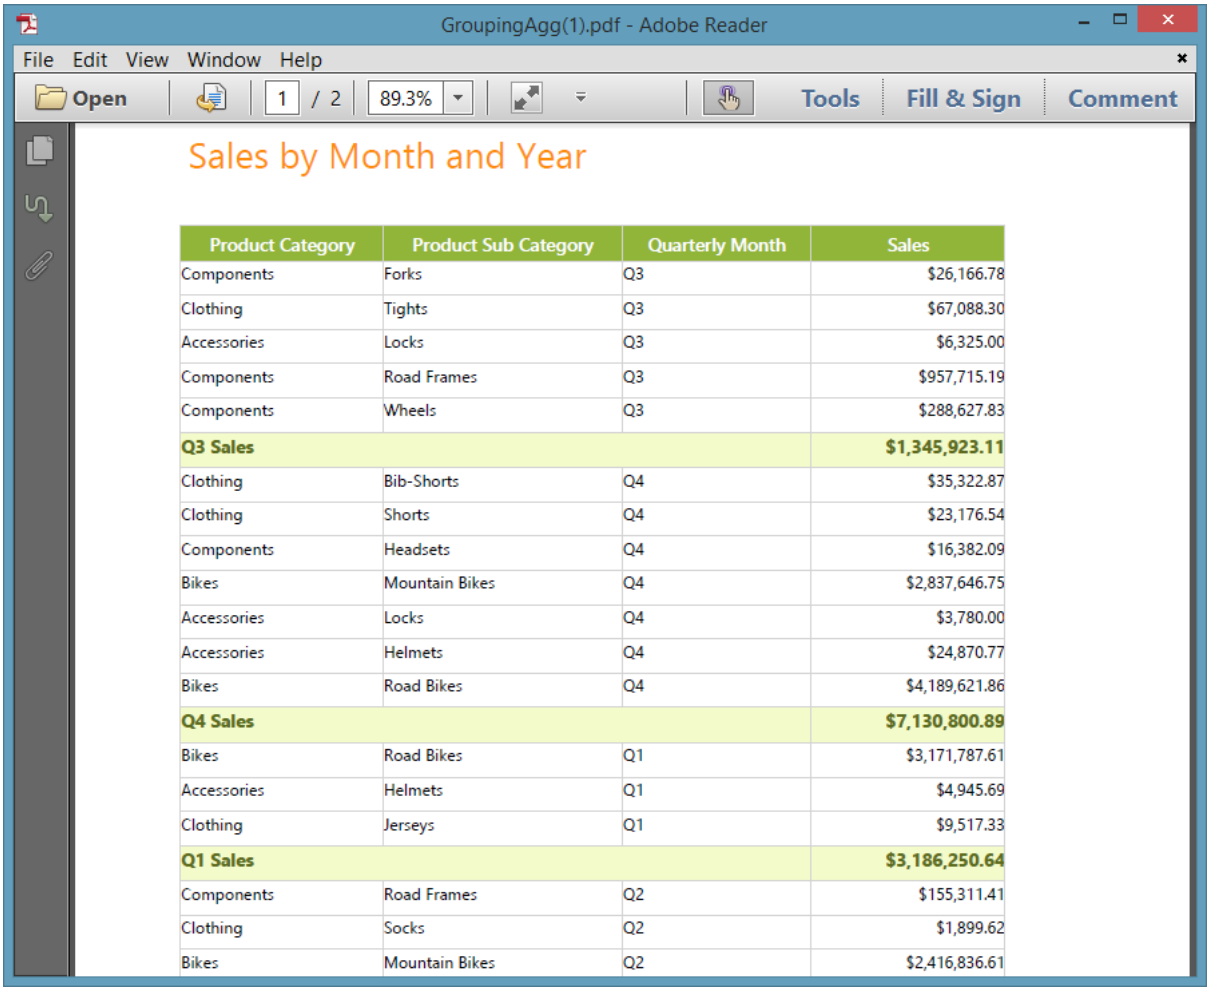
```
<body>
<div class="container">
<div class="header">
<span style="color: white; font-size: 2em">ReportWriter Demo</span>
</div>
<div class="content_section">
@{Html.BeginForm("Index", "ReportWriter", FormMethod.Post);
{
<div id="description_Pane" style="text-align: justify;">
<h3>Description</h3>
<span>
Essential ReportWriter is a powerful control for exporting RDL files into
specified
format files.The following are some of the key features of this
component: Provides
support for various chart types that include Area, Bar, Column, Pie,
Funnel, Radar, Line and
so on. Provides support for both Matrix and Table and also provides
support for
both single, and multi-level row groupings and column groupings. Provides
support
for other common controls such as Textbox, Image, Rectangle, Line and
both Circular
and Linear Gauges. Provides support for report parameter.
</span>
</div>
<div id="export_Pane" style="margin-top: 4%;">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<h3>Export Report</h3>
<span>
Choose a file format to view the selected document generated from Report
file by using Essential ReportWriter.
</span>
<div id="selection_Pane" style="margin-top: 2%;">
<span style="font-size:large;">
<strong>Save As : </strong>
</span>
<input type="radio" name="writerFormat" value="PDF" checked="checked" />
<label for="btnPDf">PDF </label>
<input type="radio" name="writerFormat" value="Word" />
<label for="btnWord">Word </label>
<input type="radio" name="writerFormat" value="xls" />
<label for="btnxls">Excel </label>
<input type="radio" name="writerFormat" value="Html" />
<label for="btnHtml">Html </label>
<input type="radio" name="writerFormat" value="PPT" />
<label for="btnHtml">PPT </label>
<input type="submit" name="button" value="Generate" style="width: 18%;
margin-left: 2%;"/>
</div>
</div>
Html.EndForm();
}
}
</div>
</div>
</body>
```

7. Run the application. The following output displays ReportWriter export options, Select the export option and click on Generate button.

8. The following output displays exported report in the PDF format.



Product Category	Product Sub Category	Quarterly Month	Sales
Components	Forks	Q3	$26,166.78
Clothing	Tights	Q3	$67,088.30

Bikes	Mountain Bikes	Q2	$2,416,836.61

Generate RDL Reports

The ReportWriter has options to save the RDL reports. The following code example helps you to generate the RDL report using ReportWriter.

Specify the `ReportPath`, `ReportProcessingMode` and `WriterFormat` properties for ReportWriter to generate report.

CSHARP

```
string reportPath = @"..\ReportTemplate\GroupingAgg.rdl";
ReportWriter reportWriter = new ReportWriter(reportPath);
reportWriter.ReportProcessingMode = ProcessingMode.Remote;
reportWriter.Save("GroupingAgg.xls", WriterFormat.Excel);
```

Generate RDLC Reports

The ReportWriter has support to view and save the RDLC reports. The following code helps you to bind data to ReportWriter.

1. Assign `ReportPath`, `ProcessingMode` and `ExportFormat` to ReportWriter.

CSHARP

Copyright © 2001 - 2020 Syncfusion Inc.

```
string reportPath = @"..ReportTemplate\RDLC\ProductCatalog.rdlc";
ReportWriter reportWriter = new ReportWriter(reportPath, dataSources);
reportWriter.ReportProcessingMode = ProcessingMode.Local;
reportWriter.Save("ProductCatalog.doc", WriterFormat.WORD);
```

2. Add Datasource to the RDLC report.

CSHARP

```
ReportDataSourceCollection dataSources = new
ReportDataSourceCollection();
dataSources.Add(new ReportDataSource { Name = "ProductCatalog", Value =
ProductCatalogSource.GetData() });
```

3. Assign values for the datasource which is given in the RDLC.

CSHARP

```
#region ProductCatalog Details
public class ProductCatalogSource
{
public string ProdSubCat { get; set; }
public string ProdModel { get; set; }
public string ProdCat { get; set; }
public string Description { get; set; }
public string ProdName { get; set; }
public string ProductNumber { get; set; }
public string Color { get; set; }
public string Size { get; set; }
public double? Weight { get; set; }
public double? StandardCost { get; set; }
public string Style { get; set; }
public string Class { get; set; }
public double? ListPrice { get; set; }
public static IList GetData()
{
List<ProductCatalogSource> datas = new List<ProductCatalogSource>();
ProductCatalogSource data = null;
data = new ProductCatalogSource()
{
ProdSubCat = "Road Frames",
ProdModel = "HL Road Frame",
ProdCat = "Components",
Description = "Our lightest and best quality aluminum frame made from the
newest alloy; it is welded and heat-treated for strength. Our innovative
design results in maximum comfort and performance.",
ProdName = "HL Road Frame - Black, 58",
ProductNumber = "FR-R92B-58",
Color = "Black",
Size = "58",
Weight = 2.24,
StandardCost = 1059.3100,
Style = "U ",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Class = "H ",
ListPrice = 1431.5000
};
datas.Add(data);
data = new ProductCatalogSource()
{
ProdSubCat = "Road Frames",
ProdModel = "HL Road Frame",
ProdCat = "Components",
Description = "Our lightest and best quality aluminum frame made from the
newest alloy; it is welded and heat-treated for strength. Our innovative
design results in maximum comfort and performance.",
ProdName = "HL Road Frame - Red, 58",
ProductNumber = "FR-R92R-58",
Color = "Red",
Size = "58",
Weight = 2.24,
StandardCost = 1059.3100,
Style = "U ",
Class = "H ",
ListPrice = 1431.5000
};
datas.Add(data);
data = new ProductCatalogSource()
{
ProdSubCat = "Helmets",
ProdModel = "Sport-100",
ProdCat = "Accessories",
Description = "Universal fit, well-vented, lightweight , snap-on visor.",
ProdName = "Sport-100 Helmet, Red",
ProductNumber = "HL-U509-R",
Color = "Red",
Size = "",
Weight = null,
StandardCost = 13.0863,
Style = "",
Class = "",
ListPrice = 34.9900
};
datas.Add(data);
return datas;
}
}
#endregion
```

Generate SSRS Reports

The ReportWriter has options to export the SSRS reports. The following code example helps you to generate the SSRS report using ReportWriter.

Specify the ReportPath, ReportServerUrl, ReportServerCredential, ReportProcessingMode and WriterFormat properties for ReportWriter to generate report.

CSHARP

```
HttpContext httpContext = System.Web.HttpContext.Current;
ReportWriter reportWriter = new ReportWriter();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
reportWriter.ReportPath = "45db67a0-3fd6-4684-b03c-aa640a521c97";
reportWriter.ReportServerUrl = "http://reportserver.syncfusion.com:80/";
reportWriter.ReportingServer = new ReportingServerExt();
reportWriter.ReportServerCredential = new
System.Net.NetworkCredential("guest", "demo");
reportWriter.ReportProcessingMode = ProcessingMode.Remote;
reportWriter.Save("GroupingAgg.doc", WriterFormat.Word,
httpContext.Response);
```

Exporting Reports

Essential ReportWriter provides support for Exporting a report as a PDF, Word, Excel, PPT and HTML documents with the help of the class ReportWriter. The report elements such as Tablix, matrices, charts, gauges, shapes, and text boxes are supported in this feature.

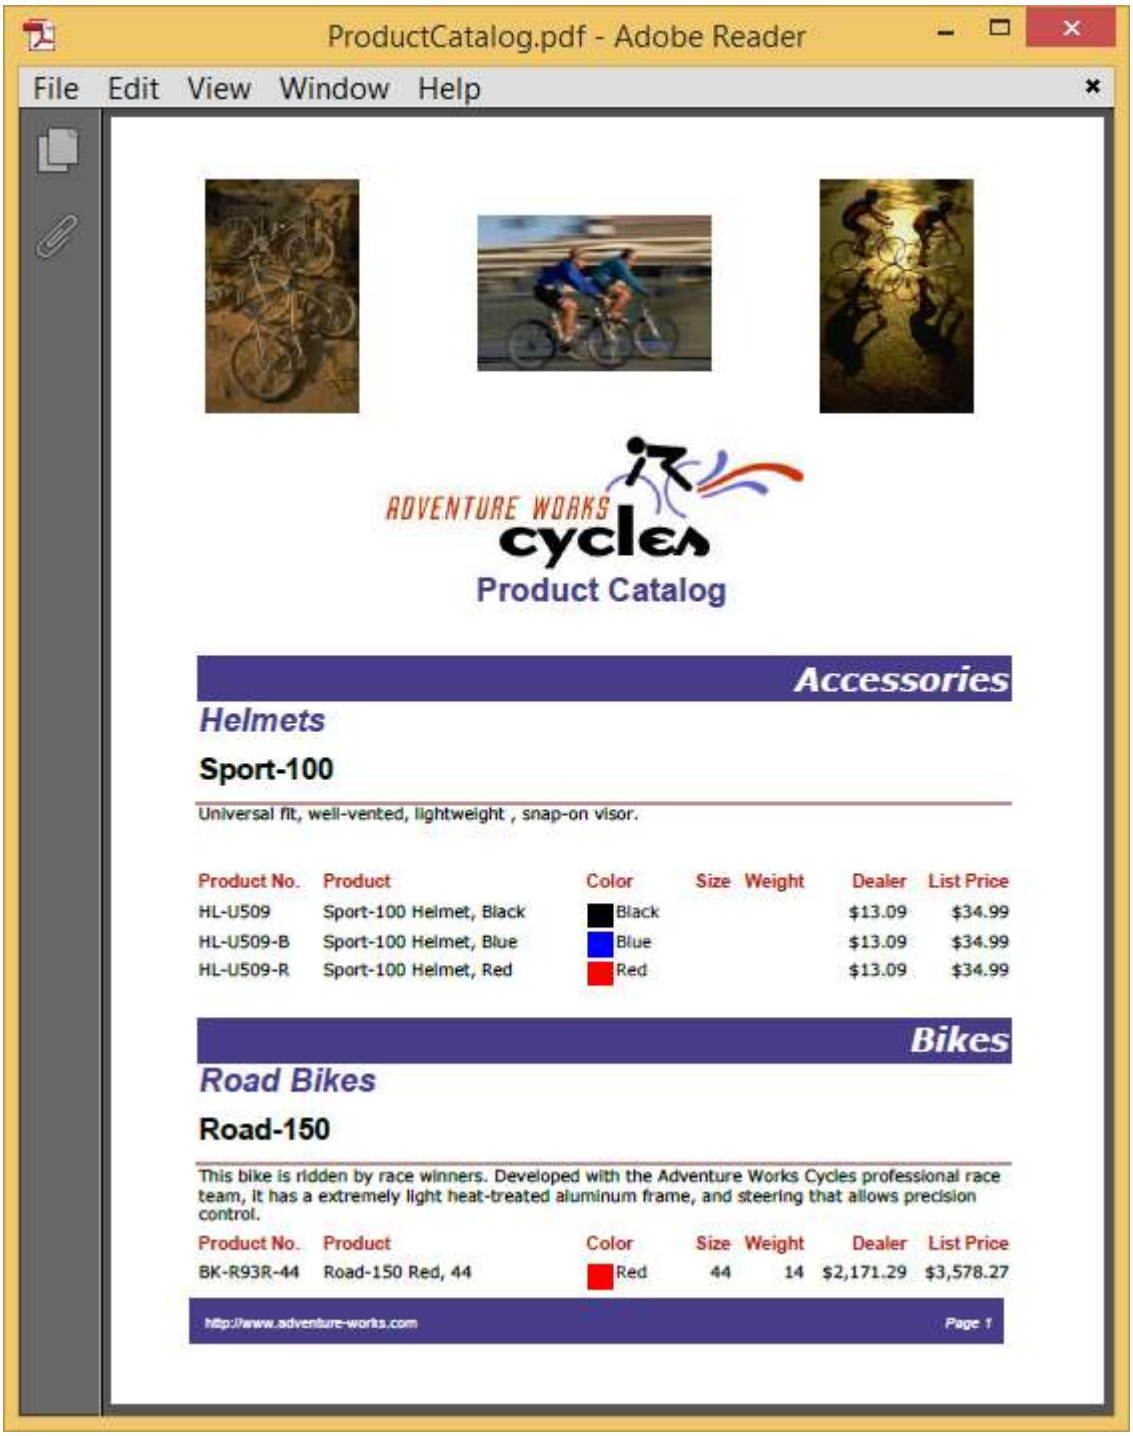
Exporting Report as PDF

The report used in ReportWriter can be exported as PDF document using the following code.

HTML

```
ReportWriter reportWriter = new ReportWriter(reportpath, dataSources);
reportWriter.Save("Sample.pdf", WriterFormat.PDF);
```

Copyright © 2001 - 2020 Syncfusion Inc.

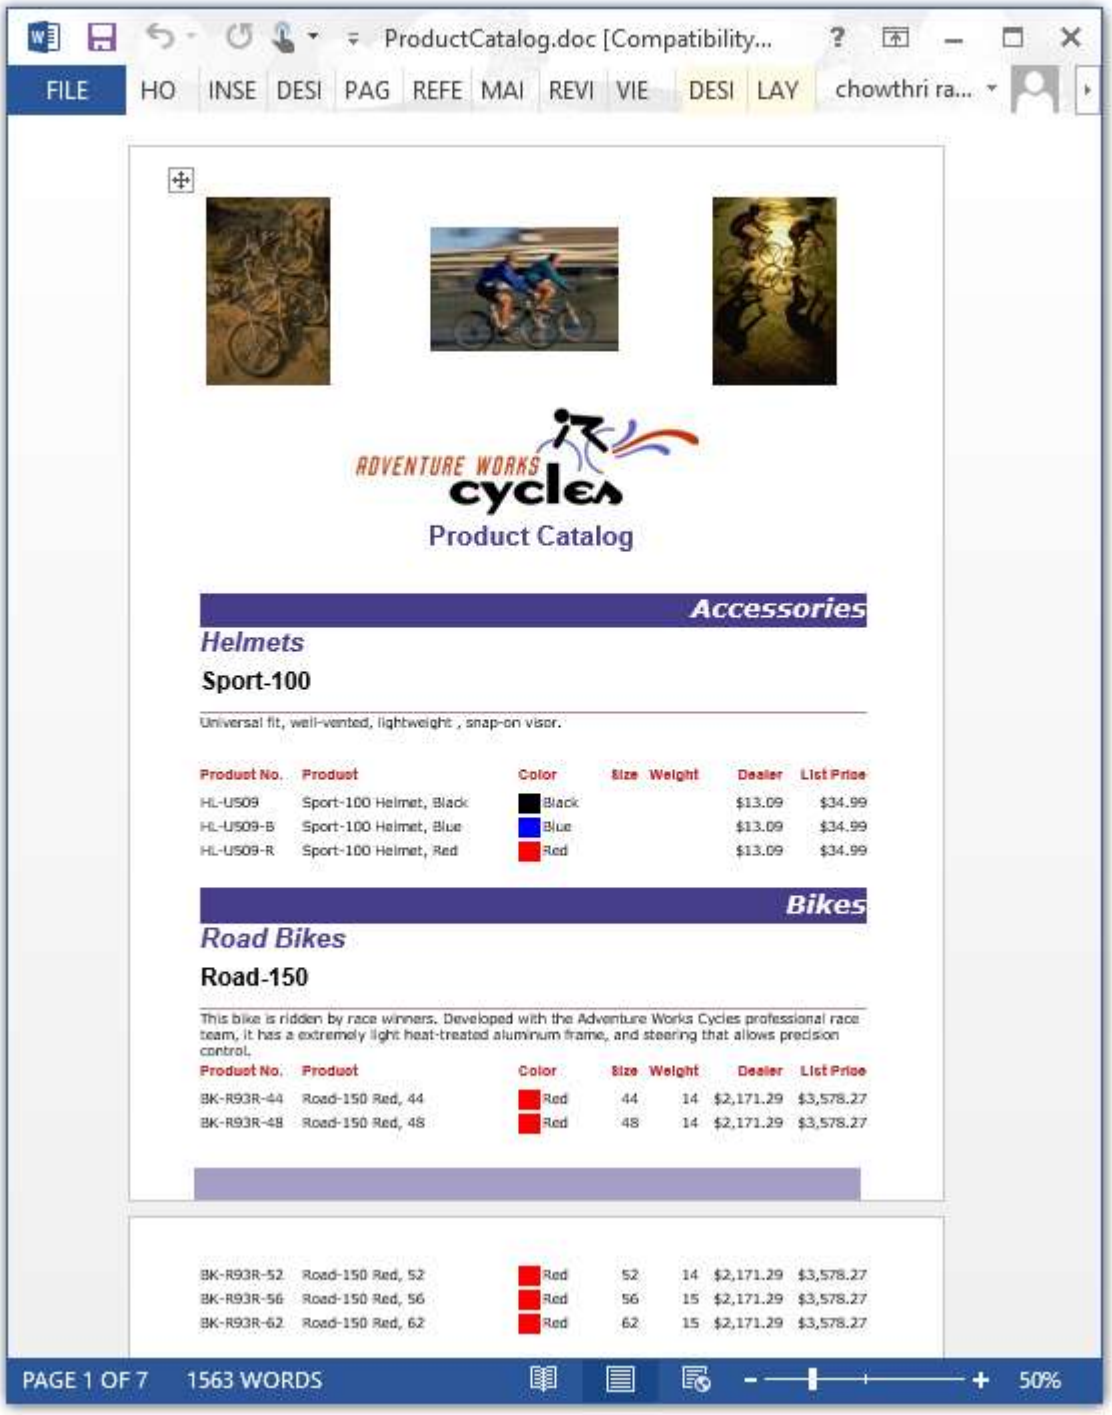


Exporting Report as Word

The report used in ReportWriter can be exported as Word document using the following code.

HTML

```
ReportWriter reportWriter = new ReportWriter(reportpath, dataSources);
reportWriter.Save("Sample.doc", WriterFormat.Word);
```



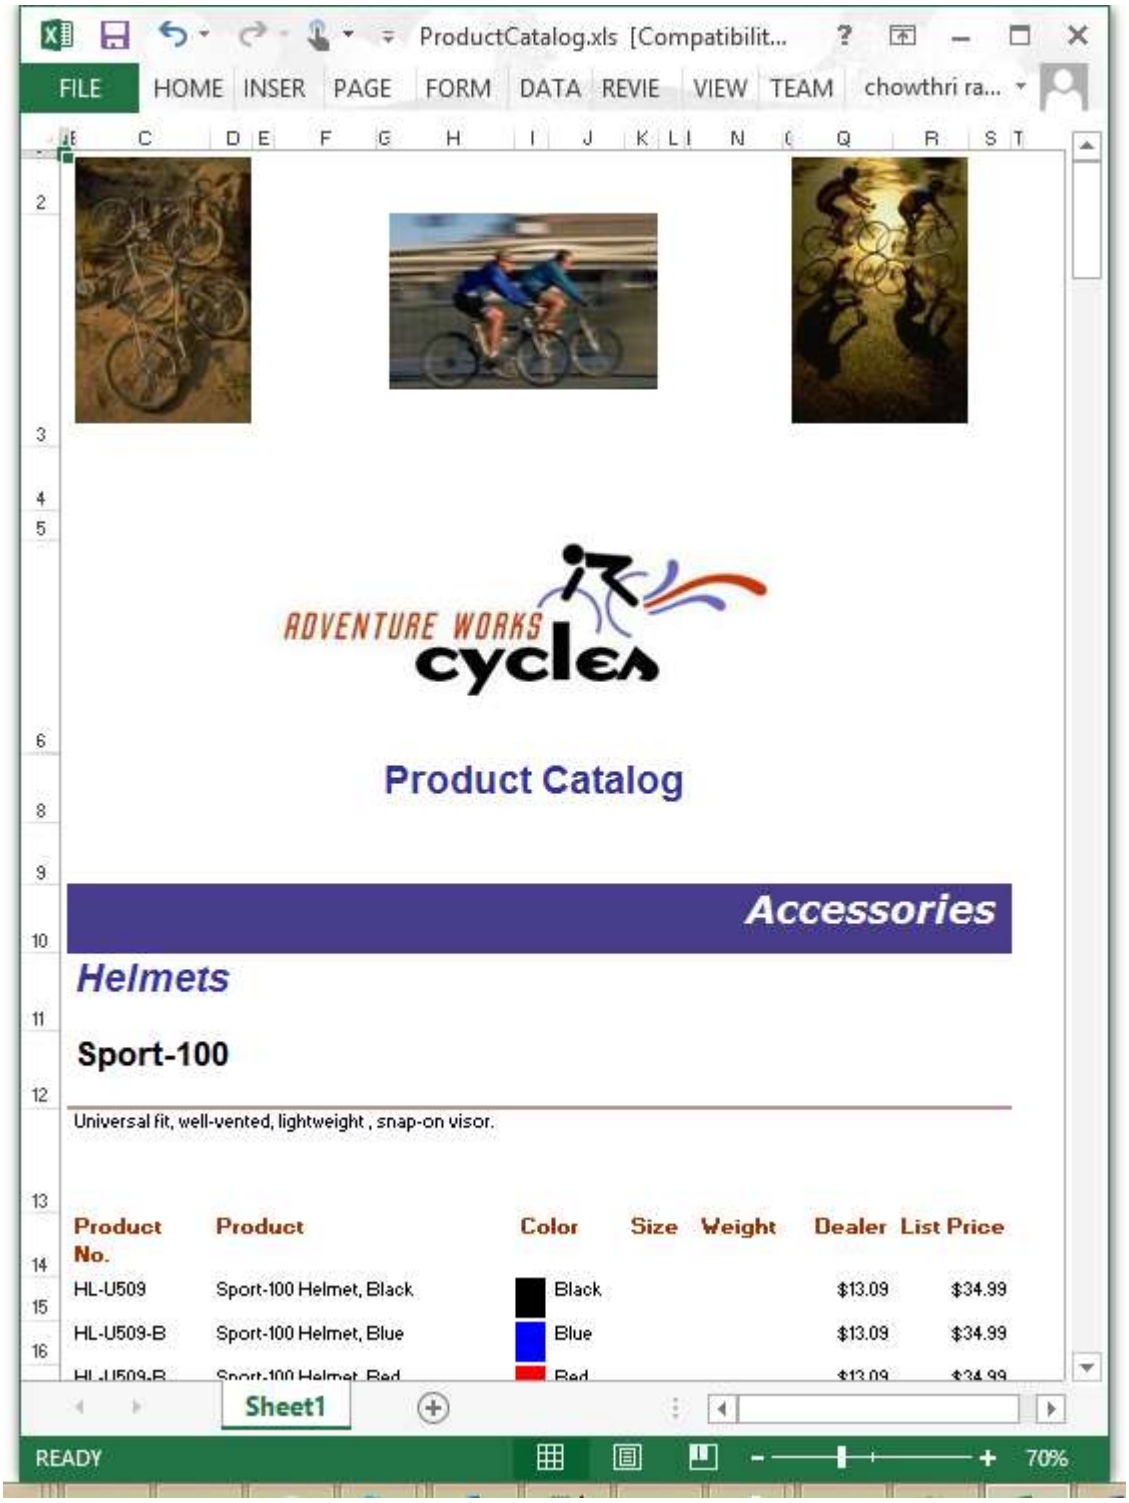
Exporting Report as Excel

The report used in ReportWriter can be exported as Excel document using the following code.

HTML

```
ReportWriter reportWriter = new ReportWriter(reportpath, dataSources);
reportWriter.Save("Sample.xls", WriterFormat.Excel);
```

Copyright © 2001 - 2020 Syncfusion Inc.

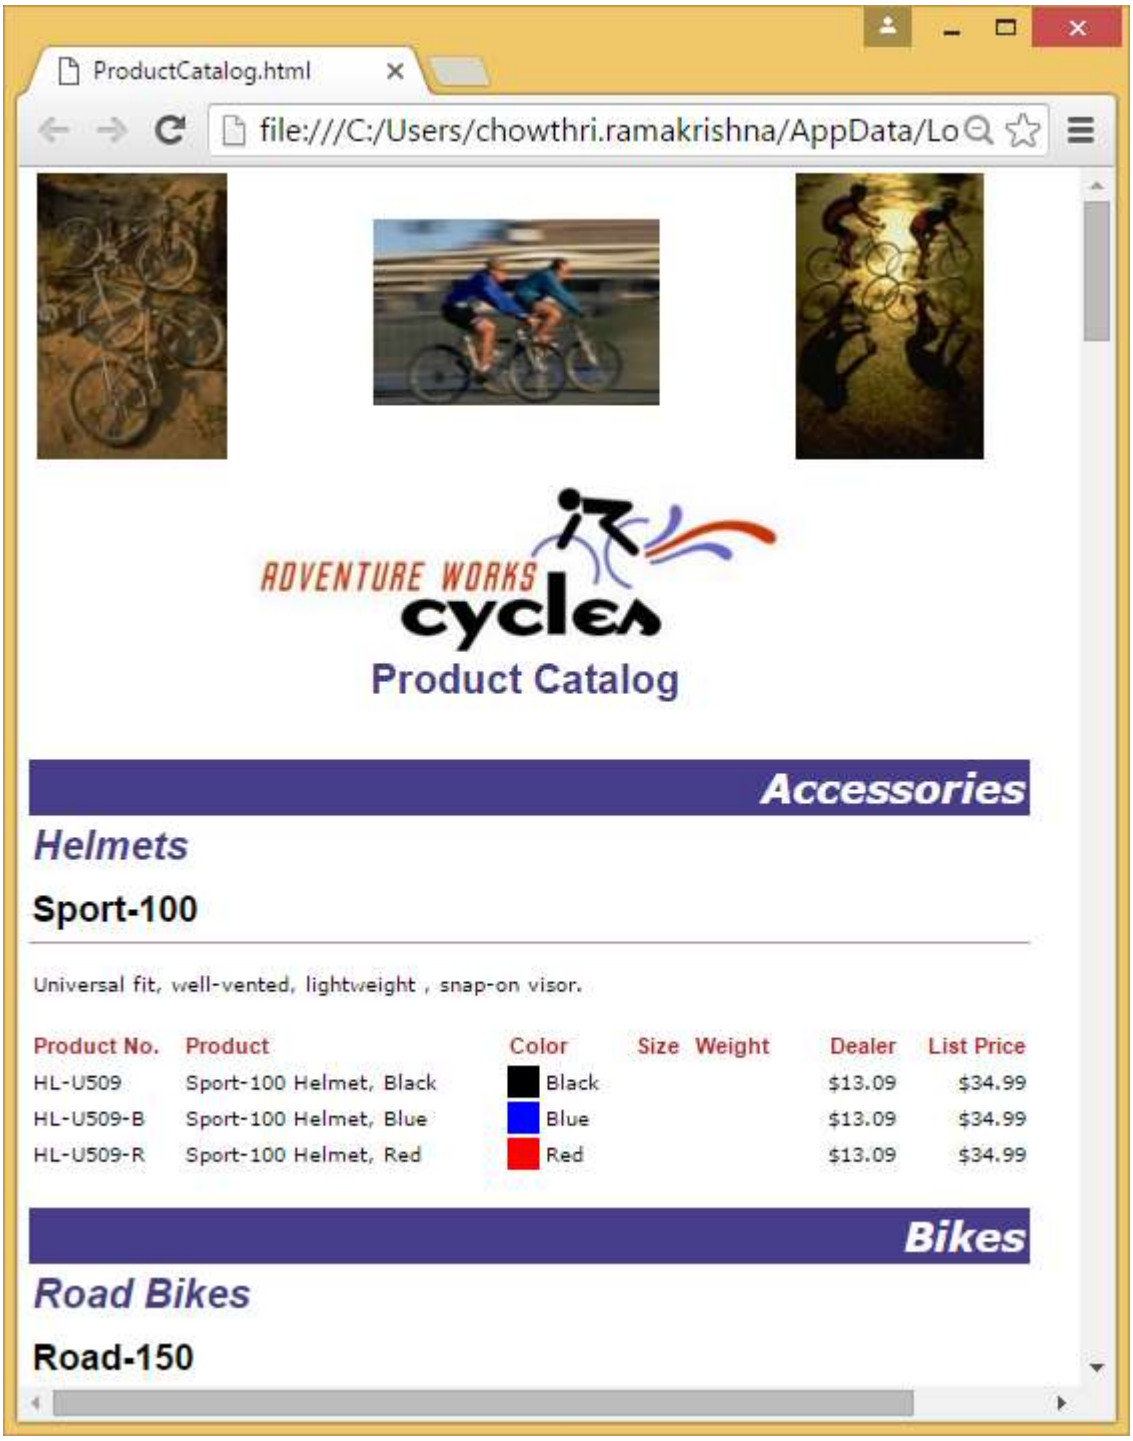


Exporting Report as HTML

The report used in ReportWriter can be exported as HTML document using the following code.

HTML

```
ReportWriter reportWriter = new ReportWriter(reportpath, dataSources);
reportWriter.Save("Sample.html", WriterFormat.HTML);
```



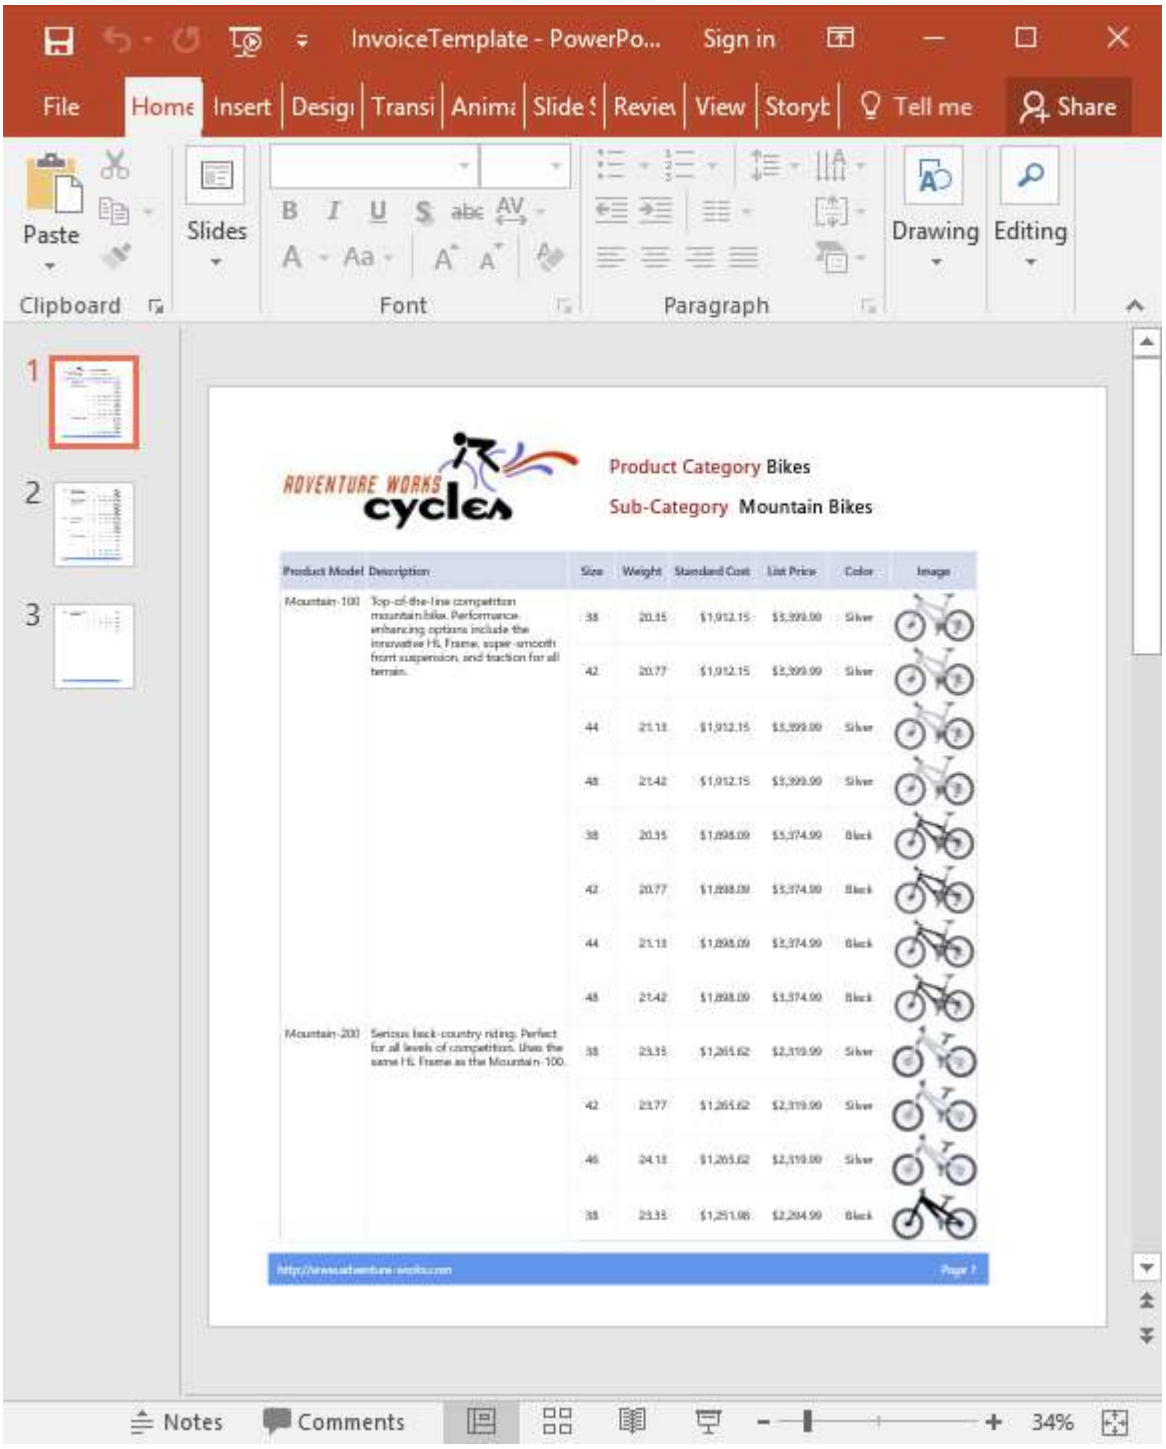
Exporting Report as PPT

The report used in ReportWriter can be exported as PPT document using the following code.

HTML

```
ReportWriter reportWriter = new ReportWriter(reportpath, dataSources);
reportWriter.Save("Sample.ppt", WriterFormat.PPT);
```

Copyright © 2001 - 2020 Syncfusion Inc.



ReportWriter API

Constructors

Name	Description
ReportWriter()	Initializes a new instance of the ReportWriter.

ReportWriter(string)	Initializes a new instance of the ReportWriter with the specified path of the report.
ReportWriter(stream)	Initializes a new instance of the ReportWriter with the stream of the report.
ReportWriter(string, ReportDataSourceCollection)	Initializes a new instance of the ReportWriter with the specified path of the report and data source collection.
ReportWriter(stream, ReportDataSourceCollection)	Initializes a new instance of the ReportWriter with the stream of the report and data source collection.

Properties

Property Name	Description
DataSources	Gets or sets the data source collection.
ReportPath	Gets or sets the report path (file name of the report with its full path).
ReportProcessingMode	Gets or sets the processing mode (either local or remote).
ReportServerCredential	Gets or sets the Report Server credential.
ReportServerFormsCredential	Gets or sets the Report Server form credential. This is used to export SQL Azure RDL reports.
ReportServerUrl	Gets or sets the ReportServerURL.

Methods

Name	Description
GetDataSetNames()	Returns the names of the data set as IList <string>.
GetParameters()	Returns the parameters of the report as ReportParameterInfoCollection.
SetParameters(IEnumerable<ReportParameters>)	Sets the parameters of the report.
LoadReport(stream)	Loads the report with the specified stream that contains the RDL contents.
Save(string,writer type)	Saves the report as a PDF, Word, Excel, PPT and HTML documents in the mentioned path.
Save(stream)	Saves the report as a PDF, Word, Excel, PPT and HTML documents in the stream.

Copyright © 2001 - 2020 Syncfusion Inc.

Events

Events	Description
ReportError	This event is triggered when Report throws Error.
ExportCompleted	This event is triggered when export is completed.
SubreportProcessing	This event is triggered when the report is RDLC and contains with subreport.

How To

How to

Save a Report as a Stream?

You can save a report as a stream using Save(Stream,WriterFormat) (overloaded method). This method is useful when generating the report on the server side and sending it to a client-side application. The following code explains how to save a report as a stream.

CSHARP

```
//Step 1: create the report data source
ReportDataSourceCollection dataSources = new
ReportDataSourceCollection();
dataSources.Add(new ReportDataSource() { Name = "Sales", Value =
GetDataSource() });
//Step 2: Instantiate the ReportWriter with the parameter "ReportPath"
and ReportDataSource Collection
ReportWriter reportWriter = new ReportWriter(reportPath, dataSources);
MemoryStream stream = new MemoryStream();
//Step 3: Save the report as PDF, Word or Excel document in the form of
stream contents
reportWriter.Save(stream, WriterFormat.PDF);
```

Ribbon

Overview

The Ribbon control for ASP.NET MVC provides with rich customizable user interfaces like Office 2010, SharePoint 2010, and Office Web Apps 2010. The Ribbon Tab appears across the top of the page. Each Tab organizes a set of groups that has labels to identify them and also contains a set of controls and group expander.

Key Feature

- **Application Tab** -Represents the menu commands which can used to do any operations, like file related commands.Supports Application Menu and Backstage.
- **Tabs** – Related groups are combined into Tabs for quick and easy access.
- **Contextual Tabs** - Allows to group number of Tabs based on some criteria.
- **Controls' support** -Supports Button, Split button and Dropdown List, Toggle button, and custom controls in the Ribbon groups.
- **Gallery** - Convenient way to visually display related options with text/images.
- **Resize** – Provides resizing to group controls dynamically based on window size.
- **Expand and Collapse** -Ribbon can be expanded and collapsed using expand/collapse button.

Copyright © 2001 - 2020 Syncfusion Inc.

- **Screen-Tip** -Supports HTML and enhanced custom tooltips for controls of Ribbon groups.
- **Theme** - **ASP.NET MVC** controls consist of 12 built-in themes (6 – flat and 6 – gradient effects). It also supports bootstrap theme.

Getting Started

This section explains briefly how to create a Ribbon in your application with ASP.NET MVC. You can refer MVC Getting Started documentation to create new project and add necessary dll's and script files.

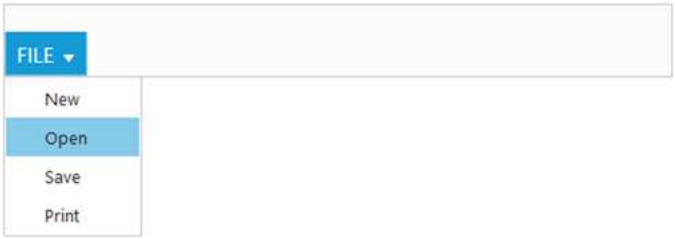
Control Initialization

Ribbon can be initialized with ApplicationTab and UL list is needed for binding Menu to application Menu which can be specified through MenuItemID which denotes Id of UL.

Define the Application Tab with Type as Menu to render simple Ribbon control.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app => {
app.Type(ApplicationTabType.Menu).MenuItemID("Ribbon").MenuSettings(new
MenuProperties() {
OpenOnClick = false
});
}))
<ul id="Ribbon">
<li>
<a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Open</a></li>
<li><a>Save</a></li>
<li><a>Save As</a></li>
<li><a>Print</a></li>
</ul>
</li>
</ul>
```



Note: Set the required Width to Ribbon, else default parent container or window Width will be considered.

Adding Tabs

RibbonTab is a set of related groups which are combined into single item. For creating Tab, Id and Text properties should be specified.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app => {
app.Type(ApplicationTabType.Menu).MenuItemID("Ribbon").MenuSettings(new
MenuProperties() {
OpenOnClick = false
});
})
.RibbonTabs(tab => {
tab.Id("home").Text("HOME").TabGroups(tabgroup => {}).Add();
})
)
<ul id="Ribbon">
<li>
<a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Open</a></li>
<li><a>Save</a></li>
<li><a>Save As</a></li>
<li><a>Print</a></li>
</ul>
</li>
</ul>
```

Configuring Groups

List of controls are combined as logical ContentGroups into RibbonTabs. TabGroup alignment type as “Rows/Columns”, Default is Rows.

Create TabGroup item with Text specified and add ContentGroup to ContentGroup collection with Button control settings.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app => {
app.Type(ApplicationTabType.Menu).MenuItemID("Ribbon").MenuSettings(new
MenuProperties() {
OpenOnClick = false
});
})
.RibbonTabs(tab => {
tab.Id("home").Text("HOME").TabGroups(tabgroup => {
tabgroup.Text("New").AlignType(RibbonAlignType.Rows).Content(ctn => {
ctn.ContentGroups(contentGroup => {
contentGroup.Id("new").Text("New").ButtonSettings(new ButtonProperties()
{
ContentType = ContentType.ImageOnly,
ImagePosition = ImagePosition.ImageTop,
PrefixIcon = "e-icon e-Ribbon e-new",
```

```
Click = "executeAction"
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.Button).Width("60px").Height("70px")).Add();
}).Add();
}).Add();
}))
<ul id="Ribbon">
<li>
<a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Open</a></li>
<li><a>Save</a></li>
<li><a>Save As</a></li>
<li><a>Print</a></li>
</ul>
</li>
</ul>
}
@section StyleSection{
<link href="~/Content/ej/Ribbon-css/ej.icons.css" rel="stylesheet" />
}
```

Adding Controls to Group

Syncfusion ASP.NET MVC Controls can be added to TabGroup's content with corresponding Type specified like Button, SplitButton, ToggleButton, DropDownList, Gallery, Custom, etc. Default type is Button.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app => {
app.Type(ApplicationTabType.Menu).MenuItemID("Ribbon").MenuSettings(new
MenuProperties() {
OpenOnClick = false
});
})
.RibbonTabs(tab => {
tab.Id("home").Text("HOME").TabGroups(tabGroup => {
tabGroup.Text("SplitButton &
Dropdown").AlignType(RibbonAlignType.Columns).Content(ctn => {
ctn.ContentGroups(contentGroup => {
contentGroup.Id("paste").Text("Paste").SplitButtonSettings(new
SplitButtonProperties() {
ContentType = ContentType.ImageOnly,
PrefixIcon = "e-icon e-Ribbon e-Ribbonpaste",
TargetID = "pasteSplit",
ArrowPosition = ArrowPosition.Bottom,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
ButtonMode = ButtonMode.Dropdown
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.SplitButton).Width("50px").Height("70px")).Add()
;
ctn.ContentGroups(contentGroup => {
contentGroup.Id("fontFamily").DropdownSettings(new
DropDownListProperties() {
DataSource = (IEnumerable < FontFamily > ) ViewBag.datasource,
Text = "Segoe UI",
Select = "executeAction",
Width = "150px"
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.DropDownList).Height("28px")).Add();
}).Add();
}).Add();
}))
<ul id="Ribbon">
<li>
<a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Open</a></li>
<li><a>Save</a></li>
<li><a>Save As</a></li>
<li><a>Print</a></li>
</ul>
</li>
</ul>
<ul id="pasteSplit">
<li><a>Paste</a></li>
</ul>
}
@section StyleSection{
<link href="~/Content/ej/Ribbon-css/ej.icons.css" rel="stylesheet" />
<style>
.e-pastetip {
background-image: url("../Content/ej/common-images/Ribbon/paste.png");
background-repeat: no-repeat;
height: 64px;
width: 64px;
}
</style>
}
```

C#

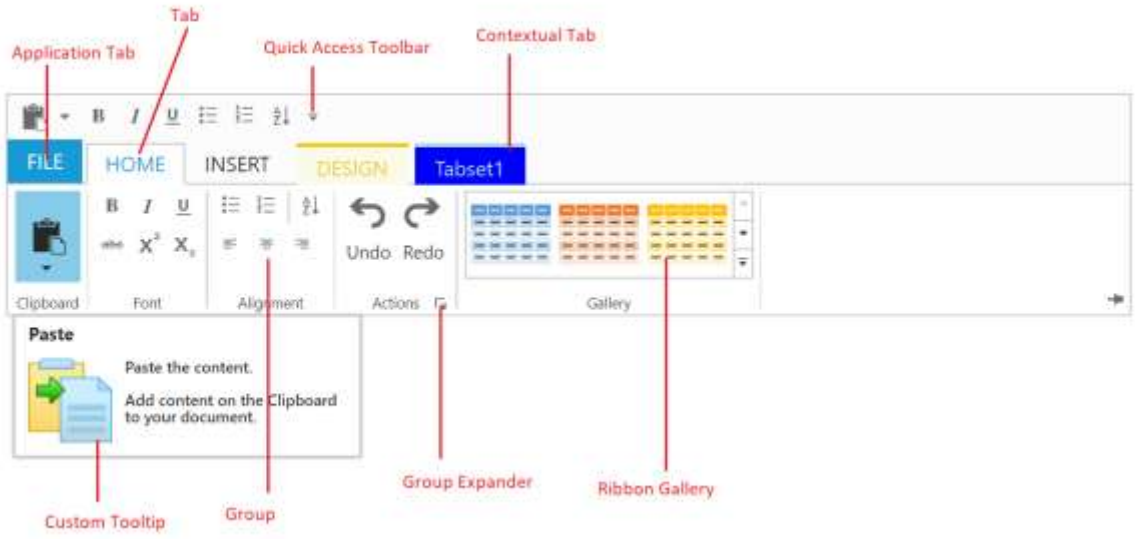
```
public partial class RibbonController: Controller
{
List<FontFamily> fontFamily1 = new List<FontFamily>();
List<FontPoint> fontPoint1 = new List<FontPoint>();
public ActionResult RibbonFeatures()
{
fontFamily1.Add(new FontFamily { text = "Segoe UI" });
fontFamily1.Add(new FontFamily { text = "Arial" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
fontFamily1.Add(new FontFamily { text = "Times New Roman" });
fontFamily1.Add(new FontFamily { text = "Tahoma" });
fontFamily1.Add(new FontFamily { text = "Helvetica" });
ViewBag.datasource = fontFamily1;
return View();
}
}
```

User Interface

Ribbon component able to integrate any custom components and customized their functionality in application end. Our Ribbon component is similar to Microsoft products(Word). The Ribbon UI consists of several sections like Application Tab, Quick Access Toolbar, Tab, Contextual Tab, Gallery and etc.The following screenshot shows the diagrammatic detail of Ribbon UI:



From above screenshot, you can see Ribbon has several subcomponents for different functionalities. The upcoming sections explains the brief details of each functionalities and their customizations.

Ribbon Dependencies

ej.web.all.js is a bundle of all *ASP.NET MVC* controls. When you use *ej.web.all.js* in your application, you can leave this section or else you can try to render *Ribbon* in your application by using *ej.ribbon* file. You can refer to the following frameworks and controls in your project.

Ribbon Dependency

FilesÂ Â Â Â Â Â Â Â Â Â Â Â Â Â	Description/Usage

Copyright © 2001 - 2020 Syncfusion Inc.

ej.core.min.js	Must always be referred to before using all the *ASP.NET MVC*controls.
ej.data.min.js	Used to handle data manger operation and should be used while binding data to *ASP.NET MVC* controls.
ej.globalize.min.js	Must be referred to localize any of the JS control's text and content.
ej.ribbon.min.js	Should be referred when using *Ribbon*control.
ej.waitingpopup.min.js	This file is used to render waiting popup when on-demand functionality is enabled in *Ribbon*control.
ej.menu.min.js	This file is used to render menu in the application tab.
ej.scroller.min.js	This file is used to render scroller in the *Ribbon* control.
ej.checkbox.min.js	This file is used to render checkboxes in the *Ribbon* control.
ej.tab.min.js	This file is used to render tabs into the *Ribbon* control.
ej.dropdownlist.min.js	These files are used to render button,split button,toggle button, and dropdown list controls in the ribbon groups.
ej.splitbutton.min.js	
ej.button.min.js	
ej.togglebutton.min.js	

Application Tab

The Application Tab is used to represent a Menu that do some operations, such as File Menu to create, open, and print documents. Application Tab classified by Type property with the following:

Menu Backstage

Application Menu

The Application Menu is similar to traditional file Menu options and Syncfusion Menu control is used internally to render this. To show Application Menu in Ribbon, set the Type as Menu and MenuSettings to customize properties of ejMenu.

*_Create Using Template_*

Set the UL element Id to MenuItemID property to create Application Menu and it will acts as template to render Menu.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app=> {
app.Type(ApplicationTabType.Menu).MenuItemID("Ribbon").MenuSettings(new
MenuProperties() {
OpenOnClick = false
});
})
.RibbonTabs(tab => {
tab.Id("home").Text("HOME").TabGroups(tab => {

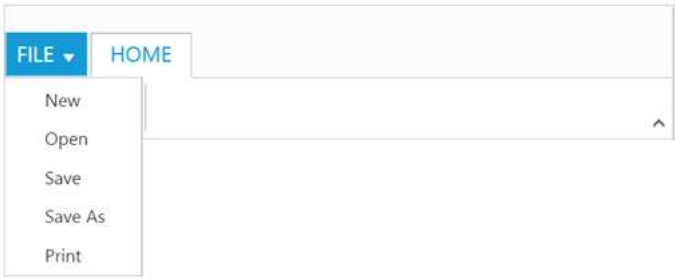
</ul>
</li>
</ul>
```



*_Binding Data Source_*

Application Menu can be rendered using JSON Data Source. Please refer this page to set data source to ejMenu.

ASPX-CS

```
@(Html.EJ().Ribbon("MenuJson")
.Width("500")
.ApplicationTab(app => {
app.Type(ApplicationTabType.Menu).MenuItemID("Ribbon").MenuSettings(new
MenuProperties() {
OpenOnClick = true,
MenuFields = new MenuFields() {
DataSource = (IEnumerable < MenuJson > ) ViewBag.datasource,
Text = "text",
ParentId = "parent",
Id = "id"
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
});
})
.RibbonTabs(tab => {
tab.Id("home").Text("HOME").TabGroups(tab => {
tab.Text("New").AlignType(RibbonAlignType.Rows).Content(ctn => {
ctn.ContentGroups(contentGroup => {
contentGroup.Id("new").Text("New").ButtonSettings(new ButtonProperties()
{
ContentType = ContentType.ImageOnly,
ImagePosition = ImagePosition.ImageTop,
PrefixIcon = "e-icon e-Ribbon e-new",
Click = "executeAction"
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.Button).Width("60px").Height("70px")).Add();
}).Add();
}).Add();
})
<ul id="Ribbon"></ul>
}
@section StyleSection{
<link href="~/Content/ej/Ribbon-css/ej.icons.css" rel="stylesheet" />
}
```

C#

```
public partial class RibbonController : Controller
{
List<MenuJson> Ribbon = new List<MenuJson>();
public ActionResult Methods()
{
Ribbon.Add(new MenuJson { id = 1, parent = null, text = "File" });
Ribbon.Add(new MenuJson { id = 11, parent = "1", text = "Open" });
Ribbon.Add(new MenuJson { id = 12, parent = "1", text = "Save" });
Ribbon.Add(new MenuJson { id = 121, parent = "12", text = "Save As" });
Ribbon.Add(new MenuJson { id = 122, parent = "12", text = "Save All" });
ViewBag.datasource = Ribbon;
return View();
}
public class MenuJson
{
public string text { get; set; }
public int id { get; set; }
public string parent { get; set; }
}
}
}
```

Backstage Page

The Backstage page is where documents and related data of those can be managed, such as Create, Save and other information.

The Backstage page has a feature to add custom Control in left side of the page which contains menu items and the right side contains corresponding user controls.

You can set Application Tab `Type` as `Backstage` and set `Id` , `Text` to Backstage items. Backstage `Pages` can be added with required `ItemType` and `ContentID` as template id to render template into Backstage.

Separator between Backstage items can be enabled by setting `EnableSeparator` as true. Width of backstage side header can be customized using `HeaderWidth`, If not set based on content given width will be considered.

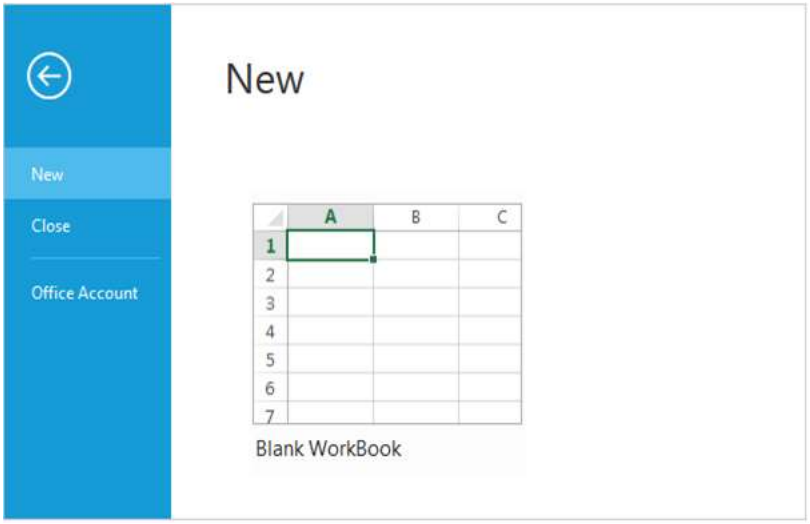
To render the Ribbon with the Backstage page, refer to the following code snippet.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app => {
app.Type(ApplicationTabType.Backstage).BackstageSettings(bsSettings => {
bsSettings.Text("FILE").Height("350").Width("100%").HeaderWidth("120").Pa
ges(bsPage => {
bsPage.Id("new").Text("New").ContentID("newCon").Add();
bsPage.Id("close").Text("Close").EnableSeparator(true).ItemType(ItemType.
Button).Add();
bsPage.Id("account").Text("Office
Account").ContentID("accountCon").Add();
});
});
})
.RibbonTabs(tab => {
tab.Id("home").Text("HOME").TabGroups(tab => {
tab.Text("New").AlignType(RibbonAlignType.Rows).Content(ctn => {
ctn.ContentGroups(contentGroup => {
contentGroup.Id("new").Text("New").ButtonSettings(new ButtonProperties()
{
ContentType = ContentType.ImageOnly,
ImagePosition = ImagePosition.ImageTop,
PrefixIcon = "e-icon e-ribbon e-new",
Click = "executeAction"
}).Add();
}).Add();
}).Add();
}).Add();
})
.ClientSideEvents(event => event.Create("createControl")))
<div id="newCon">
<table>
<tr>
<td><button id="btn1" class="e-bsnewbtnstyle">Blank
WorkBook</button></td>
</tr>
</table>
</div>
@section ScriptSection{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script>
function createControl(args) {
$("#btn1").ejButton({
size: "large",
height: 200,
width: 225,
contentType: "textandimage",
imagePosition: "imagetop",
prefixIcon: "e-icon e-blank e-infopageicon"
});
}
</script>
}
@section StyleSection{
<link href="~/Content/ej/ribbon-css/ej.icons.css" rel="stylesheet" />
<style>
.e-blank {
background-image: url("../Content/ej/common-images/ribbon/blank.png");
}
.e-infopageicon {
background-repeat: no-repeat;
height: 150px;
width: 198px;
}
.e-newpageicon {
background-repeat: no-repeat;
height: 42px;
width: 42px;
}
</style>
}
```



Note: Height & Width of backstage can be set using Height and Width, if these are not set, Ribbon's Height & Width will be considered

You can add/remove/update backStage item to the ribbon control by using addBackStageItem, removeBackStageItem and updateBackStageItem methods. Also you can show/hide the backstage page

Copyright © 2001 - 2020 Syncfusion Inc.

in ribbon control by using showBackstage and [hideBackstage](https://help.syncfusion.com/api/js/ejribbon#methods:hidebackstage methods.

Tab

RibbonTabs is a collection of control TabGroup which enables you to organize related commands into single view. Tabs can be added to Ribbon using RibbonTabs property. Id & Text properties are used to set unique ID and header text to RibbonTabs.

The manipulation of given text tab in the ribbon control can be done by using addTab, removeTab, hideTab,

showTab methods and tabAdd, tabCreate, tabRemove, tabClick and tabSelect events.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app => {
app.Type(ApplicationTabType.Menu).MenuItemID("Ribbon").MenuSettings(new
MenuProperties() {
OpenOnClick = false
});
})
.RibbonTabs(tab => {
tab.Id("home").Text("HOME").TabGroups(tabgroup => {
tabgroup.Text("Save").AlignType(RibbonAlignType.Rows).Content(ctn => {
ctn.ContentGroups(contentGroup => {
contentGroup.Id("print").Text("Print").ButtonSettings(new
ButtonProperties() {
ContentType = ContentType.TextAndImage,
ImagePosition = ImagePosition.ImageTop,
PrefixIcon = "e-icon e-Ribbon e-print"
}).Add();
contentGroup.Id("save").Text("Save").ButtonSettings(new
ButtonProperties() {
ContentType = ContentType.TextAndImage,
ImagePosition = ImagePosition.ImageTop,
PrefixIcon = "e-icon e-Ribbon e-save"
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.Button).Width("50px").Height("70px")).Add();
}).Add();
}).Add();
tab.Id("sendRec").Text("Send/Receive").TabGroups(tabgroup => {
tabgroup.Text("Send/Receive").Type("custom").ContentID("sendReceive").Ali
gnType(RibbonAlignType.Columns).Content(ctn => {
}).Add();
}).Add();
})
)
<div id="sendReceive">
Send/Receive All Folders
</div>
<ul id="Ribbon">
<li>
<a>FILE</a>
<ul>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<li><a>New</a></li>
<li><a>Open</a></li>
<li><a>Save</a></li>
<li><a>Save As</a></li>
<li><a>Print</a></li>
</ul>
</li>
</ul>
@section StyleSection{
<link href="~/Content/ej/Ribbon-css/ej.icons.css" rel="stylesheet" />
}
```

Group

Group is a collection of logical content groups that are combined under related Tab. Each group can be defined using content groups or custom content.

Adding Tab Groups

Group items can be added to Tabs by specifying Text and corresponding Content to be displayed. The content of group can be specified as either with Content collection, ContentID or CustomContent. You can add tab group dynamically in the ribbon control with given tab index, tab group object and group index position by using addTabGroup method.

Adding Content

Add content to Group item which is based on Type of content specified. The available types are Button , SplitButton, ToggleButton,Gallery, and DropDownList.

Groups and defaults settings can be added with the Content. You can add group content dynamically in the ribbon control with given tab index, group index, content, content index and sub group index position by using addTabGroupContent.

Defaults

The tabs.groups.content.defaults.height, tabs.groups.content.defaults.width,

tabs.groups.content.defaults.type, tabs.groups.content.defaults.isBig property to the controls in the group can be specified commonly.

The Height & Width applicable to Button, SplitButton, DropDownList ,ToggleButton controls and IsBig applicable to only button controls (button, split , toggle)

Adding Content Groups

Controls such as button, split button, dropdown list, toggle button, gallery in the subgroup of the Ribbon Tab can be rendered. All of these can be customized using its corresponding settings property such as ButtonSettings, DropdownSettings, etc.

Copyright © 2001 - 2020 Syncfusion Inc.

Custom controls or items (such as table, div etc.) can be added when the Type set as Custom. Defaults control settings of group can be specified for an individual group instead of specifying them to Content Groups collection commonly.

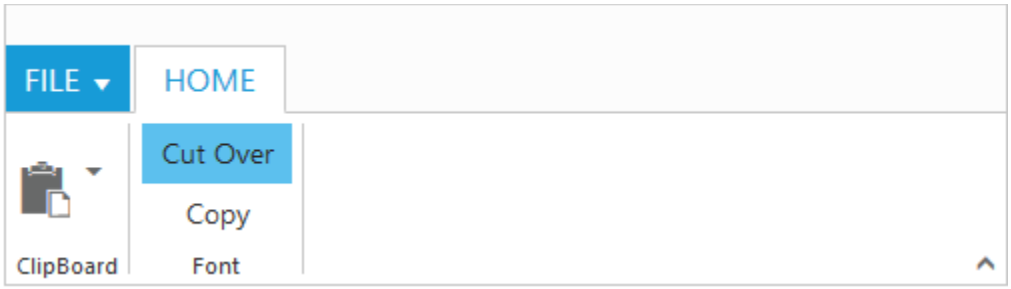
ToolTip and CustomTooltip can be specified for each group controls.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500px")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon");
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("Clipboard").Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("paste").Text("Paste").ToolTip("Paste").IsBig(true).Type(
RibbonButtonType.SplitButton).SplitButtonSettings(new
SplitButtonProperties()
{
ContentType = ContentType.ImageOnly,
PrefixIcon = "e-icon e-ribbon e-ribbonpaste",
TargetID = "pasteSplit",
}).Add();
}).Add();
}).Add();
tabgroup.Text("Font").AlignType(RibbonAlignType.Columns).Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("cut").ToggleButtonSettings(new ToggleButtonProperties()
{
DefaultText = "Cut",
ActiveText = "Cut Over"
}).Add();
contentGroup.Id("copy").ToggleButtonSettings(new ToggleButtonProperties()
{
DefaultText = "Copy",
ActiveText = "Copy Over"
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.Button).Width("75px").Height("30px").Type(Ribbon
ButtonType.ToggleButton)).Add();
}).Add();
}).Add();
})
)
<ul id="ribbon">
<li>
<a>FILE</a>
<ul>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<li><a>Open</a></li>
</ul>
</li>
</ul>
<ul id="pasteSplit">
<li><a>Paste Special</a></li>
</ul>
```



Enable Separator

Separates the control from the next control in the group when group AlignType is Rows. Set “true” to EnableSeparator.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500px")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon");
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("New").AlignType(RibbonAlignType.Rows).Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("new").Text("New").ToolTip("New").EnableSeparator(true).B
uttonSettings(new ButtonProperties()
{
Width = "100",
}).Add();
contentGroup.Id("font").Text("Font").ToolTip("Font").ButtonSettings(new
ButtonProperties()
{
Width = "150",
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.Button).Height("70px")).Add();
}).Add();
}).Add();
})
)
<ul id="ribbon">
<li>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Open</a></li>
</ul>
</li>
</ul>
```

Adding Custom Content

Set group Type as custom to add custom items such as div, table and custom controls. With type as custom, content can be added in two ways as specified below.

HTML contents can be directly added into the groups as string content using CustomContent. property

Custom template id can be specified to render those specific custom template using ContentID property

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon");
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("New").Type("custom").CustomContent("<button
id='customContent'>Using Custom Content</button>").Add();
tabgroup.Text("Data").Type("custom").ContentID("btn").Add();
}).Add();
})
)
<ul id="ribbon">
<li>
<a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Open</a></li>
</ul>
</li>
</ul>
<button id='btn'>Using Content ID</button>
```

Group Expander

Set enableGroupExpander as true to show Group Expander for each group in Tab. These expanders can be customized using groupExpand event, such as to show popup dialog. To specify tooltip for the group expander of the group tabs.groups.groupExpanderSettings and

tabs.groups.groupExpanderSettings.toolTip can be used.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon");
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("New").AlignType(RibbonAlignType.Rows).Type("custom").Enabl
eGroupExpander(true).ContentID("btn").Add();
})
.ClientSideEvents(event => event.GroupExpand("groupExpand"))
)
<ul id="ribbon">
<li>
<a>FILE</a>
<ul>
<li><a>New</a></li>
</ul>
</li>
</ul>
<button id='btn'>Home button</button>
<script>
function groupExpand(args) {
alert("Group expander click triggered");}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Controls Support

Button, SplitButton, DropDownList, ToggleButton, Gallery and Custom controls can be added to each groups. You can set Type property in group to define the controls. Default Type is Button.

Built in Controls

The following table describes about the built in controls Type and their corresponding control settings.

Type	Control Settings	Example
Button	Button - ButtonSettings	ButtonSettings: { Width: 70, ContentType: ej.ContentType.ImageOnly, PrefixIcon: "e-icon e-ribbon e-new" }
SplitButton	SplitButton - SplitButtonSettings	SplitButtonSettings: { ContentType: ej.ContentType.ImageOnly, TargetID: "pasteSplit", ButtonMode: "dropdown", ArrowPosition: ej.ArrowPosition.Bottom }
ToggleButton	ToggleButton - ToggleButtonSettings	ToggleButtonSettings: { ContentType: ej.ContentType.ImageOnly, DefaultText: "Italic", ActiveText: "Italic" }
DropDownList	DropDownList - DropDownSettings	DropDownSettings: { DataSource: size, Text: "1pt", Width: 65 }

Note: 1. You can specify type either to group's collection or to each group.

2. For Type property you can assign either string value ("SplitButton") or enum value (RibbonButtonType.SplitButton).

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("100%")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon").MenuSettings(new
MenuProperties()
{
OpenOnClick = false
});
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("New").AlignType(RibbonAlignType.Rows).Content(ctn =>
{
ctn.ContentGroups(contentTab =>
{
contentTab.Id("new").Text("New").ToolTip("New").ButtonSettings(new
ButtonProperties()
{
ContentType = ContentType.ImageOnly,
```

Copyright © 2001 - 2020 Syncfusion Inc.

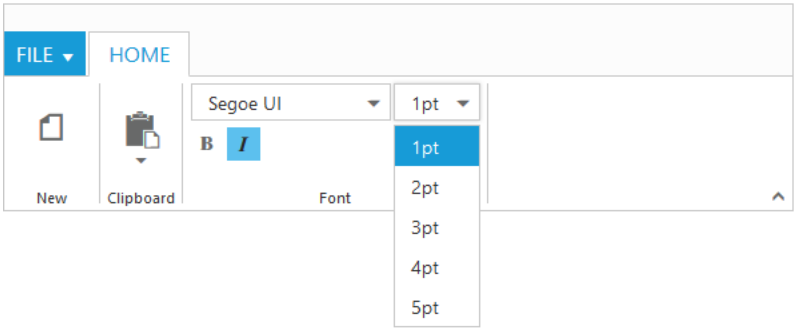
```
ImagePosition = ImagePosition.ImageTop,
PrefixIcon = "e-icon e-ribbon e-new",
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.Button).Width("60px").Height("70px")).Add();
}).Add();
tabgroup.Text("Clipboard").AlignType(RibbonAlignType.Columns).Content(ctn
=>
{
ctn.ContentGroups(contentTab =>
{
contentTab.Id("paste").Text("Paste").ToolTip("Paste").SplitButtonSettings
(new SplitButtonProperties()
{
ContentType = ContentType.ImageOnly,
PrefixIcon = "e-icon e-ribbon e-ribbonpaste",
TargetID = "pasteSplit",
ButtonMode= ButtonMode.Dropdown,
ArrowPosition = ArrowPosition.Bottom,
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.SplitButton).Width("50px").Height("70px")).Add()
;
}).Add();
tabgroup.Text("Font").AlignType(RibbonAlignType.Rows).Content(ctn =>
{
ctn.ContentGroups(contentTab =>
{
contentTab.Id("fontFamily").ToolTip("Font").DropdownSettings(new
DropDownListProperties()
{
DataSource = (IEnumerable<FontFamily>)ViewBag.datasource,
Text = "Segoe UI",
Width = "150px"
}).Add();
contentTab.Id("fontsize").ToolTip("FontSize").DropdownSettings(new
DropDownListProperties()
{
DataSource = (IEnumerable<FontPoint>)ViewBag.datasource1,
Text = "1pt",
Width = "65px"
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.DropDownList).Height("28px")).Add();
ctn.ContentGroups(contentTab =>
{
contentTab.Id("bold").ToolTip("Bold").Type(RibbonButtonType.ToggleButton)
.ToggleButtonSettings(new ToggleButtonProperties()
{
ContentType = ContentType.ImageOnly,
DefaultText = "Bold",
ActiveText = "Bold",
DefaultPrefixIcon = "e-icon e-ribbon bold",
ActivePrefixIcon = "e-icon e-ribbon bold",
}).Add();
contentTab.Id("italic").ToolTip("Italic").Type(RibbonButtonType.ToggleBut
ton).ToggleButtonSettings(new ToggleButtonProperties()
```

```
{
ContentType = ContentType.ImageOnly,
DefaultText = "Italic",
ActiveText = "Italic",
DefaultPrefixIcon = "e-icon e-ribbon e-ribbonitalic",
ActivePrefixIcon = "e-icon e-ribbon e-ribbonitalic",
}).Add();
}).ContentDefaults(df => df.IsBig(false)).Add();
}).Add();
}).Add();
})
)
<ul id="ribbon">
<li>
<a>FILE</a>
<ul>
<li>
<a>New</a>
</li>
</ul>
</li>
</ul>
<ul id="pasteSplit">
<li>
<a>Paste</a>
</li>
</ul>
```

C#

```
public partial class RibbonController: Controller
{
List<FontFamily> fontFamily1 = new List<FontFamily>();
List<FontPoint> fontPoint1 = new List<FontPoint>();
public ActionResult RibbonFeatures()
{
fontFamily1.Add(new FontFamily { text = "Segoe UI" });
fontFamily1.Add(new FontFamily { text = "Arial" });
fontFamily1.Add(new FontFamily { text = "Times New Roman" });
fontFamily1.Add(new FontFamily { text = "Tahoma" });
fontFamily1.Add(new FontFamily { text = "Helvetica" });
ViewBag.datasource = fontFamily1;
fontPoint1.Add(new FontPoint { text = "1pt" });
fontPoint1.Add(new FontPoint { text = "2pt" });
fontPoint1.Add(new FontPoint { text = "3pt" });
fontPoint1.Add(new FontPoint { text = "4pt" });
fontPoint1.Add(new FontPoint { text = "5pt" });
ViewBag.datasource1 = fontPoint1;
return View();
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Custom

You can set Type as custom to render custom controls and Custom element id has to be specified as ContentID.You can change the element defined in the custom template to appropriate Syncfusion control in the event of Ribbon Create.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("600")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon");
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("Font").Content(ctn =>
{
ctn.ContentGroups(contentTab =>
{
contentTab.Id("fontColor").ToolTip("Font
Color").ContentID("fontColor").Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.Custom).Height("30px")).Add();
}).Add();
tabgroup.Text("Operators").Type("custom").ContentID("design").Add();
}).Add();
})
.ClientSideEvents(event => event.Create("createControl"))     )
<ul id="ribbon">
<li>
<a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Print</a></li>
</ul>
</li>
</ul>
<input id="fontColor" />
<table id="design" class="e-designtablestyle">
<tr>
<td><input type="checkbox" id="check1" /><label for="check1">Header
Row</label></td>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<td><input type="checkbox" id="Check2" checked="checked" /><label
for="Check2">First Column</label></td>
</tr>
<tr><td><input type="checkbox" id="check4" checked="checked" /><label
for="check4">Total Row</label></td>
<td><input type="checkbox" id="Check5" /><label for="Check5">Last
Column</label></td>
</tr>
</table>
<script>
function createControl(args) {
$("#fontColor").ejColorPicker({ value: "#FFFF00", modelType: "palette",
cssClass: "e-ribbon", toolIcon: "e-fontcoloricon" });
}
</script>
```

Contextual Tab And Tab Set

Contextual Tabs are collection of Tabs that extended styling and can be shown based on some criteria. Contextual Tabs can be added like RibbonTabs including TabGroup and TabContent section. You can set BackGroundColor and BorderColor to highlight them as Tab set. Contextual tabs can be added or set dynamically in ribbon control using addContextualTabs with it's object and index position.

ASPX-CS

```
@(Html.EJ().Ribbon("Ribbon")
.Width("500")
.ApplicationTab(app => {
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon").MenuSettings(new
MenuProperties()
{
OpenOnClick = false
});
})
.RibbonTabs(tab => {
tab.Id("home").Text("HOME").TabGroups(tabGroup => {
tabGroup.Text("CustomControls").Type("custom").ContentID("Contents").Add(
);
}).Add();
})
.ContextualTabs(contextualTab => {
contextualTab.BackgroundColor("#FCFBEB").BorderColor("#F2CC1C").RibbonTab
s(ribbonTab => {
ribbonTab.Id("Design").Text("DESIGN").TabGroups(contextTabGroup => {
contextTabGroup.Text("Table Style
Options").Type("custom").ContentID("contextualTab").Add();
}).Add();
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
contextualTab.BackgroundColor("blue").BorderColor("lightblue").RibbonTabs
(ribbonTab => {
ribbonTab.Id("tabset1").Text("Tabset1").TabGroups(contextTabGroup => {
contextTabGroup.Text("Tabset1
Style").Type("custom").ContentID("headings").Add();
}).Add();
ribbonTab.Id("tabset2").Text("Tabset2").TabGroups(contextTabGroup => {
contextTabGroup.Text("Tabset2
Styles").Type("custom").ContentID("contextualTabset2").Add();
}).Add();
});
})
)
<ul id="ribbon">

Gallery

Galleries are used to display items that can be arranged in a grid-type layout. Items in the gallery can be customized as Button/Menu to display images, text, or both images and text. You can set Type of group as Gallery.

Gallery Items

Gallery items are collection of the items to be included in the main gallery. You can set Text and ToolTip to gallery item which can also be customized with ButtonSettings.

Number of Columns to display in gallery for each row should be specified and the Number of columns in Expanded State (ExpandedColumns) can be customized, if not set, Columns count will be set as default.

Note: The ItemHeight and ItemWidth for gallery item can be set, if not set default values will be used.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon");
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("Gallery").Type("gallery").Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("Gallery").Type(RibbonButtonType.Gallery).ItemWidth("73")
.ItemHeight("54").Columns(2).ExpandedColumns(3).GalleryItems(gallery =>
{
gallery.Text("GalleryContent1").ToolTip("GalleryContent1").ButtonSettings
(new ButtonProperties()
{
ContentType = ContentType.ImageOnly,
PrefixIcon = "e-icon e-gallerycontent1 e-gbtnimg",
CssClass = "e-gbtnposition"
}).Add();

Ribbon Gallery.

Gallery at Expanded State

Custom Gallery Items

Custom gallery items are the additional items to be displayed at gallery expanded state. You can set `CustomItemType` as `Button` or `Menu`, Default is `Button`.

You can also set `Text` and `ToolTip` to custom gallery item which can also be customized with ButtonSettings/MenuSettings based on the CustomItemType specified.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon");
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("Gallery").Type("gallery").Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("Gallery").Type(RibbonButtonType.Gallery).ItemWidth("73")
.ItemHeight("54").Columns(2).ExpandedColumns(3).GalleryItems(gallery =>
{
gallery.Text("GalleryContent1").ToolTip("GalleryContent1").ButtonSettings
(new ButtonProperties(){
ContentType=ContentType.ImageOnly,
PrefixIcon="e-icon e-gallerycontent1 e-gbtnimg",
```

```
CssClass="e-gbtnposition"
}).Add();
gallery.Text("GalleryContent2").ToolTip("GalleryContent2").ButtonSettings
(new ButtonProperties()
{
ContentType = ContentType.ImageOnly,
PrefixIcon = "e-icon e-gallerycontent2 e-gbtnimg",
CssClass = "e-gbtnposition"
}).Add();
gallery.Text("GalleryContent3").ToolTip("GalleryContent3").ButtonSettings
(new ButtonProperties()
{
ContentType = ContentType.ImageOnly,

Resize

Ribbon control dynamically resizes to display possible number of controls in the optimal layout as the application window size changes.

As the window is narrowed, controls in the Ribbon will be combined as group button with dropdown arrow, in which controls can be expanded with dropdown arrow.

Tablet Layout

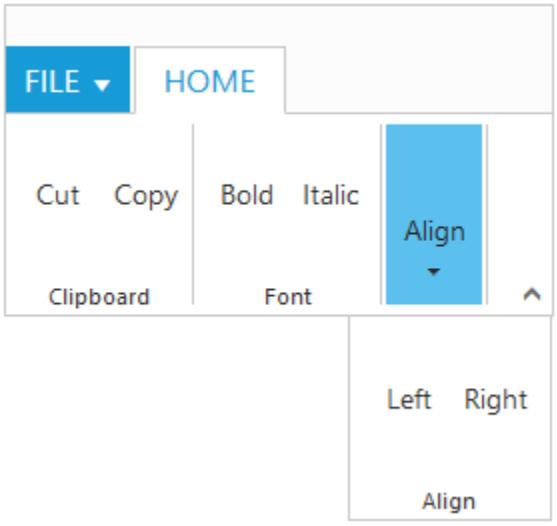
Set IsResponsive as true to enable resizing in Ribbon.If client width is above 420px or control content exceeds the page then, the ribbon will render in Tablet mode.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon").IsResponsive(true)
.Width("40%")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon");
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("Clipboard").Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("cut").Text("Cut").Add();
contentGroup.Id("copy").Text("Copy").Add();
}).ContentDefaults(df => df.Width("40px").Height("70px")).Add();
}).Add();
tabgroup.Text("Font").Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("bold").Text("Bold").Add();
contentGroup.Id("italic").Text("Italic").Add();
}).ContentDefaults(df => df.Width("40px").Height("70px")).Add();
}).Add();
tabgroup.Text("Align").Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("left").Text("Left").Add();
contentGroup.Id("right").Text("Right").Add();
}).ContentDefaults(df => df.Width("40px").Height("70px")).Add();
}).Add();
}).Add();
})
)
<ul id="ribbon">
<li><a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Open</a></li>
</ul>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</li>
</ul>
```



Mobile Layout

If client width is less than 420px, the ribbon will render in mobile mode. In which, you can see that ribbon user interface is customized and redesigned for best view in small screens.

The customized features includes responsive tab & group rendering, backstage, gallery and button controls.

Responsive Tab and group

Set IsResponsive as true to enable responsive mode in Ribbon.

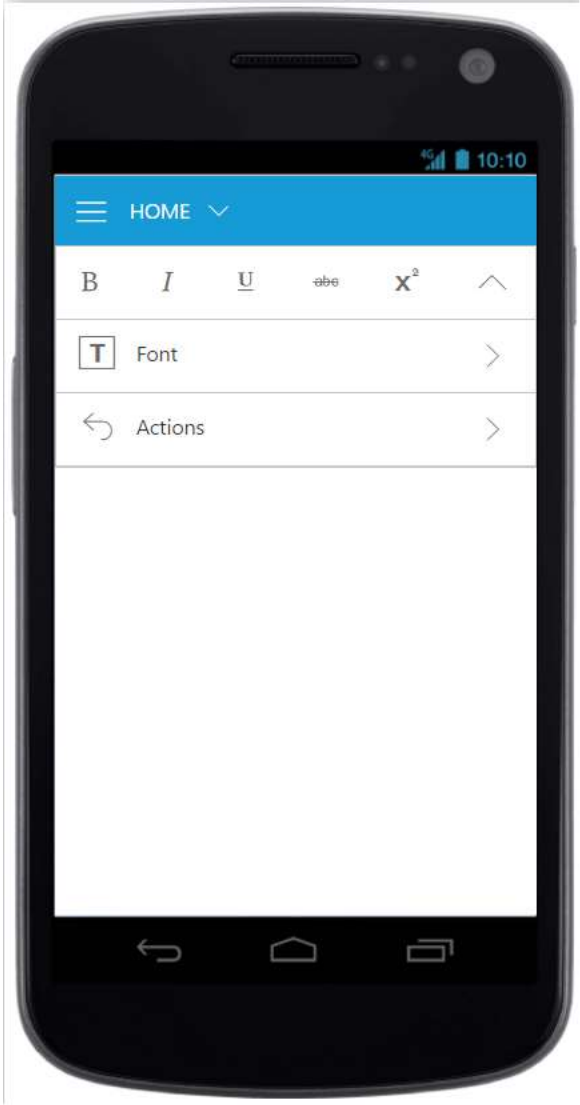
HTML

```
@(Html.EJ().Ribbon("defaultRibbon")
.IsResponsive(true)
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("Font").AlignType(RibbonAlignType.Rows).Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("bold").IsMobileOnly(true).Type(RibbonButtonType.ToggleBu
tton).ToggleButtonSettings(new ToggleButtonProperties()
{
ContentType = ContentType.ImageOnly,
DefaultText="Bold",
ActiveText="Bold",
DefaultPrefixIcon = "e-icon e-ribbon e-resbold",
ActivePrefixIcon = "e-icon e-ribbon e-resbold",
}).Add();
contentGroup.Id("italic").IsMobileOnly(true).Type(RibbonButtonType.Toggle
Button).ToggleButtonSettings(new ToggleButtonProperties()
{
ContentType = ContentType.ImageOnly,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
DefaultText = "Italic",
ActiveText = "Italic",
DefaultPrefixIcon = "e-icon e-ribbon e-resitalic",
ActivePrefixIcon = "e-icon e-ribbon e-resitalic",
}).Add();
contentGroup.Id("underline").IsMobileOnly(true).Type(RibbonButtonType.Tog
gleButton).ToggleButtonSettings(new ToggleButtonProperties()
{
ContentType = ContentType.ImageOnly,
DefaultText = "Underline",
ActiveText = "Underline",
DefaultPrefixIcon = "e-icon e-ribbon e-resunderline",
ActivePrefixIcon = "e-icon e-ribbon e-resunderline",
}).Add();
contentGroup.Id("strikethrough").IsMobileOnly(true).Type(RibbonButtonType
.ToggleButton).ToggleButtonSettings(new ToggleButtonProperties()
{
ContentType = ContentType.ImageOnly,
DefaultText = "Strikethrough",
ActiveText = "Strikethrough",
DefaultPrefixIcon = "e-icon e-ribbon strikethrough",
ActivePrefixIcon = "e-icon e-ribbon strikethrough",
}).Add();
contentGroup.Id("superscript").IsMobileOnly(true).Text("Superscript").But
tonSettings(new ButtonProperties()
{
ContentType = ContentType.ImageOnly,
PrefixIcon = "e-icon e-ribbon e-superscripticon",
}).Add();
}).ContentDefaults(df => df.IsBig(false)).Add();
}).Add();
}).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Note: To make the Ribbon control to react as responsive in mobile devices, it is necessary to refer the additional ej.responsive.css file in the application.

Mobile Toolbar Customization

Set IsMobileOnly as true to group control to show the controls

in the Mobile Toolbar of the ribbon. For each tab , first row of mobile ribbon will pick and display the controls which is set as IsMobileOnly with look adapt to mobile mode.If IsMobileOnly property is not defined to any of the control within tab, then by default fist group content will be displayed in first row toolbar.

To adapt to proper display of controls , following layout will be customized with constants display.

- First ribbon toolbar and Button controls with min-height.
- Drop down control will adapt to full screen width.
- All button controls icon will be displayed commonly as Top position.

Ribbon Responsive with gallery

Group Button Customization

Based on window size, detailed group is shrined into single button and you can expand group items with group button click.

For each group shirked for resizing, Custom Class will be added based on group text.For example, `e-Action` whereas `Action` is group text. Using this custom class, group button can be customized such as to set icons etc.

ASPX-CS

```
@section ControlsSection{

Screen Tips

ScreenTip/Tooltip is used to reduce the controls related Help that are needed to the end user to do control related actions.

HTML Tooltip

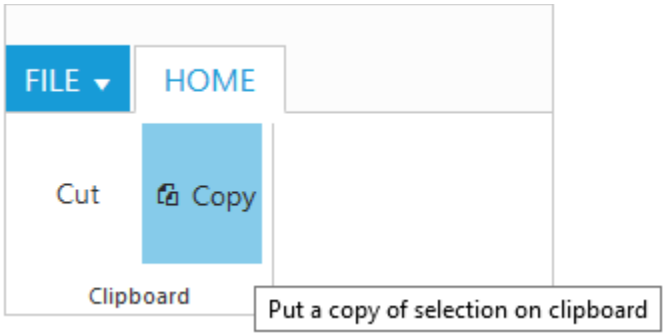
Standard html tooltip can be set using ToolTip property of each group item.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("20%")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon");
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("Clipboard").Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("cut").Text("Cut").ToolTip("Remove the selection and put
it on clipboard").Add();
contentGroup.Id("copy").Text("Copy").ToolTip("Put a copy of selection on
clipboard").ButtonSettings(new ButtonProperties()
{
ContentType = ContentType.TextAndImage,
PrefixIcon = "e-icon e-ribbon e-ribboncopy",
}).Add();
}).ContentDefaults(df => df.Width("70px").Height("60px")).Add();
}).Add();
}).Add();
})
)
<ul id="ribbon">
<li>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Open</a></li>
</ul>
</li>
</ul>
```



Custom Tooltip

Custom Tooltip is used to set detailed help to the user about the controls. You can set`Title`, `Content` and `PrefixIcon` class to customize the tooltip with icons.

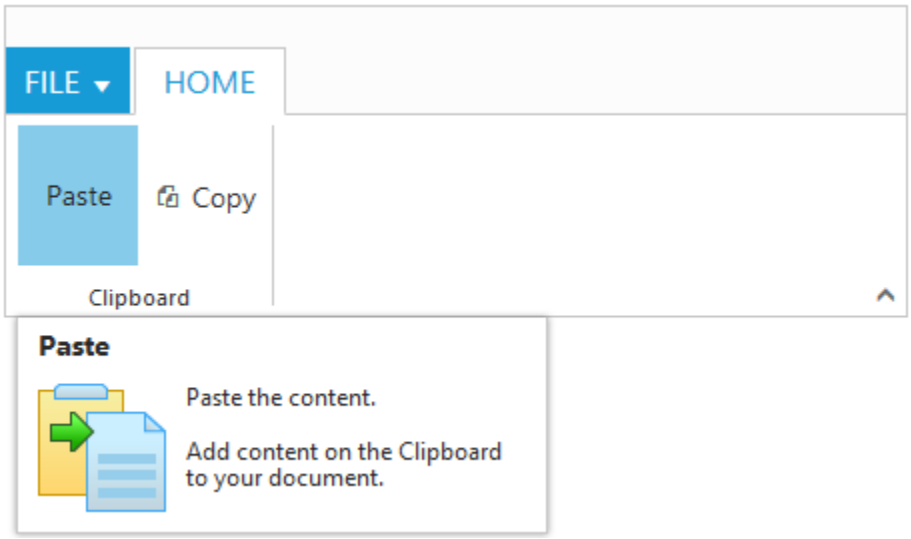
For Groups

`CustomTooltip` for each group controls can be specified. Such as to the controls Button, SplitButton, DropDownList etc.

ASPX-CS

```
@section ControlsSection {
@(Html.EJ().Ribbon("defaultRibbon")
.Width("450")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("ribbon");
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("Clipboard").Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("paste").Text("Paste").CustomToolTip(new CustomToolTip()
{
Title = "Paste",
Content = "<h6>Paste the content.<br/><br/>Add content on the Clipboard
to your document.</h6>",
PrefixIcon = "e-icon e-pastetip",
}).Add();
contentGroup.Id("copy").Text("Copy").CustomToolTip(new CustomToolTip()
{
Title = "Copy",
Content = "<h6>Copy the content.</h6>",
```

```
}).ButtonSettings(new ButtonProperties()
{
ContentType = ContentType.TextAndImage,
PrefixIcon = "e-icon e-ribbon e-ribboncopy",
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.Button).Width("70px").Height("60px")).Add();
}).Add();
}).Add();
})
)
<ul id="ribbon">
<li>
<a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Open</a></li>
</ul>
</li>
</ul>
}
@section StyleSection{
<link href="~/Content/ej/ribbon-css/ej.icons.css" rel="stylesheet" />
<style>
.e-pastetip {
background-image: url("../Content/ej/common-images/ribbon/paste.png");
background-repeat: no-repeat;
height: 64px;
width: 64px;
}
</style>
}
```



For Gallery

CustomTooltip for each Gallery and CustomGalleryItems button control can be specified.

Note: Custom gallery item Menu is not supported to Custom tooltip.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@section ControlsSection {

```

Quick Access Toolbar

Quick Access Toolbar provides the shortcuts to the most commonly used commands by placing the controls at the Quick Access Toolbar section. It can be placed at the top or bottom of the Ribbon.

Set ShowQAT as true to enable Quick Access Toolbar in Ribbon. It supports the Button, Split Button, Toggle Button controls. The QuickAccessMode is used to change the controls state in Quick Access Toolbar through options as Toolbar,Menu and none. Default value is none and QAT toolbar is created with specified controls added in Toolbar.

The ToolBar option used to set controls visibility in Quick Access Toolbar.The Menu option shows the controls in Quick Access Menu and does not show controls in Quick Access Toolbar.

Once the controls are visible in Toolbar , then controls state will be set as ticked in Quick Access Menu and vice versa.

The client side event for Quick Access Toolbar menu click is QatMenuItemClick.

More Commands command provides with Quick Access Menu. This can be customized using QatMenuItemClick event, such as to show popup dialog.

ASPX-CS

Appearance and Styling

CssClass

When you want to display the **Ribbon** widget in a different style based on the appearance of your application, you can use this **cssClass** property to apply custom theme for the **Ribbon**. Specify a class name as the value for **cssClass** property. The specified class is added to the root element of the **Ribbon** widget. Now, you can easily override the styles of the **Ribbon** widget by accessing the styles from the root level (using the cssClass specified).

In an view page, define the Ribbon control and configure the Ribbon with custom theme by using the CssClass property.

ASPX-CS

```
@(Html.EJ().Ribbon("defaultRibbon")
.Width("500")
.CssClass("custom")
.ApplicationTab(app =>
{
app.Type(ApplicationTabType.Menu).MenuItemID("Ribbon").MenuSettings(new
MenuProperties()
{
OpenOnClick = false
});
})
.RibbonTabs(tab =>
{
tab.Id("home").Text("HOME").TabGroups(tabgroup =>
{
tabgroup.Text("New").AlignType(RibbonAlignType.Rows).Content(ctn =>
{
ctn.ContentGroups(contentGroup =>
{
contentGroup.Id("new").Text("New").ButtonSettings(new ButtonProperties()
{
ContentType = ContentType.ImageOnly,
ImagePosition = ImagePosition.ImageTop,
PrefixIcon = "e-icon e-Ribbon e-new",
Click = "executeAction"
}).Add();
}).ContentDefaults(df =>
df.Type(RibbonButtonType.Button).Width("60px").Height("70px")).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}).Add();
}).Add();
}))
<ul id="Ribbon">
<li>
<a>FILE</a>
<ul>
<li><a>New</a></li>
<li><a>Open</a></li>
<li><a>Save</a></li>
<li><a>Save As</a></li>
<li><a>Print</a></li>
</ul>
</li>
</ul>
```

CSS

```
.custom.e-js .e-header {
background: #179bd7;
}
.custom.e-js .e-content {
background: #ddd;
}
.custom .e-rbn-button.e-btn.e-select {
background: #f5f5f5;
color: #333;
}
```

Execute the above code example to render the following output.

Themes

Ribbon control's style and appearance are controlled based on CSS classes and it has support of 12 default themes. You can check List of themes available for JavaScript's control which is mentioned in this page.

To modify Ribbon appearance, you need to override default CSS of Ribbon. Please find the list of CSS classes and its corresponding section in Ribbon. Also you have an option to create your own custom theme for all ASP.NET MVC controls using our Theme Studio.

To apply styles refer to two files namely

ej.widgets.core.min.css ej.theme.min.css

Copyright © 2001 - 2020 Syncfusion Inc.

When the file ej.widgets.all.min.css/ej.web.all.min.css is referred, it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project as ej.widgets.all.min.css is the combination of these two files.

Customize Styles

Override default styles of Ribbon control by using its class name to customize it.

List of custom classes that are need to override styles. The following are specific class names you can use to modify styles and appearance in Ribbon.

e-js - used to represent element ej-widget control, that is present at the container element of Ribbon control. e-header - This class is applied to the header element of the Ribbon. *e-active-content -This class is applied to the active content of the Ribbon.* e-expandcollapse - This class is applied to the expand/collapse button in the Ribbon.

Application Tab

- e-apptab - This class is applied to the application tab in the Ribbon.

Tabs & Groups

e-tab -This class is applied to the Tabs in the Ribbon. e-groupdiv -This class is applied to the groups in the Ribbon. * e-active -This class is applied to the active or selected tab in the Ribbon.

Contextual Tabs

* e-contextliset, e-contextual, e-contextualtabset -This class is applied to the contextual tab and contextual tab set in the Ribbon.

Custom Tooltip

* e-tooltipdiv, e-tooltiptitle,e-tooltipdesc, e-tooltipimg – Applies to custom tooltip and its icons settings.

Gallery

e-gallexpandcontent,e-gallerycontent - Applies to gallery items and custom items for collapse and expanded state. e-gallerymovediv,e-gallerybtn,e-moveupdiv,e-movedowndiv,e-expgallerydiv - Applies to gallery item button and navigation buttons of gallery. * e-extracontent,e-galleryextrabtn,e-gallerymenu - Applies to gallery custom items menu and button customization.

Resizing

* e-resizebtn, e-resizediv – Applies to resizing and its group button.

Back Stage

e-ribbonbackstagepage,e-ribbonbackstagetop,e-backstagetopicon – Applies to back stage top header. e-ribbonbackstagebody ,e-backstageheader,e-backstagecontent,e-backstageli,e-backstageseparator, e-backstageactive – Applies Backstage page side header and its contents.

Quick Access Toolbar

- e-rbnwithqat- This class applied to the Quick access toolbar in the Ribbon.
- e-rbnabove - This class applied to the top Quick access toolbar.
- e-qatooldiv- This class applied to individual controls in the Quick access toolbar.
- e-rbnbelow- This class applied to the bottom Quick access toolbar

AngularJS-Support

It is possible to add object, array collection in the Ribbon control with AngularJS. The one way binding support is provided for Ribbon control.

ej-ribbon is the control tag where, ej is tag prefix and Ribbon is the control name.

Tabs and Contextual Tabs

Ribbon Tabs and Contextual Tabs are Array Collections and the inner tag is used for them.

Objects with in these Array Collections can be extended by using hyphen. E.g. e-applicationTab-menuItemId="menu"

ASPX-CS

```
@section ControlsSection{
<div ng-app="ribbonApp">
<div ng-controller="RibbonCtrl">
<div id="defaultRibbon" ej-ribbon e-width="100%" e-applicationtab-
menuitemid="menu" e-expandpinsettings-tooltip="Collapse the Ribbon" e-
collapsepinsettings-tooltip="Pin the Ribbon" e-applicationtab-type="menu"
e-create="createControl">

How to

Get Ribbon object

After Ribbon initialization, Ribbon object is stored in a container element of Ribbon and it can be accessed for further processing.

JS

```
// "defaultRibbon" is Id of Ribbon control
var ribbonObject = $("#defaultRibbon").ejRibbon("instance");
[or]
var ribbonObject = $("#defaultRibbon").data("ejRibbon");
```

RichTextEditor

Overview

Rich text editor is a component that help you to display or edit the content including tables, hyperlinks, paragraphs, lists, video, and images. The editor supports file and folder management using FileExplorer component.

The following are some of the key features of the editor:

** Editing with formatting * Toolbar * Content Area with customization * Image and File browser * Links * Tables * Localization * XHTML validation*

Getting Started

This section explains the step-by-step instructions to create RichTextEditor in an ASP.NET MVC application.

Create your first RichTextEditor in MVC

1. Create Syncfusion ASP.NET MVC application. You can refer MVC Getting Started documentation to create new project and add necessary dll's and script files. 2. Add the following code example to the corresponding view page to render the RichTextEditor.

HTML

```
@Html.EJ().RTE("rteSample").Width("820px")
```

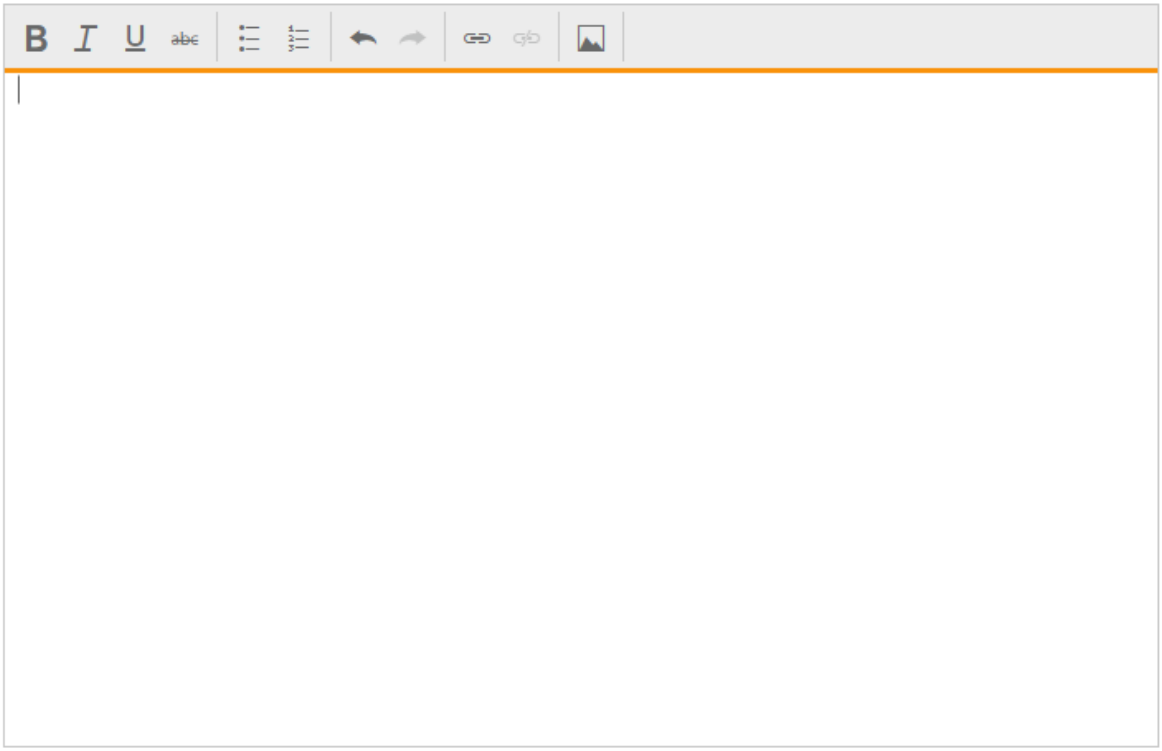
Toolbar–Configuration

You can configure the toolbar with the tools as your application requires.

HTML

```
@{
```

```
List<String> toolsList = new List<string>() { "style", "lists",
"doAction", "links", "images" };
List<String> style = new List<string>() { "bold", "italic", "underline",
"strikethrough" };
List<String> lists = new List<string>() { "unorderedList", "orderedList"
};
List<String> doAction = new List<string>() { "undo", "redo" };
List<String> links = new List<string>() { "createLink" };
List<String> images = new List<string>() { "image" };
}
@Html.EJ().RTE("rteSample").Width("820px").ToolsList(toolsList).Tools(too
l =>
tool.Styles(style).Lists(lists).DoAction(doAction).Links(links).Images(im
ages))
```



Setting and Getting Content

You can set the content of the editor as follows.

HTML

```
@Html.EJ().RTE("rteSample").Width("820px").ContentTemplate(@<div>
The Rich Text Editor (RTE) control is an easy to render in client side.
Customer easy to edit the contents and get the HTML content for the
displayed content.
A rich text editor control provides users with a toolbar that helps them
to apply rich text formats to the text entered in the text area.
</div>)
```

To retrieve the editor contents using Value property in Post Back action,

HTML

```
[HttpPost]
[ValidateInput(false)]
public ActionResult RichTextEditorFeatures(string rteSample)
{
ViewBag.data = rteSample;
return View();
}
```

Toolbar Configuration

The editor's toolbar contains a collection of tools such as bold, italic and text alignment buttons that are used to format the content.

However, in most integrations, it's desirable to change the toolbar configuration to suit needs. Fortunately, that's quite easy to do too.

Property	Description
toolsList	The toolsList option allows you to choose which tools appear on the toolbar, as well as the order and grouping of those items
tools	The toolsList property is used to get the root group order and tools property is used to get the inner order of the corresponding groups displayed.

Note: By default, when you tab from the textbox to the RTE, the first tools in the Toolbar of RTE will get focus not in the text area.

But we can able to focus the RTE text area by setting the tab index attribute as -1 to avoid the focus on RTE toolbar when we tab from textbox to RTE - Demo

Toolbar Items

The following table lists the available buttons and dropdowns on the toolbar:

Name	Summary	Initialization	isDefault ?
Font	Applies font type, size, and color to the content	List<String> toolsList = new List<string>() {" font"}; List<String> font = new List<string>() { "fontName", "fontSize", "fontColor", "backgroundColor" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. Font(font)).Render();}	No
Font style	Applies bold, italic, underline, and strikethrough formatting to the content	List<String> toolsList = new List<string>() { " style"}; List<String> style = new List<string>() { "bold", "italic", "underline", "strikethrough" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. Styles(style)).Render();}	yes

Copyright © 2001 - 2020 Syncfusion Inc.

Alignment	Align the content with left, center, and right margin.	List<String> toolsList = new List<string>() { " alignment"}; List<String> alignment = new List<string>() { "justifyLeft", "justifyCenter" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. Alignment (alignment)).Render();}	yes
List	Create a new list item (bulleted/numbered).	List<String> toolsList = new List<string>() { "lists"}; List<String> lists = new List<string>() { "unorderedList", "orderedList" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. Lists(lists)).Render();}	yes
Indents	Allows to increase/decrease the indent level of the content.	List<String> toolsList = new List<string>() { "indenting"}; List<String> indenting = new List<string> { "outdent", "indent" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. Indenting(indenting)).Render();}	yes
Undo/Redo Action	Allows to undo/redo the actions	List<String> toolsList = new List<string>() {"doAction"}; List<String> doAction = new List<string>() { "undo", "redo" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. DoAction (doAction)).Render();}	yes
Hyperlink	Creates a hyperlink to a text or image to a specific location in the content.	List<String> toolsList = new List<string>() {"links"}; List<String> links = new List<string>() { "createLink", "removeLink" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. Links (links)).Render();}	yes
Images	Inserts an image from an online source or local computer.	List<String> toolsList = new List<string>() {"images"}; List<String> images = new List<string>() { "image" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. Images (images)).Render();}	yes
Media	Allows to embed a video into the document.	List<String> toolsList = new List<string>() {"media"}; List<String> media = new List<string>() { "video" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool.Media (media)).Render();}	yes
Table	Allows to add or modify Tables	List<String> toolsList = new List<string>() {"tables"}; List<String> tables = new List<string>() { "createTable", "addRowAbove", "addRowBelow", "addColumnLeft", "addColumnRight", "deleteRow", "deleteColumn", "deleteTable" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. Tables(tables)).Render();}	yes

Copyright © 2001 - 2020 Syncfusion Inc.

Casing	Change the case of selected text in the content	List<String> toolsList = new List<string>() {"casing"}; List<String> casing = new List<string>() { "upperCase", "lowerCase" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. Casing(casing)).Render();}	no
Scripts	Makes the selected text as superscript (higher) or subscript (lower).	List<String> toolsList = new List<string>() {"effects"}; List<String> effects = new List<string>() { "superscript", "subscript" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool. Effects(effects)).Render();}	no
Format	Clears the formatting options like bold, italic, underline and more.	List<String> toolsList = new List<string>() {"formatStyle"}; List<String> formatStyle = new List<string>() { "format" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool.FormatStyle(formatStyle)).Render();}	yes
Clipboard Actions	Controls the clipboard actions by applying specific action on the selected content.	List <String> toolsList = new List<string>() {"clipboard"}; List<String> clipboard = new List<string>() { "cut", "copy", "paste" }; @{Html.EJ().RTE("rteSample").ToolsList(toolsList).Tools(tool => tool.Clipboard(clipboard)).Render();}	no

Rearrange Group

The toolbar contains groups, which are similar or related functionalities of toolbar items for efficient access. By default, the groups are arranged using the following order:

HTML

```
List<String> toolsList = new List<string>() { "formatStyle", "font",
"style", "effects", "alignment", "lists", "indenting", "clipboard",
"doAction", "clear", "links", "images", "media", "tables", "casing",
"customTool","view" };
```

The group can be rearranged on customization using the ToolsList property.

HTML

```
@{
List<String> toolsList = new List<string>() { "style", "lists",
"doAction", "links", "images" };
List<String> style = new List<string>() { "bold", "italic", "underline",
"strikethrough" };
List<String> lists = new List<string>() { "unorderedList", "orderedList"
};
List<String> doAction = new List<string>() { "undo", "redo" };
List<String> links = new List<string>() { "createLink" };
List<String> images = new List<string>() { "image" };
}
@{Html.EJ().RTE("rteSample").Width("100%").ContentTemplate(@<p>
The Rich Text Editor
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</p>)
.ShowFooter(true)
.ToolsList(toolsList)
.Tools(tool =>
tool.Links(links).Images(images).Styles(style).Lists(lists).DoAction(doAc
tion)).Render();}
```

Note: If you are not specifying any group in **ToolsList** property, the editor will create the toolbar with default group.

Undo and Redo

Undo and Redo buttons allow you to editing the text by disregard/cancel the recently made changes and restore it to previous state. It is a useful tool to restore the performed action which got changed by mistake. Up to 50 actions can be undo/redo in the editor by default.

To undo and redo operations, do one of the following:

- Press the undo/redo button on the toolbar
- Press the `Ctrl + Z` , `Ctrl + Y` combination on the keyboard

HTML

```
@{
List<String> toolsList = new List<string>() { "doAction" };
List<String> doAction = new List<string>() { "undo", "redo" };
}
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ToolsList(toolsList).Tools(tool => tool.DoAction(doAction))
.Render();}
<br />
```

Clipboard Operations

The editor provides support for the clipboard operations (cut, copy, and paste) in all text and images using the toolbar buttons and the keyboard shortcuts. Toolbar includes buttons through which the clipboard operations, such as Cut, Copy, and Paste can be accessed.

You can use the keyboard shortcuts to perform the clipboard operations.

Copyright © 2001 - 2020 Syncfusion Inc.

- Cut - CTRL + X
- Copy - CTRL + C
- Paste - CTRL + V

Some browsers block the clipboard access from JavaScript. If you want to use the Cut, Copy, and Paste buttons on the toolbar, you need to allow JavaScript to use the clipboard. If you don't want to do this configuration, use CTRL+C, CTRL+X, and CTRL+V keyboard commands.

HTML

```
@{
List<String> toolsList = new List<string>() { "clipboard" };
List<String> clipboard = new List<string>() { "cut", "copy", "paste" };
}
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ToolsList(toolsList).Tools(tool => tool.Clipboard(clipboard))
.Render();}
```

Specify Custom Tools

Beside the available built-in tools, the RichTextEditor's toolbar functionality can be extended through custom tools, defined in the tools through the customTools options, which renders the custom toolbar items along with the built-in toolbar items.

The example below demonstrates how to add a custom tool button

HTML

```
@{
List<String> toolsList = new List<string>() { "customTools" };
}
@{Html.EJ().RTE("rteSample").Width("100%").ContentTemplate(@<p>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</p>).ShowFooter(true).ToolsList(toolsList).Tools(tool =>
tool.CustomTools(customTools => customTools.Text("Insert -
O").Tooltip("Special Characters").Css("insert-special-
character").Action("CustomTool").Add())).Render();}
```

Upon clicking the "Insert" button, the special character will be added to the RTE's content.

Copyright © 2001 - 2020 Syncfusion Inc.

HTML

```
<script>
var rteObj =  $("#rteSample").data("ejRTE");
$(".insert-special-character").ejButton();
$("#specialCharacter").ejDialog({ enableResize: false, enableModal: true,
showOnInit: false, width: "auto", position: { X: 218, Y: 38 } });
$(".special-table tbody tr td" ).addClass("special-td").on( "click",
customTdClick);
function customTdClick(args) {
rteObj.executeCommand("inserthtml", args.currentTarget.innerText);
$("#specialCharacter").ejDialog("close");
}
function CustomTool(args){
$("#specialCharacter").ejDialog("open");
}
</script>
```

Define the CSS that will be applied to the custom tool.

HTML

```
<style>
.special-table tr td
{
border:1px solid #c8c8c8;
}
.special-td:hover
{
background-color:#86bcea;
cursor:pointer;
}
</style>
```

Note: The CSS class that defined for custom tool is directly applies to the newly added toolbar item.

Information: The custom buttons get a insert-special-character CSS class to allow styling, where name is the name specified in the custom tool configuration.

Types of responsive toolbar

Two types of toolbar modes are available for RTE in responsive mode. This includes "inline" and "popup". Toolbar Type can be set through API toolbarOverflowMode whose default value is "popup".

HTML

```
@{Html.EJ().RTE("rteSample").Width("100%").ContentTemplate(@<p>The Rich
Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</p>).ToolbarOverflowMode(ToolbarOverflowMode.Inline).IsResponsive(true).
Render();}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Note: If you are not specifying toolbarOverflowMode, responsive RTE will be rendered with default popup toolbar.

Working with Content

The editor creates the iframe element as the content area on control initialization, it is used to display and editing the content. In Content Area, the editor displays only the body tag of a < iframe > document. To set or modify details in the < head > tag, use Source view of the editor.

IFrame Attributes

The editor allows to passing an additional attributes to body tag of a < iframe > element using IFrameAttributes property. The property contains name/value pairs in string format, it is used to override the default appearance of the content area.

Note: The content area's font, color, margins, and background can be overridden using iframeAttributes property. You can specifies the editable behavior (content editable) of the content also in this property.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.IFrameAttributes(new Dictionary<string, object> { { "style",
"background-color:#e0ffff;color:#6495ed;" } })
.Render();}
```

Note: Background image for the RTE control : Link

Set default font for the Iframe : Link

Adding CSS File

The editor offers to add external CSS file to style the < iframe > element. Easily change the appearance of editor's content using an external CSS file. For example, apply default styles for headings (h1, h2, etc.) and lists (bulleted or numbered) of the editor's content.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ExternalCSS("/Content/Css/iframe-custom.css")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Render();}
```

The new file named iframe-custom.css is created and moved to the content folder with the following styles.

HTML

```
div {
color:navy;
margin-left:20px;
}
ul {
display:block;
list-style-type:square;
margin-left:10px;
}
ol {
display:block;
list-style-type:circle;
margin-right:10px;
}
```

Note: Our RTE control editor section is an iframe. An iframe has another scope, so we can't access it to style using class which is defined in main document. To set the styles for the contents that kept inside the editor(iframe) we have to append the styles link in iframe head section.

Content Editable

The editor provides option to control the editable behavior using AllowEditing property. When the AllowEditing property is set to false, the editor disables its editing functionality.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.AllowEditing(false)
.Render();}
```

The ContentEditable attribute allows you to make any element of HTML content to become editable or non-editable.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
<p> Cannot Edit </p>
</div>)
.ClientSideEvents(e => e.Create("Create"))
.Render();}
<script>
function Create() {
var editor = $("#rteSample").ejRTE("instance");
var iframeDoc = editor.getDocument();
var paragraph = $("p", iframeDoc.body);
$($(paragraph)[0]).attr("contenteditable", "false");
}
</script>
```

Note: Content editable is fully compatible with latest browsers, to know more details, see here.

Submit Content

The editor allows you to process its content before it is being submitted to the server on form submit event. You can use this option to validate content on the client side to prevent invalid data from being submitted to the server.

This example shows how to encode the HTML content before form submit event.

HTML

```
<form>
@{Html.EJ().RTE("rteSample").Width("100%").ContentTemplate(@<p>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</p>)
.ShowFooter(true)
.ShowHtmlSource(true)
.Render();}
<br />
@{Html.EJ().Button("Submit").Text("Submit").Type(ButtonType.Submit).Rende
r();}
</form>
<script type="text/javascript">
$("form").on("submit", function () {
var editor = $("#rteSample").data("ejRTE");
var encoded = $('<div />').text(editor.model.value).html();
$("#rteSample").val(encoded);
});
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Refresh

When you move the editor's wrapper element into another DOM element, the editor needs to be reinitialized by the refresh method to retain its content. The method reload the content area and rebind the events of the editor.

HTML

```
@{Html.EJ().RTE("rteSample").Width("100%").ContentTemplate(@<p>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</p>)
.Render();}
<br />
@{Html.EJ().Dialog("Target").Width("600px").Render();}
@{Html.EJ().Button("Append").Text("Append").ClientSideEvents(e =>
e.Click("appendTo")).Render();}
@{Html.EJ().Button("Refresh").Text("Refresh").ClientSideEvents(e =>
e.Click("refresh")).Render();}
<script type="text/javascript">
var editor;
function appendTo() {
editor = $("#rteSample").ejRTE("instance");
editor._rteWapper.appendTo($("#Target"))
}
function refresh() {
editor = $("#rteSample").ejRTE("instance");
editor.refresh()
}
</script>
```

Persistence

The editor is capable to persist its content with HTML format. By default, the persistence support is disabled in the editor. When you set the EnablePersistence property to true, the persistence will be enabled in the editor.

Note: local storage is not supported below ie9 version, therefore persistence support is fallback to cookie.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px")
.EnablePersistence(true)
.Render();}
<br/>
```

Set Default Font Name and Size

- Set a default font name and font size to the font name and size drop-down programmatically.

Copyright © 2001 - 2020 Syncfusion Inc.

Note: •By default, the editor's < iframe > is initialized with "Segoe UI" font name and 3(12pt) font size.

- To change it, select a different font name and font size from the drop-down in the editor's toolbar.

- To apply different font style for particular section of the content, select the text that you would like to change, and select a required font style from the drop-down to apply the changes to the selected text.

HTML

```
@{
List<String> toolsList = new List<string>() { "font" };
List<String> font = new List<string>() { "fontName", "fontSize",
"fontColor", "backgroundColor" };
}
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ClientSideEvents(e => e.Create("Create"))
.ToolsList(toolsList).Tools(tool => tool.Font(font))
.Render();}
<br />
<script>
function Create() {
var editor = $("#rteSample").ejRTE("instance");
var obj = editor._fontStyleDDL.ejDropDownList("instance");
obj.selectItemByIndex(7);
var dropdownSize = editor._fontSizeDDL.ejDropDownList("instance");
dropdownSize.selectItemByIndex(5);
}
</script>
```

- Set default font name and size for < iframe >'s body tag using IFrameAttributes property.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.IFrameAttributes(new Dictionary<string, object> { { "style", "font-
family:Arial;;font-size:14px;" } })
.Render();
}
```

- If you want to override the default font from CSS, create a style tag with CSS styles and append it to the < iframe >'s head tag of the editor.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ClientSideEvents(e => e.Create("Create"))
.Render();}
<br />
<script>
function Create() {
var css = "html,body{font-family:sans-serif;font-size:14px; }";
var editorDoc = $("#rteSample").ejRTE("instance").getDocument();
var styleTag = document.createElement("style");
styleTag.type = "text/css";
if (styleTag.styleSheet)
styleTag.styleSheet.cssText = css;
else
styleTag.appendChild(document.createTextNode(css));
editorDoc.head.appendChild(styleTag);
}
</script>
```

Adding Font names and size

If you want to add additional font names and sizes to font drop-down, pass the font information as JSON data and bind it with instance of drop-down.

HTML

```
@{List<String> toolsList = new List<string>() { "font" };
List<String> font = new List<string>() { "fontName", "fontSize",
"fontColor", "backgroundColor" };}
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
```

```
in the text area.</div>)
.ClientSideEvents(e => e.Create("Create"))
.ToolsList(toolsList).Tools(tool => tool.Font(font))
.Render();}
<br />
<script>
function Create() {
var editor = $("#rteSample").ejRTE("instance");
editor.defaults.fontName.push({ text: "Calibri Light", value:
"CalibriLight" }, { text: "Calibri", value: "Calibri" });
editor.defaults.fontSize.push({ text: "8 (42pt)", value: "8" });
var obj = editor._fontStyleDDL.ejDropDownList("instance");
var dropdownSize = editor._fontSizeDDL.ejDropDownList("instance");
obj.option({ "dataSource": editor.defaults.fontName });
dropdownSize.option({ "dataSource": editor.defaults.fontSize });
obj.selectItemByValue("CalibriLight");
dropdownSize.selectItemByValue("8");
}
</script>
```

Apply Font color and Background color

If you want to apply font color or background color for a selected content of RTE you can use font color and background color tools. These tools contains a color palette with basic colors along with an option called **"More colors.."** in order to choose custom colors from color picker dialog.You can apply transparent background color for selected text through **transparent** button available in background color palette.

HTML

```
@{List<String> toolsList = new List<string>() { "font" };
List<String> font = new List<string>() { "fontName", "fontSize",
"fontColor", "backgroundColor" };}
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.</div>)
.ToolsList(toolsList).Tools(tool => tool.Font(font))
.Render();}
```

Insert the content at cursor

If you want to insert/paste the content at the current cursor position (or) to replace the selected content with some formatting, you can use pasteContent method in the editor.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
```

```
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.Render();}
<br />
@{Html.EJ().Button("sample").Width("100px").Text("PasteContent").ClientSi
deEvents(e => e.Click("pasteContent")).Render();}
<script>
function pasteContent() {
var editor = $("#rteSample").ejRTE("instance");
var selectedHtml = editor.getSelectedHtml();
editor.pasteContent("<p style='background-color:yellow;color:skyblue'> "
+ selectedHtml + " </p>");
}
</script>
```

Footer

This option allows you to specify which footer elements should be shown at the bottom of the editor. The available footer elements are listed below:

1. HTML View
2. HTML Tag Info
3. Characters Count / Word Count
4. Clear Format
5. Resizer

When the footer is enabled, it displays the HTML tag, word Count, character count, clear format, resize icon and clear all the content icons, by default.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ShowFooter(true)
.Render();}
```

Source View

RichTextBox includes the ability for users to directly edit HTML code via “Source View” in a separate dialog. If you made any modification in Source view directly, click Update button to synchronize with Design view. This provides power users with more flexibility over the content they create.

Copyright © 2001 - 2020 Syncfusion Inc.

You can paste HTML text into Source view. If you cut or copy from HTML source such as page source of Browser, paste as HTML (without escape characters) into Source view.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ShowFooter(true)
.ShowHtmlSource(true)
.Render();}
```

Note: Source view is useful for working directly with raw HTML text, so this tool is mainly used for advanced users who would like to have more control over the source of their content.

HTML Tag Info

The HTML tag info tool that shows the path of currently selected tag along with hierarchy of parent tags to which it belongs. The tag information is displayed at the bottom of the editor. It is used to determine which element has the focus in the editor's content.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ShowFooter(true)
.ShowHtmlTagInfo(true)
.Render();}
```

Note: The outermost tag is the body tag of < iframe > element in design view, so it shows the path from currently selected path to the body tag.

Characters Count/Word Count

The editor automatically counts the number of characters and words in the content while you type. The characters and words count displayed at the bottom of the editor. You can limit the number of characters in your content using MaxLength property. By default, the editor sets the characters limit value as 7000 characters.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ShowFooter(true)
.ShowWordCount(true)
.ShowCharCount(true)
.Render();}
```

Note: The editor counts the characters by including the space, and this validation occurs while pasting the content into the editor also.

Clear Format

The clear format tool is useful to remove all formatting styles (such as bold, italic, underline, color, superscript, subscript, and more) from currently selected text. As a result, all the text formatting will be cleared and return to its default formatting styles. When you set the ShowClearFormat property to true, the clear format tool will be displayed at bottom of the editor.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ShowFooter(true)
.ShowClearFormat(true)
.Render();}
```

Resize Handle

When you set the EnableResize property to true, resize handle will be displayed at bottom-right corner of the editor. You can drag the handle to change its size. On resizing, the editor will automatically adjust the toolbar, content area, and footer within it accordingly. Resize limits can be defined via MinHeight, MaxHeight, MinWidth, and MaxWidth properties. You can specify the size of the editor programmatically through the Height and Width properties.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
```

```
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ShowFooter(true)
.EnableResize(true)
.MinWidth("250")
.MinHeight("250")
.MaxHeight("500")
.MaxWidth("750")
.Render();}
```

Note: 1. As resizable option will be added in the footer of RTE, so set the showFooter property also as “true”.

2. In order to showcase only the resizer, disable the other properties in the Footer such as showClearFormat, showClearFormat, showCharCount, showWordCount
3. When you set the enableRTL property to true, the resize handle will automatically positioned to the bottom-left corner of the editor.

Characters Count/Word Count

The editor automatically counts the number of characters and words in the content while you type. The characters and words count displayed at the bottom of the editor. You can limit the number of characters in your content using MaxLength property. By default, the editor sets the characters limit value as 7000 characters.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>

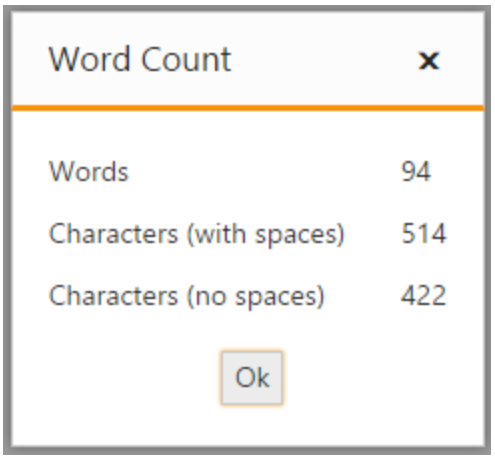
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ShowFooter(true)
.ShowWordCount(true)
.ShowCharCount(true)
.Render();}
```

By clicking the Characters Count/Word Count labels in footer , The word and character count information dialog is opened. It contains the details of the number of words and characters with and without spacing.

Copyright © 2001 - 2020 Syncfusion Inc.



Note: The editor counts the characters by including the space, and this validation occurs while pasting the content into the editor also.

Context Menu

Editor provides custom context menu support, which enables more interaction on the content modification and also it can be enabled dynamically. The showContextMenu property helps to enable custom context menu within editor area.

Based on the target content type context menu provides different actions. Refer the details with below table.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ShowContextMenu(true)
.Render();}
```

- Based on the target content type ContextMenu provides different actions- refer the details with below table.

Content-Type	Supported Actions
Text content	cut, copy, paste, add/edit/open/remove hyperlink.
Image content	cut, copy, paste, image properties.
Table content	cut, copy, paste, insert row/column, remove row/column/table, edit table properties, add/edit/open/remove hyperlink.

Copyright © 2001 - 2020 Syncfusion Inc.

Note: We have given support to own context menu by restricting the default browser context menu, which provides you the options for quick access but, with that clipboard action are restricted based on browser behavior.

However we can disable the context menu by using ShowContextMenu API and it needs to be set as false, if you wish to continue with default browser context menu.

Adding an item with the context menu

To add a new item to the editor ContextMenu, you need to use the 'insertMenuOption' method and in order to handle the ContextMenu item click using the 'contextMenuClick' client side-event.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ShowContextMenu(true)
.Render();}
<script>
$("#rteSample").ejRTE({ contextMenuClick: function(args){//handle menu-
item click action.
} });
var rteObj =  $("#rteSample").data("ejRTE");// Inserts new item to the
context menu
rteObj.insertMenuOption({newItem:"Show Table Details",
targetItem: "Table Properties",
insertType:("insertAfter"),
menuType:{text:false,image:false,hyperlink:false,table:true},
spriteCssClass:"e-rte-toolbar-icon tableProperties"});
</script>
```

Removing an item from the context menu

To remove a menu-item from the editor ContextMenu, you have to use the 'removeMenuOption' method from the ejRTE object and find the method and parameter details with the API-document.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ShowContextMenu(true)
.Render();}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script>
var rteObj = $("#rteSample").data("ejRTE");
rteObj.removeMenuOption("Table-Properties");
</script>
```

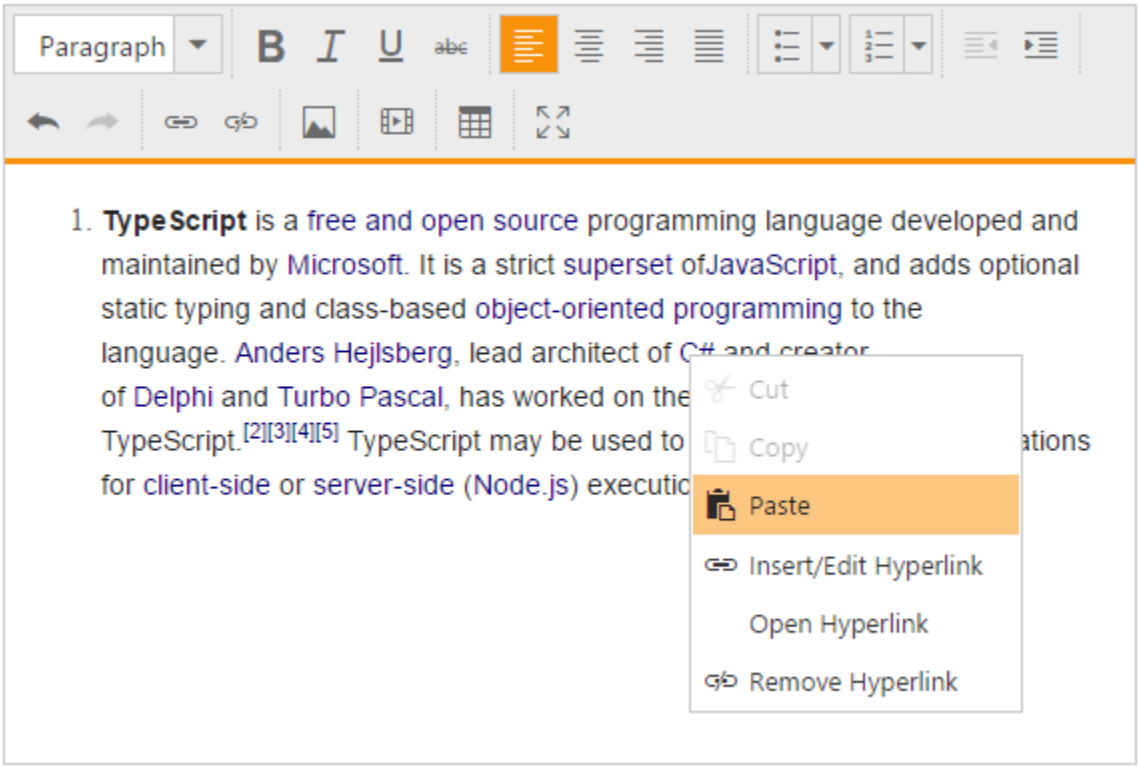


Image and File browser

The editor allows you to manage the images and files using **FileExplorer**. The FileExplorer enables you to insert images from online source as well as local computer where you want to insert the image in your content. The Image and file browser is the ability to upload pictures and link file to the editor.

Insert an Image from Online Source

If you want to insert an image from online source like Google, ping, etc., you need to enable images tool on the editor's toolbar. By default, the images tool is open a simple dialog which allows you to inserting an image from online source.

HTML

```
@{
List<String> toolsList = new List<string>() { "images" };
List<String> images = new List<string>() { "image" };
}
@{Html.EJ().RTE("rteSample").Width("100%").ContentTemplate(@<p>
The Rich Text Editor (RTE) control is an easy to render in client side.

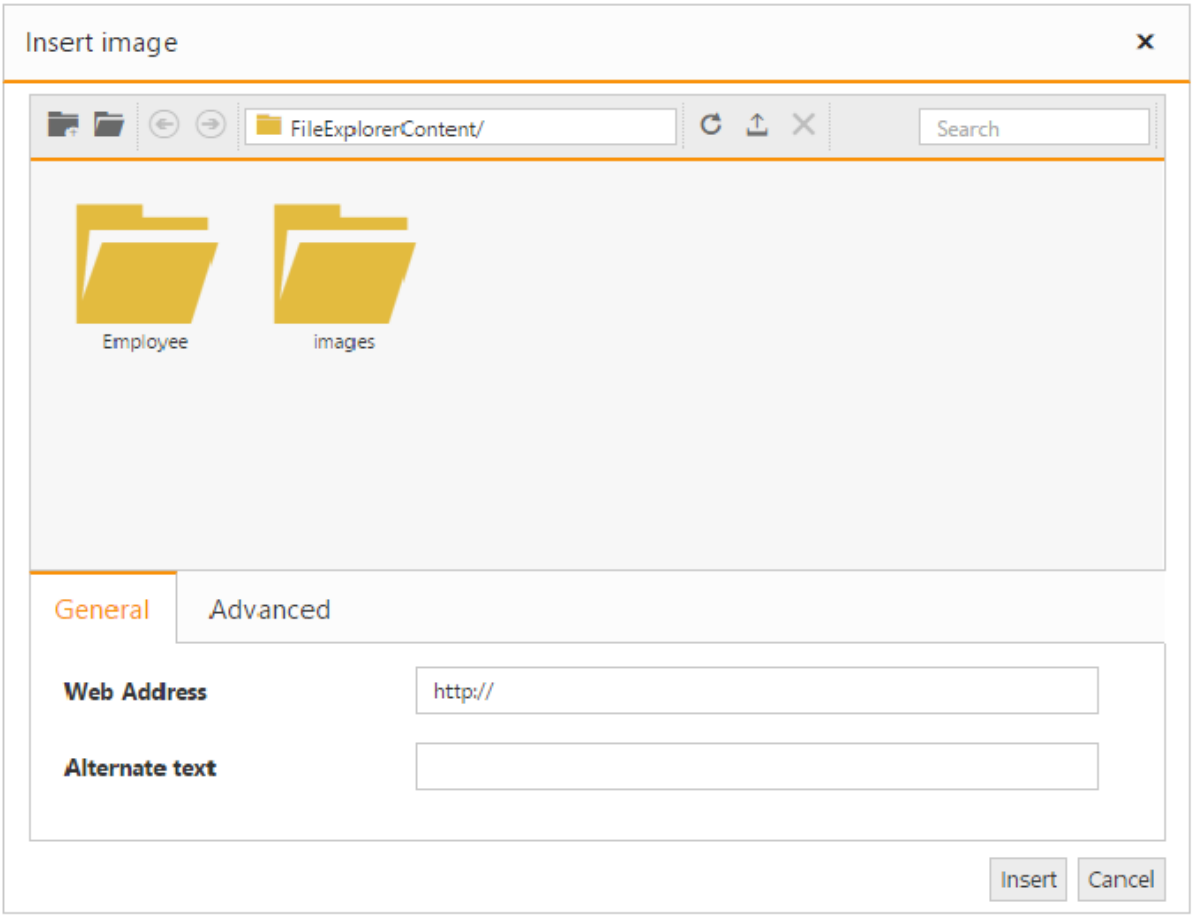
return Json("");
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

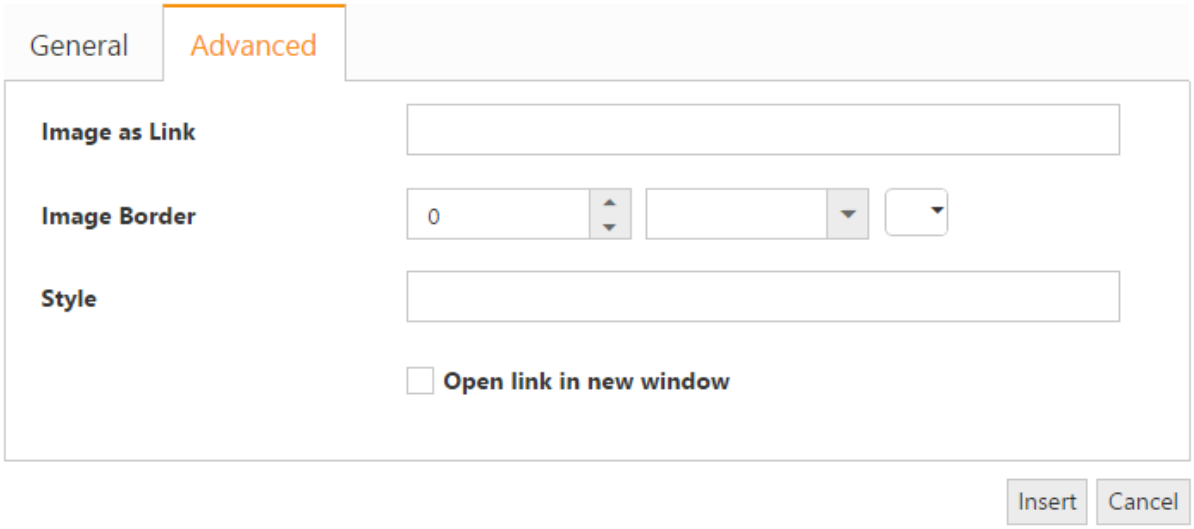


Note: FileExplorer component has been implemented and integrated with the editor in Volume 1, 2015 release. For more information about FileExplorer component, see here.

Image Properties

You can set or modify the properties of an image by using the image dialog. It allows you to add links, apply border and set additional styles to the images. The editor provides an option to specify the alternate text for an image, if the image cannot be displayed.

Copyright © 2001 - 2020 Syncfusion Inc.



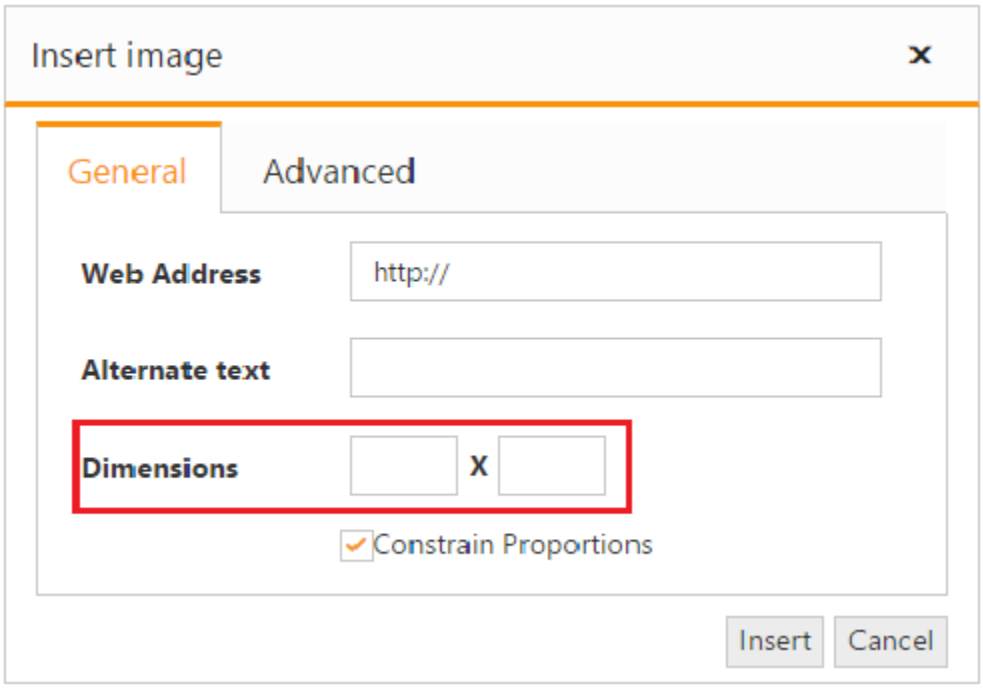
Resize an Image

You can resize an image either manually or by setting width and height in the image dialog.

Resize Manually

You can resize an image manually by selecting an image. And drag the handle until the image is resized to the desired size.

Copyright © 2001 - 2020 Syncfusion Inc.



Note: Set the default height and width of the Images which was inserted into the RTE text area in “change” event of RTE - Link

Set Width and Height

The editor provides you to set the Width and Height properties to change the size of an image (rather than forcing you to set in style attributes) using ShowDimensions property. By default, the Constrain Proportion checkbox is selected to resize an image to an exact proportion. To apply the exact width and height that you specify into the Height and Width textboxes, uncheck the Constrain Proportions checkbox.

HTML

```
@{
List<String> toolsList = new List<string>() { "images" };
List<String> images = new List<string>() { "image" };
}
@{Html.EJ().RTE("rteSample").Width("100%").ContentTemplate(@<p>

Suppression of the Image Browser

The General and Advanced tabs in the RTE Image browser can be removed by setting its corresponding display CSS property to none.

CSS

```
<style type="text/css" class="cssStyles">
div.e-rte-imageTab.e-tab.e-js.e-widget {
display: none;
}
</style>
```

Can remove the Add NewFolder button by using removeToolbarItem property of Image Browser in the RTE create event.

HTML

```
@{
List<String> toolsList = new List<string>() { "images" };
List<String> images = new List<string>() { "image" };
}
@{Html.EJ().RTE("rteSample").Width("100%").ContentTemplate(@<p>

this._explorerObj._uploadtag.data("ejUploadbox").option("autoUpload",
true);
}
</script>
```

Working with Hyperlinks

A hyperlink can be inserted into the editor for quick access to the related information. The hyperlink itself can be a text or an image.

Add and Edit a hyperlink

To add a hyperlink to the editor, follow these instructions:

1. Point the cursor anywhere within the editor where you'd like to insert the link. It is also possible to select a text or an image within the editor and can be converted to the hyperlink.
2. Click the "Insert/Edit hyperlink" tool on the Toolbar.
3. In the **Web Address** box, type or paste the destination for the link you are creating.
4. In the **Text** box, type or edit the required text that you want to display text for the link.

Note: Leave this textbox blank if you want to display the full link as hyperlink in the editor.

5. To display an additional helpful information when you place the pointer on the hyperlink, type the required text in the "Tooltip" field.
6. Click OK button to insert a hyperlink.

HTML

```
@{
List<String> toolsList = new List<string>() { "links" };
List<String> links = new List<string>() { "createLink", "removeLink" };
}
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor (RTE) control is an easy to render in client side.
Customer easy to edit the contents and get the HTML content for the
displayed content.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
A rich text editor control provides users with a toolbar that helps them
to apply rich text formats to the text entered in the text area.
</div>)
.ToolsList(toolsList).Tools(tool => tool.Links(links))
.Render();}
```

Note: hyperlinks on a picture are not always visible, but the pointer's appearance will be changed on positioning the mouse pointer over it.

Remove a hyperlink

If you want to remove a hyperlink from a text or image, select the text or image with the hyperlink and click "Remove Hyperlink" tool from toolbar. It will keep the text or image.

Working with Selection

The editor control provides option to select the all content and in addition to selection of a particular range of content.

Select All

The selectAll method enables you to select the entire content including images in the editor by programmatically.

Note: the selection highlight is invisible if the editor does not have focus. So, if you want to call the selectAll method, focus the editor before.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor (RTE) control is an easy to render in
client side. Customer easy to edit the contents and get the HTML content
for the displayed content. A rich text editor control provides users with
a toolbar that helps them to apply rich text formats to the text entered
in the text area.
</div>)
.Render();}
<br />
@Html.EJ().Button("Button1").ClientSideEvents(e =>
e.Click("selectAll")).Text("Select All")
<script>
function selectAll() {
var editor = $("#rteSample").ejRTE("instance");
editor.selectAll();
}
</script>
```

Select a Range

You can programmatically select a range of content in the editor using the selectRange method. To select a range, create a range object with desired offset position and pass it as arguments to selectRange method. The range object is created from createRange method.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
<ul>
<li>Lorem ipsum dolor sit amet, consectetuer adipiscing elit.</li>
<li>Aliquam tincidunt mauris eu risus.</li>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<li>Vestibulum auctor dapibus neque.</li>
</ul>
</div>).Render();}
<br />
@Html.EJ().Button("button1").ClientSideEvents(e =>
e.Click("select")).Text("Select")
<script>
function select() {
var editor = $("#rteSample").ejRTE("instance");
range = editor.createRange();
var liTag = $(editor.getDocument().body).find("li");
if (!editor._isIE8()) {
range.setStart(liTag[1], 0);
range.setEnd(liTag[2], 1);
}
else {
range = editor.getDocument().body.createTextRange()
range.moveToElementText(liTag[2]);
}
editor.selectRange(range);
}
</script>
```

Get Selection

The following public methods helps you to retrieve the selected content from the editor:

- getText method is used to get the currently selected content as raw text.
- getSelectedHtml method is used to get the HTML source of currently selected content.

HTML

```
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
<ul>
<li>Lorem ipsum dolor sit amet, consectetuer adipiscing elit.</li>
<li>Aliquam tincidunt mauris eu risus.</li>
<li>Vestibulum auctor dapibus neque.</li>
</ul>
</div>).Render();}
<br />
@Html.EJ().Button("button1").ClientSideEvents(e=>e.Click("select")).Text(
"Select")
<script>
function select() {
var editor = $("#rteSample").ejRTE("instance");
var selectedText = editor.getText();
var selectedHtml = editor.getSelectedHtml();
}
</script>
```

Working with Tables

The editor provides tools to add tables in your content. You can add, edit, and remove the table as well as perform other table related tasks.

Copyright © 2001 - 2020 Syncfusion Inc.

Create a Table

By default, Insert Table tool is enabled in the editor's toolbar. There are two ways to insert a table into the editor's content.

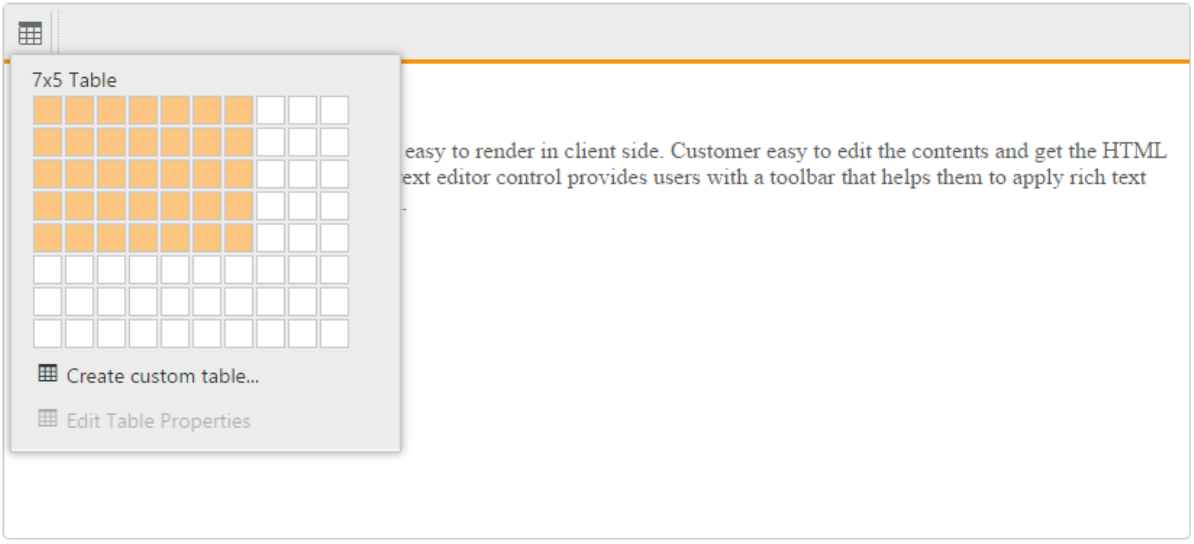
- Insert a table
- Insert a custom table

HTML

```
@{
List<String> toolsList = new List<string>() { "tables" };
List<String> tables = new List<string>() { "createTable", "addRowAbove",
"addRowBelow", "addColumnLeft", "addColumnRight", "deleteRow",
"deleteColumn", "deleteTable" };
}
<br />
@{Html.EJ().RTE("rteSample").Width("820px").ContentTemplate(@<div>
<ul>
<li>Lorem ipsum dolor sit amet, consectetuer adipiscing elit.</li>
<li>Aliquam tincidunt mauris eu risus.</li>
<li>Vestibulum auctor dapibus neque.</li>
</ul>
</div>)
.ToolsList(toolsList)
.Tools(tool => tool.Tables(tables)).Render();}
```

Insert a Table

You can insert a basic table by select the "Insert Table" tool from toolbar and drag the cursor over the grid until you highlight the number of columns and rows you want. A table can be inserted as large as with ten columns and eight rows (10 * 8 cells). When you finish inserting tables, click in a cell and start typing or insert an image.

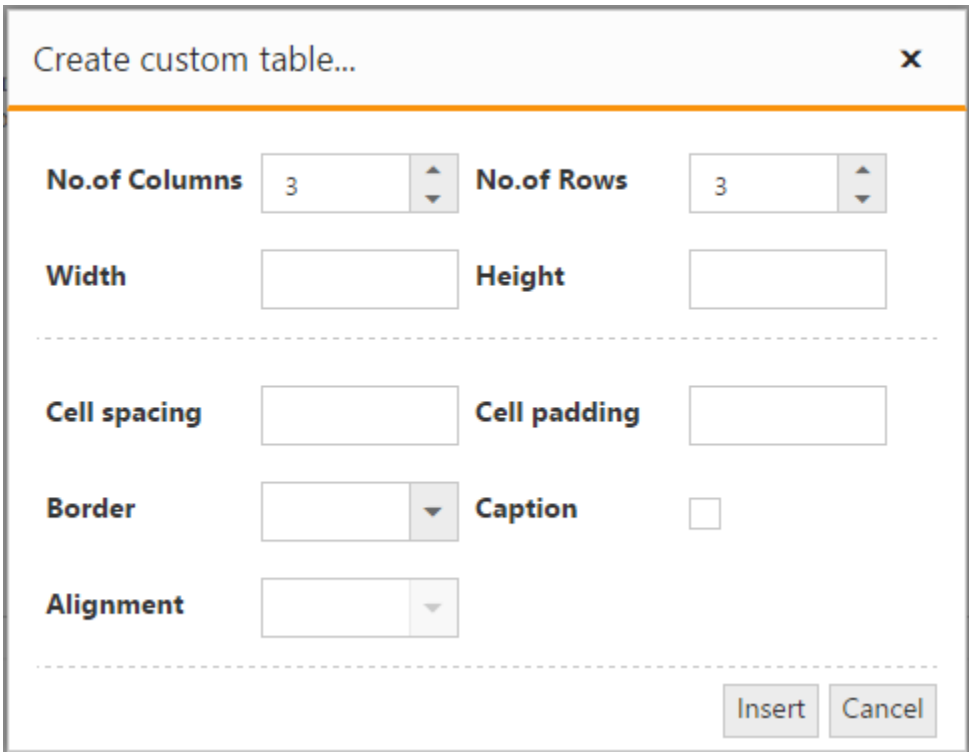


Note: If you want to make any adjustment with drawn table, you can add/remove rows and columns.

Copyright © 2001 - 2020 Syncfusion Inc.

Custom Table

You can use custom table tools to insert tables with custom behaviors. You can create a table with more than ten columns and eight rows, as well as set the table related attributes (such as width, height, cell spacing/padding, and more) using the custom table dialog.

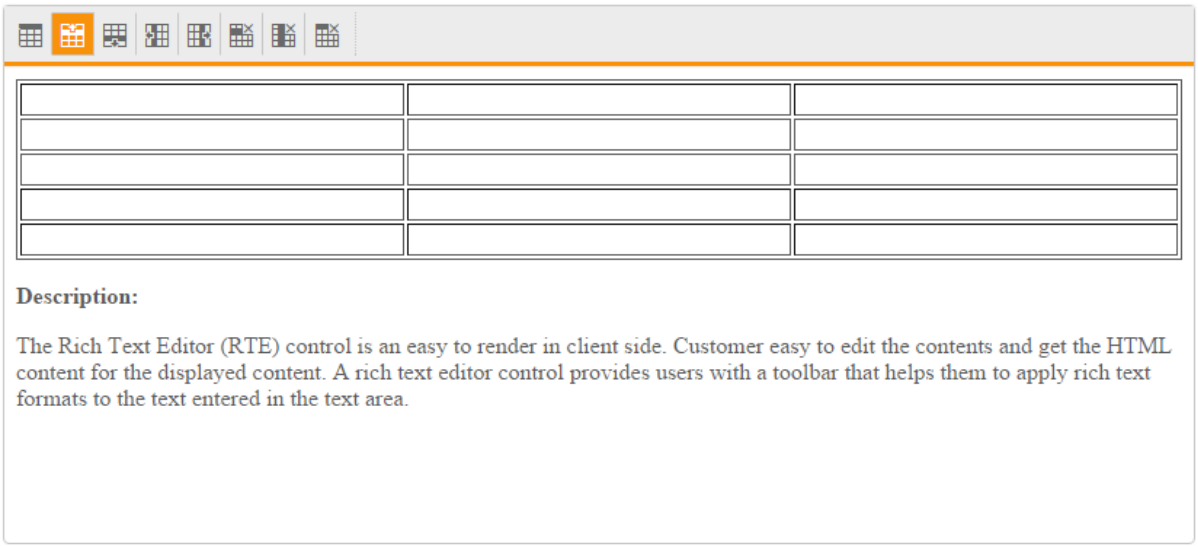


Insert and Delete a Row or Column

You can choose the following options to modify the inserted table from the toolbar, it will be enabled when you're in table cell.

- Add a row above
- Insert row below
- Insert column left
- Insert column right
- Delete a column
- Delete a row

Copyright © 2001 - 2020 Syncfusion Inc.



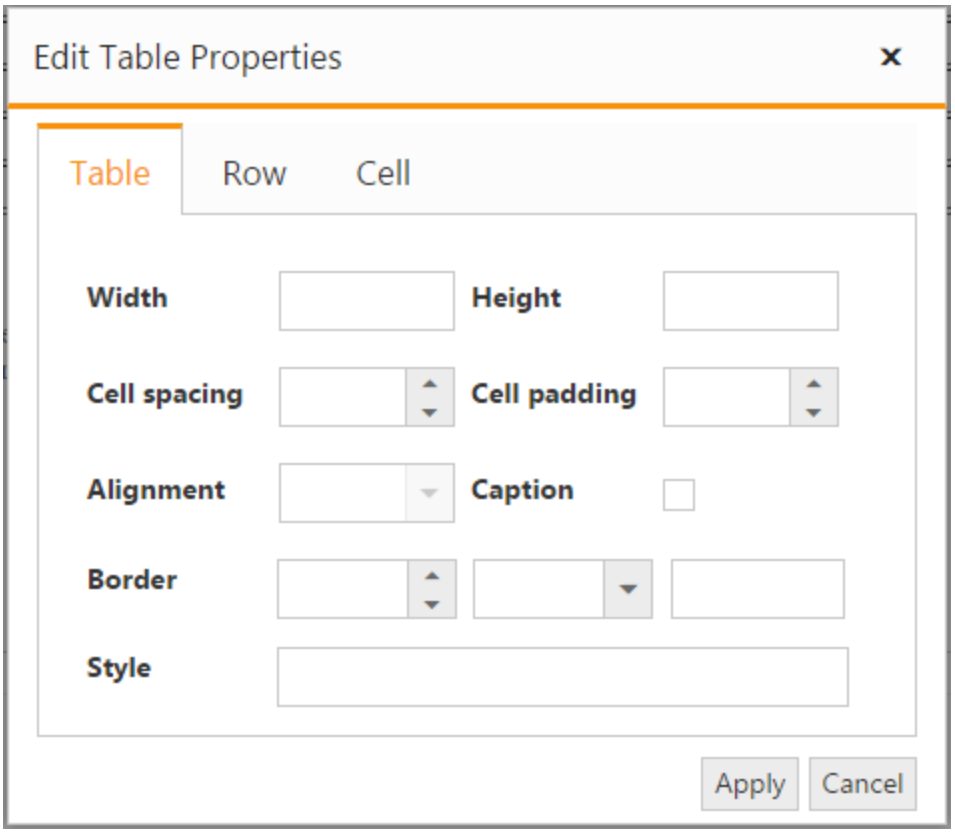
Note: You can also quickly add a new row by clicking on the lower-right cell of the table and pressing the Tab key.

Format a Table

After you create a table, you can format the entire table by using **Table Properties** dialog. In the Table Properties dialog, set or modify each table styles to apply the styles to table elements.

- Table - width, height, style, border, and alignment.
- Cell - border, spacing, and padding.
- Row - height, border, and text align.

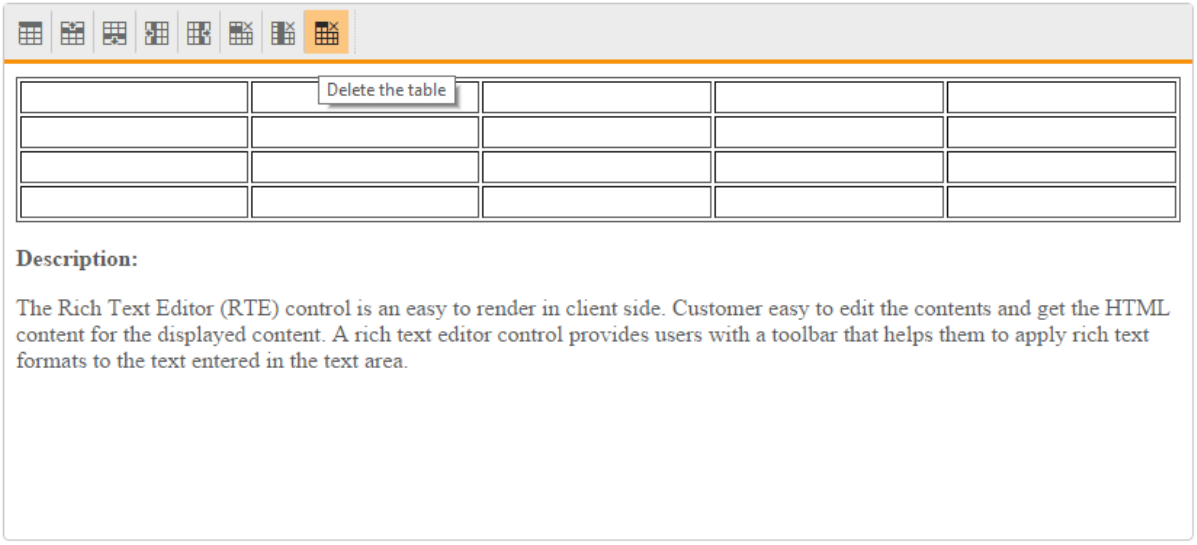
Copyright © 2001 - 2020 Syncfusion Inc.



Note: When you click in a table cell, the **Table Properties** option will be enabled under **Table** tool on the editor's toolbar.

Delete a table

To delete a table from your content, focus on the table and select "Delete a Table" tool from toolbar. It will delete the entire table with all formatting content.



Copyright © 2001 - 2020 Syncfusion Inc.

Note: To delete the table contents alone, select the required content of the table which you want to delete and press Delete key. All the content disappears but the rows and columns remain along with its formatting.

Working with Lists

The editor provides tools to makes your content as list such as an ordered and unordered list.

Create a Lists

By default, Insert Lists tool is enabled in the editor's toolbar.The editor's have ordered and unordered list types.

HTML

```
@{
List<String> toolsList = new List<string>() { "lists" };
List<String> lists = new List<string>() { "unorderedList", "orderedList"
};
}
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ToolsList(toolsList)
.Tools(tool => tool.Lists(lists))
.Render();}
<br />
```

Custom Lists

You can use custom lists tools to insert lists with custom behaviors.You can create a list with related attributes (such as listImage, listStyle, title, name, and text) using the custom list tool.Ordered and Unordered list having own customize ways to insert a list into the editor's content.

- Insert a customOrderedList
- Insert a customUnorderedList

Insert a customOrderedList

you need to enable customOrderedList tool on the editor's toolbar.

The customOrderedList having below options for an ordered list customization.

Option	Summary
name	Specifies the name for customOrderedList item.
tooltip	Specifies the title for customOrderedList item.
CSS	Specifies the styles for customOrderedList item.

Copyright © 2001 - 2020 Syncfusion Inc.

text	Specifies the text for customOrderedList item.
listStyle	Specifies the list style for customOrderedList item.
listImage	Specifies the image for customOrderedList item.

HTML

```

Clean unwanted elements and styles when copy paste from Microsoft Word

While copy pasting content from MSWord document, the content will be processed in the paste action event.pasteCleanupSettings API can be used for removing unwanted elements.

This will convert an unformatted html element (MOS XML format) content to a proper html element.Table elements also will be converted with proper elements.

Options	Description
listConversion	List Conversion option convert the list elements into a proper format pasted from MSWord document to editor.
cleanCSS	Clean Css is used to clean the unwanted css in the elements pasted from MSWord document to editor
removeStyles	Remove styles will remove all styles in the elements pasted from MSWord document to editor.
cleanElements	Clean Elements is used to clean the unwanted elements pasted from MSWord document to editor.

```

Zoom

The editor provides zoom tools which enlarges the view of an editor's object enabling you to see more detail. You can continuous zoomIn and zoomOut either using zoom tools or keyboard.

You can assign Increases and decreases of zooming range using zoomStep property

HTML

```
@{
List<String> toolsList = new List<string>() { "view" };
List<String> view = new List<string>() { "zoomIn","zoomOut" };
}
@{Html.EJ().RTE("rteSample").Width("800px").ZoomStep("0.05").ContentTempl
ate(@<div>

Find and Replace

RTE provides find and replace support, which is used to search for a keyword in RTE content and replace the matched keyword with a specified text. In order to use it, we have to enable the find and replace item in the editor toolbar (or) Press CTRL+F key.

HTML

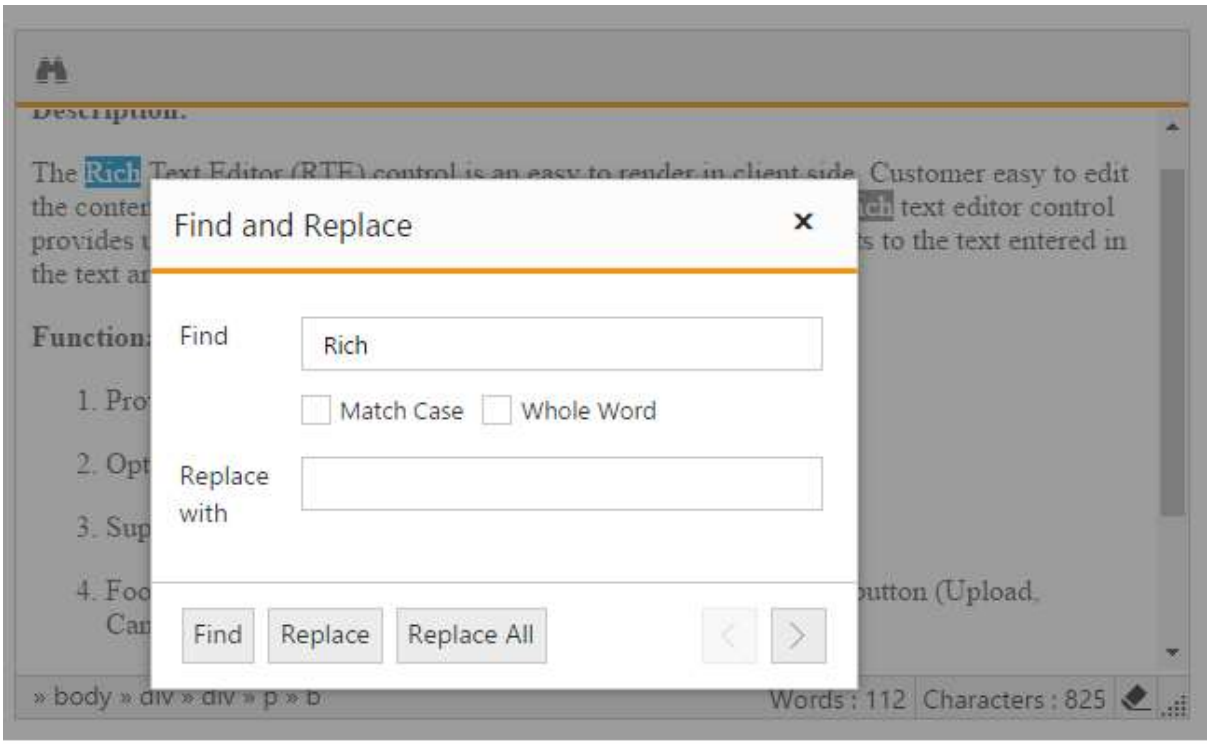
```
@{
List<String> edit = new List<string>() { "edit" };
List<String> editTool = new List<string>() { "findAndReplace" };
}
@{Html.EJ().RTE("rteSample").Width("800px").ContentTemplate(@<div>
The Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area.
</div>)
.ToolsList(edit)
.Tools(tool => tool.Edit(editTool))
```

- Find and Replace action should happen in a following sequence:

Copyright © 2001 - 2020 Syncfusion Inc.

Find => Replace (or) Replace All.

Action	Descriptions
Find	Finds a keyword matches with the editor content.it consist of following filters. *Match Case.* Whole Word.
Replace	Replaces the particular selected match with the specified text.
ReplaceAll	Replaces the entire matches with the specified text.



Note: Before performing the Replace/ReplaceAll action, we must do the find action to validate the match's availability.

Localization

The editor provides option to localize its strings, it is used to adapting the editor to a particular local language. By default, the editor will use the US English (en-US) as its language. Please find the table with list of keys and their corresponding values for default language (en-US).

HTML

new Syncfusion.JavaScript.Models.Format { Text= "Kopf 6", Value= "h6",
SpriteCssClass= "e-h6" }
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
};
rte.Format = list;
rte.Value =
"Das RichTextEditor (RTE) Steuerung ermöglicht Ihnen, den Inhalt mit Eins
atz Tisch und Bilder zu bearbeiten ," +
" sondern bietet auch eine Werkzeugleiste , die Rich-Text- Format ," +
" um die in der Textarea eingegeben Gehalt gelten können.";
rte.Locale = "de-DE";
}
@{Html.EJ().RTE("rteSample", rte)
.Render();}.
```

Keyboard Support

The editor has full keyboard accessibility that includes shortcuts to open and to do other actions with toolbar items, drop-down lists, and dialogs.

Press	To do this
Arrow keys	When a toolbar is focused Move between options in an open drop-down list
Enter	Execute the selected button, drop-down item
ESC	Cancel an action or close the dialog
HOME END	Go to first/last of the line
CTRL + HOME CTRL + END	Go to the beginning/end of a content
PAGE UP PAGE DOWN	Scroll up/down page in the content
CTRL + A	Select all content
CTRL + C	Copy the selected text or image
CTRL + X	Cut the selected text
CTRL + V	Paste text or image
CTRL + Z	Undo the last action
CTRL + Y	Redo the last action

Copyright © 2001 - 2020 Syncfusion Inc.

CTRL + U	Make text underline
CTRL + I	Make text italic
CTRL + B	Make text bold

To disable the keyboard navigation, set the AllowKeyboardNavigation property of the editor to false (its default value is true). It will disable all the keyboard navigation shortcuts except for the UP/DOWN keys and PAGE UP/PAGE DOWN keys.

HTML

```
@{Html.EJ().RTE("rteSample").Width("100%").ContentTemplate(@<p>
The Rich Text Editor (RTE) control is an easy to render in client side.
Customer easy to edit the contents and get the HTML content for the
displayed content.
A rich text editor control provides users with a toolbar that helps them
to apply rich text formats to the text entered in the text area.
</p>)
.AllowKeyboardNavigation(false)
.Render();}
```

Strongly typed HTML helper

The RTE control supports strongly typed HTML helpers which use lambda expressions to reference models or view models passed to a view template. These helpers allow you to define the value of the RichTextEditorFor from the model. The following steps explain how to use the strongly typed helpers to create RichTextEditorFor.

Add a class named "RTE" in the Models folder and replace the code with the following code:

HTML

```
public class RTE
{
public string value { get; set; }
}
```

In the controller, pass the model to the View.

HTML

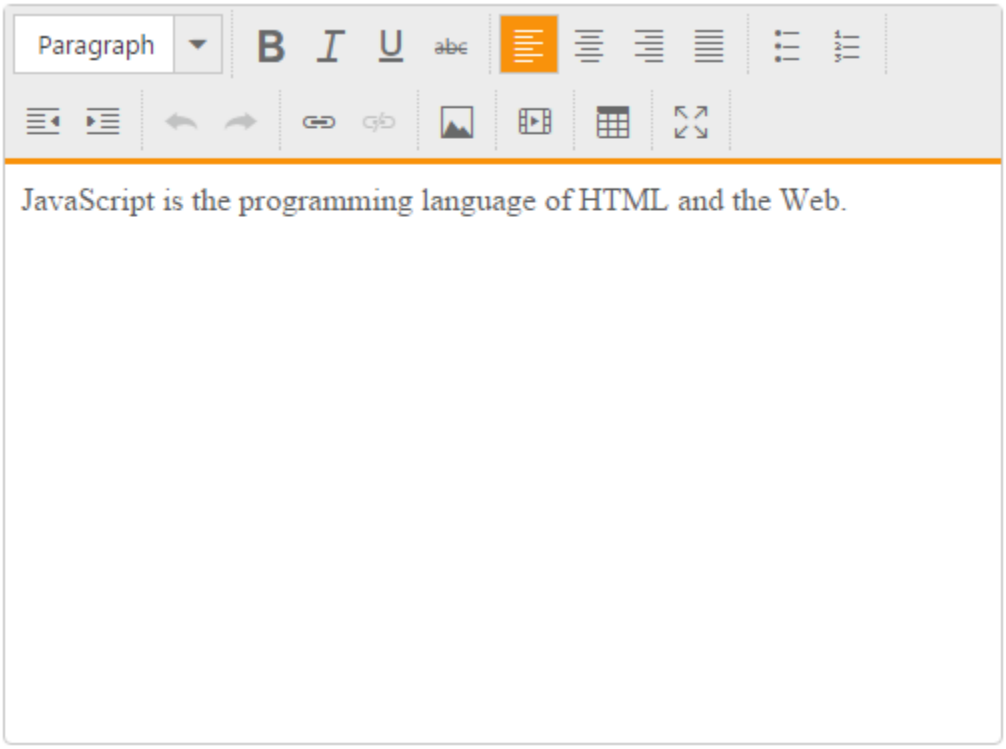
```
using UserInterface.Models;
public ActionResult RichTextEditorFeatures()
{
RTE obj = new RTE ();
obj.value = "JavaScript is the programming language of HTML and the
Web.";
return View(obj);
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

In View, invoke the strongly typed RichTextEditor helper with the lambda expression to set the default value.

HTML

```
@model UserInterface.Models.RTE
@using (Html.BeginForm())
{
@Html.EJ().RTEFor(model => model.value )
}
```



XHTML Validation

The editor provides option to validate its content through the EnableXHTML property. When you set or modify the content into the editor, it continuously checks whether the HTML source of the content that you are creating is valid. The editor examines the HTML markup and then removes the elements or attributes that are not valid.

RAZOR

```
@{
Html.EJ().RTE("rteSample").Width("820px").ContentTemplate(@<div>
The RichTextEditor (RTE) control enables you to edit the contents with in
sert table and images
It also provides a toolbar that helps to apply rich text formats to the c
ontent entered in the TextArea
</div>)
.EnableXHTML(true)
.Render();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

The editor checks the following settings on validation:

- **Attributes**
- Must be specified in lowercase
- Proper use of quotation marks around the attributes
- Must be valid attributes for corresponding HTML element
- All the required attributes must be included in the HTML element
- Accepts the allowed values alone such as true or false.
- **HTML Elements**
- Must be in lowercase
- All opening tags must be closed
- Allows only the valid HTML elements

Import

Import feature provides support to import a word document into the editor `textarea`. To enable import option in the RTE tool bar, `import` toolbar items needs to be added in RTE toolbar toolsList using `importExport` which adds the tool in the toolbar. In `ImportSettings` Url option, the server page for import is needed to be mapped. When you click the toolbar import icon, it opens a dialog to browse the select a word file. The selected word file will be imported into the editor `textarea`.

RAZOR

```
@{
List<String> toolsList = new List<string>() { "importExport" };
List<String> ImportExport = new List<string>() { "import" };
}
@{
Html.EJ().RTE("rteSample").Width("100%").ContentTemplate(@<div>

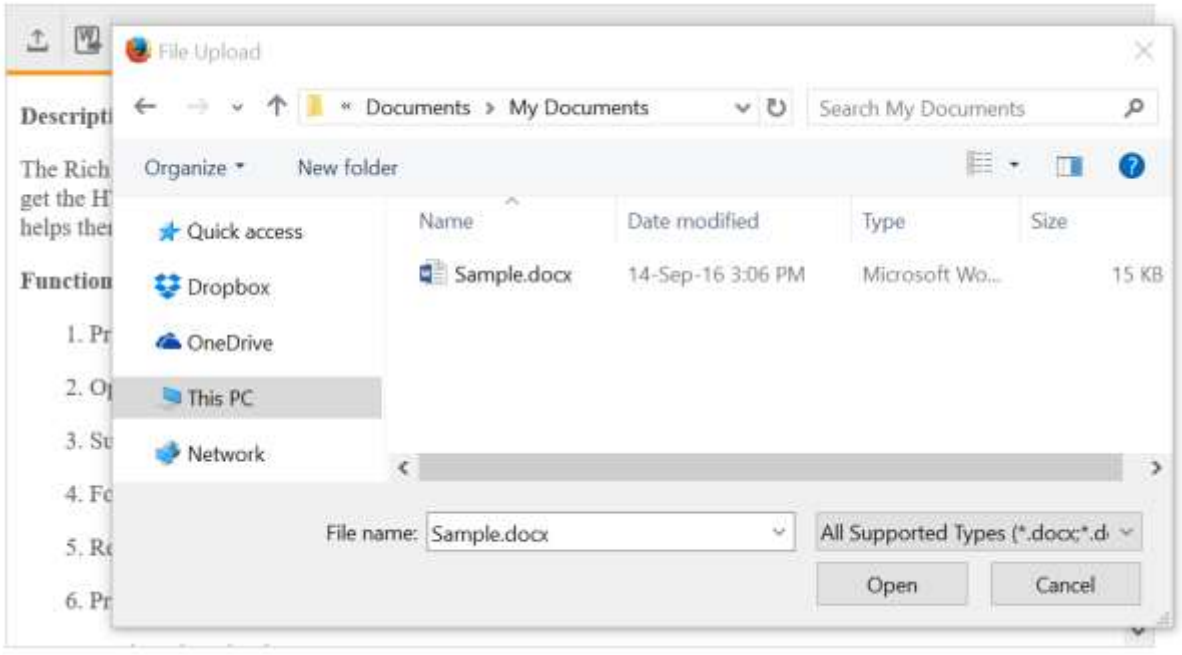
Import Server Dependencies

Full list of assemblies needed for RTE Import are as follows

1. Syncfusion.EJ
2. Syncfusion.EJ.Export
3. Syncfusion.Linq.Base

Copyright © 2001 - 2020 Syncfusion Inc.

4. Syncfusion.Compression.Base
5. Syncfusion.DocIO.Base



Export

Export feature provides support to export editor textarea content into word and PDF files. To enable Export option in the RTE tool bar, wordExport , pdfExport toolbar items needs to be added in RTE toolbar toolsList using importExport which adds the tool in the toolbar. ExportToWordSettings consists of Url and FileName sub properties. In Url property, the server page for export to word is needed to be mapped and In FileName property, the name for the exported word file is given. ExportToPdfSettings consists of Url and FileName sub properties. In Url property, the server page for export to PDF is needed to be mapped and In FileName property, the name for the exported PDF file is given. When you click the toolbar pdfExport or wordExport icon, the contents of RTE are sent to the server. It performs XHTML Validation on the editor textarea content on the server. Once the XHTML validation and formatting is successful, it exports the content into a Word or PDF File.

RAZOR

```
@{
List<String> toolsList = new List<string>() { "importExport" };

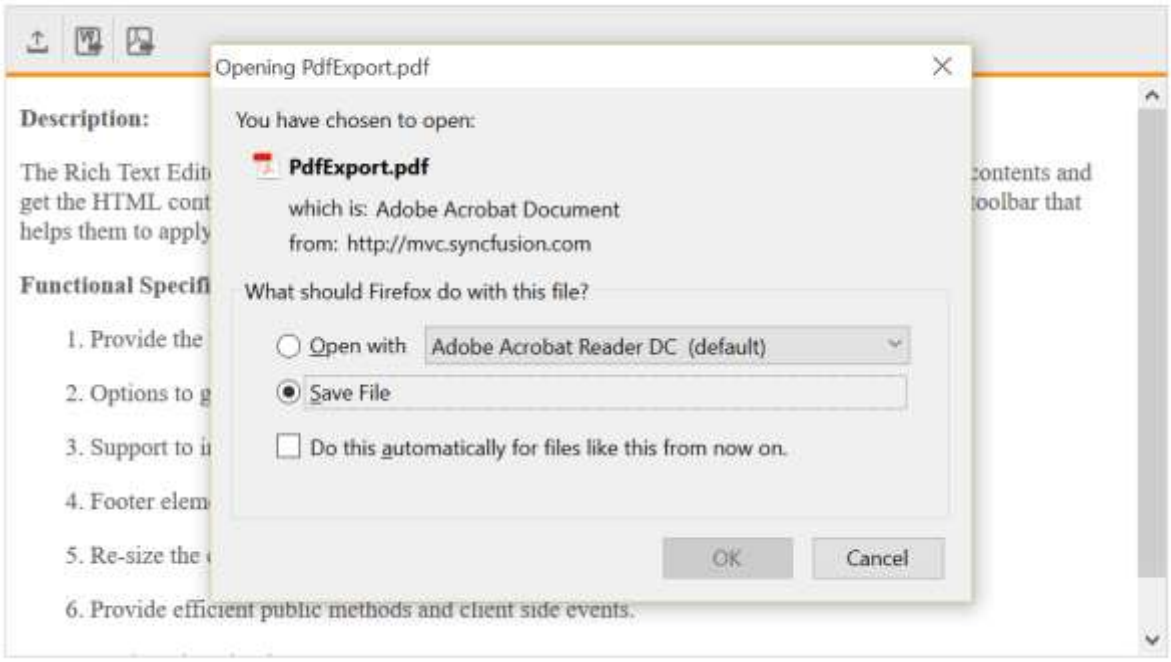
PDF Export



Validation

It's easy to validate the RichTextEditor's value on form submission by applying ValidationRules and ValidationMessage to the RichTextEditor.

Note: jquery.validate.min script file should be referred for validation, for more details, refer here.

jQuery Validation Methods

The following are jQuery validation methods.

List of jQuery validation methods

Rules	Description
required	Requires value for the RichTextEditor control.
minWordCount	Requires the value to be of given minimum words count.
minlength	Requires the value to be of given minimum characters count.
maxlength	Requires the value to be of given maximum characters count.

Validation Rules

The validation rules help you to verify the content by adding validation attributes to the text area. This can be set by using ValidationRules property.

Validation Messages

You can set your own custom error message by using ValidationMessage property. To display the error message, specify the corresponding annotation attribute followed by the message to display.

Copyright © 2001 - 2020 Syncfusion Inc.

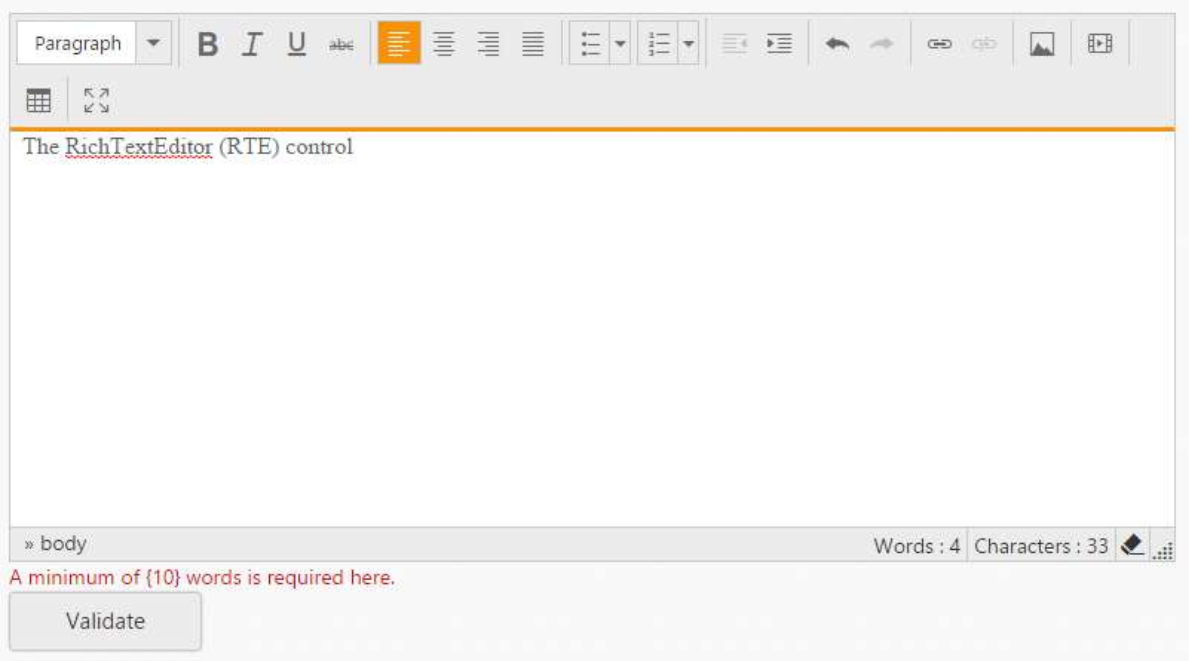
Note: jQuery predefined error messages to that annotation attribute will be shown when this property is not defined.

When you initialize the RichTextEditor widget, it creates a text area hidden element which is used to store the value. Hence, the validation is performed based on the value stored in this hidden element.

Required field and minWordCount values validation is demonstrated in the below given example.

HTML

```
@using (Html.BeginForm())
{
<br />
@Html.EJ().RTE("RTE1").ValidationRules(new Dictionary<string, object> { { "required", "true" }, { "minWordCount", 15 } }).ValidationMessage(new Dictionary<string, object> { { "minWordCount", "A minimum of {10} words is required here" }, { "Required", "Please enter the content" } })
<br />
@Html.EJ().Button("Btn1").Text("Validate")
}
```



Client Side Validation

In the Client Side Validation you can provide a better user experience by responding quickly at the browser level. When you perform a Client Side Validation, all the user inputs validated in the user's browser itself. Client Side validation does not require a round trip to the server, so the network traffic which will help your server perform better.

ASP.NET MVC supports client side validation. First of all you need to take a reference of two JavaScript files from Scripts folder, jquery.validate.min.js and jquery.validate.unobtrusive.min.js in your layout file as shown below.

HTML

```
<script src="~/Scripts/jquery.validate.min.js"></script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script src="~/Scripts/jquery.validate.unobtrusive.min.js"></script>
```

Now, add following two settings in <appSettings> section of web.config, if it is not there.

HTML

```
<appSettings>
<add key="ClientValidationEnabled" value="true" />
<add key="UnobtrusiveJavaScriptEnabled" value="true" />
</appSettings>
```

1. DataAnnotations provides a built-in set of validation attributes that you can apply declaratively to any class or property. Create RTE class to take advantage of the built-in Required validation attributes.

HTML

```
using System.ComponentModel.DataAnnotations;
public class RTE
{
[Required(ErrorMessage = "RTE value is Required")]
public string value { get; set; }
}
```

2. After that you need to create the controller's action methods. These render views on the UI and bind a model with the view. So let's create a controller as follows.

HTML

```
public ActionResult RichTextEditorFeatures()
{
controlInitialization();
return View();
}
[HttpPost]
public ActionResult RichTextEditorFeatures(RTE model)
{
if (ModelState.IsValid)
{
//perform some action
return RedirectToAction("Home");
}
controlInitialization();
return View(model);
}
public void controlInitialization()
{
RTEproperties property = new RTEproperties();
List<String> toolsList = new List<string>() { "alignment" };
List<String> alignment = new List<string>() { "justifyLeft",
"justifyCenter" };
property.ToolsList = toolsList;
RTEtools tools = new RTEtools();
tools.Alignment = alignment;
ViewData["edit"] = property;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
```

In our example, the form is not posted to the server when there are validation errors detected on the client side.

3. Below is the RichTextEditorFeatures.cshtml view and It's used by the action methods shown above both to display the initial form and to redisplay it in the event of an error.

HTML

```
@using (Html.BeginForm())
{
@Html.ValidationSummary(true)
@Html.EJ().RTEFor(model => model.value,
(Syncfusion.JavaScript.Models.RTEproperties)ViewData["edit"])
@Html.ValidationMessageFor(model => model.value)
<br />
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("Post").Type(ButtonT
ype.Submit)
}
```

Server side Validation

In the Server Side Validation, the input submitted by the user is being sent to the server and validated using one of server side scripting languages. After the validation process on the Server Side, the feedback is sent back to the client.

ASP.NET MVC uses Data Annotations attributes to implement validations. Data Annotations includes built-in validation attributes for different validation rules, which can be applied to the properties of model class. ASP.NET MVC Framework will automatically enforce these validation rules and display validation messages in the view.

1. First of all, apply DataAnnotation attribute on the properties of RTE model class. Here, we have validate the value of the RichTextEditor should not be empty.

HTML

```
using System.ComponentModel.DataAnnotations;
public class RTE
{
[Required(ErrorMessage = "RTE value is Required")]
public string value { get; set; }
}
```

2. Create an action method in the controller that returns a view with a model after the post request.

HTML

```
public ActionResult RichTextEditorFeatures()
{
controlInitialization();
return View();
}
[HttpPost]
public ActionResult RichTextEditorFeatures(RTE model)
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
if (ModelState.IsValid)
{
//perform some action
return RedirectToAction("Home");
}
controlInitialization();
return View(model);
}
public void controlInitialization()
{
RTEproperties property = new RTEproperties();
List<String> toolsList = new List<string>() { "alignment" };
List<String> alignment = new List<string>() { "justifyLeft",
"justifyCenter" };
property.ToolsList = toolsList;
RTEtools tools = new RTEtools();
tools.Alignment = alignment;
ViewData["edit"] = property;
}
```

As you can see in the POST Edit method, we first check if the ModelState is valid or not. If ModelState is valid then perform some action, if not then return RichTextEditorFeatures view again with the same RTE data.

ModelState.IsValid determines that whether submitted values satisfy all the DataAnnotation validation attributes applied to model properties.

3. After that, created a view for RichTextEditor.

HTML

```
@model ClientValidation.Models.RTE
@{
ViewBag.Title = "RTE";
Layout = "~/Views/Shared/_Layout.cshtml";
}
<h2>RTE Features:</h2>
<br/>
@using (Html.BeginForm())
{
@Html.EJ().RTEFor(model => model.value,
(Syncfusion.JavaScript.Models.RTEproperties)ViewData["edit"])
@Html.ValidationMessageFor(model => model.value)
<br />
@Html.EJ().Button("btn").Size(ButtonSize.Small).Text("Post").Type(ButtonT
ype.Submit)
}
```

As you can see in the above RichTextEditorFeatures.cshtml, it calls HTML Helper method ValidationMessageFor for every field. ValidationMessageFor is responsible to display error message for the specified field.

So now, it will display default validation message when you submit the form without entering a value for the RichTextEditor.

Copyright © 2001 - 2020 Syncfusion Inc.

How to

Render the RichTextEditor in Partial View

While rendering a control in the partial view, we need to specify @Html.EJ().ScriptManager() in the partial view page after the initializing the control.

Create a Partial View and define as follows

HTML

```
@Html.EJ().RTE("RTE1").Value("Model Binding allows you to map and bind
the HTTP request data with a model. If you want to work with the form
data, Model Binding makes it easier because the requested data is
submitted automatically into a data model that we
specify.").Width("650px")
@Html.EJ().ScriptManager()
```

Render the partial view into parental view.

HTML

```
@Html.Partial("~/Views/Temp.cshtml");
```

Note: When unobtrusive is set to true in the application, then the script manager can be excluded, as the control is initialized using HTML5 attributes.

If suppose, you require the Unobtrusive to set to true in your application, then you need to include the ej.unobtrusive.min.js file as a reference to your application and set the value of UnobtrusiveJavaScriptEnabled to true in Root directory web.config file.

Copyright © 2001 - 2020 Syncfusion Inc.

Import word document to the RichTextEditor and Export to word document/pdf

Using customTools property in the RichTextEditor to specify which tools to be displayed in the toolbars or create your own command elements, be it Buttons or DropDownList.

In controller, defines the property for the RichTextEditor as well as define your custom tools as follows as.

HTML

```
public ActionResult RichTextEditorFeatures()
{
Syncfusion.JavaScript.Models.RTEproperties property = new
Syncfusion.JavaScript.Models.RTEproperties();
List<Syncfusion.JavaScript.Models.CustomTools> customTool = new
List<Syncfusion.JavaScript.Models.CustomTools>();
customTool.Add(new Syncfusion.JavaScript.Models.CustomTools { Name =
"Import", Text = "Import", Css = "codeCheck", Action = "OnCheck" });
customTool.Add(new Syncfusion.JavaScript.Models.CustomTools { Name =
"Export", Text = "Export", Css = "codeCheck", Action = "OnCheck" });
customTool.Add(new Syncfusion.JavaScript.Models.CustomTools { Name =
"DropType", Text = "DropType", Css = "codeCheck", Action = "OnCheck" });
Syncfusion.JavaScript.Models.RTEtools tools = new
Syncfusion.JavaScript.Models.RTEtools();
tools.CustomTools = customTool;
property.PreRender = "OnRender";
List<String> toolsList = new List<string>() { "customTools" };
property.ToolsList = toolsList;
property.Tools = tools;
property.Value = "Please load the file";
property.ShowFooter = true;
property.EnableXHTML = true;
ViewBag.property = property;
return View();
}
```

Add the following code snippet to the corresponding view page to render the RichTextEditor.

HTML

```
@using (Html.BeginForm())
{
@Html.EJ().RTE("rte2",
(Syncfusion.JavaScript.Models.RTEproperties)ViewBag.property)
}
<div id="TargetList">
<ul>
<li>Word Document</li>
<li>PDF</li>
</ul>
</div>
```

In RichTextEditor’s preRender event, define your custom Tools as follows.

HTML

```
function OnRender(args) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
var importDocs = $("#Import");
$("#Import").find("div").remove();
var target = $("<div id='importFiles'></div>");
importDocs.append(target);
var exportDocs = $("#Export");
$("#Export").find("div").remove();
var export = $("<button id='exportFiles'></button>");
exportDocs.append(export);
var drop = $("#DropType");
$("#DropType").find("div").remove();
var dropTarget = $("<input id='selectType'></div>");
drop.append(dropTarget);
$("#importFiles").ejUploadbox({
saveUrl: "/saveFiles.ashx",
removeUrl: "/removeFiles.ashx",
extensionsAllow: ".doc, .docx, .pdf",
autoUpload: true,
showFileDetails: false,
dialogAction: { content: "body" },
complete: "onComplete"
});
$("#exportFiles").ejButton({
size: "small",
text: "Export",
type : "submit",
});
$('#selectType').ejDropDownList({
watermarkText: 'Select Type',
targetID: "TargetList",
width: "150px",
selectedIndex: 0
});
}
```

HTML

```
function onComplete(args) {
var fileName = args.files.name;
var extension = args.files.extension;
$.ajax({
type: "POST",
contentType: 'application/json; charset=utf-8',
url: '@(Url.Action("Extract"))',
data: JSON.stringify({ name : fileName, ext : extension }),
dataType: "html",
success: function (result) {
if (result != null) {
$("#rte2").ejRTE({ value: result });
}
},
error: function (jqXHR, textStatus, errorThrown) {
alert("Request failed: " + jqXHR.responseStart + "-" + textStatus + "-" +
errorThrown);
}
});
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

In AJAX post back, Retrieve the content from the uploaded files and set the extracted text to the RichTextEditor.

HTML

```
public string Extract(string name, string ext)
{
string value = " ";
if (ext == ".pdf")
{
String path = HttpContext.Server.MapPath("~/uploadfiles/" + name);
Stream sfile1 = new FileStream(path, FileMode.Open, FileAccess.Read,
FileShare.Read);
PdfLoadedDocument loadDocument = new PdfLoadedDocument(sfile1);
// Loading Page collections
PdfLoadedPageCollection loadedPages = loadDocument.Pages;
// Extract text from PDF document pages
foreach (PdfLoadedPage loadPage in loadedPages)
{
value += loadPage.ExtractText();
}
}
else
{
WordDocument document = new WordDocument();
String path = HttpContext.Server.MapPath("~/uploadfiles/" + name);
document.Open(path);
MemoryStream stream = new MemoryStream();
document.Save(stream, FormatType.Html);
stream.Position = 0;
StreamReader reader = new StreamReader(stream);
value = reader.ReadToEnd();
}
return xhtmlValidation(value);
}
```

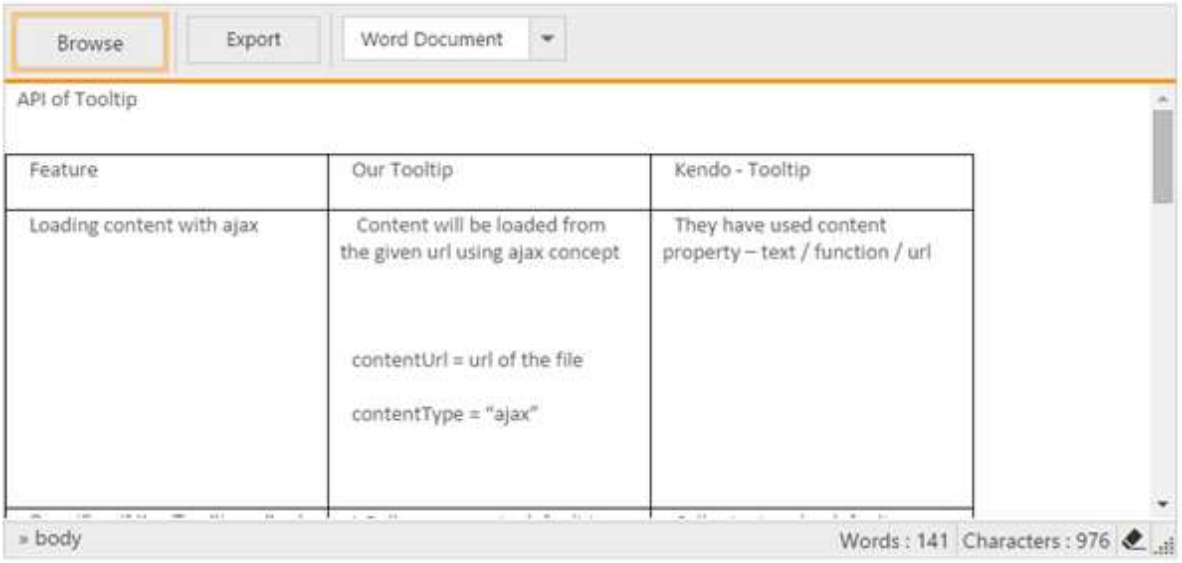
HTML

```
public string xhtmlValidation(string value)
{
if (value != null)
{
if (value.Contains("<html"))
{
int number = value.IndexOf("<body>");
value = value.Remove(0, number + 6);
value = value.Replace("</body></html>", "");
}
value = value.Replace("\"", "'");
value = value.Replace("\r", " ");
value = value.Replace("\n", "<br/> ");
value = value.Replace("\r\n", " ");
value = value.Replace("( )+", " ");
value = value.Replace(" ", " ");
value = value.Replace("&#8226;", "*");
```

Copyright © 2001 - 2020 Syncfusion Inc.

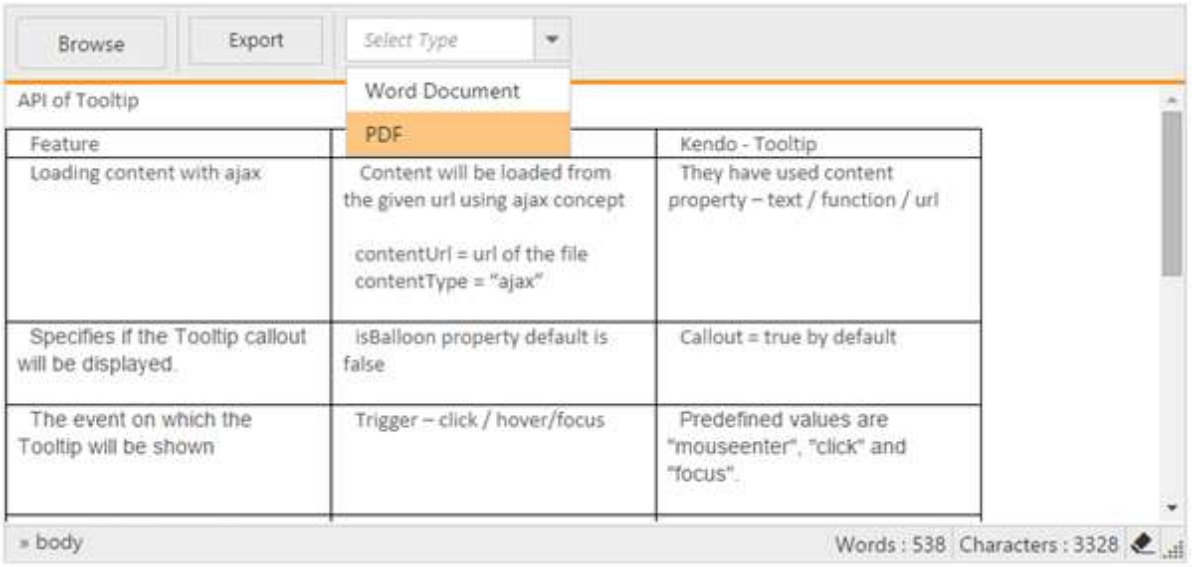
```
value = value.Replace("&#8249;", "<");
value = value.Replace("&#8250;", ">");
value = value.Replace("&#8482;", "(tm)");
value = value.Replace("&#169;", "(c)");
value = value.Replace("&#174;", "(r)");
}
return value;
}
```

Note: If you have selected the document in .pdf format, the text only extracted from the document and set as value to the RichTextEditor.



In above screenshot, use Browse options to browse your files and upload the content to RichTextEditor.

Use DropDownList control in the toolbar to choose the any one type be it is PDF or word document and click Export button to export the content of the RichTextEditor to the selected type.



Upon clicking to the Export button, the post back action has been raised, in that content from the RichTextEditor retrieved and stored as the corresponding format.

HTML

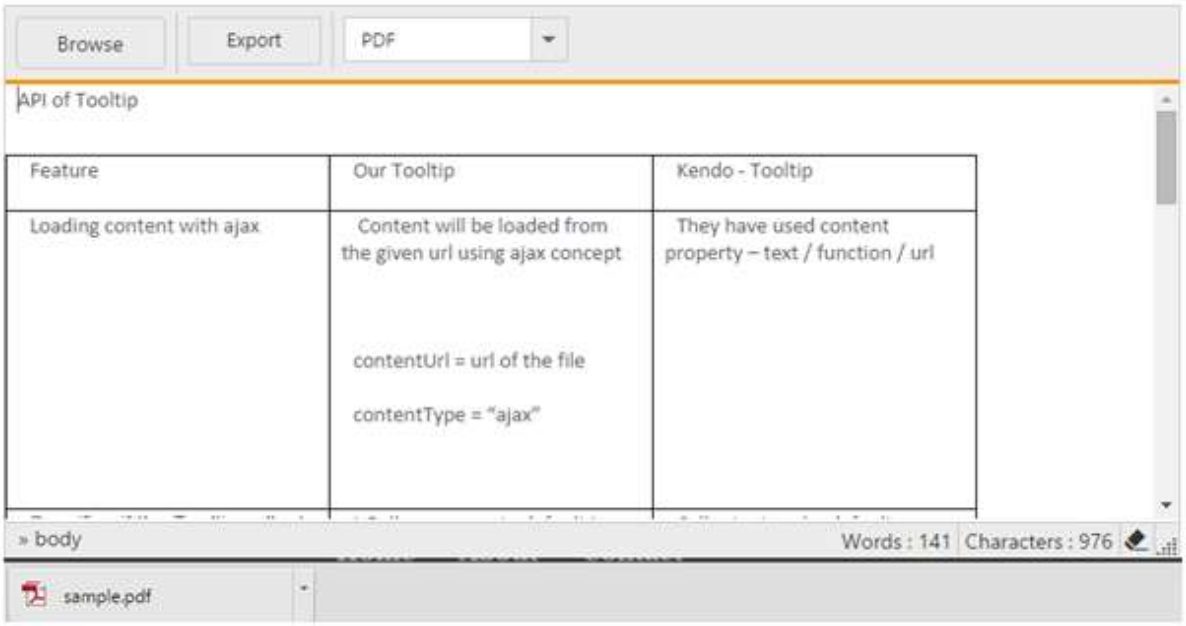
```
[HttpPost]
[ValidateInput(false)]
public void RichTextEditorFeatures(string rte2, string selectType)
{
if (selectType == "PDF")
{
PdfDocument document = new PdfDocument();
ThreadStart starter = () => CreateDocument(rte2);
Thread t = new Thread(starter);
t.SetApartmentState(ApartmentState.STA);
t.Start();
t.Join();
}
else
{
WordDocument document = new WordDocument();
MemoryStream stream = new MemoryStream();
StreamWriter writer = new StreamWriter(stream,
System.Text.Encoding.Default);
string htmlText = rte2;
writer.Write(htmlText);
writer.Flush();
stream.Position = 0;
document = new WordDocument(stream, FormatType.Html,
XHTMLValidationType.Strict);
document.Save("Sample.docx", FormatType.Docx,
HttpContext.ApplicationInstance.Response,
HttpContentDisposition.Attachment);
}
}
```

HTML

```
public void CreateDocument(string rte2)
{
PdfDocument pdfDocument = new PdfDocument();
pdfDocument.PageSettings.Margins.All = 0;
PdfPage page = pdfDocument.Pages.Add();
SizeF pageSize = page.GetClientSize().ToSize();
AspectRatio dimension = AspectRatio.KeepWidth;
HtmlConverter html = new HtmlConverter();
PdfUnitConvertor converter = new PdfUnitConvertor();
float width = converter.ConvertToPixels(pageSize.Width,
PdfGraphicsUnit.Point);
float height = converter.ConvertToPixels(pageSize.Height,
PdfGraphicsUnit.Point);
PdfMetafileLayoutFormat metafileFormat = new PdfMetafileLayoutFormat();
metafileFormat.Break = PdfLayoutBreakType.FitPage;
metafileFormat.Layout = PdfLayoutType.Paginate;
metafileFormat.SplitTextLines = false;
metafileFormat.SplitImages = false;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
string htmlText = @"<html><head><title></title></head><body><div>" + rte2
+ "</div></body></html>";
HtmlToPdfResult result =
html.Convert(htmlText,"",Syncfusion.HtmlConverter.ImageType.Metafile,
(int)width, (int)height, dimension);
result.Render(page, metafileFormat);
pdfDocument.Save("sample.pdf", HttpContext.ApplicationInstance.Response,
HttpReadType.Save);
}
```



Enable the Browser Spell checker in RTE

Currently we do not have in-built spell checker support in RTE. But we can use the Browser spell checker.

1. First, disable the context menu option from RTE. To do this, please refer the below code snippet.

HTML

```
@{Html.EJ().RTE("rteSample").Width("100%").EnableRTL(true).ShowContextMen
u(false).IFrameAttributes(parameters).Locale("en-
US").ContentTemplate(@<p>
Description:
The Rich Text Editor (RTE) control is an easy to render in client side.
Customer easy to edit the contents and get the HTML content for the
displayed content. A rich text editor control provides users with a
toolbar that helps them to apply rich text formats to the text entered in
the text area.
</p>).Render();}
```

2. Enable the spellcheck property in RTE iframe element. To do this, please refer the below code snippet.

Copyright © 2001 - 2020 Syncfusion Inc.

HTML

```
IDictionary<string, object> parameters = new Dictionary<string,
object>();
parameters.Add("spellcheck", "true");
```

In the above sample, we have disabled the RTE content menu by setting “ShowContextMenu” property as false, so that on right click to the RTE we can get the browser spell check suggestion after enabling the spell checker in Iframe by setting the spellcheck as true in iframeAttributes property.

Pass the RTE from partial view to main view using AJAX call

In main view, the Button control is rendered, upon clicking to the Button, the AJAX call is initiated.

HTML

```
@Html.EJ().Button("button1").Text("Load
RTE").ShowRoundedCorner(true).Size(ButtonSize.Small).ClientSideEvents(e
=> e.Click("onClick"))
<div id="display"></div>
<script type="text/javascript">
var value;
function onClick(e) {
$.ajax({
type: "Post",
url: "/RichTextEditor/LoadRTE",
contentType: "application/json; charset=utf-8",
async: false,
success: function (value) {
$("#display").html(value);
ej.widget.init("#display");
}
});
}
</script>
```

The controller returns the partial view to the AJAX call. In the success function of the AJAX, the returned HTML appended to the div element. In this case, the Syncfusion widgets need to be initiated.

HTML

```
public ActionResult RichTextEditorFeatures()
{
return View();
}
public ActionResult LoadRTE(string value)
{
RTEModel.text = value;
return PartialView("~/Views/RichTextEditor/RTE.cshtml");
}
```

In the partial view, the RTE is rendered as follows

HTML

```
@model  RTEPartialView.Models.RTEModel
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@{Html.EJ().RTE("Id1").Width("100%").ContentTemplate(@<p>
</p>).ShowHtmlSource(true).ShowFooter(true).Value(RTEPartialView.Models.R
TEModel.text).Render();}
```

Render RichTextEditor from code behind

RichTextEditor can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of RichTextEditor using RichTextEditor properties from code behind.

RAZOR

```
@model  Syncfusion.JavaScript.Models.RTEproperties
@{
Html.EJ().RTE("rteSample",
(Syncfusion.JavaScript.Models.RTEproperties)ViewData["RTEModel"]).Render(
);   // render the RTE in view
}
```

C#

```
public ActionResult Index()
{
RTEproperties RTEObj = new RTEproperties();
RTEObj.ContentTemplate = new MvcTemplate<object>
{
RazorViewTemplate = (data) =>
{
return "This is RTE content";
}
};
RTEObj.Width = "550";
RTEObj.IsResponsive = true;
ViewData["RTEModel"] = RTEObj;
return View(RTEObj);
}
```

Display content from db and post content to db in RTE

We can use setHtml() method in the RTE control to display the content from the database into RTE.We can edit this content in RTE and get the modified content through getHtml() method of RTE and pass this to controller and save in your database.

The following code illustrates how to set content from db

RAZOR

```
<div>
@{Html.EJ().RTE("rteSample").ContentTemplate(@<p>
&#60;p&#62;&#60;b&#62;Description:&#60;/b&#62;&#60;/p&#62; &#60;p&#62;The
Rich Text Editor
(RTE) control is an easy to render in client side. Customer easy to edit
the contents
and get the HTML content for the displayed content. A rich text editor
control provides
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
users with a toolbar that helps them to apply rich text formats to the
text entered
in the text area. &#60;/p&#62; &#60;p&#62;&#60;b&#62;
</p>).ClientSideEvents(e=> e.Create("onCreate")).Render();}
</div>
<br /><br />
<button id="set" >Import content from Server</button>
<button id="get">Get Content from RTE</button>
<script>
var rteObj;
$(function () {
$("#set").on("click", function () {
$.ajax({
url: "@Url.Action("GetData", "Home")",
type: "GET",
contentType: "application/json; charset=utf-8",
success: function (e) {
rteObj.setHtml(e); //set content from server
}
});
});
$("#get").on("click", function () {
alert(rteObj.getHtml()); //get content from RTE
});
});
function onCreate() {
rteObj = this;
}
</script>
```

C#

```
public ActionResult GetData()
{
var NewContent = "<p>This is <b>New</b> content from the
<i>Controller</i></p>";
return Content(NewContent);    //return data from db
}
```

Rotator

Rotator

The ASP.NET MVCRotator control displays a set of slides. Each slide may contain images or images with content, or content with user-defined transition between them. It supports Data Binding, Thumbnail, Pager, dynamic number of slide move options, and all custom animations. It supports all types of image formats (JPEG, GIF, and so on).

Key Features

- Data Binding: Supports data binding with JSON data as well as remote data.
- Image with Content: Supports to render an image, content, or image with content.
- Display Dynamic number of Slide: Supports dynamic (one or more) number of slides.

Copyright © 2001 - 2020 Syncfusion Inc.

- Move Dynamic Number of Slide: Supports to move dynamic (one or more) number of slides at a time.
- Autoplay: Supports autoplay mode for slide transition.
- Pager and Thumbnail: Support to navigate between slides.

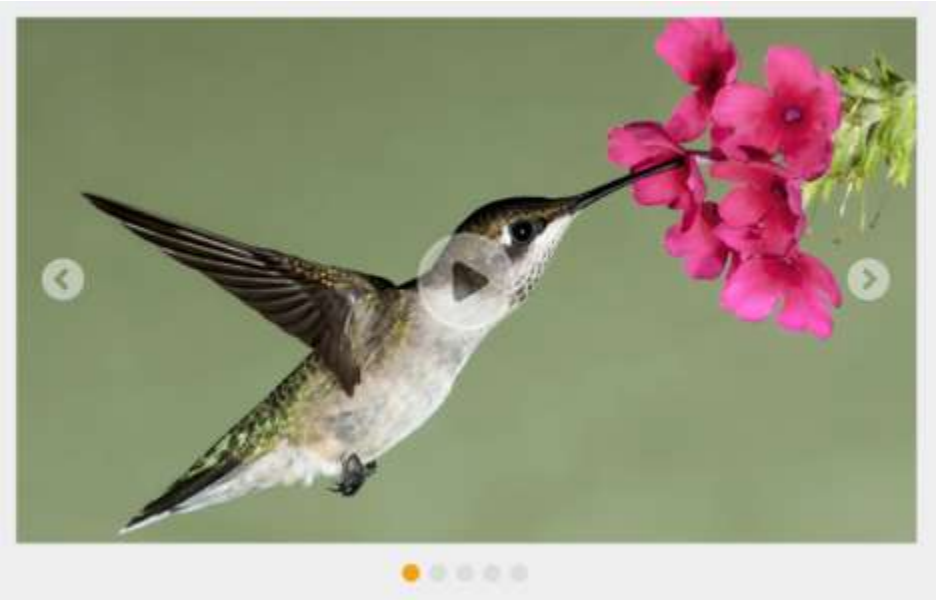
Getting Started

This section explains briefly about how to create a Rotator in your ASP.NET MVC application.

Create your first Rotator in MVC

ASP.NET MVC Rotator provides support to display the provided number of images within your web page in a rotating manner. Refer the following guidelines to create a Rotator widget for a real-time website banner scenario that has five images that slide automatically. When you click the center button, images slide in a rotating manner and on second click, the rotation stops.

The following screenshot illustrates a Rotator widget.



Rotator

Create a Rotator

Essential Studio ASP.NET MVCRotator widget has built-in features such as unobtrusive and flexible APIs. You can easily create the Rotator widget using simple HTML helper as follows.

1. Create a MVC Project and add necessary assemblies, styles, and scripts to it.

Refer MVC-Getting Started.

2. Add the following code example to the corresponding view page to render Rotator. Move the images under the folder ~/Images/rotator.

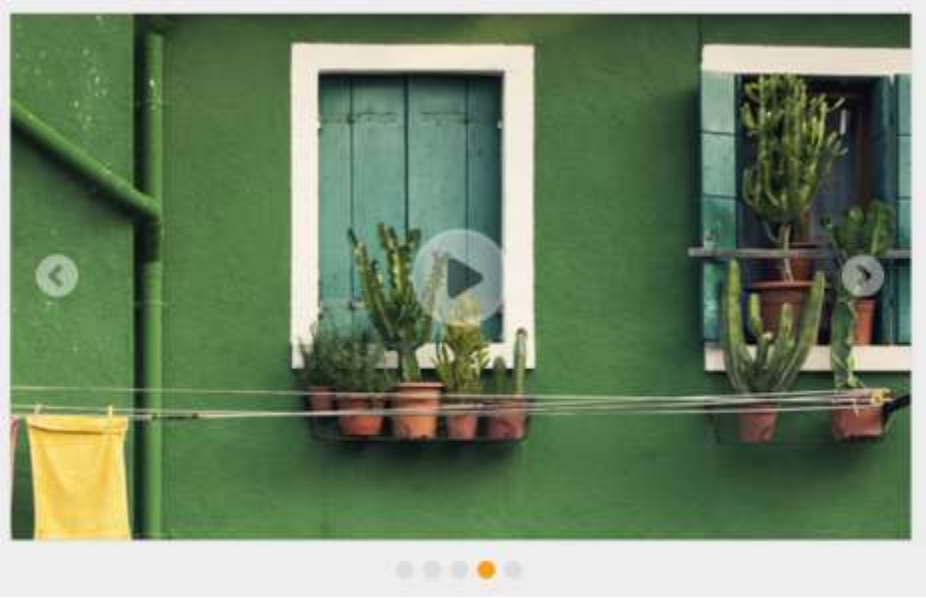
ASPX-CS

```
<div class="frame">
@{Html.EJ().Rotator("content").Items(item =>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
item.Add().ContentTemplate(@<div>
<img class="image" src="@Url.Content("~/Images/rotator/Untitled.png")" />
</div>);
item.Add().ContentTemplate(@<div>
<a href="~/Views/Home/Index.cshtml"></a>
<img class="image" src="@Url.Content("~/Images/rotator/Untitled1.png")"
/>
</div>);
item.Add().ContentTemplate(@<div>
<img class="image" src="@Url.Content("~/Images/rotator/Untitled2.png")"
/>
</div>);
item.Add().ContentTemplate(@<div>
<img class="image" src="@Url.Content("~/Images/rotator/Untitled3.png")"
/>
</div>);
item.Add().ContentTemplate(@<div>
<img class="image" src="@Url.Content("~/Images/rotator/Untitled4.png")"
/>
</div>);
})
.SlideWidth("600px").SlideHeight("350px").ShowPlayButton(true).Render();}
</div>
```

3. The following banner is displayed as output.



Data Binding

Rotator provides a flexible approach for binding the data from various data sources. There are various properties in Rotator for Data Binding. The value set to this property is object type.

Copyright © 2001 - 2020 Syncfusion Inc.

Data Fields and Configuration

The following sub-properties provide a way to bind the data either locally/remotely to the Rotator control.

DataSource

This property specifies the list of data that contains a set of data fields. Each data value is used to render an item for the Rotator. Datasource receives Essential DataManager object and JSON object. The value set to this property is object type.

Fields

It defines mapping fields for the data items of the Rotator. The value set to this property is object type.

Text

It specifies the text content of the Image in Rotator control. The value set to this property is string type.

Url

This property specifies the URL for an image. The value set to this property is string type.

Query

This property receives query to retrieve data from the table (query is same as SQL).This property is applicable only when a remote data source is used. Each data value is used to render an item for the Rotator. The value set to this property is object type.

Local data binding

Rotator provides the data binding support for the Rotator item. So you can bind the data from JSONData. For this behavior, you need to map the corresponding filed with their column names. The data can be bound as a list and it is assigned to Datasource property. You can refer the following code example to bind local data.

C#

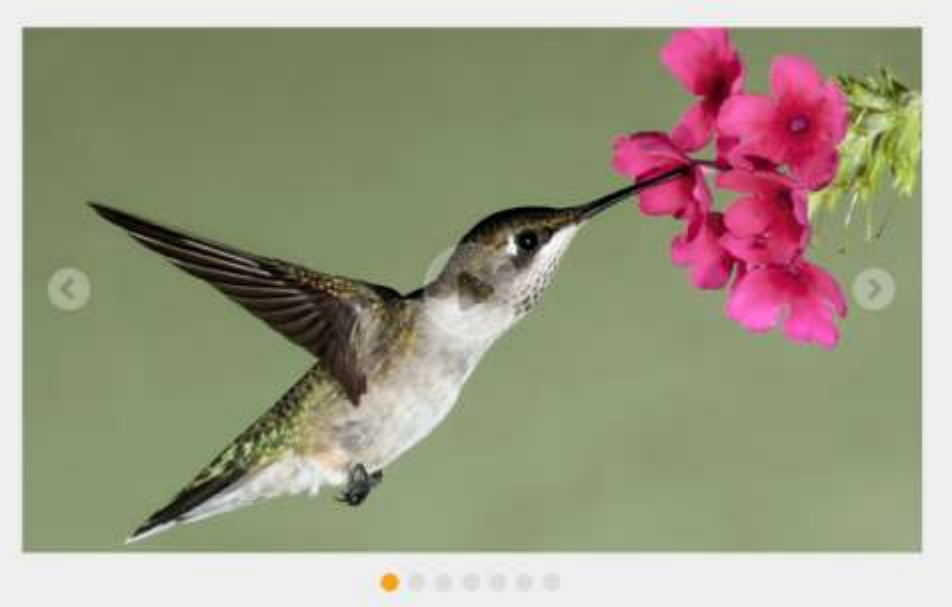
```
// Add the following data list to be bind in the controller page and
define the corresponding data.
// Define local data source elements with  fields
public class LocalData
{
public string Text { get; set; }
public string Url { get; set; }
}
//Refer the Model in the controller
using <Application name>.Models;
List<LocalData> localValues = new List<LocalData>();
public ActionResult Index()
{
localValues.Add(new LocalData { Text = "Beautiful Bird", Url =
"../Images/rotator/bird.jpg" });
localValues.Add(new LocalData { Text = "Colorful Night", Url =
"../Images/rotator/night.jpg" });
localValues.Add(new LocalData { Text = "Technology", Url =
"../Images/rotator/tablet.jpg" });
localValues.Add(new LocalData { Text = "Nature", Url =
"../Images/rotator/nature.jpg" });
localValues.Add(new LocalData { Text = "Snow Fall", Url =
"../Images/rotator/snowfall.jpg" });
localValues.Add(new LocalData { Text = "Credit Card", Url =
"../Images/rotator/card.jpg" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
localValues.Add(new LocalData { Text = "Amazing Sculptures", Url =
"../Images/rotator/sculpture.jpg" });
ViewBag.datasource = localValues;
return View();
}
```

ASPX-CS

```
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text")
.Url("Url")).SlideWidth("600px")
.SlideHeight("350px")
.ShowPlayButton(true)
```



Rotator control with local data binding

Behavior settings

Enabling rotator

Enabled property is a Boolean type, which allow us to enables or disable the Rotator control. The default value is ‘true’. You can specify the property Enabled in the script as follows.

ASPX-CS

```
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px").SlideHeight("350px").Enabled(false)
```

The following banner displaying as output.

Copyright © 2001 - 2020 Syncfusion Inc.

Responsive rotator

IsResponsive

IsResponsive property is Boolean type, which allow us to resizes the Rotator when the browser window is resized. The default value is ‘false’. You can specify the property IsResponsive in the script as follows.

ASPX-CS

```
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url")).SlideWidth("600px")
.SlideHeight("350px").IsResponsive(true)
```

EnableAutoPlay

The Rotator Items continuously rotate without user interference by enable the EnableAutoPlay property. The default value is ‘false’. The value set to this property is Boolean. You can specify the property EnableAutoPlay in the script as follows.

ASPX-CS

```
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url")).SlideWidth("600px")
.SlideHeight("350px").EnableAutoPlay(true)
```

StopOnHover

StopOnHover property is Boolean type, which allow us to pause the auto play while hover on the Rotator content. The default value is ‘false’. You can specify the property StopOnHover in the script as follows.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url")).SlideWidth("600px")
.SlideHeight("350px").EnableAutoPlay(true).StopOnHover(true)
```

Pager settings

PagerPosition

This property specifies the position of the Pager in the Rotator Item. The default value is ‘Outside’. This property is only applicable when ShowPager property is set true. The value set to the PagerPosition property is string or enum.

- Syncfusion.JavaScript.PagerPosition.BottomLeft
- Syncfusion.JavaScript.PagerPosition.BottomRight
- Syncfusion.JavaScript.PagerPosition.Outside
- Syncfusion.JavaScript.PagerPosition.TopCenter
- Syncfusion.JavaScript.PagerPosition.TopLeft
- Syncfusion.JavaScript.PagerPosition.TopRight

You can specify the property PagerPosition in the script as follows.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px").SlideHeight("350px")
.PagerPosition(Syncfusion.JavaScript.PagerPosition.TopLeft)
```

ShowPager

This property turns on or off the pager support in the Rotator control. The Pager is used to navigate the Rotator Items. The default value is ‘true’. The value set to this property is Boolean.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url")).SlideWidth("600px")
.SlideHeight("350px").ShowPager(false)
```

Show options

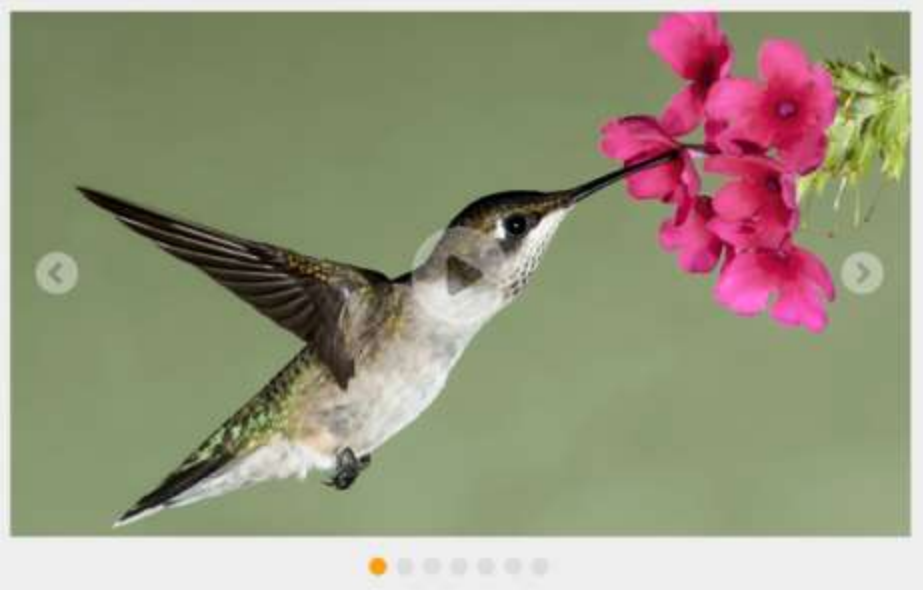
ShowPlayButton

ShowPlayButton property is Boolean type which allow us to enable play / pause button on Rotator. The default value of ShowPlayButton is ‘false’.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource).RotatorFields(t =>
t.Text("Text").Url("Url")).SlideWidth("600px").SlideHeight("350px").ShowP
layButton(true)
```

Copyright © 2001 - 2020 Syncfusion Inc.

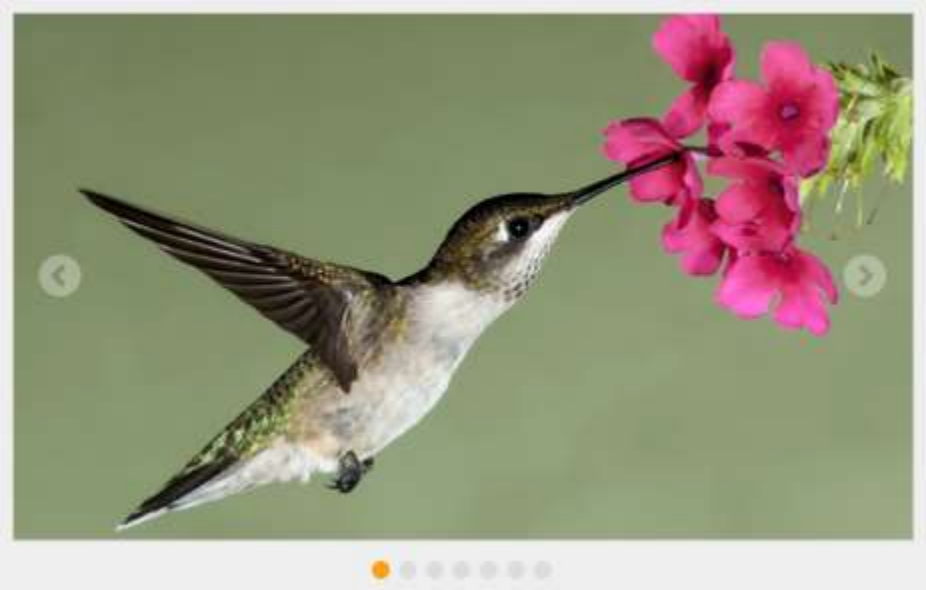


ShowNavigateButton

This property turns on or off the slide buttons (next and previous) in the Rotator Items. Slide buttons are used to navigate the Rotator Items. The default value is ‘false’. The value set to this property is Boolean.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px").SlideHeight("350px").ShowNavigateButton(true)
```



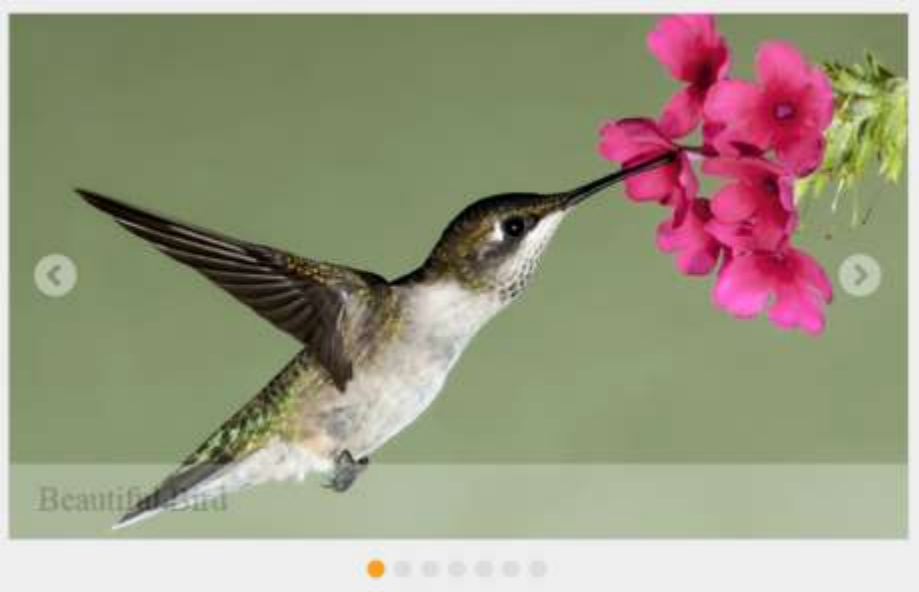
Copyright © 2001 - 2020 Syncfusion Inc.

ShowCaption

When the Rotator Item is an image, you can specify a caption for the Rotator Item. The caption text for each Rotator Item is shown by using ShowCaption property. This property is Boolean type, which allow us to Show or Hide the Caption about Images on bottom of Image. The caption cannot be displayed when multiple Rotator Items are present. The default value is ‘false’.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url")).SlideWidth("600px")
.SlideHeight("350px").ShowCaption(true)
```



Thumbnail

This feature implements Thumbnail in Rotator control. You can view or access any of the Rotator items instantly. All the images are given as Thumb Element to use this feature.

The property ShowThumbnail is Boolean type, which allow us to Show or Hide the Thumbnail in Rotator control. Thumbnail is used to navigate between slides. Thumbnail supports only single slide transition. You must specify the source for thumbnail elements through the ThumbnailSourceID property. The default value is ‘false’.

The property ThumbnailSourceID specifies the source for thumbnail elements. The default value is null. The value set to this property is object.

You can refer the following code example of Thumbnail in Rotator.

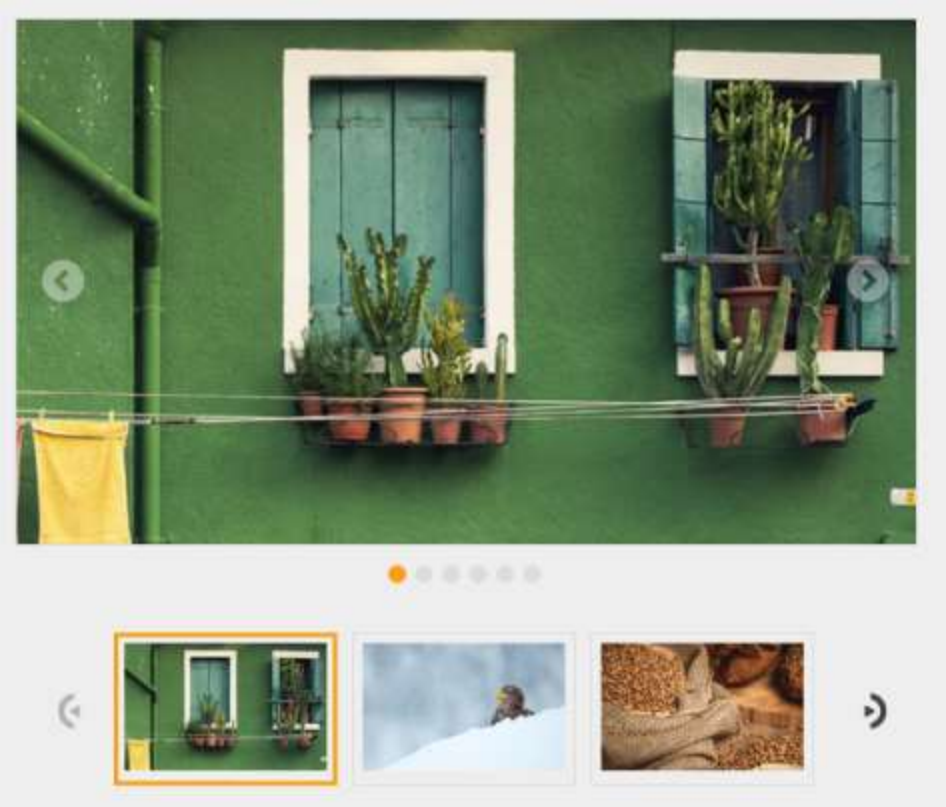
ASPX-CS

```
<ul id="slide" style="display: none">
<li>
<img src="@Url.Content("~/Images/rotator/green.jpg")" title="Green"
/></li>
<li>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<img src="@Url.Content("~/Images/rotator/snow.jpg")" title="Snow" /></li>
<li>
<img src="@Url.Content("~/Images/rotator/wheat.jpg")" title="Wheat"
/></li>
<li>
<img src="@Url.Content("~/Images/rotator/tablet.jpg")" title="Tablet"
/></li>
<li>
<img src="@Url.Content("~/Images/rotator/sea.jpg")" title="Sea" /></li>
<li>
<img src="@Url.Content("~/Images/rotator/bread.jpg")" title="Bread"
/></li>
</ul>
@Html.EJ().Rotator("sliderContent").Items(itemElement =>
{
itemElement.Add().ContentTemplate(@<div>
<img class="image" src="@Url.Content("~/Images/rotator/green.jpg")" />
</div>);
itemElement.Add().ContentTemplate(@<div>
<img class="image" src="@Url.Content("~/Images/rotator/snow.jpg")"/>
</div>);
itemElement.Add().ContentTemplate(@<div>
<img class="image" src="@Url.Content("~/Images/rotator/wheat.jpg")" />
</div>);
itemElement.Add().ContentTemplate(@<div>
<img class="image" src="@Url.Content("~/Images/rotator/tablet.jpg")" />
</div>);
itemElement.Add().ContentTemplate(@<div>
<img class="image" src="@Url.Content("~/Images/rotator/sea.jpg")" />
</div>);
itemElement.Add().ContentTemplate(@<div>
<img class="image" src="@Url.Content("~/Images/rotator/bread.jpg")" />
</div>);
}).SlideWidth("600px").SlideHeight("350px").ShowThumbnail(true).Thumbnail
SourceID("slide")
```

Copyright © 2001 - 2020 Syncfusion Inc.



Orientation

The Rotator control supports both vertical and horizontal orientations allowing it to fit into any scenario. The Orientation property defines the Orientation where the control is rendered. The value set to this property is enum or string type. It accepts the following values.

- ej.Orientation.Horizontal or “Horizontal”
- ej.Orientation.Vertical or “Vertical”

The following steps explain you how to set Orientation for the Rotator.

Horizontal

This property sets the Rotator in HorizontalOrientation. You can refer the following steps to set Horizontal Orientation for Rotator control. In Rotator control, the Default value of Orientation is Horizontal.

1. In View, create ul-li list of Rotator items and invoke the Rotator helper.
2. Add the following script in your CSHTML page.

ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.SlideHeight("350px")
.Orientation(Syncfusion.JavaScript.Orientation.Horizontal)
```

Vertical

This property sets the Rotator in vertical orientation. You can refer the following steps to set VerticalOrientation for Rotator control.

1. Create ul-li list of Rotator items and invoke the Rotator helper.
2. Add the following script in your CSHTML page.

ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px").SlideHeight("350px")
.Orientation(Syncfusion.JavaScript.Orientation.Vertical)
```

Appearance and Styling

Adjusting rotator item size

SlideWidth

This property sets the Width of a Rotator Item. The value set to this property is string or number.

ASPX-CS

```
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px").SlideHeight("350px")
```

SlideHeight

This property sets the Height of a Rotator Item. The value set to this property is string or number.

ASPX-CS

```
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<Localdata>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px").SlideHeight("350px")
```

Image with Contents

This feature allows you to add text along with the image in Rotator control. This is achieved by splitting the content into two panels. In the following code example, image is given in the left panel and text is given in the right panel.

ASPX-CS

```
@{Html.EJ().Rotator("sliderContent").Items(itemElement =>
{
itemElement.Add().ContentTemplate(@<div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div class="leftPanel">
<img src="@Url.Content("~/Images/rotator/tablet.jpg")" />
</div>
<div class="rightPanel black">
<div class="contentPanel">Tablet </div>
<ul>
<li>A tablet computer, or simply tablet, is a mobile computer with
display, circuitry and battery in a single unit.</li>
<li>
Tablets are equipped with sensors, including cameras, microphone,
accelerometer and touchscreen,
</ul>
</div>
</div>);
itemElement.Add().ContentTemplate(@<div>
<div class="leftPanel">
<img src="@Url.Content("~/Images/rotator/rose.jpg")" />
</div>
<div class="rightPanel">
<div class="contentPanel">Rose </div>
<ul>
<li>A rose is a woody perennial of the genus Rosa, within the family
Rosaceae</li>
<li>Flowers vary in size and shape and are usually large and showy,
There are over 100 species
</li>
</ul>
</div>
</div>);
itemElement.Add().ContentTemplate(@<div>
<div class="leftPanel">
<img src="@Url.Content("~/Images/rotator/snowfall.jpg")" />
</div>
<div class="rightPanel rightSide">
<div class="contentPanel">Snowfall </div>
<ul>
<li>Mt. Baker ski area in Washington State has the world record for
snowfall at 1,140 inches of snow in the 1998/1999 winter season</li>
<li>Mt. Baker ski area is located near but not on the real 10,781’ Mount
Baker</li>
</ul>
</div>
</div>);
itemElement.Add().ContentTemplate(@<div>
<div class="leftPanel">
<img src="@Url.Content("~/Images/rotator/nature.jpg")" />
</div>
<div class="rightPanel">
<div class="contentPanel">Nature </div>
<ul>
<li>The health of the natural environment is critical to the long-term
future of the planet</li>
<li>Nature, in the broadest sense, is equivalent to the natural,
physical, or material world or universe.</li>
</ul>
</div>
</div>);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
itemElement.Add().ContentTemplate(@<div>
<div class="leftPanel">
<img src="@Url.Content("~/Images/rotator/card.jpg")" />
</div>
<div class="rightPanel credit">
<div class="contentPanel">Credit card </div>
<ul>
<li>A credit card is a payment card issued to users as a system of
payment</li>
<li>It allows the card holder to pay for goods and services based on the
holder's promise to pay for them</li>
</ul>
</div>
</div>);
}).SlideWidth("700px").SlideHeight("300px").ShowPlayButton(true).Render()
;}
```

CSS

```
<style type="text/css" class="cssStyles">

Display items

DisplayItemCount

This property specifies the number of Rotator Items to be displayed. The default value is ‘1’. The value set to this property is string or number.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url")).SlideWidth("600px")
.SlideHeight("350px").DisplayItemCount("3")
```

NavigateSteps

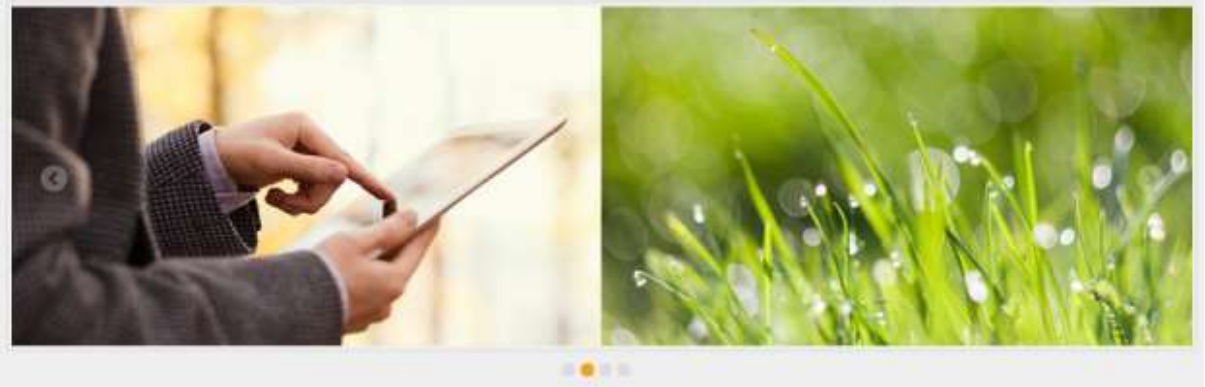
This property specifies the number of Rotator Items to navigate on a single click (next/previous/play buttons). The NavigateSteps property value must be less than or equal to the DisplayItemCount property value. The default value is ‘1’. The value set to this property is string or number.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.SlideWidth("600px").SlideHeight("350px")
.DisplayItemCount("2").NavigateSteps("2")
```

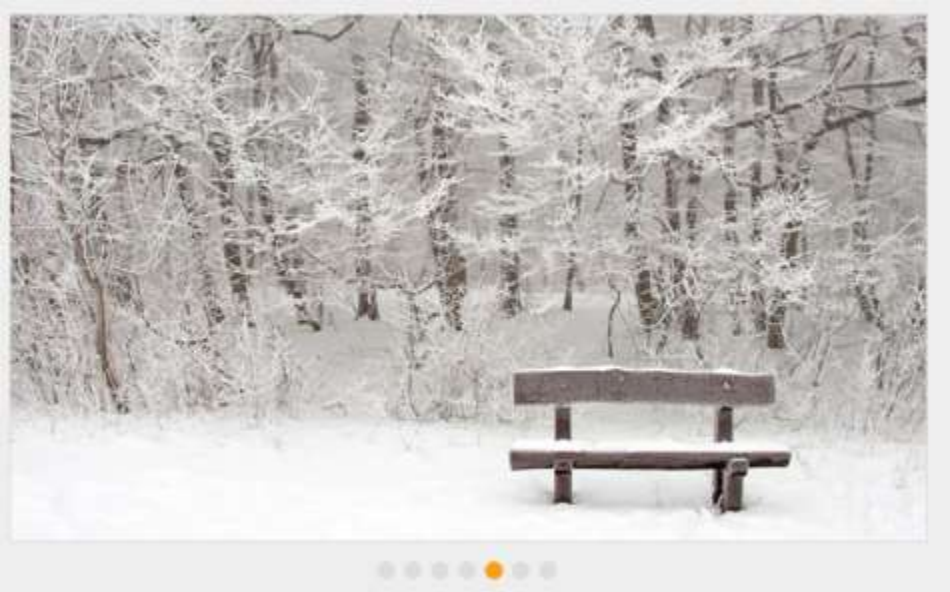


StartIndex

This property sets the index of the slide that is displayed first. The default value is ‘0’. The value set to this property is string or number.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url")).SlideWidth("600px")
.SlideHeight("350px").StartIndex("4")
```



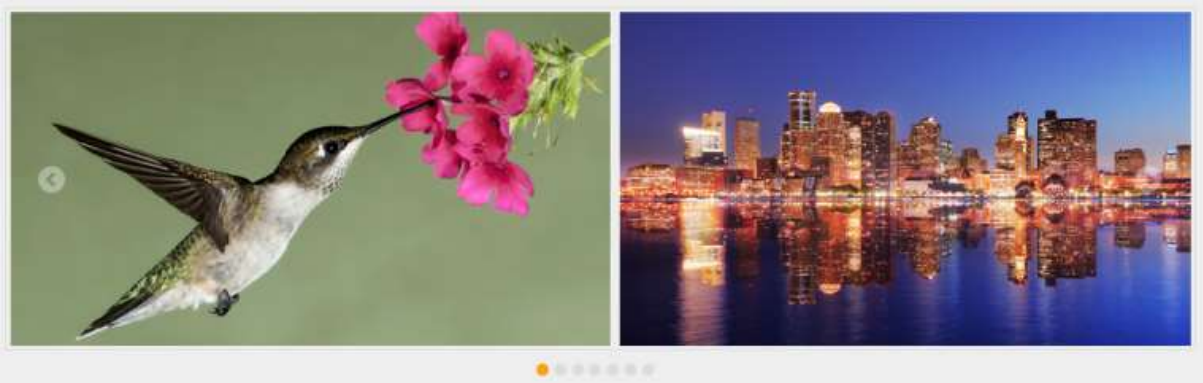
FrameSpace

This property sets the space between the Rotator Items. The value set to this property is string or number.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url")).SlideWidth("600px")
.SlideHeight("350px").DisplayItemCount("2").FrameSpace("40px")
```



AnimationType

AnimationType property specifies the Type of Animation for the Rotator Item. AnimationType options include slide, fastSlide, slowSlide, and other custom easing Animation Types. The default value is ‘slide’. The value set to this property is string.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px")
.SlideHeight("350px")
.AnimationType("fastSlide")
```

AnimationSpeed

This property sets the speed of slide transition. The default value of AnimationSpeed is ‘600’. The value set to this property is string or number.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text")
.Url("Url")).SlideWidth("600px")
.SlideHeight("350px")
.AnimationSpeed(2000)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Delay

This property sets the delay between the Rotator Items to move after the slide transition. The default value is 500. The value set to this property is string or number.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px")
.SlideHeight("350px")
.Delay(2000)
```

Theme

Rotator control's style and appearance are controlled based on CSS classes. In order to apply styles to the Rotator control, you can refer 2 files namely, ej.widgets.core.min.css and ej.theme.min.css. When the file ej.widgets.all.min.css is referred, then it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these both.

By default, there are 12 themes support available for Rotator control as follows,

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

CssClass

This property is used to set root class for Rotator control theme. The value set to this property is string type.

ASPX-CS

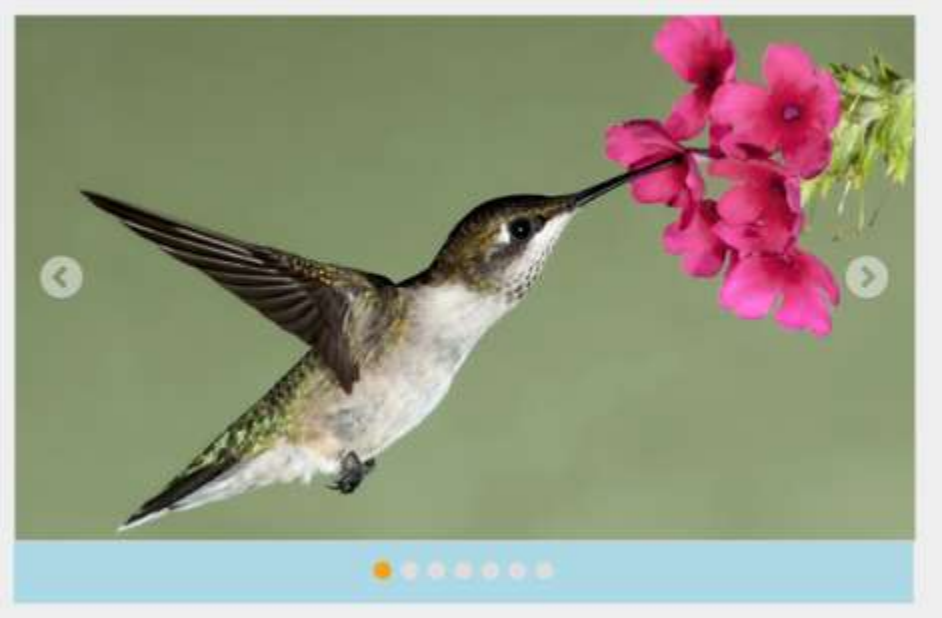
```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px")
.SlideHeight("350px")
.CssClass("myCss")
```

Copyright © 2001 - 2020 Syncfusion Inc.

Add the following code in your CSS.

CSS

```
<style>
.flat-lime
{
background-color: yellowgreen;
}
</style>
<style type="text/css">
.blue
{
background-color: lightblue;
}
</style>
```



Template

This Template feature implements in Rotator control. Rotator template will allow you to customize the rendering structure for its li elements. Using template API with data binding can render image, audio or video inside the Rotator control.

The property template specifies the structure for slide li elements. The default value is null. The value set to this property is string.

1. Add the below code in your view page to render the Rotator

ASPX-CS

```
// Add the following code in View page to configure Rotator widget
<div class="frame">
@Html.EJ().Rotator("rot").Datasource((IEnumerable<LocalData>)ViewBag.data
source).SlideWidth("100%").SlideHeight("350px").IsResponsive(true)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Template("<div class='image'><img src = ${url} title = ${text}
class='image'/> </div>")
</div>
```

CSHARP

```
// Add the following code to add slide image items in the controller page
List<LocalData> localValues = new List<LocalData>();
public ActionResult LocalData()
{
localValues.Add(new LocalData{ text= "Beautiful Bird", url=
"../Images/rotator/bird.jpg" });
localValues.Add(new LocalData { text = "Colorful Night", url =
"../Images/rotator/night.jpg" });
localValues.Add(new LocalData { text = "Technology", url =
"../Images/rotator/tablet.jpg" });
localValues.Add(new LocalData { text = "Nature", url =
"../Images/rotator/nature.jpg" });
localValues.Add(new LocalData { text = "Snow Fall", url =
"../Images/rotator/snowfall.jpg" });
localValues.Add(new LocalData { text = "Credit Card", url =
"../Images/rotator/card.jpg" });
localValues.Add(new LocalData { text = "Amazing Sculptures", url =
"../Images/rotator/sculpture.jpg" });
ViewBag.datasource=localValues;
return View();
}
```

2. CSS.

CSS

```
<style type="text/css" class="cssStyles">
.frame {
width: 100%;
box-sizing : border-box;
}
#rot > li img {
width: 100%;
height: 350px;
}
</style>
```

RTL Support

EnableRTL feature supports to change the left-to-right alignment of the Rotator to right-to-left (RTL). (I.e.) Sets the Rotator to do its actions from right to left. The EnableRTL property sets the Rotator from right to left. The value set to this property is Boolean type.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
binding Rotator items.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().Rotator("sliderContent").Datasource((IEnumerable<LocalData>)Vi
ewBag.datasource)
.RotatorFields(t => t.Text("Text").Url("Url"))
.SlideWidth("600px").SlideHeight("350px")
.EnableRTL(true)
```

Keyboard interaction

The AllowKeyboardNavigation property turns on keyboard interaction with the Rotator items. You must set this property to ‘true’ to access the keyboard shortcuts. The default value is ‘true’. The value set to this property is Boolean.

The entire Rotator commands are accessed through the keyboard by specifying the KeyboardShortcut in the following table.

Keyboard Shortcut	Function
Alt + j	Focuses the control
Up/ Right	Move to next slide
Down/Left	Move to previous slide.
Space	Move to Play/Pause slide.
Alt + Right	Move thumbnail item to right and select item.
Alt + Left	Move thumbnail item to left and select item.
Enter	Selected the thumbnail item

You can refer the following code example for keyboard navigation.

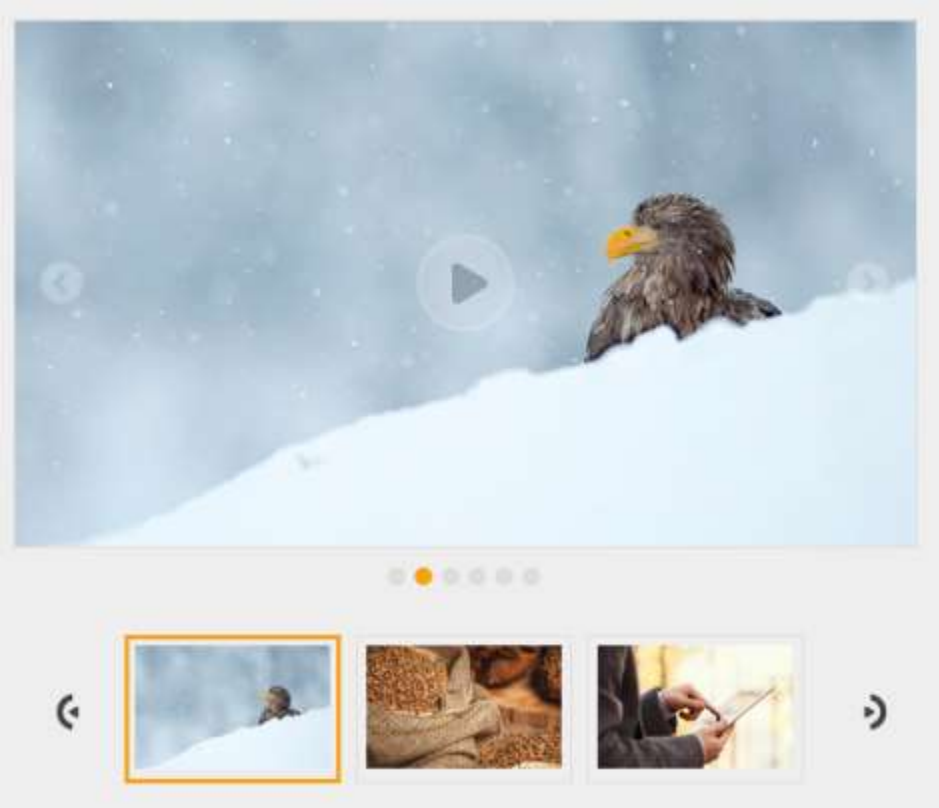
ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
binding Rotator items.
<ul id="slide" style="display: none">
<li> <img src="@Url.Content("~/Images/rotator/green.jpg")" title="Green"
/> </li>
<li> <img src="@Url.Content("~/Images/rotator/snow.jpg")" title="Snow" />
</li>
<li> <img src="@Url.Content("~/Images/rotator/wheat.jpg")" title="Wheat"
/> </li>
<li> <img src="@Url.Content("~/Images/rotator/tablet.jpg")"
title="Tablet" /> </li>
<li>        <img src="@Url.Content("~/Images/rotator/sea.jpg")"
title="Sea" /></li>
<li>        <img src="@Url.Content("~/Images/rotator/bread.jpg")"
title="Bread" /></li>
</ul>
@Html.EJ().Rotator("sliderContent").Items(itemElement =>  {
itemElement.Add().ContentTemplate(@<div> <img class="image"
src="@Url.Content("~/Images/rotator/green.jpg")" /> </div>);
itemElement.Add().ContentTemplate(@<div> <img class="image"
src="@Url.Content("~/Images/rotator/snow.jpg")"/>  </div>);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
itemElement.Add().ContentTemplate(@<div> <img class="image"
src="@Url.Content("~/Images/rotator/wheat.jpg")" />  </div>);
itemElement.Add().ContentTemplate(@<div> <img class="image"
src="@Url.Content("~/Images/rotator/tablet.jpg")" /> </div>);
itemElement.Add().ContentTemplate(@<div> <img class="image"
src="@Url.Content("~/Images/rotator/sea.jpg")" /> </div>);
itemElement.Add().ContentTemplate(@<div> <img class="image"
src="@Url.Content("~/Images/rotator/bread.jpg")" /> </div>);})
.SlideWidth("600px").SlideHeight("350px")
.ShowThumbnail(true).ThumbnailSourceID("slide")
.AllowKeyboardNavigation(true).ShowPlayButton(true)
<script type="text/JavaScript">
$(function ()
{
//Control focus key
$(document).on("keydown", function (e)
{
if (e.altKey && e.keyCode === 74)
{
// j- key code.
$("#sliderContent")[0].focus();
}
});
});
</script>
```

Run the above sample, we get the output like this,



Copyright © 2001 - 2020 Syncfusion Inc.

How to

Render Rotator from Code behind

Rotator can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side

The following code illustrates the initialization of Rotator properties in the controller.

C#

```
//Namespace to get the JavaScript (Rotator) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class RotatorController: Controller
{
public ActionResult RotatorFeatures()
{
// initialize the data list
List<LocalData> localValues = new List<LocalData>();
localValues.Add(new LocalData { Text = "Beautiful Bird", Url =
"../Images/rotator/bird.jpg" });
localValues.Add(new LocalData { Text = "Colorful Night", Url =
"../Images/rotator/night.jpg" });
localValues.Add(new LocalData { Text = "Technology", Url =
"../Images/rotator/tablet.jpg" });
localValues.Add(new LocalData { Text = "Nature", Url =
"../Images/rotator/nature.jpg" });
localValues.Add(new LocalData { Text = "Snow Fall", Url =
"../Images/rotator/snowfall.jpg" });
localValues.Add(new LocalData { Text = "Credit Card", Url =
"../Images/rotator/card.jpg" });
localValues.Add(new LocalData { Text = "Amazing Sculptures", Url =
"../Images/rotator/sculpture.jpg" });
//Initializing the Rotator model
RotatorProperties RotatorObj = new RotatorProperties();
//Initializing the datasource and other properties
RotatorObj.DataSource = localValues;
RotatorObj.RotatorFields.Text = "Text";
RotatorObj.RotatorFields.Url = "Url";
RotatorObj.SlideWidth = "600px";
RotatorObj.SlideHeight = "350px";
RotatorObj.ShowPlayButton = true;
//Passing Rotator properties using the ViewData
ViewData["RotatorModel"] = RotatorObj;
return View();
}
}
}
```

Binding the Rotator properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Html.EJ().Rotator("sliderContent",
(Syncfusion.JavaScript.Models.RotatorProperties)ViewData["RotatorModel"])
.Render();
}
```

Schedule

Overview

The **EJMVC Scheduler** is an event calendar that manages the list of various activities (events/appointments) in different available views (day, week, workweek, month and agenda) for various resources. It is mainly for tracking the user appointments and allows them to create a new or edit/delete the older ones. It is simply a server-side wrapper of JS Scheduler component and almost all the features in JS Scheduler are applicable to Scheduler in MVC platform.

Key Features

Some of the key features of Scheduler are as follows,

- **DataSource** - Supports various client-side and remote data sources such as JSON, RESTful services, OData services, WCF services and much more.
- **Views** - 6 types of views are available namely Day, Week, WorkWeek, Month, Agenda and Custom View (user-specific date rendering).
- **Adaptive** - Scheduler UI layout adapts automatically according to the desktop/mobile mode (responsive support).
- **Resize & Drag** - Appointments can be resized and dragged anywhere within the Scheduler. External drag and drop of appointments are also applicable now.
- **Multiple Resources & Grouping** - Allows the Scheduler to categorize and display resources in a hierarchical structure either in a horizontal or vertical manner.
- **Orientation** - Two types of control orientation is supported namely – Vertical and Horizontal (Timeline View).
- **Categories** - 6 default types of Appointment categories along with user customization options are available to differentiate the appointment status.
- **Template** - Template customization provided for appointments, resource header, cells, date header, priority, tooltip, time scale and agenda view.
- **TimeZone & DST** - Supports observation of Daylight Saving Time in Scheduler for whichever time zone it is applicable.
- **Export & Print** - Supports exporting of single/all appointment(s) to an ICS file and also Prints all/specific appointment(s).
- **PDF Export** - Supports exporting of entire Scheduler into PDF format.
- **Appointment window Customization** – Entire appointment window can be customized with the user required fields.
- **Recurrence Editor** - Complete recurrence related options of Scheduler are collectively defined as a separate plug-in, which can be utilized directly within the customized appointment window.

Getting Started

Follow the steps pointed out in the Getting Started page of the Introduction part to create an MVC application with required assembly references, scripts and stylesheets.

Copyright © 2001 - 2020 Syncfusion Inc.

Create a new Class in controller page to define the data to be passed to the Scheduler as mentioned below,

C#

```
public class ScheduleData
{
public int ProgramId { get; set; }
public string ProgramName { get; set; }
public string Comments { get; set; }
public DateTime ProgramStartTime { get; set; }
public DateTime ProgramEndTime { get; set; }
public bool IsAllDay { get; set; }
public bool IsRecurrence { get; set; }
public string RecurrenceRule { get; set; }
}
```

Now create an instance of the class and add the list of Scheduler data to it within the Index method in controller page, which will then be passed to the View page and bound to the Scheduler dataSource.

C#

```
public ActionResult Index()
{
List<ScheduleData> data = new List<ScheduleData> {
new ScheduleData {
ProgramName = "Turtle Walk",
Comments = "Night out with turtles",
ProgramStartTime = new DateTime(2016, 6, 2, 3, 0, 0),
ProgramEndTime = new DateTime(2016, 6, 2, 4, 0, 0),
IsAllDay = true
},
new ScheduleData {
ProgramName = "Winter Sleepers",
Comments = "Long sleep during winter season",
ProgramStartTime = new DateTime(2016, 6, 3, 1, 0, 0),
ProgramEndTime = new DateTime(2016, 6, 3, 2, 0, 0)
},
new ScheduleData {
ProgramName = "Estivation",
Comments = "Sleeping in hot season",
ProgramStartTime = new DateTime(2016, 6, 4, 3, 0, 0),
ProgramEndTime = new DateTime(2016, 6, 4, 4, 0, 0)
}
};
return View(data);
}
```

Add the Scheduler code in View page as shown below,

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014,6,2))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.AppointmentSettings(fields => fields.Datasource(Model)
.Id("ProgramId")
.Subject("ProgramName")
.StartTime("ProgramStartTime")
.EndTime("ProgramEndTime")
.Description("Comments")
.AllDay("IsAllDay")
.Recurrence("IsRecurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

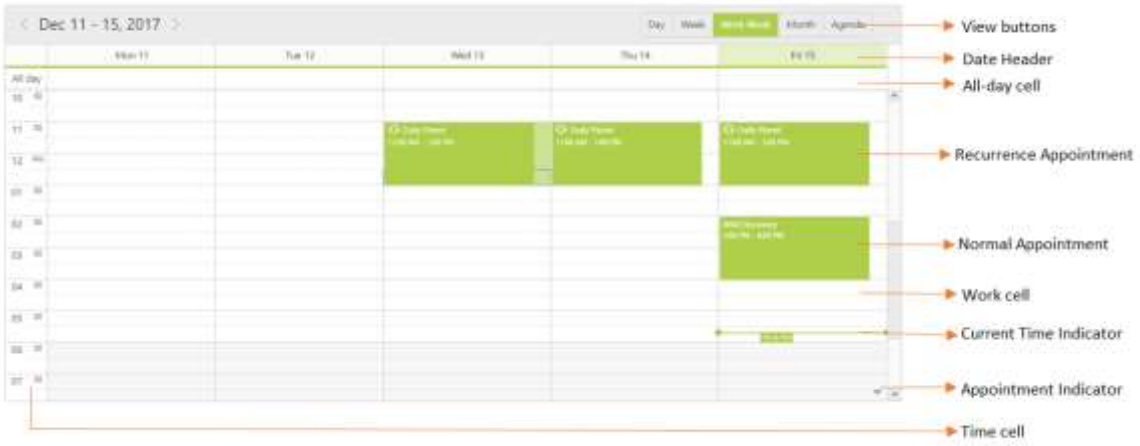
Note: The appointment fields like Id, Subject, Description and other required fields are needed to be mapped with the appropriate column names from the dataSource as done in the above code example.

To bind the remote data directly to the Scheduler instead of passing data from the Model as previously depicted, refer the below code snippet.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014,6,2))
.AppointmentSettings(fields =>
fields.Datasource("http://mvc.syncfusion.com/ODataServices/Northwnd.svc/"
)
.Query("ej.Query().from('Events').take(10)")
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

To bind the data to the Scheduler from database or any other dataSources, refer here.



Data Binding

Appointment Fields

The below listed names are the appointment fields which holds the appropriate column names from the dataSource.

Field name	Description
Id	Binds the Id field name for indexing and performing CRUD operation on the appointments. Itâ€™s optional.
StartTime	Binds the appointment start time field name which is mandatory and also its related validation rules.
StartTimeZone	Binds the name of the start timezone field in the dataSource and also its related validation rules. If the StartTimeZone field is not mentioned, then the appointment makes use of the Scheduler timeZone or System timeZone.
EndTime	Binds the appointment end time field name which is mandatory and also its related validation rules.
EndTimeZone	Binds the name of the end timezone field in the dataSource and also its related validation rules. If the EndTimeZone field is not mentioned, then the appointment makes use of the Scheduler timeZone or System timeZone.
Subject	Binds the appointment subject field name which holds the summary of the appointment and also its related validation rules.
Location	Binds the name of the location field and also its related validation rules. It indicates the appointment location/occurrence place. This field needs to be bind to the Scheduler, when an API ShowLocationField is set to true.
Description	Binds the appointment description field name and also its related validation rules.
AllDay	Binds the name of the AllDay field. It accepts the boolean value and indicates whether the appointment is an all-day appointment or not.
Categorize	Binds the name of the categorize field and also its related validation rules. It indicates the category or status value (red categorize, green, yellow and so on).
Priority	Binds the name of the priority field and its related validation rules, which indicates the priority (high, low, medium and none) of the appointments. This field should be bind to the Scheduler, when PrioritySettings.Enable is set to true.
ResourceFields	Binds one or more fields in the resource collection. It maps the resource field names with the appointments, denoting to which resource the appointments actually belongs.

Copyright © 2001 - 2020 Syncfusion Inc.

Recurrence	Binds the name of the recurrence field. It accepts the boolean value and indicates whether the appointment is a recurrence appointment or not.
RecurrenceRule	Binds the name of the recurrenceRule field. It holds the recurrence pattern associated with the appointments.
RecurrenceId	Binds the recurrence Id field which acts as a parent id for Scheduler recurrence appointments.
RecurrenceExDate	Binds the recurrence Exception field which accepts the recurrence Exception date values.

The below example depicts the appointment fields accepting the string type mapper fields.

Create a new Class **ScheduleData** to define the appointment related data to be passed to the Scheduler as mentioned below,

C#

```
public class ScheduleData
{
public string Id { get; set; }
public string Subject { get; set; }
public string Description { get; set; }
public DateTime StartTime { get; set; }
public DateTime EndTime { get; set; }
public string Categorize { get; set; }
public string RoomId { get; set; }
public string OwnerId { get; set; }
public string Priority { get; set; }
public bool AllDay { get; set; }
public bool Recurrence { get; set; }
public string RecurrenceRule { get; set; }
}
```

Also, define the below model classes in your application, if there is a need to make use of the features such as multiple resources, categories, priorities, context menu and timezone collection in your sample application.

C#

```
// Define the below class, whenever the multiple resources and grouping
feature is used in your sample project.
public class ResourceFields
{
public string Text { set; get; }
public string Id { set; get; }
public string GroupId { set; get; }
public string Color { set; get; }
public int WorkHourStart { set; get; }
public int WorkHourEnd { set; get; }
public List<string> CustomDays { set; get; }
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
// Define the below class, whenever the category related data is to be
used in Scheduler.
public class CategorizeSettings
{
public string Text { set; get; }
public string Id { set; get; }
public string FontColor { set; get; }
public string Color { set; get; }
}
// Define the below class, whenever the priorities are to be used for
Scheduler appointments.
public class PrioritySettings
{
public string Text { set; get; }
public string Value { set; get; }
}
// Define the below two classes (Appointment and Cells), if context menu
items are to be used in the Scheduler.
public class Appointment
{
public string Text { set; get; }
public string Id { set; get; }
}
public class Cells
{
public string Text { set; get; }
public string Id { set; get; }
public string ParentId { set; get; }
}
// Define the below class, if timezone collection to be specified for
Scheduler.
public class TimezoneCollection
{
public string Text { set; get; }
public string Id { set; get; }
public string Value { set; get; }
}
```

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleData> Appoint = new List<ScheduleData>();
Appoint.Add(new ScheduleData { Id = "1", Subject = "Meeting", StartTime =
new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015, 11,
10, 11, 00, 00), Description = "", AllDay = false, Recurrence = false,
RecurrenceRule = "" });
<!-- Datasource for Grouping Resources -->
List<String> Group = new List<String>();
Group.Add("Owners");
<!-- Datasource for Resources -->
List<ResourceFields> Resources = new List<ResourceFields>();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Resources.Add(new ResourceFields { Id = "1", Text = "Nancy", Color =
"#f8a398" });
Resources.Add(new ResourceFields { Id = "3", Text = "Steven", Color =
"#56ca85" });
Resources.Add(new ResourceFields { Id = "5", Text = "Michael", Color =
"#51a0ed" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.Group(gr => { gr.Resources(Group); })
.Resources(res => {
res.Field("OwnerId").Title("Owner").Name("Owners").AllowMultiple(true).Re
sourceSettings(fields =>
fields.Datasource(Resources).Text("Text").Id("Id").Color("Color")).Add();
})
.ShowLocationField(true)
.CategorizeSettings(cat => cat.Enable(true))
.PrioritySettings(pri => pri.Enable(true))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.StartTimeZone("StartTimeZone")
.EndTime("EndTime")
.EndTimeZone("EndTimeZone")
.Description("Description")
.Location("Location")
.AllDay("AllDay")
.Priority("Priority")
.Categorize("Categorize")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.RecurrenceId("RecurrenceId")
.RecurrenceExDate("RecurrenceExDate")
.ResourceFields("OwnerId"))
)
```

Appointment Field Validation

It is possible to validate the required fields of the appointment window from client-side before submitting it, by adding appropriate validation rules to each of the fields. The appointment fields have been extended to accept both String and object type values. Therefore, in order to perform validations, it is necessary to specify object values for the appointment fields.

Refer the appointment fields specified with validation rules from the following code example.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for CategorizeSettings -->
List<CategorizeSettings> CategorizeValue = new
List<CategorizeSettings>();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
CategorizeValue.Add(new CategorizeSettings { Text = "Blue Category", Id =
"1", Color = "#43b496", FontColor = "#ffffff" });
CategorizeValue.Add(new CategorizeSettings { Text = "Green Category", Id
= "2", Color = "#7f993e", FontColor = "#ffffff" });
CategorizeValue.Add(new CategorizeSettings { Text = "Orange Category", Id
= "3", Color = "#cc8638", FontColor = "#ffffff" });
CategorizeValue.Add(new CategorizeSettings { Text = "Purple Category", Id
= "4", Color = "#ab54a0", FontColor = "#ffffff" });
CategorizeValue.Add(new CategorizeSettings { Text = "Red Category", Id =
"5", Color = "#dd654e", FontColor = "#ffffff" });
CategorizeValue.Add(new CategorizeSettings { Text = "Yellow Category", Id
= "6", Color = "#d0af2b", FontColor = "#ffffff" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ShowLocationField(true)
.CategorizeSettings(fields =>
fields.Datasource(CategorizeValue).Enable(true).AllowMultiple(false).Id("
Id").Text("Text").Color("Color").FontColor("FontColor"))
.AppointmentSettings(fields => fields
.Id("Id")
.Subject(subject => subject.Field("Subject").ValidationRules(v =>
v.AddRule("required", true)))
.Location(location => location.Field("Location").ValidationRules(v =>
v.AddRule("required", true).AddRule("customRule", "/^[a-zA-Z0-9- ]*$/")))
.StartTime("StartTime")
.EndTime("EndTime")
.Description(des => des.Field("Description").ValidationRules(v =>
v.AddRule("required", true).AddRule("minlength", 5).AddRule("maxlength",
500)))
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.Categorize(categorize =>
categorize.Field("Categorize").ValidationRules(v => v.AddRule("required",
true))))
)
```

HTML

```
<script src="@Url.Content("~/Scripts/jquery.validate.min.js")"></script>
<script
src="@Url.Content("~/Scripts/jquery.validate.unobtrusive.min.js")"></scri
pt>
<script type="text/javascript">
$(function () {
$.validator.addMethod("customRule", function (value, element, options) {
var expression = /^[a-zA-Z0-9- ]*$/;
return expression.test(value);
}, "Special character(s) not allowed in Location field");
});
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Binding to Simple List Data Array

Scheduler supports binding the appointment data to it through the list of appointment object collection as depicted in the below code example.

Example - Array of List Data Binding

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Binding Remote Data Service

The appointment data can be bound to the Scheduler through Odata remote services, by configuring the service URL to the Schedule dataSource API.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields =>
fields.Datasource("http://mvc.syncfusion.com/OdataServices/Northwnd.svc/"
).Query("ej.Query().from('Events').take(10)")
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

OData V4

The OData v4 is an improved version of OData protocols. Scheduler supports retrieving and consuming appointment data from OData v4 services, just similar to the other remote services.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.EnableLoadOnDemand(true)
.AppointmentSettings(fields => fields.Datasource(dataSource =>
dataSource.URL("http://services.odata.org/V4/Northwind/Northwind.svc/Orde
rs/").Adaptor(AdaptorType.ODataV4Adaptor))
.Id("Id")
.Subject("ShipName")
.StartTime("OrderDate")
.EndTime("RequiredDate")
.Description("ShipAddress"))
)
```

WebAPI Binding

The Schedule appointment data can also be bound through the Web API services. It is a programmatic interface to define the request and response messages system that is mostly exposed in **JSON** or **XML**.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(dataSource =>
dataSource.URL("http://mvc.syncfusion.com/OdataServices/api/ScheduleData/
").CrossDomain(true))
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

The server-side code to retrieve the appointments are as follows.

C#

```
// To retrieve the appointments from database and bind it to Scheduler
public IEnumerable<Event> GetData(String CurrentDate, String CurrentView,
String CurrentAction)
{
return new NORTHWNDEntities().Events.ToList();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Data Binding using OLEDB

The appointment data can also be bound to the Scheduler using OLEDB database as depicted below.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(dataSource =>
dataSource.URL("Home/GetData").CrudURL("Home/Batch").Adaptor("UrlAdaptor"
))
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.StartTimeZone("StartTimeZone")
.EndTimeZone("EndTimeZone")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

The server-side controller code to retrieve and bind the appointment data to Scheduler are as follows. Also, define a class with all the required appointment fields as depicted in the below code example.

C#

```
// Define a class with all appointment fields
public class ScheduleData
{
public int Id { get; set; }
public string Subject { get; set; }
public DateTime StartTime { get; set; }
public DateTime EndTime { get; set; }
public Boolean AllDay { get; set; }
public Boolean Recurrence { get; set; }
public string RecurrenceRule { get; set; }
public string StartTimeZone { get; set; }
public string EndTimeZone { get; set; }
public string Description { get; set; }
}
// To retrieve the appointments from database and bind it to Scheduler
public JsonResult GetData()
{
// Mention your own dataSource to be used here.
string stringAccessConn = "Provider=Microsoft.Jet.OLEDB.4.0;Data
Source=|DataDirectory|/ScheduleDb.MDB";
DataSet myDataSet = new DataSet();
OleDbConnection myAccessConn = new OleDbConnection(stringAccessConn);
OleDbCommand myAccessCommand = new OleDbCommand("SELECT * FROM
DefaultSchedule", myAccessConn);
OleDbDataAdapter myDataAdapter = new OleDbDataAdapter(myAccessCommand);
myAccessConn.Open();
myDataAdapter.Fill(myDataSet, "DefaultSchedule");
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
List<ScheduleData> datasource = new List<ScheduleData>();
datasource = myDataSet.Tables[0].AsEnumerable().Select(dataRow => new
ScheduleData { Id = dataRow.Field<int>("Id"), Subject =
dataRow.Field<string>("Subject"), StartTime =
dataRow.Field<DateTime>("StartTime"), EndTime =
dataRow.Field<DateTime>("EndTime"), AllDay =
dataRow.Field<bool>("AllDay"), Recurrence =
dataRow.Field<bool>("Recurrence"), RecurrenceRule =
dataRow.Field<string>("RecurrenceRule"), Description =
dataRow.Field<string>("Description"), StartTimeZone =
dataRow.Field<string>("StartTimeZone"), EndTimeZone =
dataRow.Field<string>("EndTimeZone") }).ToList();
myAccessConn.Close();
return Json(datasource, JsonRequestBehavior.AllowGet);
}
```

The controller code to handle the CRUD operation are as follows.

C#

```
public JsonResult Batch(EditParams param)
{
// Mention your own dataSource to be used here.
string stringAccessConn = "Provider=Microsoft.Jet.OLEDB.4.0;Data
Source=|DataDirectory|/ScheduleDb.MDB";
if (param.action == "insert" || (param.action == "batch" && param.added
!= null))  // this block of code will execute while inserting the
appointments
{
var value = param.action == "insert" ? param.value : param.added[0];
using (OleDbConnection myCon = new OleDbConnection(stringAccessConn))
{
OleDbCommand cmd = new OleDbCommand();
cmd.CommandType = CommandType.Text;
cmd.CommandText = "INSERT INTO
DefaultSchedule(Subject,StartTime,EndTime,AllDay,Recurrence,RecurrenceRul
e,Description,StartTimeZone,EndTimeZone) VALUES
(@Subject,@StartTime,@EndTime,@AllDay,@Recurrence,@RecurrenceRule,@Descri
ption,@StartTimeZone,@EndTimeZone)";
if (string.IsNullOrEmpty(value.Subject))
cmd.Parameters.AddWithValue("@Subject", DBNull.Value);
else
cmd.Parameters.AddWithValue("@Subject", value.Subject);
cmd.Parameters.AddWithValue("@StartTime", value.StartTime);
cmd.Parameters.AddWithValue("@EndTime", value.EndTime);
cmd.Parameters.AddWithValue("@AllDay", value.AllDay);
cmd.Parameters.AddWithValue("@Recurrence", value.Recurrence);
if (string.IsNullOrEmpty(value.RecurrenceRule))
cmd.Parameters.AddWithValue("@RecurrenceRule", DBNull.Value);
else
cmd.Parameters.AddWithValue("@RecurrenceRule", value.RecurrenceRule);
if (string.IsNullOrEmpty(value.Description))
cmd.Parameters.AddWithValue("@Description", DBNull.Value);
else
cmd.Parameters.AddWithValue("@Description", value.Description);
if (string.IsNullOrEmpty(value.StartTimeZone))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
cmd.Parameters.AddWithValue("@StartTimeZone", DBNull.Value);
else
cmd.Parameters.AddWithValue("@StartTimeZone", value.StartTimeZone);
if (string.IsNullOrEmpty(value.EndTimeZone))
cmd.Parameters.AddWithValue("@EndTimeZone", DBNull.Value);
else
cmd.Parameters.AddWithValue("@EndTimeZone", value.EndTimeZone);
cmd.Connection = myCon;
myCon.Open();
cmd.ExecuteNonQuery();
myCon.Close();
}
}
if (param.action == "remove" || param.deleted != null)  // this block of
code will execute while removing the appointment
{
if (param.action == "remove")
{
using (OleDbConnection myCon = new OleDbConnection(stringAccessConn))
{
myCon.Open();
OleDbCommand cmd = new OleDbCommand("DELETE FROM DefaultSchedule WHERE Id
= @Key", myCon);
cmd.Parameters.AddWithValue("@Key", param.key);
cmd.ExecuteNonQuery();
myCon.Close();
}
}
else
{
foreach (var apps in param.deleted)
{
using (OleDbConnection myCon = new OleDbConnection(stringAccessConn))
{
myCon.Open();
OleDbCommand cmd = new OleDbCommand("DELETE FROM DefaultSchedule WHERE Id
= @Key", myCon);
cmd.Parameters.AddWithValue("@Key", apps.Id);
cmd.ExecuteNonQuery();
myCon.Close();
}
}
}
}
if ((param.action == "batch" && param.changed != null) || param.action ==
"update")   // this block of code will execute while updating the
appointment
{
var value = param.action == "update" ? param.value : param.changed[0];
using (OleDbConnection myCon = new OleDbConnection(stringAccessConn))
{
myCon.Open();
OleDbCommand cmd = new OleDbCommand("UPDATE DefaultSchedule SET

public List<ScheduleData> changed { get; set; }
public List<ScheduleData> deleted { get; set; }
public ScheduleData value { get; set; }
}
```

Controller Action Binding with CRUD operation

Scheduler supports binding appointment data from the controller by using various available options of DataSource property like URL, BatchURL, InsertURL, UpdateURL, RemoveURL and Adaptor.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(dataSource =>
dataSource.URL("Home/GetData").BatchURL("Home/Crud").InsertURL("Home/add"
).UpdateURL("Home/update").RemoveURL("Home/remove").Adaptor(AdaptorType.U
rlAdaptor))
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

The server-side controller code to handle the CRUD operations are as follows.

C#

```
// To initially bind the appointments with Scheduler
public JsonResult GetData()
{
// ScheduleDataDataContext is a LINQ-to-SQL data class name that is
defined in the .dbml file to access the tables from the database
IEnumerable data = new ScheduleDataDataContext().Appointments.Take(100);
return Json(data, JsonRequestBehavior.AllowGet);
}
// Triggers while saving a new appointment through quick window
public JsonResult add(Appointment value)
{
ScheduleDataDataContext db = new ScheduleDataDataContext();
int intMax = db.Appointments.ToList().Count > 0 ?
db.Appointments.ToList().Max(p => p.Id) : 1;
Appointment appoint = new Appointment()
{
Id = intMax + 1,
StartTime = value.StartTime,
EndTime = value.EndTime,
Subject = value.Subject,
Description = value.Description,
OwnerId = value.OwnerId,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Recurrence = value.Recurrence,
AllDay = value.AllDay,
RecurrenceRule = value.RecurrenceRule
};
db.Appointments.InsertOnSubmit(appoint);
db.SubmitChanges();
IEnumerable data = new ScheduleDataDataContext().Appointments.Take(500);
return Json(data, JsonRequestBehavior.AllowGet);
}
// Triggers while editing/dragging/resizing the existing appointment
public JsonResult update(Appointment value)
{
ScheduleDataDataContext db = new ScheduleDataDataContext();
var filterData = db.Appointments.Where(c => c.Id ==
Convert.ToInt32(value.Id));
Appointment appoint = db.Appointments.Single(A => A.Id ==
Convert.ToInt32(value.Id));
if (filterData.Count() > 0)
{
DateTime startTime = Convert.ToDateTime(value.StartTime);
DateTime endTime = Convert.ToDateTime(value.EndTime);
appoint.StartTime = startTime;
appoint.EndTime = endTime;
appoint.Subject = value.Subject;
appoint.Description = value.Description;
appoint.OwnerId = value.OwnerId;
appoint.Recurrence = Convert.ToByte(value.Recurrence);
appoint.AllDay = value.AllDay;
appoint.RecurrenceRule = value.RecurrenceRule;
}
db.SubmitChanges();
IEnumerable data = new ScheduleDataDataContext().Appointments.Take(500);
return Json(data, JsonRequestBehavior.AllowGet);
}
// Triggers when an appointment is deleted
public JsonResult remove(string key)
{
ScheduleDataDataContext db = new ScheduleDataDataContext();
Appointment app = db.Appointments.Where(c => c.Id ==
Convert.ToInt32(key)).FirstOrDefault();
if (app != null) db.Appointments.DeleteOnSubmit(app);
db.SubmitChanges();
IEnumerable data = new ScheduleDataDataContext().Appointments.Take(500);
return Json(data, JsonRequestBehavior.AllowGet);
}
// Triggers for any of the Scheduler CRUD operation
public JsonResult Crud(EditParams param)
{
ScheduleDataDataContext db = new ScheduleDataDataContext();

Description = value.Description,
OwnerId = value.OwnerId,
Recurrence = value.Recurrence,
AllDay = value.AllDay,
RecurrenceRule = value.RecurrenceRule
};
db.Appointments.InsertOnSubmit(appoint);
db.SubmitChanges();
}
else if (param.action == "remove")  // this block of code will execute
while removing the appointment
{
Appointment app = db.Appointments.Where(c => c.Id ==
Convert.ToInt32(param.key)).FirstOrDefault();
if (app != null) db.Appointments.DeleteOnSubmit(app);
db.SubmitChanges();
}
else if ((param.action == "batch" && param.changed != null) ||
param.action == "update")   // this block of code will execute while
updating the appointment
{
var value = param.action == "update" ? param.value : param.changed[0];
var filterData = db.Appointments.Where(c => c.Id ==
Convert.ToInt32(value.Id));
if (filterData.Count() > 0)
{
DateTime startTime = Convert.ToDateTime(value.StartTime);
DateTime endTime = Convert.ToDateTime(value.EndTime);
Appointment appoint = db.Appointments.Single(A => A.Id ==
Convert.ToInt32(value.Id));
appoint.StartTime = startTime;
appoint.EndTime = endTime;
appoint.Subject = value.Subject;
appoint.Description = value.Description;
appoint.OwnerId = value.OwnerId;
appoint.Recurrence = Convert.ToByte(value.Recurrence);
appoint.AllDay = value.AllDay;
appoint.RecurrenceRule = value.RecurrenceRule;
}
db.SubmitChanges();
}
IEnumerable data = new ScheduleDataDataContext().Appointments.Take(500);
return Json(data, JsonRequestBehavior.AllowGet);
}
// Class definition for EditParams to be used as parameter in the above
Crud method for receiving the object value in it.
public class EditParams
{
public string key { get; set; }
public string action { get; set; }
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public List<Appointment> added { get; set; }
public List<Appointment> changed { get; set; }
public Appointment value { get; set; }
}
```

Loading Data on Demand

Load on demand feature allows the Scheduler to retrieve only the filtered appointment data (for the current Scheduler date range) from the service/database during **loading time**, and that too only for the current Scheduler view. There are 3 parameters made available on the server-side namely **CurrentDate**, **CurrentView** and **CurrentAction** through which only the necessary appointments are retrieved from the database and then assigned to the Scheduler dataSource. With this kind of Scheduler action, consuming only lesser data will reduce the usage of network bandwidth size and loading time.

The **EnableLoadOnDemand** property is used to enable or disable the load on demand functionality of the schedule.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.EnableLoadOnDemand(true)
.AppointmentSettings(fields => fields.Datasource(dataSource =>
dataSource.URL("http://mvc.syncfusion.com/OdataServices/api/ScheduleData/
").CrossDomain(true))
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

The server-side code to load the Scheduler data on demand is as follows.

C#

```
// retrieve the appointments based on the current date.
public IEnumerable<Event> GetData(String CurrentDate, String CurrentView,
String CurrentAction)
{
var dateString = Regex.Match(CurrentDate.ToString(),
@"^(\w+\b.*?){4}").ToString();
string format = "ddd MMM dd yyyy";
DateTime dateTimeValue;
try
{
dateTimeValue = DateTime.ParseExact(dateString, format,
CultureInfo.InvariantCulture);
}
catch(FormatException)
{
```

```
var dateSplit = CurrentDate.Split(' ');//For IE<=10 Fri Mar 20 11:00:22
UTC+0530 2015
if (dateSplit[2].Length == 1) dateSplit[2] = string.Concat("0",
dateSplit[2]);
dateString = string.Concat(dateSplit[0], ' ', dateSplit[1], ' ',
dateSplit[2], ' ', dateSplit[dateSplit.Length - 1]);
dateTimeValue = DateTime.ParseExact(dateString, format,
CultureInfo.InvariantCulture);
}
// AppointmentReposit is a user-defined class within which the
FilterAppointment method is defined.
AppointmentReposit rep = new AppointmentReposit();
var data = rep.FilterAppointment(dateTimeValue, CurrentAction,
CurrentView);
return data;
}
// Method to filter the appointments based on the date range
public List<Event> FilterAppointment(DateTime CurrentDate, String
CurrentAction, String CurrentView)
{
DateTime CurrDate = Convert.ToDateTime(CurrentDate);
DateTime StartDate = FirstWeekDate(CurrDate.Date);
DateTime EndDate = FirstWeekDate(CurrDate.Date);
List<Event> appointmentList = new NORTHWNDEntities().Events.ToList();
switch (CurrentView)
{
case "day":
StartDate = CurrentDate;
EndDate = CurrentDate;
break;
case "week":
EndDate = EndDate.AddDays(7);
break;
case "workweek":
EndDate = EndDate.AddDays(5);
break;
case "month":
StartDate = CurrDate.Date.AddDays(-CurrDate.Day + 1);
EndDate = StartDate.AddMonths(1);
break;
}
appointmentList = new NORTHWNDEntities().Events.ToList().Where(app =>
((Convert.ToDateTime(app.StartTime).Date >=
Convert.ToDateTime(StartDate.Date)) &&
(Convert.ToDateTime(app.EndTime).Date <=
Convert.ToDateTime(EndDate.Date)))).ToList();
return appointmentList;
}
internal static DateTime FirstWeekDate(DateTime CurrentDate)
{
try
{
DateTime FirstDayOfWeek = CurrentDate;
DayOfWeek WeekDay = FirstDayOfWeek.DayOfWeek;
switch (WeekDay)
{
case DayOfWeek.Sunday:
```

break;
}
return (FirstDayOfWeek);
}
catch
{
return DateTime.Now;
}
}
```

Entity Framework Data Binding

The appointment data can be bound to the Scheduler through Entity Framework which supports Entity Data Model(EDM) defining the data at conceptual level. To know more on how to create and use the Entity Data Model, refer here.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(Model)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

C#

```
ScheduleControlDataEntities db = new ScheduleControlDataEntities(); //
Create an object of the entity class to access its underlying tables
within the controller page.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult Index()
{
return View();
}
public JsonResult GetData()
{
IEnumerable data = new
ScheduleControlDataEntities().Appointments.Take(100);
return Json(data, JsonRequestBehavior.AllowGet);
}
public JsonResult Batch(EditParams param)
{
// this block of code will execute while inserting the appointments
if (param.action == "insert" || (param.action == "batch" && param.added
!= null))
{
var value = param.action == "insert" ? param.value : param.added[0];
int intMax = db.Appointments.ToList().Count > 0 ?
db.Appointments.ToList().Max(p => p.Id) : 1;
DateTime startTime = Convert.ToDateTime(value.StartTime);
DateTime endTime = Convert.ToDateTime(value.EndTime);
var currentTimeZone = TimeZone.CurrentTimeZone;
Appointment appoint = new Appointment()
{
Id = value.Id,
StartTime = startTime,
EndTime = endTime,
StartTimeZone=value.StartTimeZone,
EndTimeZone=value.EndTimeZone,
Subject = value.Subject,
Description = value.Description,
Recurrence = value.Recurrence,
RoomId = value.RoomId,
OwnerId = value.OwnerId,
CategoryId = value.CategoryId,
AllDay = value.AllDay,
RecurrenceRule = value.RecurrenceRule,
};
db.Appointments.Add(appoint);
db.SaveChanges();
}
if (param.action == "remove" || param.deleted != null)
// this block of code will execute while removing the appointment
{
if (param.action == "remove")
{
int key = Convert.ToInt32(param.key);
Appointment app = db.Appointments.Where(c => c.Id ==
key).FirstOrDefault();
if (app != null) db.Appointments.Remove(app);
}
else
{
foreach (var apps in param.deleted)
{
Appointment app = db.Appointments.Where(c => c.Id ==
apps.Id).FirstOrDefault();
```

```
if (apps != null) db.Appointments.Remove(app);
}
}
db.SaveChanges();
}
if ((param.action == "batch" && param.changed != null) || param.action ==
"update")
{
// this block of code will execute while updating the appointment
var value = param.action == "update" ? param.value : param.changed[0];
var filterData = db.Appointments.Where(c => c.Id ==
Convert.ToInt32(value.Id));
if (filterData.Count() > 0)
{
DateTime startTime = Convert.ToDateTime(value.StartTime);
DateTime endTime = Convert.ToDateTime(value.EndTime);
Appointment appoint = db.Appointments.Single(A => A.Id ==
Convert.ToInt32(value.Id));
appoint.StartTime = startTime;
appoint.EndTime = endTime;
appoint.Subject = value.Subject;
appoint.StartTimeZone = value.StartTimeZone;
appoint.EndTimeZone = value.EndTimeZone;
appoint.Description = value.Description;
appoint.OwnerId = value.OwnerId;
appoint.Recurrence = Convert.ToByte(value.Recurrence);
appoint.RoomId = value.RoomId;
appoint.AllDay = value.AllDay;
appoint.RecurrenceRule = value.RecurrenceRule;
}
db.SaveChanges();
}
IEnumerable data = new
ScheduleControlDataEntities().Appointments.Take(500); //
new.Appointment.Take(5);
return Json(data, JsonRequestBehavior.AllowGet);
}
```

SQL Data Binding

Binding SQL data to Scheduler is quite simple and also it supports the complete CRUD operation to be performed on the appointment data easily.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(dataSource =>
dataSource.URL("/Home/GetData").CrudURL("/Home/Batch").Adaptor("UrlAdapto
r"))
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

C#

```
// Mention the correct path of the database to connect. Also ensure,
whether the provided database already exists.
SqlConnection connection = new SqlConnection(@"Data
Source=(LocalDB)\MSSQLLocalDB;AttachDbFilename=|DataDirectory|\ScheduleDa
tabase.mdf;Integrated Security=True");
public ActionResult Index()
{
return View();
}
public JsonResult GetData()
{
using (connection)
{
DataTable myDataSet = new DataTable();
SqlConnection myAccessConn = new SqlConnection(@"Data
Source=(LocalDB)\MSSQLLocalDB;AttachDbFilename=|DataDirectory|\ScheduleCo
ntrolData.mdf;Integrated Security=True");
SqlCommand myAccessCommand = new SqlCommand("SELECT * FROM ScheduleData",
myAccessConn);
SqlDataAdapter myDataAdapter = new SqlDataAdapter(myAccessCommand);
myAccessConn.Open();
myDataAdapter.Fill(myDataSet);
List<DataRow> datasource = myDataSet.AsEnumerable().ToList();
List<ScheduleDatabase> scheduleList = new List<ScheduleDatabase>();
for (int i = 0; i < datasource.Count; i++)
{
ScheduleDatabase datum = new ScheduleDatabase();
datum.Id = Convert.ToInt32(datasource[i]["Id"]);
datum.Subject = datasource[i]["Subject"].ToString();
datum.StartTime = Convert.ToDateTime(datasource[i]["StartTime"]);
datum.EndTime = Convert.ToDateTime(datasource[i]["EndTime"]);
datum.AllDay = Convert.ToBoolean(datasource[i]["AllDay"]);
datum.Recurrence = Convert.ToBoolean(datasource[i]["Recurrence"]);
datum.RecurrenceRule = datasource[i]["RecurrenceRule"].ToString();
datum.StartTimeZone = datasource[i]["StartTimeZone"].ToString();
datum.EndTimeZone = datasource[i]["EndTimeZone"].ToString();
datum.Description = datasource[i]["Description"].ToString();
scheduleList.Add(datum);
}
myAccessConn.Close();
return Json(scheduleList, JsonRequestBehavior.AllowGet);
}
}
public class ScheduleDatabase
{
public int Id { get; set; }
public string Subject { get; set; }
public DateTime StartTime { get; set; }

value.Description + "')";
adapter1.InsertCommand = new SqlCommand(sqlCommand, connection);
adapter1.InsertCommand.ExecuteNonQuery();
connection.Close();
}
if (param.action == "remove" || param.deleted != null)
{
connection.Open();
if (param.action == "remove")
{
int key = Convert.ToInt32(param.key);
SqlCommand delete = new SqlCommand("delete from ScheduleData where Id=" +
key + "", connection);
delete.ExecuteNonQuery();
}
else
{
foreach (var apps in param.deleted)
{
SqlCommand delete = new SqlCommand("delete from ScheduleData where Id=" +
apps.Id + "", connection);
delete.ExecuteNonQuery();
}
}
connection.Close();
}
if ((param.action == "batch" && param.changed != null) || param.action ==
"update")
{
connection.Open();
var value = param.action == "update" ? param.value : param.changed[0];
sqlCommand = "update scheduleData set EndTime='" + value.EndTime +
"',Recurrence='" + value.Recurrence + "',StartTime='" + value.StartTime +
"',Subject='" + value.Subject + "',AllDay='" + value.AllDay +
"',RecurrenceRule='" + value.RecurrenceRule + "',StartTimeZone = '" +
value.StartTimeZone + "',EndTimeZone = '" + value.EndTimeZone + "'where
Id='" + value.Id + "'";
```

```
adapter1.UpdateCommand = new SqlCommand(sqlCommand, connection);
adapter1.UpdateCommand.ExecuteNonQuery();
connection.Close();
}
return GetData();
}
```

Views

The number of days and its associated appointments are usually grouped together in Scheduler to organize different views. The available view options in Scheduler are as follows,

- Day
- Week
- Workweek
- Month
- Custom View
- Agenda
- Timeline View

Usually these view options are displayed as a toolbar in the date-header section of the Schedule control. The items within the views toolbar can be added/removed based on the value passed to the Views property.

By default, the Schedule control's active view is **Week** view. Also, it is possible to change the active view of the Scheduler by setting CurrentView option with the required view name as depicted below.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@{List<string> view = new List<string>() { "Day", "Week", "WorkWeek",
"Month" };}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.Views(view)
.CurrentView(CurrentView.Week)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

Note: The **CurrentView** property accepts Enum value of CurrentView.<ViewName>.

Day

It represents a single day Scheduler view (single date display) with all its related appointments.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentView(CurrentView.Day)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Week

It's a view displaying a count of 7 days (from Sunday to Saturday) with all its related appointments. The first day of the week can be changed using the FirstDayOfWeek API which accepts either the integer (Sunday=0, Monday=1, Tuesday=2, etc) or string ("Sunday", "Monday", etc) or DayOfWeek enum type value. The default value of this **FirstDayOfWeek** depends on the current culture (language) used in the Scheduler.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.CurrentView(CurrentView.Week)
.FirstDayOfWeek(DayOfWeek.Monday)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Work Week

Work week view displays the working days of the week (count of 5 days) and its associated appointments. It is also possible to customize the days to be displayed in the work week view using WorkWeek API which accepts the string array such as ["Monday", "Tuesday", "Wednesday", "Thursday" and "Friday"]. By default, it renders from Monday to Friday (5 days).

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@{List<string> workWeek = new List<string>() { "Monday", "Tuesday"
,"Wednesday", "Friday", "Saturday" };}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentView(CurrentView.Workweek)
.WorkWeek(workWeek)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Month

Month view displays the entire days of a particular month and all its related appointments. An alternative way to navigate to a particular date in a day view directly from Month view, clicking on the appropriate month cell date header will do so. If the week date range column is clicked, it will navigate to the corresponding week view.

Copyright © 2001 - 2020 Syncfusion Inc.

The next and previous month date cells in the Month view can be shown/hidden on the Scheduler using ShowNextPrevMonth property by setting it to *false*.

For example – To set the Month view as current view in Scheduler and to hide the other month days in it, refer the below code example.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentView(CurrentView.Month)
.ShowNextPrevMonth(false)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: An appointment directly created in Month view will be considered as an all-day appointment.

Customizing number of days (Custom View)

The Scheduler can be displayed with the user-specified date ranges, such as 4 days or any specific date ranges instead of default view options, by making use of the RenderDates property. This property includes two sub properties namely **Start** and **End**, which accepts the date object or date value in string format to specify the date range.

To display the custom view option in the toolbar-like view options in the scheduler header area, add the CustomView value to the views property array collection as shown below.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@{List<string> view = new List<string>() { "Day", "Week", "WorkWeek",
"Month", "CustomView" };}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 5, 2))
.Views(view)
.CurrentView(CurrentView.CustomView)
.RenderDates(dt => dt.Start("5/01/2014").End("5/06/2014"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

When the date difference between the provided start and end date is greater than 7, then the month-like view will get displayed in Vertical Scheduler mode - whereas with the date difference less than 7 days displays the Scheduler with exact count of the specified days.

Note: When the CurrentDate property of Scheduler is set with a date, that lies beyond the specified custom date range - then the Scheduler navigates to the current date with the mentioned date differences.

Agenda

This View option lists out the appointments in a grid-like view for the next 7 days by default from the current date. The count of the number of appointments to be listed in this view can be customized using the AgendaViewSettings.DaysInAgenda.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.CurrentView(CurrentView.Agenda)
.AgendaViewSettings(agendaViewSettings =>
agendaViewSettings.DaysInAgenda(5))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: In Agenda view, the templates can be applied for the date and time columns. Also, the template passed through the AppointmentTemplateId will gets applied to the event column in Agenda view.

Restriction on View Navigation

It is possible to restrict the users to display only the specific list of views in the Schedule header section and also not to navigate to other views that are not listed.

For example, if the views property is set only with Month view – then the Schedule header section displays only the Month option in the view toolbar and also other additional available actions like navigating to day/week view on clicking the month header dates and week date-range is stopped.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@{List<string> views = new List<string>() { "Month" };}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.Views(views)
.CurrentDate(new DateTime(2014, 6, 2))
.CurrentView(CurrentView.Agenda)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: Even though Week view is the active view in Scheduler by default, if it is not listed in the views collection – then the first listed option in the views collection will be taken as current view of the Scheduler.

Timeline View

Timeline view displays the day, time and its associated events horizontally arranged from left to right. By default, Scheduler renders in vertical mode and it can be changed to the timeline mode using Orientation property which accepts both the string and Orientation enum value.

Copyright © 2001 - 2020 Syncfusion Inc.

All the applicable features in Vertical mode works similar with Timeline mode (Horizontal) and only the visualization of the layout changes based on the orientation.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.Orientation(Orientation.Horizontal)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Working with Appointments

An appointment represents a certain time interval in a schedule cell depicting a plan made for the specified time interval.

Appointment Types

The types of appointments available within Scheduler can be categorized as follows

Normal

Represents an appointment that is created for a certain time interval in one or more number of days. If the normal appointment is created for more than 24 hours, then those longer appointments will be rendered on the all-day row.

Note: If the normal appointment is to be created for two days (say from November 25, 2015 – 11.00 PM to November 26, 2015 2.00 AM) but less than 24 hour time interval, then the appointment is split into two partitions and will be displayed appropriately on both the days.

All-Day

Represents an appointment that is created for an entire day such as holiday events. It renders separately in All-day row, a separate place for all-day appointments. In Timeline (horizontal) view, all-day appointment renders in the usual work cells, as no all-day cells are present in that view.

Note: An all-day row is normally visible on the Scheduler, as the ShowAllDayRow property is set to true by default.

Copyright © 2001 - 2020 Syncfusion Inc.

Recurrence

Represents an appointment that is created for a certain time interval that occurs repeatedly in a daily, weekly, monthly, yearly or every weekday basis at the same time interval based on the recurrence rule. The other available options and validations that can be performed on recurrence appointments can be referred from here.

CRUD operation

Appointments play a dynamic role within the Schedule control with which the users mostly interact. You can manipulate (add/edit/delete/drag/resize) the required appointments that reveals one of the main purpose of the Schedule control.

Add/Edit Appointments

The appointments can be added/edited in the Scheduler using any one of the following ways,

- Quick window
- Inline creation/editing
- Default appointment window
- Context menu
- Through programmatically

Quick Window

The Quick window usually pops out while single clicking on the Scheduler cells or appointments. It requires the user to enter the Subject to proceed with the appointment creation. It also includes an **Edit Appointment** option displayed at the bottom left corner – on selection which opens up the normal appointment window.

On single clicking the scheduler appointments, the pop-up that shows up contains the appointment information along with the other options that are listed below,

- Edit Appointment
- Edit Series (only for the recurrence appointments)
- Delete icon

The quick window option can be enabled/disabled by using `ShowQuickWindow` API, whereas its default value is set to **true**.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.ShowQuickWindow(false)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: Select multiple cells either using mouse or keyboard access keys (shift+arrow keys) and press enter key, so that the quick window opens up for the selected date/time range.

Another way to disable the quick window option at dynamic time can be achieved through the CellClick and AppointmentClick events. The below code example shows the way to disable the quick appointment window only while clicking on the cells, but displays for appointments.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.ShowQuickWindow(true)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event => event.CellClick("onCellClick"))
)
```

JS

```
function onCellClick(args) {
args.cancel = true;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Inline Appointment Creation/Editing

Another easier way, for adding or editing the appointment's subject alone can be achieved using inline Add/Edit support. It allows the user to add and edit the appointments inline.

To get familiar with inline Add mode, single click on any of the Scheduler cells or press enter key on the selected cells. When the inline adding mode is ON, a text box will get created within the clicked Scheduler cells with a blinking cursor in it, requiring the user to enter the subject of an appointment. Once the subject is entered, the appointment will be saved on pressing the enter key.

To enable inline edit mode, single click on any of the existing appointment's subject, so that the user can edit the subject of that appointment. The edited subject of that appointment is then updated on pressing the enter key.

The inline option can be enabled/disabled on Scheduler by using the AllowInline API, whereas its default value is set to **false**.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AllowInline(true)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Enabling Inline Edit alone

It is possible to disable the inline appointment creation and enabling only the editing mode of inline by making use of the CellClick event. The below code example shows the way to disable the inline appointment creation while clicking on the cells, but appointments can be edited while clicking on it's subject.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AllowInline(true)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event => event.CellClick("onCellClick"))
)
```

JS

```
function onCellClick(args) {
args.cancel = true;
}
```

Default Appointment Window

The default appointment window is availed with options like

- Subject
- Start and End Time
- All-Day
- TimeZone (for both Start and End time)
- Repeat options
- Description

The other additional options available are listed below for which the appropriate API's are needed to be configured to display these options on the appointment window.

- Location (ShowLocationField)
- Priority (PrioritySettings)
- Categorize (CategorizeSettings)
- Resources

The appointments can be created by double-clicking the Scheduler cells across the required time slots, which makes the Create Appointment window to pop-up. The start and end time fields will get automatically populated, according to the time-slot selection. Clicking on the done button in an appointment window will create the appointment for the selected time cells.

Copyright © 2001 - 2020 Syncfusion Inc.

Note: Select multiple cells both using mouse or keyboard access keys (shift+arrow keys) and press Alt+N key, so that the default appointment window opens up for the selected date/time range with the Start and End time fields automatically filled in.

To prevent the display of default appointment window on double clicking the Scheduler cells, either the AppointmentWindowOpen or CellDoubleClick event can be used, within which the **args.cancel** needs to be set to true. This behavior is depicted in the below code example.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event =>
event.AppointmentWindowOpen("onAppointmentWindowOpen"))
)
```

JS

```
function onAppointmentWindowOpen(args) {
args.cancel = true;
}
```

Through Programmatically

You can add/edit the appointments dynamically through the public method saveAppointment. It accepts the JSON Object data (either a new or updated appointment object) as its argument.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event =>
event.AppointmentWindowOpen("onAppointmentWindowOpen"))
)
@Html.EJ().Button("add").Text("Add").ClientSideEvents(event =>
event.Click("addAppointment"))
```

JS

```
function addAppointment() {
//appointment details
var appointment = {
Subject: "Gym",
StartTime: new Date("2015/11/7 03:30 AM"),
EndTime: new Date("2015/11/7 04:30 AM")
};
//create the schedule object
var schObj = $("#Schedule1").data("ejSchedule");
//pass the JSON object in the public method
schObj.saveAppointment(appointment);
}
```

Delete Appointments

The appointments can be deleted in either of the following ways,

- Selecting an appointment and clicking the delete icon in the quick appointment window.
- Hovering the mouse over appointments and clicking on Inline delete option which is enabled by default for all the appointments.
- Selecting an appointment and pressing `Delete` key.
- Through Programmatically.

A pop-up with a confirmation message will get displayed before deleting an appointment, which can be either switched on/off using the API `ShowDeleteConfirmationDialog`. Also, the confirmation text in that pop-up can be customized as mentioned here.

For example, to localize only the delete confirmation message in the delete window -

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.ShowDeleteConfirmationDialog(true)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<script>
var deleteCustomizationMessage = {
// customize the confirmation message
DeleteConfirmation: "Do you want to delete this Event?",
// customize the delete window title
MouseOverDeleteTitle: "Delete Event",
// customize the recurrence delete window title
RecurrenceDeleteTitle: "Delete Repeat Event"
};
// Extend only the required changes to the original locale collection
$.extend(ej.Schedule.Locale["en-US"], deleteCustomizationMessage);
</script>
```

Note: All these CRUD operations on appointments (add/edit/delete) can also be done through the default Context Menu options **Add Appointment**, **Edit Appointment** and **Delete Appointment** which is available, when context menu settings is enabled within Scheduler.

Through Programmatically

You can delete the appointments dynamically using the method `deleteAppointment`, which accepts the Guid of the appointment or complete appointment data as its argument. The Guid is availed as one of the appointment element's attribute.

Example 1 - Using GUID

The below code example depicts the way to delete the appointments using GUID programmatically by calling the **deleteAppointment** function within the `AppointmentClick` event, which triggers whenever the user clicks on an appointment.

Copyright © 2001 - 2020 Syncfusion Inc.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event =>
event.AppointmentClick("onAppointmentClick"))
)
```

JS

```
function onAppointmentClick(args) {
var schObj = $("#schedule").data("ejSchedule");
schObj.deleteAppointment(args.appointment.Guid);
}
```

Example 2 - Using Appointment object

The below code example depicts the way to delete the appointments using appointment data programmatically by calling the **deleteAppointment** function within the AppointmentClick event, which triggers whenever the user clicks on an appointment.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event =>
event.AppointmentClick("onAppointmentClick"))
)
```

JS

```
function onAppointmentClick(args) {
var schObj = $("#schedule").data("ejSchedule");
schObj.deleteAppointment(args.appointment);
}
```

Handling Appointment Actions

It is possible to define some specific actions to take place before the CRUD operation occurs on the Scheduler appointments through the following available client-side events,

- BeforeAppointmentCreate
- BeforeAppointmentChange
- BeforeAppointmentRemove

BeforeAppointmentCreate – Triggers before saving a new appointment.

BeforeAppointmentChange – Triggers when an appointment is edited and before it is being updated to the dataSource.

BeforeAppointmentRemove – Triggers before deleting an existing appointment.

To stop the save, edit and delete actions on the Scheduler appointments, following code example can be used.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event =>
event.BeforeAppointmentCreate("onAppointmentSave").BeforeAppointmentChang
e("onAppointmentEdit").BeforeAppointmentRemove("onAppointmentDelete"))
)
```

JS

```
function onAppointmentSave(args) {
args.cancel = true; // cancels the save action on appointments.
}
function onAppointmentEdit(args) {
args.cancel = true; // cancels the edit action on appointments.
}
function onAppointmentDelete(args) {
args.cancel = true; // cancels the delete action on appointments.
}
```

Read Only

An interaction with the appointments of the Scheduler can be enabled/disabled through the ReadOnly property. When the ReadOnly property is set to true, it is not possible to do any actions on the appointments, but you can navigate between the schedule dates, views and can also be able to see the appointment details in the quick window. By default, this property is set to false.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class

)
```

Note: When the ReadOnly property is set to true – double clicking the cells will open the appointment window filled with appointment details, which can be allowed to view but cannot be edited or saved.

Drag and Drop

The appointment time can be modified through the drag and drop behavior, by dragging and dropping it to the new location, so that the start time and end time of the appointment gets changed automatically. We can enable/disable the drag and drop functionality through the AllowDragAndDrop property. By default, it is set to true.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AllowDragAndDrop(false)

.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Handling Drag Actions Dynamically

The drag and drop functionality can be handled with the following three events,

- DragStart
- Drag
- DragStop

dragStart – Triggers when the appointments are started to drag from its source location.

drag – Triggers when the appointments are being dragged over.

dragStop – Triggers when the appointments are dropped on a destined location.

The following code example shows how to cancel the dragging functionality with the help of one of these events.

Copyright © 2001 - 2020 Syncfusion Inc.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event=>event.DragStop("onDragStop"))
)
```

JS

```
function onDragStop(args) {
args.cancel = true; // cancels the drag action on appointments.
}
```

External Drag and Drop

It is possible to drag and drop the external items to and fro the Scheduler control. This action is handled through the property AppointmentDragArea which specifies the draggable area which states whether the appointments can be dragged outside of the control or within it.

The following code example lets you dragging and dropping external items to and from the Scheduler control.

HTML

```
<div class="row">
<div class="col-md-2">
<span class=""><b>Tutorials </b> </span>
@Html.EJ().TreeView("drag").Items(items => {
items.Add().Text("HTML").Id("HTML").Expanded(true).Children(child => {
child.Add().Text("Introduction");
child.Add().Text("Editors");
child.Add().Text("Styles");
child.Add().Text("Formatting");
child.Add().Text("Tables");
});
```

}
}
```

Resize

Resizing an appointment is another way to change its start and end time. Mouse hover on the appointments, so that the resizing handlers gets displayed on either sides of the appointment which allows resizing. The resizing functionality can be enabled/disabled by setting the `EnableAppointmentResize` property. By default it is set to `true`.

.RecurrenceRule("RecurrenceRule"))
)
```

Handling Resize Actions Dynamically

The appointment resizing functionality can be handled through the following three events,

- ResizeStart
- Resize
- ResizeStop

ResizeStart – Triggers when the appointments are started resizing from its original time.

Resize – Triggers when the appointment resizing is in progress.

ResizeStop – Triggers when the appointment resizing is done.

The following code example shows how to cancel the resizing functionality with the help of one of these events.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to

.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event=>event.ResizeStart("onResizeStart"))
)
```

JS

```
function onResizeStart(args) {
args.cancel = true; // Blocks the resize action on appointments.
}
```

Categorization

It allows to differentiate the appointments with various categorize options and individual colors. You can also denote the status of the appointments using this categorize option and can specify your own user-defined category collection. It is also possible to select multiple categorize for a single appointment.

Categorize Settings

The CategorizeSettings holds the below categorize related properties such as,

- Enable - It accepts true or false value, denoting whether to enable/disable the categorize option. Its default value is false.
- AllowMultiple – It enables or disables the multiple selection of categories for each appointments in the appointment window as well as in the context menu. Its default value is false.
- DataSource – Binds the categorize dataSource collection. This property should be assigned with the JSON data array collection or instance of ej.DataManger.

We have below 6 default values for Categorize dataSource collection.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for CategorizeSettings -->
List<CategorizeSettings> CategorizeValue = new
List<CategorizeSettings>();
CategorizeValue.Add(new CategorizeSettings { Text = "Blue Category", Id =
"1", Color = "#43b496", FontColor = "#ffffff" });
CategorizeValue.Add(new CategorizeSettings { Text = "Green Category", Id
= "2", Color = "#7f993e", FontColor = "#ffffff" });
CategorizeValue.Add(new CategorizeSettings { Text = "Orange Category", Id
= "3", Color = "#cc8638", FontColor = "#ffffff" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
CategorizeValue.Add(new CategorizeSettings { Text = "Purple Category", Id
= "4", Color = "#ab54a0", FontColor = "#ffffff" });
CategorizeValue.Add(new CategorizeSettings { Text = "Red Category", Id =
"5", Color = "#dd654e", FontColor = "#ffffff" });
CategorizeValue.Add(new CategorizeSettings { Text = "Yellow Category", Id
= "6", Color = "#d0af2b", FontColor = "#ffffff" });
}
```

The below categorize fields holds the appropriate column names from the dataSource -

Field name	Description
Id	It holds the binding name for Id field in the categorize dataSource
Text	It holds the binding name for Text field in the categorize dataSource
Color	It holds the binding name for Color field in the categorize dataSource.
FontColor	It holds the binding name for FontColor field in the categorize dataSource. This font color apply in the appointment.

)
```

Priority

This option prioritize the appointments based on its importance and it can be differentiated with each individual icons/images. By default, there are some specific set of default priority collection and you can also customize it with your own priority collection.

Priority Settings

The PrioritySettings holds the below priority related properties such as,

- Enable - It accepts true or false value, denoting whether to enable/disable the priority option. Its default value is **false**.
- Template – Customize the priority icon/images using template options.
- DataSource – binds the priority dataSource collection. This property should be assigned with the JSON data array collection or instance of ej.DataManger.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to

Search or Filter Appointments

Appointment Search

The public method searchAppointments is used to search the appointments in the Scheduler dataSource. It contains the below four arguments such as search string, search field, filter operator and ignore case.

searchString - It is used to search the given word/sentence within the appointment data.

fields - It is the field with which the search operation takes place. It's an optional argument.

filterOperator – It denotes the filter type like contains, greaterthan or lessthan. It's an optional argument.

ignoreCase – It is a boolean value to set the search string as case sensitive or not. It's an optional argument.

Appointment Filters

The appointments can be filtered or shortlisted based on the simple or complex conditions with four available properties such as **field**, **operator**, **value** and **predicate** which is passed to the public method filterAppointments.

field - It is the field, with which the search operation takes place. It's an optional argument.

operator – It is generally used to specify the filter type.

value – It is the filter keyword based on which the records are filtered.

predicate – To add more than one conditional query, need to use and, or predicate.

RAZOR

allowPaging: true
});
}
}
</script>
```

Recurrence Options

There are scenarios where you require the same appointments to be repeatedly created for multiple days on daily, weekly, monthly, and yearly or on every weekday basis.

In appointment data collection, **Recurrence** and **RecurrenceRule** are dependent fields. While creating or binding the recurrence appointment, the **Recurrence** field is set to **true** and **RecurrenceRule** contains recurrence pattern in string format.

Recurrence Rule

The recurrence appointments are created based on the recurrence rule. The RecurrenceRule is a string value that contains the details of the recurrence appointments like

- repeat type - daily/weekly/monthly/yearly/every weekday
- how many times it needs to be repeated
- the interval duration
- the time period to render the appointment, etc.,

It has the following properties based on which the recurrence appointments are rendered in the Schedule control with its respective time period.

S.No	Property	Purpose
1	FREQ	Maintains the Repeat type value of the appointment. (Example: Daily, Weekly, Monthly, Yearly, Every week day) Example: FREQ=DAILY;INTERVAL=1

Copyright © 2001 - 2020 Syncfusion Inc.

2	INTERVAL	Maintains the Repeat type value of the appointment. (Example: Daily, Weekly, Monthly, Yearly, Every weekday) Example: FREQ=DAILY;INTERVAL=1
3	COUNT	It holds the appointmentâ€™s count value. For example, When the recurrence appointment count value is 10, which means that 10 instances of appointments are created in the recurrence series. Example: FREQ=DAILY;INTERVAL=1;COUNT=10
4	UNTIL	This property is used to store the recurrence end date value. For example, when you set the end date of appointment as 11/30/2015, the UNTIL property holds the end date value denoting when the recurrence actually ends. Example: FREQ=DAILY;INTERVAL=1;UNTIL=11/30/2015
5	BYDAY	It holds the DAY values, representing on which the appointments actually renders. For example, Create the weekly appointment, and select the day(s) from the day options (Monday/Tuesday/Wednesday/Thursday/Friday/Saturday/Sunday). When Monday is selected, the first two letters of the selected day â€œMOâ€• is saved in the BYDAY property. When multiple days are selected, the values are separated by commas. Example: FREQ=WEEKLY;INTERVAL=1;BYDAY=MO,WE;COUNT=10
6	BYMONTHDAY	This property is used to store the date value of the Month, while creating the Month recurrence appointment. For example, when you create a Monthly recurrence appointment for every 3rd day of the month, then BYMONTHDAY holds the value 3 and creates the appointment on 3rd day of every month. Example: FREQ=MONTHLY;BYMONTHDAY=3;INTERVAL=1;COUNT=10
7	BYMONTH	This property is used to store the index value of the selected Month while creating the yearly appointments. For example, when you create the yearly appointment on June month, the index value of June month 6 will get stored in the BYMONTH field. The appointment is created on every 6th month of a year.

Copyright © 2001 - 2020 Syncfusion Inc.

		Example: FREQ=YEARLY;BYMONTHDAY=16;BYMONTH=6;INTERVAL=1;COUNT=10
8	BYSETPOS	This property is used to store the index value of the week. For example, when you create the monthly appointment in second week of a month, the index value of the second week (2) is stored in BYSETPOS. Example: FREQ=MONTHLY;BYDAY=MO;BYSETPOS=2;UNTIL=8/11/2015
9	WKST	This property is used to store the start day value of a week. For example, when you render the workweek the â€œWKSTâ€• value is Monday.
10	EXDATE	EXDATE is used to hold the modified appointment date details (date value) in the recurrence appointment series. For example, when you change the recurrence appointment instance under the date â€œ6/19/2015â€•, then this date is added to the recurrence rule EXDATE field. â€œEXDATEâ€• is also used to differentiate the edited occurrence of the recurrence series for some internal process while doing the â€œEdit Series or Delete seriesâ€• actions. Example: FREQ=WEEKLY;BYDAY=MO,TU,WE,TH,FR;COUNT=10;EXDATE=6/18/2015,6/20/2015;RECUREDITID=1651
11	RECUREDITID	This property contains the Parent Id value of the edited appointment. It is used to track the edited appointment occurrence with its parent recurrence appointment series. For example, when you edit the particular occurrence of the recurrence appointment series, the â€œRECUREDITIDâ€• is added to that edited appointment depicting its parent Id. Example: FREQ=WEEKLY;BYDAY=MO,TU,WE,TH,FR;COUNT=10;EXDATE=6/18/2015,6/20/2015;RECUREDITID=1651

To know more about other possible combinations of above specified recurrence rule properties, refer here.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
```

```
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "FREQ=DAILY;INTERVAL=1;COUNT=5" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
// Recurrence mapper field
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Recurrence Validation

The default recurrence validation has been included for recurrence appointments similar to the one available in outlook. The validation occurs during the recurrence appointment creation, drag and drop or resizing of the recurrence appointments and also if any single occurrence changes. The validation can be disabled by setting the `EnableRecurrenceValidation` to `false`.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "FREQ=DAILY;INTERVAL=1;COUNT=5" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.EnableRecurrenceValidation(false) // Disable Recurrence Validation
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")

.AllDay("AllDay")
// Recurrence mapper field
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Note: You can parse the **RecurrenceRule** of an appointment from the server-side by making use of a new generic utility class **RecurrenceHelper**. Refer this KB document.

Recurrence Edit and Delete options

The recurring appointments can be edited or deleted in three ways as below:

- Single occurrence
- Following appointments
- Entire series

Single occurrence

When an option "Only this Appointment" is selected, a single occurrence of the recurrence appointment alone will be edited or deleted.

Following appointments

When an option "Following Appointments" is selected, all the following events of the recurrence appointment from the current instance will be edited or deleted. The previous instances of the recurrence appointment before this current instances will be retained as it is on the Scheduler.

Entire series

The entire recurrence series will be edited / deleted, on selecting this option.

Reminder

Reminder option notifies all the appointments before some specific time. By default, it notifies before 5 minutes. Each and every appointment triggers the Reminder event and can utilize this event for other user actions like mailing particular event to someone or to do any kind of manipulations with the reminder appointments and so on. The ReminderSettings includes the following 2 properties namely,

- **Enable** - To enable the reminder settings of the Schedule control, set the **Enable** property as true within the Reminder
- **AlertBefore** - Accepts the integer value to denote the time, before how long the reminder should be notified to the user.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "FREQ=DAILY;INTERVAL=1;COUNT=5" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ReminderSettings(rem => rem.Enable(true).AlertBefore(10))
.ScheduleClientSideEvents(event => event.Reminder("reminderCustom"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

RAZOR

```
function reminderCustom(args) {
alert("Reminder Appointment");
}
```

Note: Whenever the reminder setting is enabled in the Scheduler with some specific value (in minutes) assigned to the **AlertBefore** property, the **Reminder** event gets triggered before this specified value. It includes the reminder appointment's entire information within its arguments.

Block Time Intervals

It allows to block the particular timeslots in Schedule. When specific timeslots are blocked, the appointments that lies in that range can either be made read-only or else can be allowed to interact with the users based on the value assigned to the IsBlockAppointment property.

Blockout Settings

The BlockoutSettings holds the below block intervals related properties such as,

- Enable - It accepts true or false value, denoting whether to enable/disable the block intervals option. It's default value is false.
- TemplateId – It applies the template design to block the intervals.
- Datasource – Binds the block intervals dataSource collection. This property should be assigned either with the JSON data array collection or instance of DataManager (ej.DataManager).

The below blockout fields holds the appropriate column names from the dataSource -

Field name	Description
Id	It holds the binding name for Id field in the blockout dataSource
Subject	It holds the binding name for Subject field in the blockout dataSource
StartTime	It holds the binding name for StartTime field in the blockout dataSource.
EndTime	It holds the binding name for EndTime field in the blockout dataSource.
IsBlockAppointment	It holds the binding name for IsBlockAppointment field in the blockout dataSource.

Copyright © 2001 - 2020 Syncfusion Inc.

IsAllDay	It holds the binding name for IsAllDay field in the blockout dataSource.
ResourceId	It holds the binding name for ResourceId field in the blockout dataSource.
CustomStyle	It holds the binding name for CustomStyle field in the blockout dataSource.

The below example depicts the appointment fields accepting the string type mapper fields.

Create a new Class to define the block intervals to be passed to the Scheduler as mentioned below,

C#

```
public class BlockData
{
public int Id { get; set; }
public string Subject { get; set; }
public DateTime StartTime { get; set; }
public DateTime EndTime { get; set; }
public Boolean IsBlockAppointment { get; set; }
public string ResourceId { get; set; }
public bool IsAllDay { get; set; }
}
```

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Block Intervals -->
List<BlockData> blockData = new List<BlockData>();
blockData.Add(new BlockData { Id = 1, Subject = "Service", StartTime =
new DateTime(2015, 11, 10, 9, 00, 00), EndTime = new DateTime(2015, 11,
10, 10, 00, 00), IsBlockAppointment = true });
blockData.Add(new BlockData { Id = 2, Subject = "Maintenance", StartTime
= new DateTime(2015, 11, 11, 11, 00, 00), EndTime = new DateTime(2015,
11, 11, 13, 00, 00), IsBlockAppointment = true });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 10))
.BlockoutSettings(fields => fields.Enable(true)
.Datasource(blockData)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.IsBlockAppointment("IsBlockAppointment"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Blocking Appointments

The Appointments that lies within the blocked time range can be restricted to perform CRUD operations in it and can be made read-only. This can be achieved by setting IsBlockAppointment property to true.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Block Intervals -->
List<BlockData> blockData = new List<BlockData>();
blockData.Add(new BlockData { Id = 1, Subject = "Service", StartTime =
new DateTime(2015, 11, 10, 9, 00, 00), EndTime = new DateTime(2015, 11,
10, 10, 00, 00), IsBlockAppointment = true });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 10))
//Configure the blockout settings
.BlockoutSettings(fields => fields.Enable(true)
.Datasource(blockData)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
//Bind the block appointment field in datasource
.IsBlockAppointment("IsBlockAppointment"))
)
```

Customizing block time intervals

The BlockoutSettings holds the below properties to customize the block intervals such as,

- TemplateId - Template design that applies on the block intervals.
- CustomStyle - The custom CSS that applies on the blocked intervals.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Block Intervals -->
List<BlockData> blockData = new List<BlockData>();
blockData.Add(new BlockData { Id = 1, Subject = "Service", StartTime =
new DateTime(2015, 11, 10, 9, 00, 00), EndTime = new DateTime(2015, 11,
10, 10, 00, 00), IsBlockAppointment = true });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 10))
//Configure the blockout settings
.BlockoutSettings(fields => fields.Enable(true)
.TemplateId("#blockTemplate")
.Datasource(blockData)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.IsBlockAppointment("IsBlockAppointment"))
)
```

HTML

```
<!--Template to apply block intervals-->
<script id="blockTemplate" type="text/x-jsrender">
<div style="height:100%">
<div>{{:Subject}}</div>
</div>
</script>
```

Blocking time interval based on resources

- ResourceId property used within the BlockoutSettings which accepts the resource id's can be used to apply the block intervals based on the resources.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Block Intervals -->
List<BlockData> blockData = new List<BlockData>();
blockData.Add(new BlockData { Id = 1, Subject = "Service", StartTime =
new DateTime(2015, 11, 10, 9, 00, 00), EndTime = new DateTime(2015, 11,
10, 10, 00, 00), IsBlockAppointment = true, ResourceId = "1" });
<!-- Datasource for Appointments -->
List<ScheduleData> Appoint = new List<ScheduleData>();
Appoint.Add(new ScheduleData { Id = "1", Subject = "Meeting", StartTime =
new DateTime(2015, 11, 11, 10, 00, 00), EndTime = new DateTime(2015, 11,
11, 11, 00, 00), Description = "", AllDay = false, Recurrence = false,
RecurrenceRule = "",OwnerId="1" });
<!-- Define the Group -->
List<String> Group = new List<String>();
Group.Add("Owners");
<!-- Datasource for Owners -->
List<ResourceFields> Owner = new List<ResourceFields>();
Owner.Add(new ResourceFields { Id = "1", Text = "Nancy", Color =
"#f8a398", GroupId = "1" });
Owner.Add(new ResourceFields { Id = "2", Text = "Steven", Color =
"#56ca95", GroupId = "1" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 10))
//Configure the blockout settings
.BlockoutSettings(fields => fields.Enable(true)
.Datasource(blockData)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.IsBlockAppointment("IsBlockAppointment")
//resource id mapper field
.ResourceId("ResourceId"))
.Group(gr => { gr.Resources(Group); })
.Resources(res =>
{
res.Field("OwnerId").Title("Owner").Name("Owners").AllowMultiple(true).Re
sourceSettings(fields =>
fields.Datasource(Owner).Text("Text").Id("Id").Color("Color")).Add();
})
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("OwnerId"))
)
```

Context Menu

Scheduler provides default context menu options for both appointments as well as work cells. It also allows to define additional custom context menu options.

The options that are available under `ContextMenuSettings` are as follows,

- **Enable** - Enables/disables the context menu option in Scheduler.
- **MenuItems** - Contains the sub-menu collections related to both the appointment and cells.

Default Menu Options

The menu items contains two separate collection based on the appointment and cells.

Appointment

The appointment collection includes the following options.

Open Appointment (default)
Delete Appointment (default)
Print Appointment
Categorize

Cells

The default options available within the cell collection includes -

Copyright © 2001 - 2020 Syncfusion Inc.

New Appointment
New Recurring Appointment
Today
Go to date
Settings (View, TimeMode, Work Hours)

The following code snippet shows how to enable the context menu settings in Scheduler and to make use of it with default available options.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- List of Appointment menu options -->
List<Appointment> AppMenu = new List<Appointment>();
AppMenu.Add(new Appointment { Id = "open", Text = "Open Appointment" });
AppMenu.Add(new Appointment { Id = "delete", Text = "Delete Appointment"
});
<!-- List of Cell menu options -->
List<Cells> CellMenu = new List<Cells>();
CellMenu.Add(new Cells { Id = "new", Text = "New Appointment" });
CellMenu.Add(new Cells { Id = "recurrence", Text = "New Recurring
Appointment" });
CellMenu.Add(new Cells { Id = "today", Text = "Today" });
CellMenu.Add(new Cells { Id = "goToDate", Text = "Go to date" });
CellMenu.Add(new Cells { Id = "settings", Text = "Settings" });
CellMenu.Add(new Cells { Id = "view", Text = "View", ParentId =
"settings" });
CellMenu.Add(new Cells { Id = "timeMode", Text = "TimeMode", ParentId =
"settings" });
CellMenu.Add(new Cells { Id = "view_Day", Text = "Day", ParentId = "view"
});
CellMenu.Add(new Cells { Id = "view_Week", Text = "Week", ParentId =
"view" });
CellMenu.Add(new Cells { Id = "view_Workweek", Text = "WorkWeek",
ParentId = "view" });
CellMenu.Add(new Cells { Id = "view_Month", Text = "Month", ParentId =
"view" });
CellMenu.Add(new Cells { Id = "timeMode_Hour12", Text = "12 Hour",
ParentId = "timeMode" });
CellMenu.Add(new Cells { Id = "timeMode_Hour24", Text = "24 Hour",
ParentId = "timeMode" });
CellMenu.Add(new Cells { Id = "workhours", Text = "Work Hours", ParentId
= "settings" });
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ContextMenuSettings(contextMenu =>
contextMenu.Enable(true).MenuItems(items =>
items.Appointment(AppMenu).Cells(CellMenu)))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: In agenda view, only the appointment menu items shows up in the context menu options. For default menu items, the id must be defined with the same value as mentioned in the above code example – as we have processed the menus based on this id within our source.

Custom Menu Options

Apart from the default available options, it is also possible to add custom menu options to the context-menu of both the appointment and cell collection.

The following code example depicts how **to add the custom menu items** to the appointment and cell collection of the context menu settings.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- List of Appointment menu options -->
List<Appointment> AppMenu = new List<Appointment>();
AppMenu.Add(new Appointment { Id = "open", Text = "Open Appointment" });
AppMenu.Add(new Appointment { Id = "delete", Text = "Delete Appointment"
});
AppMenu.Add(new Appointment { Id = "option1", Text = "User Option 1" });
<!-- List of Cell menu options -->
List<Cells> CellMenu = new List<Cells>();
CellMenu.Add(new Cells { Id = "customOption", Text = "User Option" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.ContextMenuSettings(contextMenu =>
contextMenu.Enable(true).MenuItems(items =>
items.Appointment(AppMenu).Cells(CellMenu)))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: The **Id** given for the custom menu items **must be unique** in both the appointment and cell collection.

Handling Menu Actions

To define specific actions for a click made on the custom menu items, the client-side event MenuItemClick can be used as depicted in the below code example.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- List of Appointment menu options -->
List<Appointment> AppMenu = new List<Appointment>();
AppMenu.Add(new Appointment { Id = "open", Text = "Open Appointment" });
AppMenu.Add(new Appointment { Id = "delete", Text = "Delete Appointment"
});
AppMenu.Add(new Appointment { Id = "option1", Text = "User Option 1" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ContextMenuSettings(contextMenu =>
contextMenu.Enable(true).MenuItems(items =>
items.Appointment(AppMenu).Cells(CellMenu)))
.ScheduleClientSideEvents(event =>
event.MenuItemClick("onMenuItemClick"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.RecurrenceRule("RecurrenceRule"))
)
```

JS

```
function onMenuItemClick(args) {
//args.events contains information of the clicked menu item.
if (args.events.ID == "option1")
alert("Custom menu clicked");
}
```

Also, it is possible to predict the target on which the right click is made, either on the cells or appointments with the use of the event BeforeContextMenuOpen. The below code example shows how to block the display of context menu when right clicked on the cells by setting **args.cancel** as **true**.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- List of Appointment menu options -->
List<Appointment> AppMenu = new List<Appointment>();
AppMenu.Add(new Appointment { Id = "open", Text = "Open Appointment" });
AppMenu.Add(new Appointment { Id = "delete", Text = "Delete Appointment"
});
AppMenu.Add(new Appointment { Id = "option1", Text = "User Option 1" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ContextMenuSettings(contextMenu =>
contextMenu.Enable(true).MenuItems(items =>
items.Appointment(AppMenu).Cells(CellMenu)))
.ScheduleClientSideEvents(event =>
event.BeforeContextMenuOpen("beforeContextMenuOpen"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

JS

Copyright © 2001 - 2020 Syncfusion Inc.

```
function beforeContextMenuOpen(args) {
//args.events.target - target information to depict either
cell/appointment
if ($(args.events.target).hasClass("e-workcells") ||
$(args.events.target).hasClass("e-monthcells"))
args.cancel = true;
}
```

Adding Categorize Option

To include the default categorize options within the context menu, it is necessary to enable the CategorizeSettings property as shown in the below code example.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- List of Appointment menu options -->
List<Appointment> AppMenu = new List<Appointment>();
AppMenu.Add(new Appointment { Id = "open", Text = "Open Appointment" });
AppMenu.Add(new Appointment { Id = "delete", Text = "Delete Appointment"
});
AppMenu.Add(new Appointment { Id = "categorize", Text = "Categorize" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ContextMenuSettings(contextMenu =>
contextMenu.Enable(true).MenuItems(items =>
items.Appointment(AppMenu).Cells(CellMenu)))
.CategorizeSettings(cat => cat.Enable(true))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: The **Categorize** option must be added to the **Appointment** collections simply with an id "categorize", which displays on right clicking the appointments.

Copyright © 2001 - 2020 Syncfusion Inc.

Resources

The Scheduler provides **Resources** support, with which the single Scheduler is shared by multiple resources simultaneously. Each resource in the Scheduler is arranged in a column/row wise, with individual spacing to display all its respective appointments on a single page. It also supports the grouping of resources, thus enabling the categorization of resources in a hierarchical structure and shows it either in expandable groups (**Horizontal view**) or else vertical hierarchy one after the other (**Vertical view**).

One or more resources can be assigned to the Scheduler appointments by making selection of the resource options available in the appointment window.

Fields of Resources

The default options available within the Resources collection are as follows,

*Name (**String**)*

A unique resource name which is used for differentiating various resource objects while grouping it in levels.

*Title (**String**)*

It holds the title name of the resource field to be displayed on the Scheduler appointment window.

*Field (**String**)*

It holds the name of the resource field to be bound to the Scheduler appointments which contains the resource Id.

*AllowMultiple (**Boolean**)*

When set to true, allows multiple selection of resource names, thus creating multiple instances of same appointment for the selected resources.

*ResourceSettings (**Object**)*

It holds the field names of the resources dataSource to be bound to the Scheduler.

The following are the resource fields which must be defined within the **ResourceSettings** that holds the appropriate column names from the dataSource.

Field name	Description
Text	Binds the Text field name in the dataSource to the ResourceSettings Text. These text gets listed out in the resources field of the appointment window. Itâ€™s mandatory.
Id	Binds the Id field name in the dataSource to the ResourceSettings Id. Itâ€™s mandatory.
GroupId	Binds the GroupId field name in the dataSource to the ResourceSettings GroupId. This field is not necessary for a resource object (resource data) defined as first level within the resources collection.
Color	Binds the Color field name in the dataSource to the ResourceSettings Color. It is optional.

Copyright © 2001 - 2020 Syncfusion Inc.

AppointmentClass	Binds the AppointmentClass field name in the dataSource. It applies the custom CSS class name to the appointments based on the resources.
Start	Binds the starting work hour field name in the dataSource. It's optional, but when provided with some numeric value will set the starting work hour for specific resources.
End	Binds the end work hour field name in the dataSource. It's optional, but when provided with some numeric value will set the end work hour for specific resources.
WorkWeek	Binds the resources working days field name in the dataSource. It's optional, and accept array of strings which is nothing but only the week day names. When provided with some values (array of day names), only those days will render for the specific resources.

Example: To set the resources options using all the above specified fields,

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "", RoomId = "2" });
<!-- Datasource for Owners -->
List<ResourceFields> Owner = new List<ResourceFields>();
Owner.Add(new ResourceFields { Id = "1", Text = "Nancy", Color =
"#f8a398" });
Owner.Add(new ResourceFields { Id = "2", Text = "Steven", Color =
"#56ca95" });
<!-- Datasource for Rooms -->
List<ResourceFields> Room = new List<ResourceFields>();
Room.Add(new ResourceFields { Id = "1", Text = "Room1", Color =
"#f8a398", GroupId = "1", WorkHourStart=10, WorkHourEnd=18, CustomDays:
["Monday","Wednesday","Friday"]});
Room.Add(new ResourceFields { Id = "2", Text = "Room2", Color =
"#56ca85", GroupId = "2", WorkHourStart=6, WorkHourEnd=10, CustomDays:
["Monday","Saturday"]});
Room.Add(new ResourceFields { Id = "3", Text = "Room3", Color =
"#56ac88", GroupId = "2", WorkHourStart=11, WorkHourEnd=15, CustomDays:
["Tuesday","Friday"]});
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.Resources(res => {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
res.Field("OwnerId").Title("Owner").Name("Owners").AllowMultiple(false).R
esourceSettings(fields =>
fields.Datasource(Owner).Text("Text").Id("Id").Color("Color")).Add();
res.Field("RoomId").Title("Room").Name("Rooms").AllowMultiple(true).Resou
rceSettings(fields =>
fields.Datasource(Room).Text("Text").Id("Id").Color("Color").GroupId("Gro
upId").Start("WorkHourStart").End("WorkHourEnd").WorkWeek("CustomDays")).
Add();
})
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("OwnerId,RoomId"))
)
```

Note: The resource object defined at **First Level** within the **Resources** collection doesn't make use of the **GroupId** field, as there is no previous levels applicable to map.

Data Binding

The resources data can be bound to the Schedule control through the **ResourceSettings** option available within the **Resources** property. The data-binding can be done either using JSON object collection or DataManager (ej.DataManager) instance which contains the resources related data.

List Data

Example: To set the resource data with array of **List** data collection

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- Datasource for Owners -->
List<ResourceFields> Owner = new List<ResourceFields>();
Owner.Add(new ResourceFields { Id = "1", Text = "Nancy", Color =
"#f8a398", GroupId = "1" });
Owner.Add(new ResourceFields { Id = "2", Text = "Steven", Color =
"#56ca95", GroupId = "1" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.Resources(res => {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
res.Field("OwnerId").Title("Owner").Name("Owners").AllowMultiple(true).Re
sourceSettings(fields =>
fields.Datasource(Owner).Text("Text").Id("Id").Color("Color")).Add();
})
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("OwnerId"))
)
```

Remote Data

Example: To set the resource data through remote service URL,

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.Resources(res => {
res.ResourceSettings(fields => fields.Datasource(dataSource =>
dataSource.URL("http://mvc.syncfusion.com/OdataServices/Northwnd.svc")).T
ext("CategoryName").Id("CategoryId").Query("ej.Query().select('CategoryID
', 'CategoryName').from('Categories').take(5)")).Add();
})
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("OwnerId"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Multiple Resources (Without Grouping)

It is possible to display the Scheduler in default look without visually showcasing all the resources on it, but it allow the user to assign the required resources to the appointments through the appointment window resource options.

The appointments belonging to all the resources will be displayed on the Scheduler which will be differentiated based on the resource color assigned in the **ResourceSettings** (depicting to which resource that particular appointment belongs).

Example: To display default Scheduler with multiple resource options in the appointment window,

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- Datasource for Owners -->
List<ResourceFields> Owner = new List<ResourceFields>();
Owner.Add(new ResourceFields { Id = "1", Text = "Nancy", Color =
"#f8a398", GroupId = "1" });
Owner.Add(new ResourceFields { Id = "2", Text = "Steven", Color =
"#56ca95", GroupId = "1" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.Resources(res => {
res.Field("OwnerId").Title("Owner").Name("Owners").AllowMultiple(true).Re
sourceSettings(fields =>
fields.Datasource(Owner).Text("Text").Id("Id").Color("Color")).Add();
})
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("OwnerId"))
)
```

Note: Setting **AllowMultiple** to **true** in the above code snippet allows the user to select multiple resources in the appointment window and also creates multiple copies of the same appointment in the Scheduler for each resources while saving.

Copyright © 2001 - 2020 Syncfusion Inc.

Grouping

Scheduler supports both single and multiple levels of resource grouping that can be customized either in horizontal or vertical Scheduler views. In Vertical view - the levels are displayed in a tree structure one after the other, but in horizontal view – the levels are grouped in a vertically expandable/collapsible structure.

Single-Level

This type of grouping allows the Scheduler to display all the resources at a single level simultaneously. The appointments will make use of the **Color** defined for the first resource instance as its background color.

Example: To display the Scheduler with single level resource grouping options,

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- Define the Group -->
List<String> Group = new List<String>();
Group.Add("Owners");
<!-- Datasource for Owners -->
List<ResourceFields> Owner = new List<ResourceFields>();
Owner.Add(new ResourceFields { Id = "1", Text = "Nancy", Color =
"#f8a398", GroupId = "1" });
Owner.Add(new ResourceFields { Id = "2", Text = "Steven", Color =
"#56ca95", GroupId = "1" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.Group(gr => { gr.Resources(Group); })
.Resources(res => {
res.Field("OwnerId").Title("Owner").Name("Owners").AllowMultiple(true).Re
sourceSettings(fields =>
fields.Datasource(Owner).Text("Text").Id("Id").Color("Color")).Add();
})
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("OwnerId"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Note: The **Name** field mentioned in the **Resource** object needs to be specified within the **Group** property in order to enable the grouping option in Scheduler.

Multi-Level

This type of grouping displays the resources in the Scheduler at multiple levels with a set of resources grouped under each parent. The appointments will make use of the **Color** defined for the first/top level resource instance as its background color.

Example: To display the Scheduler with multiple level resource grouping options,

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "", RoomId = "1", OwnerId = "1" });
<!-- Datasource for Grouping -->
List<String> Group = new List<String>();
Group.Add("Owners");
Group.Add("Rooms");
<!-- Datasource for Owners -->
List<ResourceFields> Owner = new List<ResourceFields>();
Owner.Add(new ResourceFields { Id = "1", Text = "Nancy", Color =
"#f8a398", GroupId = "1" });
Owner.Add(new ResourceFields { Id = "2", Text = "Steven", Color =
"#56ca95", GroupId = "1" });
<!-- Datasource for Rooms -->
List<ResourceFields> Room = new List<ResourceFields>();
Room.Add(new ResourceFields { Id = "1", Text = "Room1", Color =
"#f8a398", GroupId = "1" });
Room.Add(new ResourceFields { Id = "2", Text = "Room2", Color =
"#56ca85", GroupId = "2" });
Room.Add(new ResourceFields { Id = "3", Text = "Room3", Color =
"#56ac88", GroupId = "2" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.Group(gr => { gr.Resources(Group); })
.Resources(res => {
res.Field("OwnerId").Title("Owner").Name("Owners").AllowMultiple(true).Re
sourceSettings(fields =>
fields.Datasource(Owner).Text("Text").Id("Id").Color("Color")).Add();
res.Field("RoomId").Title("Room").Name("Rooms").AllowMultiple(true).Resou
rceSettings(fields =>
fields.Datasource(Room).Text("Text").Id("Id").Color("Color").GroupId("Gro
upId")).Add();
})
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("OwnerId,RoomId"))
)
```

Note: Here, the appointments will make use of the **Color** defined for the Owners resource instance as its background color.

Different Working days and Hours for Resources

It is possible to assign different workdays and workhours for each resources present within the Scheduler. The process of assigning different working days for every individual resources is applicable only for the vertical Scheduler mode and not for timeline view, whereas the customization of workhours for each resources is applicable on both the Scheduler orientation. The custom workdays and workhours needs to be defined within the ResourceSettings property using the following 3 sub-properties available within it.

- **Start** – To define the work start hour for each individual resources
- **End** – To define the work end hour for each individual resources
- **WorkWeek** – To define the working days for each individual resources

Example: To display the Scheduler with each resources having different workhours and workdays, the code example is depicted below.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "", RoomId = "1", OwnerId = "5" });
<!-- Datasource for Grouping -->
List<String> Group = new List<String>();
Group.Add("Owners");
Group.Add("Rooms");
<!-- Datasource for Rooms -->
List<ResourceFields> Room = new List<ResourceFields>();
Room.Add(new ResourceFields { Id = "1", Text = "Room1", Color =
"#f8a398", GroupId = "1" });
Room.Add(new ResourceFields { Id = "2", Text = "Room2", Color =
"#56ca95", GroupId = "1" });
<!-- Datasource for Owners -->
List<ResourceFields> Owner = new List<ResourceFields>();
Owner.Add(new ResourceFields { Text = "Nancy", Id= "1", GroupId = "1",
Color = "#ffaa00", Start = "10", End = "18", WorkWeek = new List<string>
{ "Monday", "Wednesday", "Friday" } });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Owner.Add(new ResourceFields { Text = "Steven", Id = "3", GroupId = "2",
Color = "#f8a398", Start = "6", End = "10", WorkWeek = new List<string> {
"Tuesday", "Thursday" } });
Owner.Add(new ResourceFields { Text = "Michael", Id = "5", GroupId = "1",
Color = "#7499e1", Start = "11", End = "15", WorkWeek = new List<string>
{ "Sunday", "Tuesday", "Thursday", "Saturday" } });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.Group(gr => { gr.Resources(Group); })
.Resources(res => {
res.Field("RoomId").Title("Room").Name("Rooms").AllowMultiple(true).Resou
rceSettings(fields =>
fields.Datasource(Room).Text("Text").Id("Id").Color("Color").GroupId("Gro
upId")).Add();
res.Field("OwnerId").Title("Owner").Name("Owners").AllowMultiple(true).Re
sourceSettings(fields =>
fields.Datasource(Owner).Text("Text").Id("Id").Color("Color").GroupId("Gr
oupId").Start("Start").End("End").WorkWeek("WorkWeek")).Add();
})
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("RoomId,OwnerId"))
)
```

Customization

The Scheduler can be customized in various aspects like -

- Setting different Start/end hour limits
- Highlighting the working hours
- Setting different Date format
- Specifying minimum and maximum date ranges
- Customize the entire appointment window with the user required fields
- Setting different time Slot duration
- Complete Scheduler customization using QueryCellInfo event
- Setting different FirstDayOfWeek

Hour Customization

It includes customization of displaying Scheduler with specific Start/End hours and also defining the working hour time range which is differentiated as business hours.

Copyright © 2001 - 2020 Syncfusion Inc.

Schedule Display Hours

It denotes the start and end hour time limits to be displayed on the Scheduler. To set this time limit, two properties namely StartHour and EndHour can be used.

- **StartHour** - The hour from which the Scheduler time display actually starts.
- **EndHour** - The hour on which the Scheduler time display should end.

The following code example renders the scheduler from 7.00 AM to 6.00 PM.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.StartHour(7)
.EndHour(18)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Working Hours

Working hours indicates the work hour limit within the Scheduler, which is highlighted visually with white colored work cells. To enable the highlighting of work hours on the Scheduler, set the **Highlight** option available within the WorkHours property to **true**. By default, it is set to true and includes the below specified options,

- **Highlight** – enables/disables the highlighting of work hours.
- **Start** - sets the start time of the working/business hour in a day.
- **End** - sets the end time limit of the working/business hour in a day.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.WorkHours(hrs => hrs.Highlight(true).Start(8).End(16))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: By default, work hour **Start** is set to **9** and **End** is set to **18**. Also, the Scheduler cells automatically scrolls up or down based on the starting work hour, to make the user to view that particular time initially.

Hide Weekend days

The Scheduler can be customized to display only the working days, thus hiding the weekend days from it. The working days render based on the values given in the WorkWeek property. The days that are not mentioned in the WorkWeek collection is considered to be the weekend days and it can be hidden from the Scheduler by setting false to the ShowWeekend property.

The following code example renders the Scheduler by hiding the weekend days.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ShowWeekend(false)
.AppointmentSettings(fields => fields
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

TimeScale

The TimeScale allows the user to set the required time slot duration for the work cells that displays on the Scheduler. It provides option to customize both the major and minor slots using template option. It includes the below properties such as,

Copyright © 2001 - 2020 Syncfusion Inc.

- Enable - It accepts true or false value, denoting whether to show or hide the time slots. Its default value is true.
- MajorSlot – Specifies the major time slot duration.
- MinorSlotCount – Specifies the value, based on which the minor time slots are divided into appropriate count.
- TimeScale Templates – 2 template options available for customizing time scales namely MinorSlotTemplateId and MajorSlotTemplateId.

The MajorSlot and MinorSlot can be customized with the following code example.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.TimeScale(ts => ts.Enable(true).MajorSlot(60).MinorSlotCount(6))
.AppointmentSettings(fields => fields
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Date Customization

The date in the Scheduler can be customized by setting specific minimum and maximum date ranges and also defining various date formats to it.

Current Date

The Current date indicates the date with which the Scheduler loads initially and based on which the appropriate date range displays in the week/workweek/month/agenda views. To set the current date to the Scheduler – use the following code example,

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: By default, the System current date will be taken as Scheduler's current date.

MinDate and MaxDate

Providing the MinDate and MaxDate property with some date values, allows the Scheduler to set the minimum and maximum date range. The Scheduler date that lies beyond these minimum and maximum date range will be in a disabled state, so that the date navigation is blocked beyond these specified date range. Also, the appointments that lies beyond these date ranges will not be displayed on the Scheduler.

The following code example shows how to set the MinDate and MaxDate properties of the Scheduler.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.MinDate(new DateTime(2015, 11, 4))
.MaxDate(new DateTime(2015, 11, 8))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: The **MaxDate** value provided should always be greater than that of **MinDate** value.

Appointment Window Customization

It is possible to use the custom appointment window option to design it with the user-required extra fields apart from the other default available fields. To make use of the customized appointment window, it is necessary to use the AppointmentWindowOpen event within which the display of default appointment window is prevented.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example lets you create the custom appointment window (using recurrence editor feature) with a single extra field for defining the appointment type.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ScheduleClientSideEvents(event =>
event.AppointmentWindowOpen("onAppointmentWindowOpen"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<div id="customWindow" style="display: none">
<div id="appWindow">
<form id="custom">
<table width="100%" cellpadding="5">
<tbody>
<tr style="display: none">
<td>
Id:
</td>
<td colspan="2">
<input id="customId" type="text" name="Id" />
</td>
</tr>
<tr>
<td>
Subject:
</td>
<td colspan="2">
<input id="subject" type="text" value="" name="Subject" onfocus="temp()"
style="width: 100%" />
</td>
</tr>
<tr>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<td>
Description:
</td>
<td colspan="2">
<textarea id="customdescription" name="Description" rows="3" cols="50"
style="width: 100%; resize: vertical"></textarea>
</td>
</tr>
<tr>
<td>
StartTime:
</td>
<td>
@Html.EJ().DateTimePicker("StartTime").Width("150px")
</td>
</tr>
<tr>
<td>
EndTime:
</td>
<td>
@Html.EJ().DateTimePicker("EndTime").Width("150px")
</td>
</tr>
<tr>
<td colspan="3">
<div class="customcheck">AllDay:</div>
<div class="customcheck">
<input id="allDay" type="checkbox" name="AllDay" onchange="allDayCheck()"
/>
</div>
<div class="customcheck">Recurrence:</div>
<div>
<input id="recurrence" type="checkbox" name="Recurrence" />
</div>
</td>
</tr>
<tr id="summaryTr" style="display:none;">
<td colspan="3">
<div class="recSummary">Summary:</div>
<div>
<label id="recSummary" name="Summary"></label>
</div>
</td>
</tr>
<tr id="editor" style="display:none;">
<td colspan="3">
<div><a id="recedit" onclick="recurrenceRule()">Edit</a></div>
</td>
</tr>
</tbody>
</table>
</form>
<div>
<button type="submit" onclick="cancel()" id="buttonCancel"
style="float:right;margin-right:20px;margin-bottom:10px;">Cancel</button>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<button type="submit" onclick="save()" id="buttonSubmit"
style="float:right;margin-right:20px;margin-bottom:10px;">Submit</button>
</div>
</div>
<div id="recWindow" style="display: none">
<div style="margin: 0 15%;">
@(Html.EJ().RecurrenceEditor("recurrenceEditor").SelectedRecurrenceType(0
).Frequencies(new List<string> { "daily", "weekly", "monthly", "yearly",
"everyweekday" }))
</div>
<div>
<button type="submit" id="recCancel">Cancel</button>
<button type="submit" id="recSubmit">Submit</button>
</div>
</div>
</div>
```

The styles to be applied for the controls within the custom appointment window are as follows.

HTML

```
<style>
.customcheck {
float: left;
margin-right: 10px;
}
.error {
background-color: #FF8A8A;
}
#custom table td {
padding:5px;
}
</style>
```

Now, define the Schedule control with custom appointment window within script as shown below.

HTML

```
<script>
$(function () {
// defining sub-controls used within custom appointment window
$("#buttonCancel").ejButton({ width: '85px' });
$("#buttonSubmit").ejButton({ width: '85px' });
$("#recurrence").ejCheckBox({ change: "recurCheck" });
$("#recCancel,#recSubmit").ejButton({ click: "onRecurrenceClick" });
// defining dialog control to be used as custom appointment window
$("#customWindow").ejDialog({
width: 600,
height: "auto",
position: { X: 200, Y: 100 },
showOnInit: false,
enableModal: true,
title: "Appointment Window",
enableResize: false,
allowKeyboardNavigation: false,
close: "clearFields"
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
});
});
</script>
```

The following function needs to be defined within script section, which gets called before the default appointment window opens.

JS

```
function onAppointmentWindowOpen(args) {
args.cancel = true; // prevents the display of default appointment window
var schObj = $("#Schedule1").data("ejSchedule");
// When double clicked on the Scheduler cells, fills the StartTime and
EndTime fields appropriately
$("#StartTime").ejDateTimePicker({ value: args.startTime });
$("#EndTime").ejDateTimePicker({ value: args.endTime });
$("#recWindow").css("display", "none");
$("#appWindow").css("display", "");
if (!ej.isNullOrUndefined(args.target)) {
// When double clicked on the Scheduler cells, if the target is allDay or
month cells - only then enable check mark on the allDay checkbox
if ($(args.target.currentTarget).hasClass("e-alldaycells") ||
(args.startTime.getHours() == 0 && args.endTime.getHours() == 23))
$("#allDay").prop("checked", true);
else
args.model.currentView == "month" ? $("#allDay").prop("checked", true) :
$("#allDay").prop("checked", false);
// If the target is allDay or month cells - disable the StartTime and
EndTime fields
$("#StartTime,#EndTime").ejDateTimePicker({
enabled: ($(args.target.currentTarget).hasClass("e-alldaycells") ||
(args.startTime.getHours() == 0 && args.endTime.getHours() == 23) ||
$(args.target.currentTarget).hasClass("e-monthcells") ||
args.model.currentView == "month") ? false : true
});
}
// If double clicked on the appointments, fill the custom appointment
window fields with appropriate values.
if (!ej.isNullOrUndefined(args.appointment)) {
$("#customId").val(args.appointment.Id);
$("#subject").val(args.appointment.Subject);
$("#StartTime").ejDateTimePicker({ value: new
Date(args.appointment.StartTime) });
$("#EndTime").ejDateTimePicker({ value: new
Date(args.appointment.EndTime) });
$("#recurrence").ejCheckBox({ checked: args.appointment.Recurrence });
if (args.appointment.Recurrence) {
$("#editor").css("display", "");
$("#recSummary").html(args.appointment.RecurrenceRule);
$("#summaryTr").css("display", "");
recObj._recRule = args.appointment.RecurrenceRule; // app recurrence rule
is stored in Recurrence editor object
recObj.recurrenceRuleSplit(args.appointment.RecurrenceRule,
args.appointment.recurrenceExDate); //splitting the recurrence rule
recObj.showRecurrenceSummary(args.appointment.Id); // updating the
recurrence rule in Recurrence editor
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
}
$("#customWindow").ejDialog("open");
}
```

On clicking the **Submit** button within the Custom Appointment window, the following function gets executed – which will validate the appointment fields and then save it appropriately.

JS

```
function save() {
// checks if the subject value is not left blank before saving it.
if ($.trim($("#subject").val()) == "") {
$("#subject").addClass("error");
return false;
}
var obj = {}, temp = {}, rType;
var formElement = $("#customWindow").find("#custom").get(0);
// looping through the custom form elements to get each value and form a
JSON object
for (var index = 0; index < formElement.length; index++) {
var columnName = formElement[index].name, $element =
$(formElement[index]);
if (columnName != undefined) {
if (columnName == "")
columnName = formElement[index].id.replace(this._id, "");
if (columnName != "" && obj[columnName] == null) {
var value = formElement[index].value;
if (columnName == "Id" && value != "")
value = parseInt(value);
if ($element.hasClass("e-datetimepicker"))
value = new Date(value);
if (formElement[index].type == "checkbox")
value = formElement[index].checked;
obj[columnName] = value;
}
}
}
obj["RecurrenceRule"] = (obj.Recurrence) ? recurRule : null;
$("#customWindow").ejDialog("close");
var object = $("#Schedule1").data("ejSchedule");
object.saveAppointment(obj);
clearFields();
}
// This function executes when the submit/cancel button in the recurrence
editor window is pressed.
function onRecurrenceClick(args) {
if ($(args.e.currentTarget).attr("id") == "recSubmit") {
recObj = $("#recurrenceEditor").ejRecurrenceEditor('instance');
recObj.closeRecurPublic();
recurRule = recObj._recRule;
$("#recSummary").html(recurRule);
}
else
if (($(args.e.currentTarget).attr("id") == "recCancel")) {
if ($("#recSummary").html() == "") {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$("#editor").css("display", "none");
$("#recurrence").ejCheckBox({ checked: false });
}
else
$("#recurrence").ejCheckBox({ checked: true });
}
$("#recWindow").css("display", "none");
$("#appWindow").css("display", "");
if ($("#recSummary").html() != "")
$("#summaryTr").css("display", "");
}
// This function executes when the Edit anchor tag in the edit
appointment window is clicked.
function recurrenceRule() {
$("#recWindow").css("display", "");
$("#appWindow").css("display", "none");
}
// Clears all the field values of the custom window after saving
appointments
function clearFields() {
$("#customId").val("");
recObj.clearRecurrenceFields();
$("#subject").val("");
$("#recSummary").html("");
$("#summaryTr").css("display", "none");
$("#recurrence").ejCheckBox({ checked: false });
$("#editor").css("display", "none");
$("#StartTime,#EndTime").ejDateTimePicker({ enabled: true });
}
// This function executes when the recurrence checkbox is checked in the
custom appointment window
function recurCheck(args) {
if (args.isInteraction) {
if ($("#recurrence").get(0).checked == true) {  // Displays the
recurrence field, when recurrence checkbox is checked.
$("#recWindow").css("display", "");
$("#appWindow").css("display", "none");
$("#editor").css("display", "");
}
else {
$("#recWindow").css("display", "none");
$("#editor").css("display", "none");
$("#recSummary").html("");
$("#summaryTr").css("display", "none");
}
}
}
// This function executes when the All-day checkbox is checked in the
custom appointment window
function allDayCheck() {
// Disables and sets the specific hours to the StartTime and EndTime
fields, when the all-day checkbox is checked
if ($("#allDay").prop("checked")) {
var a = $("#StartTime").data("ejDateTimePicker").model.value;
a.setHours(0, 0, 0);
var b = $("#EndTime").data("ejDateTimePicker").model.value;
b.setHours(23, 59, 0);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$("#StartTime").ejDateTimePicker({
value: new Date(a),
enabled: false
});
$("#EndTime").ejDateTimePicker({
value: new Date(b),
enabled: false
});
} else {
$("#StartTime").ejDateTimePicker({
enabled: true
});
$("#EndTime").ejDateTimePicker({
enabled: true
});
}
}
// This function executes when the subject text field is currently being
focused
function temp() {
$("#subject").removeClass("error");
}
// This function executes when the cancel button in the custom
appointment window is pressed.
function cancel() {
recObj = $("#recurrenceEditor").ejRecurrenceEditor('instance');
clearFields();
$("#customWindow").ejDialog("close");
}
```

Scheduler Customization using QueryCellInfo

It is possible to format and customize almost every child elements of scheduler such as work cells, header cells, time cells and so on using QueryCellEvent event.

The following code snippet shows how to customize the appointment and work cells based on the query cell info event.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ScheduleClientSideEvents(event => event.QueryCellInfo("checkFormat"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

While loading the scheduler using above code, the below function gets triggered by the QueryCellInfo event which customizes the corresponding DOM element.

HTML

```
<script type="text/javascript">
function checkFormat(args) {
switch (args.requestType) {
case "workcells":
args.element.css("background-color", "#ffe9cc");
break;
case "monthcells":
args.element.css("background-color", "#faa41a");
args.element.css("border-color", "#faa41a");
break;
}
}
</script>
```

The Scheduler elements are listed below which can be formatted through this event. The names are listed in the format with which it can be accessed or used within the requestType argument of the event.

Request Type	Description
appointment	Depicts the appointment element within the Scheduler.
agendacells	Depicts the Agenda Cell element within the Scheduler.
alldaycells	Depicts the AllDay cell element within the Scheduler.
headercells	Depicts the header cell element within the Scheduler.
resourceheadercells	Depicts the resource header cell element within the Scheduler.
leftheadercells	Depicts the left empty space on header cell element within the Scheduler.
leftindentcells	Depicts the left empty space on date cell element within the Scheduler.
timecells	Depicts the left side time panel cell element within the Scheduler.
headerdate	Depicts the header date cell element within the Scheduler.
emptytd	Depicts the empty space above the vertical scroller within the Scheduler.
resourcegroupheader	Depicts the header group cell in horizontal orientation in the Scheduler.

Copyright © 2001 - 2020 Syncfusion Inc.

Request Type	Description
monthcells	Depicts the month cell element within the Scheduler.
workcells	Depicts the work cell element within the Scheduler.

Navigation

Navigation in Scheduler can be classified based on Scheduler views, date and also the appointments in it.

View Navigation

By default, all the available view options except the custom view are available at the top right corner of the Schedule header, which can be traverse through continuously as and when needed.

Clicking on the particular date header in the Week/Work Week/Month/Custom View will navigate to the day view automatically. Also, clicking on the week header ranges displayed at the left side in the month view will navigate to the Week view. These particular actions can take place only if the Week and Day view options are present in the Views Collection.

Handling View navigation actions

Usually, the Navigation event gets triggered whenever the views/dates are being navigated. To block the navigation to day and week views from month view, the **Navigation** event can be used in the following way.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event => event.Navigation("onNavigation"))
)
```

JS

```
function onNavigation(args) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
// args.target.currentTarget - target element which is clicked.
var target = $(args.target.currentTarget);
if (args.requestType == "viewNavigate" && (target.hasClass("e-
headercells") || target.hasClass("e-monthheader") || target.hasClass("e-
timecells")))
args.cancel = true;
}
```

Note: Based on the navigation, the appointments that lies between the particular date ranges of the current view are fetched and rendered in the Scheduler.

Date Navigation

The Scheduler date can be navigated on two aspects either in a continuous or random manner. On pressing the previous and next navigation arrow icons in the Scheduler header will move the scheduler one date back and forth respectively.

Another way of navigating through date is by making use of the built-in calendar available within the Scheduler, which pops out when the header date range is clicked. Selecting any date in the calendar will make the Scheduler to move to that particular date appropriately.

Handling date navigation actions

To handle the date navigation actions, the Navigation event can be used. For example, to block the date navigation, follow the below code example.

HTML

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
.ScheduleClientSideEvents(event => event.Navigation("onNavigation"))
)
```

JS

```
function onNavigation(args) {
//args.target - target element which is clicked.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//args.currentDate - current date of the Scheduler.
//args.requestType - Specifies the navigation type.
if (args.requestType == "dateNavigate")
args.cancel = true;
}
```

Appointment Navigation

The Appointment navigation bars (labeled **Previous/Next Appointment**) are rendered parallel to each other on the left and right centric corners of the Schedule control. It is controlled by an API ShowAppointmentNavigator which is set to true by default. When it is set to false, these bars will not be displayed on the Scheduler.

Whenever the previous/Next Appointment bars are clicked, it navigates the Scheduler to the corresponding closest date where the appointments are available. If no appointments are available beyond the current date, then these appointment bars will be in a disabled state.

The following code example shows the way to define the **ShowAppointmentNavigator** property for Scheduler.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ShowAppointmentNavigator(true)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Template

Template is applicable to all the below specified elements of the Scheduler,

- Appointments
- Cells
- Date header
- Resource header

Copyright © 2001 - 2020 Syncfusion Inc.

- Priority field
- TimeScale
- Date and time columns in Agenda view
- Tooltip

Appointment Template

The template design that applies on for the Scheduler appointments. The field names that are mapped from the dataSource to the appropriate field properties within the AppointmentSettings can be accessed within the template.

Apart from the dataSource field names, the template can also access the current view of the Scheduler using the name **View** – which can contain either of the following values in lowercase.

- day
- week
- workweek
- agenda
- month
- customview

It is controlled by an API named AppointmentTemplateId which accepts the id value of the template design block preceded by a symbol **#**.

Usually, the appointments are displayed with its **Subject** and **Start/End time** on the Scheduler. If suppose, the subject needs to be accompanied with location text, it can be done with the following code example.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentTemplateId("#appTemplate")
.AppointmentSettings(fields => fields.Datasource(Model)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

HTML

```
<!-- Template for Appointment -->
<script id="appTemplate" type="text/x-jsrender">
{{"{{"}}if View !== "agenda"{{}}}}
<div style="height:100%; background-color:orange; margin-left: 5px;">
<div style="margin-left: 2px;">{{"{{"}}:Subject{{}}}}</div>
<div style="margin-left: 2px;">{{"{{"}}:Location{{}}}}</div>
</div>
{{"{{"}}else{{}}}}
<div>{{"{{"}}:Subject{{}}}}{{"{{"}}:Location{{}}}}</div>
{{"{{"}}/if{{}}}}
</script>
```

Cells Template

The template design that applies on the Scheduler elements such as all-day cells, work cells and month cells which allows the customization to be done based on the date, view, resources and timescale. The cells can be customized to add images, colors, and other elements etc and can also access the current view of the Scheduler using the name **view**.

All-day cells - An API named `AllDayCellsTemplateId` can be used to customize the all-day cells, which accepts the id of the template design block preceded with a symbol **#**.

Work cells and Month cells - An API named `WorkCellsTemplateId` can be used to customize the work cells in all the views, which accepts the id of the template design block preceded by a symbol **#**.

The cells can be customized with the following code example.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AllDayCellsTemplateId("#allDayTemplate") // Alldaycells Template ID
.WorkCellsTemplateId("#workTemplate") // Workcells Template ID
.AppointmentSettings(fields => fields
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<!-- Template for Alldaycells -->
<script id="allDayTemplate" type="text/x-jsrender">
<div class="e-icon e-scheduleallday" style="opacity:0.5"></div>
<span style="opacity:0.5">AllDay</span>
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<!-- Template for Workcells and Monthcells -->
<script id="workTemplate" type="text/x-jsrender">
{{"{{"}}if resource.classname == 'e-parentnode'{{}}}}
{{"{{"}}:resource.text{{}}}}
{{"{{"}}else{{}}}}
{{"{{"}}if date.getDay() == 0 || date.getDay() == 6{{}}}}
<div style="background-color:lightblue">Weekend</div>
{{"{{"}}else{{}}}}
{{"{{"}}if view == 'month' && resource.text == 'Party Hall-A' &&
date.getDay() == 5{{}}}}
<div style="background-color:burlywood">Meeting</div>
{{"{{"}}else resource.text != 'Party Hall-B' && date.getDate() ==
15{{}}}}
<div style="background-color:thistle">Holiday</div>
{{"{{"}}else view != 'month' && resource.text == 'Party Hall-A' &&
date.getDay() == 5 && date.getHours() == 10{{}}}}
<div style="background-color:burlywood">Meeting</div>
{{"{{"}}else view == 'month' && resource.text == 'Party Hall-B' &&
date.getDay() == 5{{}}}}
<div style="background-color:lightblue">Conf.</div>
{{"{{"}}else resource.text == 'Party Hall-B' && date.getDate() ==
16{{}}}}
<div style="background-color:darkkhaki">HappyDay</div>
{{"{{"}}else view != 'month' && resource.text == 'Party Hall-B' &&
date.getDay() == 5 && date.getHours() == 12{{}}}}
<div style="background-color:goldenrod">Conf.</div>
{{"{{"}}else date.getDate() == 10 && date.getMonth() == 11{{}}}}
<div style="background-color:palegreen">Day Special</div>
{{"{{"}}else date.getDate() == 25 && date.getMonth() == 11{{}}}}
<div style="background-color:sandybrown">Christmas</div>
{{"{{"}}/if{{}}}}
{{"{{"}}/if{{}}}}
{{"{{"}}/if{{}}}}
</script>
```

Date Header Template

The template design that applies on for the date header part of the Scheduler. An API named DateHeaderTemplateId] can be used to customize the date header which accepts the id value of the template design block preceded by a symbol **#**. The template can also access the current view of the Scheduler in using the name **view**.

The Date header can be customized with the following code example.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.DateHeaderTemplateId("#dateTemplate") // Date header Template ID
.AppointmentSettings(fields => fields
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<!-- Template for Date header -->
<script id="dateTemplate" type="text/x-jsrender">
<div>{{"{{"}}:~dTemplate(date){{}}}}</div>
</script>
<script>
function _dateFormat(date) {
var dFormat = ej.format(new Date(date), "dd/MM");
return dFormat;
}
$.views.helpers({ dTemplate: _dateFormat });
</script>
```

Resource Header Template

The template structure that applies on the resource headers of the Scheduler. By default, only the resource names will be displayed on the resource header bar. Also, the way of rendering resource headers on the Scheduler is comparatively different for both the vertical and horizontal scheduler views.

The field names that are mapped from the dataSource to the appropriate field properties within the **ResourceSettings** can be accessed within the resource header template.

Resource Header Template in Vertical View

To customize the resource header with some additional images or other customizations in **Vertical Scheduler View** – refer the below code example.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- Datasource for Grouping -->
List<String> Group = new List<String>();
Group.Add("Rooms");
<!-- Datasource for Rooms -->
List<ResourceFields> Room = new List<ResourceFields>();
Room.Add(new ResourceFields { Id = "1", Text = "Room1", Color =
"#f8a398", GroupId = "1" });
Room.Add(new ResourceFields { Id = "2", Text = "Room2", Color =
"#56ca85", GroupId = "2" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Group(gr => { gr.Resources(Group); })
.ResourceHeaderTemplateId("#resTemplate")
.Resources(res => {
res.Field("RoomId").Title("Room").Name("Rooms").AllowMultiple(true).Resou
rceSettings(fields =>
fields.Datasource(Room).Text("Text").Id("Id").Color("Color").GroupId("Gro
upId")).Add();
})
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("RoomId"))
)
```

HTML

```
<!-- Template for ResourceHeader in Vertical -->
<script id="resTemplate" type="text/x-jsrender">
<div style="height:100%">
<div style="width:15px;height:15px;margin-left:150px;margin-
top:2px;float:left;background:{{"{{"}}:Color{{}}}};"></div><div
style="float:left;margin-left:5px;">{{"{{"}}:Text{{}}}}</div>
</div>
</script>
```

Resource Header Template in Horizontal View

To perform the above specified same customization in **Horizontal Scheduler view**, the template structure varies a little bit as depicted below.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "", RoomId = "1" });
<!-- Datasource for Grouping -->
List<String> Group = new List<String>();
Group.Add("Rooms");
<!-- Datasource for Rooms -->
List<ResourceFields> Room = new List<ResourceFields>();
Room.Add(new ResourceFields { Id = "1", Text = "Room1", Color =
"#f8a398", GroupId = "1" });
Room.Add(new ResourceFields { Id = "2", Text = "Room2", Color =
"#56ca85", GroupId = "2" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.Orientation(Orientation.Horizontal)
.Group(gr => { gr.Resources(Group); })
.ResourceHeaderTemplateId("#resTemplate")
.Resources(res => {
res.Field("RoomId").Title("Room").Name("Rooms").AllowMultiple(true).Resou
rceSettings(fields =>
fields.Datasource(Room).Text("Text").Id("Id").Color("Color").GroupId("Gro
upId")).Add();
})
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("RoomId"))
)
```

HTML

```
// Template for ResourceHeader in Horizontal
<script id="resTemplate" type="text/x-jsrender">
<div style="height:100%">
<div style="width:15px;height:15px;margin-
top:2px;float:left;background:{{"{{"}}:Color{{}}}};"></div><div
style="float:left;margin-left:5px;">{{"{{"}}:Text{{}}}}</div>
</div>
</script>
```

Note: In horizontal Scheduler, the header template makes use of an additional field namely **classname** which holds either **e-parentnode** or **e-childnode** value. The field **classname** can be used in the application scenario to check for the parent or child header node. You can apply the different template customization accordingly based on it.

TimeScale with Template

The TimeScale is an object collection that holds below timescale related properties such as,

The TimeScale is also availed with template options to allow customization. It includes the following 2 properties for customization -

- MajorSlotTemplateId - Accepts the id value of the template design block preceded by a symbol **#**, which gets applied for the major time slots.
- MinorSlotTemplateId - Accepts the id value of the template design block preceded by a symbol **#**, which gets applied for the minor time slots.

Copyright © 2001 - 2020 Syncfusion Inc.

The template customization for major and minor timeslots can be referred from the following code example.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.TimeScale(ts =>
ts.Enable(true).majorSlot(60).majorSlotTemplateId("#majorTemplate").minor
SlotCount(6).minorSlotTemplateId("#minorTemplate"))
.AppointmentSettings(fields => fields
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<!-- Template for Majorslot -->
<script id="majorTemplate" type="text/x-jsrender">
<div>{{"{{"}}:~major(date){{}}}}</div>
</script>
<!-- Template for Minorslot -->
<script id="minorTemplate" type="text/x-jsrender">
<div>{{"{{"}}:~minor(date){{}}}}</div>
</script>
<script>
function _majorFormat(date) {
var dFormat = ej.format(new Date(date), "hh:mm:ss");
return dFormat;
}
$.views.helpers({ major: _majorFormat });
function _minorFormat(date) {
var dFormat = ej.format(new Date(date), "hh:mm:ss");
return dFormat;
}
$.views.helpers({ minor: _minorFormat });
</script>
```

Priority Settings Template

The template design which can be applied to the content of the priority field in the appointment window. By default, the appropriate icons are displayed for each priority options such as **None**, **High**, **Medium** and **Low**.

When template is applied for the PrioritySettings, these default icons will be replaced by the custom icons or styles defined newly. The following code example depicts the way to enable the priority settings and to define the new custom styles to replace the default icons in the Priority field.

RAZOR

Copyright © 2001 - 2020 Syncfusion Inc.

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "", Priority = "critical" });
<!-- Datasource for PrioritySettings -->
List<PrioritySettings> Priority = new List<PrioritySettings>();
Priority.Add(new PrioritySettings { Text = "none", Value = "none" });
Priority.Add(new PrioritySettings { Text = "critical", Value = "critical"
});
Priority.Add(new PrioritySettings { Text = "ultra-critical", Value =
"ultra-critical" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.PrioritySettings(priority =>
priority.Enable(true).Datasource(Priority).Text("Text").Value("Value").Te
mplate("<div class='${Text}'></div>"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Priority("Priority")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<!-- Style for Priority Template -->
<style type="text/css">
.critical,
.ultra-critical,
.none {
height: 13px;
width: 13px;
float: left;
margin-right: 4px;
background-repeat: no-repeat;
background-size: 60px;
padding: 1px;
margin-top: 2px;
}
.critical {
background-color: orange;
background-position: -13px;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.ultra-critical {
background-color: #56ca85;
background-position: -59px;
}
</style>
```

The custom style class names defined for the priority template should be same as that of the values defined for each priority option within the dataSource, so that it applies properly.

Note: Additionally, the priority field within the AppointmentSettings should be defined with appropriate dataSource field name. When an appointment is assigned with a priority value, the custom style/icon defined for that priority option will get applied over that appointment.

Tooltip Template

The tooltip can be applied with the customized template design. Currently the tooltip support is provided only for the appointments and the default tooltip displays the Subject and duration on hovering across the appointments.

By making use of template feature with tooltip, all the field names that are mapped from the dataSource to the appropriate field properties within the **AppointmentSettings** can be accessed.

To define the template option for tooltip, the TooltipSettings must be enabled first. The following code example depicts the way to add the tooltip template.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "", Location = "US" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.TooltipSettings(tooltip =>
tooltip.Enable(true).TemplateId("#tooltipTemplate"))
.AppointmentSettings(fields => fields.Datasource(Model)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Location("Location")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

Copyright © 2001 - 2020 Syncfusion Inc.

```
<!-- Template for Tooltip -->
<script id="tooltipTemplate" type="text/x-jsrender">
<div style="width:145px">
<div style="padding-top:3px;">
<div style="float:left; font:13px Segoe UI; font-
weight:bold;">Subject: </div>
<div style="padding-top:2px; font:12px Segoe UI
SemiBold;">{{"{{"}}:Subject{{}}}}</div>
</div>
<div style="padding-top:3px">
<div style="float:left; font:13px Segoe UI; font-
weight:bold;">Location: </div>
<div style="padding-top:2px; font:12px Segoe UI
SemiBold;">{{"{{"}}:Location{{}}}}</div>
</div>
</div>
</script>
```

Agenda View Templates

Agenda View provides two separate templates – one for date column and another for time column. These templates allows the customization of the content of both the date and time columns. Apart from this, the event column can also be customized through the existing API named `AppointmentTemplateId`.

The following code snippet shows how to customize the content of the date, time and event column.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
// Datasource for Appointments
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AgendaViewSettings(agenda =>
agenda.TimeColumnTemplateId("#timeTemplate").DateColumnTemplateId("#dateT
emplate"))
.AppointmentTemplateId("#appTemplate")
.AppointmentSettings(fields => fields.Datasource(Model)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<!-- Template for date column -->
<script id="dateTemplate" type="text/x-jsrender">
<div style="height:100%">
<div>
<div>{{"{{"}}:~dateDisplay(StartTime){{}}}}</div>
</div>
</div>
</script>
<!-- Template for time column -->
<script id="timeTemplate" type="text/x-jsrender">
<div style="height:100%">
<div>
<div>{{"{{"}}:~timeDisplay(StartTime){{}}}}</div>
</div>
</div>
</script>
<!-- Template for appointment which applies for event column in agenda
view. -->
<script id="appTemplate" type="text/x-jsrender">
{{"{{"}}if View !== "agenda"{{}}}}
<div style="height:100%; background-color:orange; margin-left: 5px;">
<div style="margin-left: 2px;">{{"{{"}}:Subject{{}}}}</div>
<div style="margin-left: 2px;">{{"{{"}}:Location{{}}}}</div>
</div>
{{"{{"}}else{{}}}}
<div>{{"{{"}}:Subject{{}}}} {{"{{"}}:Location{{}}}}</div>
{{"{{"}}/if{{}}}}
</script>
```

JS

```
function _getDate(date) {
var dateCol = new Date(date);
return dateCol.toDateString();
}
function _getTime(date) {
var time = new Date(date);
return time.toLocaleTimeString();
}
$.views.helpers({
dateDisplay: _getDate,
timeDisplay: _getTime
});
```

Globalization and Localization

Globalization

The Scheduler control is built with default **globalization** support as it format the dates according to the user's locale automatically and processes it internally without any need for manual conversions. This kind of default handling of Scheduler dates is achieved through the built-in **ej.globalize** library which globalize the date, day and month names accordingly.

Copyright © 2001 - 2020 Syncfusion Inc.

Localization

Scheduler also comes with default localization support which allows it to customize the display of text within the Scheduler in a user-specific culture and locale. The Schedule control can be localized in specific culture using the common API Locale along with the collection of localized words defined for that culture using the ej.Schedule.Locale [**culture-code**].

Note: By default, the Schedule control is localized in **en-US** culture.

To localize Scheduler into any particular culture, it is necessary to refer the culture-specific script files in your application after the reference of **ej.web.all.min.js** file, which are available under the following location.

<Installed location>\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n

The following code example shows how to localize the Schedule control in **fr-FR** culture.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.Locale("fr-FR")
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<script src="@Url.Content("~/Scripts/i18n/ej.culture.fr-
FR.min.js")"></script>
<script>

```

Note: Refer the **ej.culture.fr-FR.min.js** file in your HTML application and also define the **Locale** property for the Schedule control with the appropriate **culture-code** [**fr-FR**].

For further information on – how to refer the required culture scripts into your application, refer here.

Localizing Specific Words

To customize or localize only some specific words in the default ej.Schedule.Locale[“en-US”] collection, the words to be localized/customized can be defined in a separate variable and then extended to the original collection as depicted in the following code example.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<script>
var customizationMessage = {
// customize the appointment window title
CreateAppointmentTitle: "Create Event",
// customize the view options text in the Schedule header
Day: "1 Day",
Week: "7 Days",
WorkWeek: "5 Days",
Month: "Month"
};
// Extend only the required changes to the original locale collection
$.extend(ej.Schedule.Locale["en-US"], customizationMessage);
</script>
```

Time Zone

The Scheduler makes use of the System time zone by default. If it needs to follow some other user-specific time zone, then the API TimeZone can be used. Also, the Scheduler can be set to observe the Daylight Saving Time (DST) with its **isDST** property which is set to **false** by default.

When IsDST property is set to **true**, the Scheduler internally processes the time difference values (for the Start and end time of the appointments) related to the Scheduler time zone that observes daylight savings time.

The following code example shows the way to set the specific time zone value with the daylight savings time observed in the Scheduler.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
<@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.TimeZone("UTC +05:30")
.IsDST(true)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Different TimeZone for Scheduler Appointments

Apart from the default action of applying specific timezone to the entire Scheduler, it is also possible to set different time zone values for each appointments through the properties **startTimeZone** and **endTimeZone** which can be defined as separate fields within the appointment dataSource. When these properties are not explicitly defined for appointments, the appointments Start and End time will be processed based on the Scheduler time zone.

Note: The **IsDST** property closely relies on the appointment fields like StartTimeZone and EndTimeZone, for appropriate time difference calculations. If these two fields are not defined for appointments, then **IsDST** depends on the System **TimeZone** value.

The following code snippet shows how to define isDST and the time zones for specific appointments.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "", StartTimeZone = "UTC +02:00", EndTimeZone =
"UTC +02:00" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.IsDST(true)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.StartTimeZone("StartTimeZone")
.EndTimeZone("EndTimeZone"))
)
```

Customizing TimeZone Collection

It is also possible to define or customize the default time zone collection of the Scheduler, by using the TimeZoneCollection API as follows.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- Datasource for TimezoneCollection -->
List<TimezoneCollection> TimeZone = new List<TimezoneCollection>();
TimeZone.Add(new TimezoneCollection { Text = "UTC -04:00", Id = "10",
Value = "UTC -04:00" });
TimeZone.Add(new TimezoneCollection { Text = "UTC -03:30", Id = "11",
Value = "UTC -03:30" });
TimeZone.Add(new TimezoneCollection { Text = "UTC -03:00", Id = "12",
Value = "UTC -03:00" });
TimeZone.Add(new TimezoneCollection { Text = "UTC -02:00", Id = "13",
Value = "UTC -02:00" });
TimeZone.Add(new TimezoneCollection { Text = "UTC -01:00", Id = "14",
Value = "UTC -01:00" });
TimeZone.Add(new TimezoneCollection { Text = "UTC +00:00", Id = "15",
Value = "UTC +00:00" });
TimeZone.Add(new TimezoneCollection { Text = "UTC +01:00", Id = "16",
Value = "UTC +01:00" });
TimeZone.Add(new TimezoneCollection { Text = "UTC +02:00", Id = "17",
Value = "UTC +02:00" });
TimeZone.Add(new TimezoneCollection { Text = "UTC +03:00", Id = "18",
Value = "UTC +03:00" });
TimeZone.Add(new TimezoneCollection { Text = "UTC +03:30", Id = "19",
Value = "UTC +03:30" });
TimeZone.Add(new TimezoneCollection { Text = "UTC +04:00", Id = "20",
Value = "UTC +04:00" });
TimeZone.Add(new TimezoneCollection { Text = "UTC +04:30", Id = "21",
Value = "UTC +04:30" });
TimeZone.Add(new TimezoneCollection { Text = "UTC +05:00", Id = "22",
Value = "UTC +05:00" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.TimeZoneCollection(fields =>
fields.Datasource(TimeZone).Text("Text").Id("Id").Value("Value"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Priority("Priority")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: The values defined within the **TimeZoneCollection** dataSource are usually the only options displayed within the start and end time zone dropdown fields of the appointment window.

Time Mode

The time mode of the Scheduler can be either **12** or **24 hours** format which is based on the Locale set to the Scheduler. Since the default locale value of the Scheduler is **en-US**, therefore the time mode will be set to **12 hours** format (by default) automatically based on the culture.

The user can also set specific time mode for the Scheduler using TimeMode property which accepts either **String** or **enum** value. It accepts the following **enum** values,

- TimeMode.Hour12
- TimeMode.Hour24

The following code snippet shows the way to set specific **24 hour format** time mode for the Scheduler.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.TimeMode(TimeMode.Hour24)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Note: If the **TimeMode** property is not set with specific value, then the value will be taken based on the locale assigned for the Scheduler.

Date Format

Scheduler can be used with all valid date formats. The default date format used in Scheduler is "MM/dd/yyyy".

If the DateFormat property is not specified particularly, then it will be taken based on the locale that is assigned to the Scheduler. The default locale applied on the Scheduler is “en-US”, which makes it to follow the "MM/dd/yyyy" pattern by default.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.DateFormat("yyyy/MM/dd")
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

First Day of Week

The FirstDayOfWeek property allows to set any of the week days as start of the week/workweek/month view in Scheduler. It accepts either the integer (Sunday=0, Monday=1, Tuesday=2, etc) or string (“Sunday”, “Monday”, etc) value. The default value of this FirstDayOfWeek property depends on the current culture (language) assigned to the Scheduler.

To set different first day of week in Scheduler,

RAZOR

```
@using Syncfusion.JavaScript.Models;
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 9))
.FirstDayOfWeek(DayOfWeek.Monday)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: The sub-control datepicker which is used within Scheduler for start/end time fields in appointment window and for date navigation purposes will also follow the same first day of week.

Keyboard Navigation

The shortcut keys for accessing the sub-elements of the scheduler and other Scheduler actions are tabulated in the following table.

Keys	Functionality description
arrow keys	To traverse through the Scheduler cells.
Shift+arrow keys	Multiple cell selection
Enter	Pressing enter key, after a single/multiple scheduler cell selection will make the quick appointment window to pop-up. Also, when the focus is being moved on to the fields like checkbox or buttons of the appointment window, pressing enter will select that particular action.
Esc	Closes any of the popup that displays on the Schedule control
Alt+N	Opens the Create Appointment window
Ctrl+E	Opens the Edit Appointment window
Alt+C	Opens the calendar popup within the Scheduler.
Ctrl+left arrow	Previous date navigation
Ctrl+right arrow	Next date navigation
Alt++	Forward traversing of view items in the toolbar
Alt+-	Reverse traversing of view items in the toolbar

Copyright © 2001 - 2020 Syncfusion Inc.

Space	When the previous/next navigation icons are currently being focused, pressing space navigates through the corresponding dates. Also, when the focus is being moved on to the fields like checkbox or buttons of the appointment window, pressing enter will select that particular action.
Del	Deletes the currently selected appointment
Tab	Traversing through the appointments.
Shift+tab	Traversing through the appointments in a forward direction

Note: By default AllowKeyboardNavigation property is set to **true**, which allows the Scheduler to be accessed through the above specified keys.

Setting Dimension

The dimension normally refers to the height and width of the element. With Scheduler, it is possible to set 2 kinds of dimensions.

- Scheduler dimension (Scheduler control height and width)
- Cell dimension (Scheduler cells height and width)

Scheduler Dimension

The Height and Width properties can be defined to set the outer dimension of the Scheduler control.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("70%")
.Height("500px")
.CurrentDate(new DateTime(2015,11, 5))
)
```

Note: The height and width properties accepts both **Pixel** and **Percentage** values.

Scheduler Cell Dimensions

Cell Height

The CellHeight property allows the Scheduler to set the height of the cells in pixels. The appointment height in vertical mode changes accordingly as per the cell size within which it renders.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CellHeight("40px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: In **Desktop** mode, the default height value of the cells is set to **20px**, whereas for **Mobile** mode – the Scheduler cells are rendered with **40px** by default.

Cell Auto-Height

The height of the cells specifically in timeline view can be made to adjust automatically based on its exceeding appointment count. It is controlled by an API named ShowOverflowButton which accepts true or false value, denoting whether to enable/disable the cell auto-height adjusting option. To enable this option, set the value of ShowOverflowButton as false whereas its default value is true.

In **Vertical** view, the same functionality is made applicable only in the **Month View** whereas in **Horizontal** mode, it is applicable in all the views.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.CurrentView(CurrentView.Month)
.ShowOverflowButton(false)
.AppointmentSettings(fields => fields
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Cell Width

The CellWidth property allows the Scheduler to set the width of the cells in pixels. The appointment width adjusts based on the cell width of the Scheduler.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CellWidth("97px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: When the **CellHeight** and **CellWidth** properties are set with some specific pixel values, the cell size does not adapt to the responsive behavior of the Scheduler while resizing it in desktop/mobile mode.

Responsiveness

Scheduler is provided with default **responsive** support, so that it adjust or auto-resize it's UI content based on the window or the container size on which it is placed.

Auto-Resizing Scheduler

By default, setting 100% width to the Scheduler makes it adaptable to the window or its parent container, as and when the browser is resized. This will not allow the scheduler to adapt height-wise.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

To auto-resize the Scheduler height – set the **Height** property of the Scheduler to **100%** and also set some specific height (either percentage or pixel values) to its parent container (or) to the HTML and body tag elements as shown below.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Height("800px")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: When the Scheduler width is set to have **less than 600px**, then the View selection options will be displayed in a **navigation drawer**.

Also, whenever the Scheduler resizes - the width of the work cells adjusts automatically (if no **CellWidth** property is specified with pixel values), but the height of the cells are kept to remain as same as 20px until **CellHeight** property is set explicitly with some pixel values.

Scheduler in Mobile/Tablets

The Scheduler layout adapts automatically in the mobile and tablet devices with the appropriate UI changes, as the IsResponsive property is set to **true** by default. In case, if the user wants to display the normal scheduler in mobile devices without any adaptive enhancements, then the IsResponsive property can be set to false.

Some of the default changes done for adaptive Scheduler to render in mobile devices are as follows,

- Animation effect introduced between view/date navigation.
- Cell Height increased
- The header date display changes (displayed next to the navigation icons).
- View options displayed in Navigation drawer
- Time cell width decreased

Copyright © 2001 - 2020 Syncfusion Inc.

- Quick window display blocked on cell/appointment single click.
- Appointment resizing action blocked.
- Multiple cell selection blocked.
- Delete appointment option made available within the appointment window.
- Week header display in month view hidden.
- With Multiple resources - only one resource is viewable initially on the screen and to further look onto other resources, user need to swipe the screen.

Note: To make the Scheduler control to react as responsive in mobile/tablet devices, it is necessary to refer the additional [ej.responsive.css](http://cdn.syncfusion.com/{{ site.releaseversion }}/js/web/responsive-css/ej.responsive.css) file in the application.

The following code snippet depicts the Scheduler code with responsive set to true.

HTML

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.CurrentDate(new DateTime(2014, 6, 2))
.IsResponsive(true)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Persistence

State persistence allows the Scheduler to retain the current model value in the browser cookies for state maintenance. This action is handled through the property EnablePersistence which is set to false by default.

When it is set to **true**, some of the Schedule control model values will be retained even after refreshing the page which are listed below.

CurrentView	TimeMode
FirstDayOfWeek	DateFormat
IsDST	TimeZone
TimeScale	StartHour

Copyright © 2001 - 2020 Syncfusion Inc.

EndHour	WorkHours
Height	Width
CellHeight	CellWidth
CurrentDate	MinDate
MaxDate	RenderDates
Orientation	Views
WorkWeek	AgendaViewSettings.DaysInAgenda
EnableLoadOnDemand	ShowLocationField
ShowAllDayRow	IsResponsive
EnableRecurrenceValidation	ShowOverflowButton
AllowDragAndDrop	ShowDeleteConfirmationDialog
ShowNextPrevMonth	AppointmentDragArea

The Schedule properties that are not retained while maintaining state persistence are included within the **ignoreOnPersist** list, which makes it not to persist by default.

Export and Print

Export Appointments to ICS file

The Appointments can be exported as a whole collection or else a single appointment alone can be exported from the Scheduler. By default, the appointments are exported to .ics format which can then be imported and used in any of the other external calendars.

Single Appointment Exporting

A single appointment can be exported by making use of its Id. You can achieve this functionality by making use of a client-side exportSchedule method by passing the id of an appointment to export as one of its parameter.

It can also be achieved in another way by enabling the context menu settings and then adding a custom menu option for export appointment functionality. When right clicked on an appointment, and **export Appointment** option is chosen, the exporting functionality can be handled through the MenuItemClick event, within which the exportSchedule method should be defined with the following parameters,

- Action name (to be called in the server-side)
- Server Event (optional)
- Appointment Id (mandatory for single Appointment exporting)

The following code example shows the way to export single appointment from the Scheduler.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- List of Appointment Menu options -->
List<Appointment> AppMenu = new List<Appointment>();
AppMenu.Add(new Appointment { Id = "open", Text = "Open Appointment" });
AppMenu.Add(new Appointment { Id = "delete", Text = "Delete Appointment"
});
AppMenu.Add(new Appointment { Id = "export", Text = "Export Appointment"
});
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.ContextMenuSettings(contextMenu =>
contextMenu.Enable(true).MenuItems(items => items.Appointment(AppMenu)))
.ScheduleClientSideEvents(event =>
event.MenuItemClick("onMenuItemClick"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

JS

```
function onMenuItemClick(args) {
if (args.events.ID == "export") {
var obj = $("#Schedule1").data("ejSchedule");
obj.exportSchedule("ExportToICS", null, args.targetInfo.Id);
}
}
```

Note: The Id value of the appointment passed in the above code example can be retrieved in the server-side action through Request.Form["AppointmentId"], as the id passed from the script is stored as hidden value in the input field of the form under this name internally.

Exporting all Appointments

To export the entire Scheduler appointments, the same `exportSchedule` method can be used without passing the id value to its parameter list. To achieve this, keep an individual button to export, and when it is clicked - the Scheduler can be allowed to export all the appointments.

The following code example depicts the way to export all the Scheduler appointments as a whole.

RAZOR

Copyright © 2001 - 2020 Syncfusion Inc.

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
@(Html.EJ().Button("export").Text("Export").ClientSideEvents(event =>
event.Click("onClick")))
```

JS

```
function onClick() {
var obj = $("#Schedule1").data("ejSchedule");
obj.exportSchedule("ExportToICS", null, null);
}
```

The server-side action **ExportToICS** contains the following code example to export the Scheduler appointments.

C#

```
public void ExportToICS(FormCollection form)
{
IEnumerable data;
string JSONModel = Request.Form["ScheduleModel"];
var model = JsonConvert.DeserializeObject<Dictionary<string,
object>>(JSONModel);
var Id = Request.Form["AppointmentId"];
if(Id != null)
// To export single appointment
data = db.DefaultSchedules.Where(app => app.Id.ToString() ==
Id.ToString()).ToList();
else
// To export all the appointments
data = db.DefaultSchedules.ToList();
ScheduleExport obj = new ScheduleExport(model, data);
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

PDF Export

Scheduler supports exporting it along with all its appointments in PDF format, for which the same exportSchedule method can be used without passing any id value to its parameter list. To achieve this, keep an individual button to export and when it is clicked, the Scheduler with appointments can be allowed to export as PDF.

The following code example depicts the way to export the Scheduler with appointments in PDF format.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.AppointmentSettings(fields => fields.Datasource(Model)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence"))
)
@Html.EJ().Button("submit").Text("Export").Width("80px").Height("30px").C
lientSideEvents(event => event.Click("onPDFExport"))
```

JS

```
function onPDFExport(args) {
var obj = $("#Schedule1").data("ejSchedule");
obj.exportSchedule("ExportAsPDF", null, null);
}
```

The server-side action **ExportAsPDF** contains the following code example to export the Scheduler.

C#

```
public ActionResult ExportAsPDF(string scheduleModel)
{
JavaScriptSerializer serializer = new JavaScriptSerializer();
SchedulePDFExport convert = new SchedulePDFExport();
// Here calling the public method to convert the model values to
ScheduleProperties type from string type
ScheduleProperties scheduleObject =
convert.ScheduleSerializeModel(Request.Form["ScheduleModel"]);
// Here converting the schedule appointments data into enumerable object
by deserializing
IEnumerable scheduleAppointments =
(IEnumerable)serializer.Deserialize(Request.Form["ScheduleProcesedApps"],
typeof(IEnumerable));
PdfExport exp = new PdfExport();
PdfPageSettings pageSettings = new PdfPageSettings(50f);
pageSettings.Orientation= PdfPageOrientation.Landscape;
// Here passing the theme values from enum collection
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
PdfDocument document = exp.Export(scheduleObject, scheduleAppointments,
ExportTheme.FlatSaffron, Request.Form["locale"], pageSettings);
document.Save("Schedule.pdf", HttpContext.ApplicationInstance.Response,
HttpReadType.Save);
return RedirectToAction("PDFExportController");
}
```

Note: To pass the theme value as a string instead of the enum value, refer to the following code example of passing the string type theme value.

C#

```
PdfDocument document = exp.Export(scheduleObject, scheduleAppointments,
"flat-saffron",Request.Form["locale"]);
```

Setting Page Options:

It is possible to set/change the PDF page settings such as size, margins (left, right, top and bottom), transition, and rotate angle and header/footer values by passing the page settings and page document template object values into the export method.

Page Settings:

You can set/apply the following page property values to the PDF file before exporting it with the Scheduler by using the PdfPageSettings object.

- Page Size
- Orientation
- Margins (Left, Right, Top, Bottom)
- Transition (Direction, Dimension, Duration, Motion, PageDuration, Scale, Style)
- Rotate (RotateAngle0, RotateAngle90, RotateAngle180, RotateAngle270)
- Height
- Width

To apply the above page setting values, you need to create an object for the PdfPageSettings class. Then, you can assign the values to the available properties within it such as Size = PdfPageSize.A3, Orientation = PdfPageOrientation.Landscape and so on. Once done, pass this object into the export method which will set these page settings values to the PDF file before exporting it. Refer to the following code example (server-side) to set/change the page settings values.

C#

```
public ActionResult ExportAsPDF(string scheduleModel)
{
JavaScriptSerializer serializer = new JavaScriptSerializer();
SchedulePDFExport convert= new SchedulePDFExport();
ScheduleProperties scheduleObject =
convert.ScheduleSerializeModel(scheduleModel); // Here calling the public
method to convert the model values to ScheduleProperties type from string
type
IEnumerable scheduleAppointments =
(IEnumerable)serializer.Deserialize(Request.Form["ScheduleProcesedApps"],
typeof(IEnumerable)); // Here deserialize the appointments to enumerable
object
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
PdfExport exp = new PdfExport();
// Here the 50f is the default value for the margins. If you are not
assigning any separate values like Margins.Left = 15 means 50f value will
be setting to all the Margin properties.
PdfPageSettings pageSettings = new PdfPageSettings(50f);
// Here you can assign the PdfPageSize enum value (ex: A3, A4)
pageSettings.Size = PdfPageSize.A3;
// Here Landscape value assigned to the orientation. You can set either
Landscape/Portrait for this Orientation property
pageSettings.Orientation = PdfPageOrientation.Landscape;
// Here assigned different values for the margins
pageSettings.Margins.Left = 15;
pageSettings.Margins.Right = 15;
pageSettings.Margins.Top = 20;
pageSettings.Margins.Bottom = 20;
// Here assigned the Transition Direction as BottomToTop. You can also
set any of the Transition values to this property
pageSettings.Transition.Direction= PdfTransitionDirection.BottomToTop;
// Here assigned the Rotate Angle as RotateAngle180. You can also set any
of the Rotate values to this property
pageSettings.Rotate = PdfPageRotateAngle.RotateAngle180;
// Here passing the page settings object value into the export method.
PdfDocument document = exp.Export(scheduleObject, scheduleAppointments,
ExportTheme.FlatSaffron, Request.Form["locale"], pageSettings);
document.Save("Schedule.pdf", HttpContext.ApplicationInstance.Response,
HttpReadType.Save);
return RedirectToAction("PDFExportController");
}
```

Header/Footer Settings:

You can also set the header and footer options to the PDF page before it is being exported, by passing the PDFDocumentTemplate object values as mentioned in the following code example.

C#

```
public ActionResult ExportAsPDF(string scheduleModel)
{
JavaScriptSerializer serializer = new JavaScriptSerializer();
SchedulePDFExport convert= new SchedulePDFExport();
ScheduleProperties scheduleObject =
convert.ScheduleSerializeModel(scheduleModel); // Here calling the public
method to convert the model values to ScheduleProperties type from string
type
IEnumerable scheduleAppointments =
(IEnumerable)serializer.Deserialize(Request.Form["ScheduleProcesedApps"],
typeof(IEnumerable)); // Here deserialize the appointments to enumerable
object
PdfExport exp = new PdfExport();
PdfDocument document = new PdfDocument();
PdfPage pdfPage = document.Pages.Add();
//Create a header and draw the string.
// Here the bounds value is used to store the position/axis value, where
the header and footer content to be displayed
RectangleF bounds = new RectangleF(0, 0,
document.Pages[0].GetClientSize().Width, 50);
// Creating object for the PdfPageTemplateElement
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
PdfPageTemplateElement header = new PdfPageTemplateElement(bounds);
// Here setting the font style and color to display the header/footer
content
PdfSolidBrush brush = new PdfSolidBrush(Color.Gray);
PdfFont font = new PdfStandardFont(PdfFontFamily.Helvetica, 6,
PdfFontStyle.Bold);
PdfStringFormat format = new PdfStringFormat();
format.Alignment = PdfTextAlignment.Center;
format.LineAlignment = PdfVerticalAlignment.Middle;
header.Graphics.DrawString("Schedule", font, brush, new RectangleF(0, 18,
header.Width, header.Height), format);
//Create a Page template that can be used as footer (here creating
template to display the page number).
PdfPageTemplateElement footer = new PdfPageTemplateElement(bounds);
//Create page number field.
PdfPageNumberField pageNumber = new PdfPageNumberField(font, brush);
//Create page count field.
PdfPageCountField count = new PdfPageCountField(font, brush);
//Add the fields in composite fields.
PdfCompositeField compositeField = new PdfCompositeField(font, brush,
"Page {0} of {1}", pageNumber, count);
compositeField.Bounds = footer.Bounds;
//Draw the composite field in footer.
compositeField.Draw(footer.Graphics, new PointF(470, 40));
PdfDocumentTemplate headerFooterTemplate = new PdfDocumentTemplate();
//Here assigning the header template value to the PdfDocumentTemplate
Object.
headerFooterTemplate.Top = header;
//Here assigning the footer template value to the PdfDocumentTemplate
Object.
headerFooterTemplate.Bottom = footer;
//Here passing the PdfDocumentTemplate Object value into the export
method.
document = exp.Export(scheduleObject, scheduleAppointments,
ExportTheme.FlatSaffron, Request.Form["locale"], headerFooterTemplate);
document.Save("Schedule.pdf", HttpContext.ApplicationInstance.Response,
HttpReadType.Save);
return RedirectToAction("PDFExportController");
}
```

Note: The header and footer values can be passed to the PDF file only through the template option. In the above mentioned code example, the template has been written with the text “Schedule” to display it as the header text and the page number (ex: Page 1 of 2) has been displayed in the footer part.

It is also possible to pass both the PageSettings and header/footer template objects in the export method altogether to apply the page settings as well as the header and footer options to the PDF file which can be referred from the following code example,

C#

```
public ActionResult ExportAsPDF(string scheduleModel)
{
//Here add the code example of both the page settings and header/footer
values settings.
//Then pass both PdfPageSettings and PdfDocumentTemplate object into the
export method.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
document = exp.Export(scheduleObject, scheduleAppointments,
ExportTheme.FlatSaffron, Request.Form["locale"], pageSettings,
headerFooterTemplate);
document.Save("Schedule.pdf", HttpContext.ApplicationInstance.Response,
HttpReadType.Save);
return RedirectToAction("PDFExportController");
}
```

Print

Two types of Print options are available – either to print the entire Scheduler layout including all the appointments in it or else to print any particular appointment alone. The public method Print is used to print the entire Scheduler.

Print the Scheduler

The following code example shows the way to print the entire Scheduler, by keeping an extra button in a page – on which clicking the button will print the entire Scheduler.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
@Html.EJ().Button("print").Text("Print").ClientSideEvents(event =>
event.Click("onClick"))
```

JS

```
function onClick(args) {
var obj = $("#Schedule1").data("ejSchedule");
obj.print();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Printing Specific Appointments

To print a particular appointment, either the default context menu **print** option can be used or else the print method can be used by passing the id of the appointment to be printed as its argument.

Note: To handle this functionality, the context menu settings needs to be enabled with print option added to the appointment items.

The following code example depicts the way to print a particular appointment.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
<!-- List of Appointment Menu options -->
List<Appointment> AppMenu = new List<Appointment>();
AppMenu.Add(new Appointment { Id = "open", Text = "Open Appointment" });
AppMenu.Add(new Appointment { Id = "delete", Text = "Delete Appointment"
});
AppMenu.Add(new Appointment { Id = "print", Text = "Print Appointment"
});
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.ContextMenuSettings(contextMenu =>
contextMenu.Enable(true).MenuItems(items => items.Appointment(AppMenu)))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Using print() method

The client-side public method print needs to be used here by passing the appointment object as its argument, that needs to be printed.

For example, here the below code example depicts the way to print the particular appointment programmatically by calling the **print** function within the AppointmentClick event, which triggers whenever the user clicks on an appointment.

RAZOR

```
@using Syncfusion.JavaScript.Models;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 9))
.ScheduleClientSideEvents(event =>
event.AppointmentClick("onAppointmentClick"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

JS

```
function onAppointmentClick(args) {
var schObj = $("#Schedule1").data("ejSchedule");
schObj.print(args.appointment);
}
```

Import Appointments

To import appointments into the Scheduler, server-side method renderingImportAppointments needs to be used, which returns the list of appointments retrieved from the specified file path.

Refer the following code example to import the appointments into Scheduler.

RAZOR

```
@Html.EJ().Button("submit").Text("Submit").ClientSideEvents(event =>
event.Click("ScheduleImport"))
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2014, 6, 2))
.AppointmentSettings(fields => fields
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
function ScheduleImport() {
var dataManger = ej.DataManager({ url: '@Url.Action("ScheduleImportData",
"Schedule")', crossDomain: true });
$("#Schedule1").ejSchedule({
appointmentSettings: {
dataSource: dataManger
}
});
}
```

The server-side action ScheduleImportData contains the following code example to import the Scheduler appointments.

C#

```
public JsonResult ScheduleImportData() {
var destinationPath = @"FilePath\iCalender.ics";
ScheduleImport importApps = new ScheduleImport();
var app = importApps.renderingImportAppointments(destinationPath);
int intMax = app.Max(a => a.Id);
List<ScheduleAppointmentsObjData> result = new
List<ScheduleAppointmentsObjData>();
for (var i = 0; i < app.Count; i++) {
app[i].Id = intMax + 1;
ScheduleAppointmentsObjData row = new
ScheduleAppointmentsObjData(app[i].Id, app[i].Subject, app[i].Location,
app[i].StartTime, app[i].EndTime, app[i].Description, null, null,
app[i].Recurrence, null, null, app[i].AppointmentCategorize, null,
app[i].AllDay, null, null, app[i].RecurrenceRules, null, null);
result.Add(row);
intMax = app[i].Id;
}
return Json(result, JsonRequestBehavior.AllowGet);
}
```

Miscellaneous

Time Indicator

The current system time can be depicted in a scheduler with an indication of a piece of text displaying the time over a horizontal line across today's date (Vertical Scheduler mode). In Horizontal mode, the time indicator is displayed as a small vertical line within the header time cells (depicting current time).

It is enabled by default in Scheduler and to hide it, ShowCurrentTimeIndicator property needs to be set as **false** as shown below.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ShowCurrentTimeIndicator(false)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Note: When Scheduler rendered with multiple resources, multiple time indicators are displayed in Vertical mode – whereas single indicator displays for horizontal mode.

Show/Hide All-Day Row

The All-day row cell is a single row region displayed at the top of the work cells area to hold the all-day appointments together. The Scheduler displays it by default and if it needs to be hidden, the ShowAllDayRow property can be set to **false** as shown below.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ShowAllDayRow(false)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Note: The All-day row expands vertically, whenever more number of appointments are populated in one or more days.

Show/Hide Header bar

The header bar is the top most region of the Scheduler which includes the date navigation icons and view navigation options – and also shown on the Scheduler by default. To hide the header bar, set the ShowHeaderBar property to **false** as shown below.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ShowHeaderBar(false)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Show/Hide Location Field

The Location field in the default appointment window can be displayed or hidden from it using the ShowLocationField property. By default, this property is set to false. To display the location option in the appointment window, then set **ShowLocationField** to **true** and also bind the appropriate field to the location property within the appointmentSettings as shown below.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ShowLocationField(true)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.AllDay("AllDay")
.Location("EventLocation")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Recurrence Editor

The Recurrence Editor includes the entire recurrence related information in a separate portable manner which can be either utilized as a separate widget or else can be embed within the appointment window of Scheduler to enable recurrence options within it. The recurrence rule can be easily generated based on the frequency selected. The customizations such as changing the labels of the recurrence editor is also possible to achieve through its properties. The frequencies available are Never, Daily, Weekly, Monthly, Yearly and Every weekday.

Getting Started

Follow the steps as mentioned in the Getting Started page of the Introduction part to create an MVC application with required assembly references, scripts and stylesheets to render the Recurrence Editor.

Add the basic Recurrence Editor code in the View page as shown below,

RAZOR

```
@(Html.EJ().RecurrenceEditor("RecurrenceEditor")
.SelectedRecurrenceType(0)
)
```

Generating Recurrence Rule

The Recurrence Editor can be used to generate the recurrence rule as a string, based on the repeat options selected.

The following code example depicts the way to generate the recurrence rule.

RAZOR

```
@(Html.EJ().RecurrenceEditor("RecurrenceEditor")
.SelectedRecurrenceType(2)
.RecurrenceEditorClientSideEvents(evt=>evt.Create("onCreate"))
)
```

Define a button separately and add it to the page as shown below and while clicking on it, make use of the client-side public method `getRecurrenceRule` of the Recurrence Editor to generate the recurrence rule string explicitly.

HTML

Copyright © 2001 - 2020 Syncfusion Inc.

```
<button onclick="closeRecurrence()" id="donerecur1" class='recurbutton'
style="float:right;margin-right:20px;margin-bottom:10px;">Recurrence
String</button>
```

JS

```
$(function () {
$("#donerecur1").ejButton({ width: '155px', height: '35px',
showRoundedCorner: true });
$("#RecurrenceEditor").after($("#donerecur1"));
});
function closeRecurrence() {
var obj = $(".e-recurrenceeditor").data("ejRecurrenceEditor");
alert(obj.getRecurrenceRule()) ; // recurrence rule generated as per the
options selected in the recurrence editor will be displayed here
}
function onCreate() {
this.element.find("#recurrencetype_wrapper").css("width", "33%");
}
```

How To

Validate the Custom Appointment Window Fields

The client-side validation of the fields present within the custom appointment window can be handled before submitting it, by adding appropriate validation classes to each field.

Refer the steps here and create a sample for Custom Appointment window, before proceeding with the following validations.

In the custom appointment window sample, create an additional CSS class **validation** as mentioned below to add it to the appropriate fields, if the validation of such fields fails.

CSS

```
<style>
.validation {
border-color: red;
}
</style>
```

The sample contains the fields like Subject, Description, StartTime and EndTime which needs to be validated at client-side. To do so, add the required validation code within the script section as follows.

HTML

```
<script type="text/javascript">
// To Validate the Subject field.
$("#subject").focusout(function() {
if ($.trim($("#subject").val()) == "") {
$("#subject").addClass("validation");
return false;
}
})
// To Validate the Description field.
$("#customDescription").focusout(function() {
if ($.trim($("#customDescription").val()) == "") {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$("#customDescription").addClass("validation");
return false;
}
})
// To Validate the Time duration of the appointments
$("#EndTime").focusout(function() {
if (new Date($("#EndTime").val()).getDate() >= new
Date($("#StartTime").val()).getDate()) {
if (new Date($("#StartTime").val()).getTime() >= new
Date($("#EndTime").val()).getTime())
alert("EndTime value is lesser than the StartTime value");
}
})
</script>
```

Now, after adding the above validations – whenever the fields within the custom appointment window are skipped without filling any information, it will be notified to the users appropriately.

Highlight Different Work Hours for Each Resources

By default, the work hours of the Scheduler is highlighted based on the start and end values provided within the WorkHours property. It remains same for all the resources, when the Scheduler is rendered with multiple resources. To customize this behavior so as to highlight different working hour range for each of the resources, the following workaround can be utilized by making use of the Scheduler events Create and ActionComplete.

Initially, set the Highlight as false for the WorkHours, so as to disable the highlighting of default work hour range.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "", OwnerId = "1" });
<!-- Datasource for Grouping -->
List<String> Group = new List<String>();
Group.Add("Owners");
<!-- Datasource for Owners -->
List<ResourceFields> Owner = new List<ResourceFields>();
Owner.Add(new ResourceFields { Id = "1", Text = "Nancy", Color =
"#f8a398" });
Owner.Add(new ResourceFields { Id = "3", Text = "Steven", Color =
"#56ca85" });
Owner.Add(new ResourceFields { Id = "5", Text = "Michael", Color =
"#51a0ed" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.ShowCurrentTimeIndicator(false)
.WorkHours(hrs => hrs.Highlight(false))
.Group(gr => gr.Resources(Group))
.Resources(res => {
res.Field("OwnerId").Title("Owner").Name("Owners").ResourceSettings(field
s =>
fields.Datasource(Owner).Text("Text").Id("Id").Color("Color")).Add(); })
.ScheduleClientSideEvents(event =>
event.Create("onCreate").ActionComplete("onCreate"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule")
.ResourceFields("OwnerId"))
)
```

JS

```
// This function executes during the initial control creation and also on
completion of each action like date/view navigation.
function onCreate(args) {
if (args.requestType == "viewNavigate" || args.requestType ==
"dateNavigate" || args.type == "create") {
// declare different start and end work hour values for each resources
var resourceOneStart = 9,
resourceOneEnd = 18;
var resourceTwoStart = 13,
resourceTwoEnd = 18;
var resourceThreeStart = 10,
resourceThreeEnd = 18;
this.option("workHours.highlight", (this.currentView() != "month") ?
false : true);
var trElements = this.$WorkCellDiv.find("tr");    // Get the Scheduler
work cell rows
for (var i = 0; i < trElements.length; i++) {
var tdElements = $(trElements[i]).find("td");  // Get the Scheduler work
cell columns
for (var j = 0; j < tdElements.length; j++) {
switch (this.currentView()) {
case "day":
switch (j) {
case 0: // column index 0 represents first resource in day view
$(tdElements[j]).addClass(((i > (resourceOneStart * 2) - 1) && (i <=
(resourceOneEnd * 2) - 1)) ? "e-businesshighlightworkcells" : "");
break;
case 1: // column index 1 represents second resource in day view
$(tdElements[j]).addClass(((i > (resourceTwoStart * 2) - 1) && (i <=
(resourceTwoEnd * 2) - 1)) ? "e-businesshighlightworkcells" : "");
break;
case 2: // column index 2 represents third resource in day view
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
$(tdElements[j]).addClass(((i > (resourceThreeStart * 2) - 1) && (i <=
(resourceThreeEnd * 2) - 1)) ? "e-businesshighlightworkcells" : "");
break;
}
break;
case "week":
switch (j) {
case 0:
case 1:
case 2:
case 3:
case 4:
case 5:
case 6: // column indexes 0 to 6 belongs to first resource in week view
(7 days)
$(tdElements[j]).addClass(((i > (resourceOneStart * 2) - 1) && (i <=
(resourceOneEnd * 2) - 1)) ? "e-businesshighlightworkcells" : "");
break;
case 7:
case 8:
case 9:
case 10:
case 11:
case 12:
case 13: // column indexes 7 to 13 belongs to second resource in week
view (7 days)

break;
case 10:
case 11:
case 12:
case 13:
case 14:
// column indexes 10 to 14 belongs to third resource in workweek view (5
days)
$(tdElements[j]).addClass(((i > (resourceThreeStart * 2) - 1) && (i <=
(resourceThreeEnd * 2) - 1)) ? "e-businesshighlightworkcells" : "");
break;
}
break;
}
}
}
}
}
```

Display Scheduler with Appointments Filtered by Subject

It is possible to display the Scheduler with appointments, which is filtered based on the Subject. For example, if we keep a text box and start typing a character – the list of appointments whose subject matches the typed character alone will be shown on the Scheduler. The following code example depicts the way to achieve this.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
Appoint.Add(new ScheduleFields { Id = "2", Subject = "Bering Sea Gold",
StartTime = new DateTime(2015, 11, 10, 01, 00, 00), EndTime = new
DateTime(2015, 11, 10, 02, 30, 00), Description = "", AllDay = false,
Recurrence = false, RecurrenceRule = "" });
Appoint.Add(new ScheduleFields { Id = "3", Subject = "Deadest Catch",
StartTime = new DateTime(2015, 11, 10, 11, 00, 00), EndTime = new
DateTime(2015, 11, 10, 11, 30, 00), Description = "", AllDay = false,
Recurrence = false, RecurrenceRule = "" });
Appoint.Add(new ScheduleFields { Id = "4", Subject = "What Happened
Next?", StartTime = new DateTime(2015, 11, 10, 15, 00, 00), EndTime = new
DateTime(2015, 11, 10, 17, 30, 00), Description = "", AllDay = false,
Recurrence = false, RecurrenceRule = "" });
Appoint.Add(new ScheduleFields { Id = "5", Subject = "Daily Planet",
StartTime = new DateTime(2015, 11, 10, 20, 00, 00), EndTime = new
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
DateTime(2015, 11, 10, 22, 30, 00), Description = "", AllDay = false,
Recurrence = false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ShowCurrentTimeIndicator(false)
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<!-- Textbox for entering search character -->
<input id='txtSearch' type='text' onkeyup='searchKeyUp()' />
<script>
function searchKeyUp() {
var searchString = $("#txtSearch").val();
var schObj = $("#Schedule1").data("ejSchedule");
var result = schObj.searchAppointments(searchString);
schObj.option("appointmentSettings", { dataSource: [] });
if (!ej.isNullOrUndefined(result) && result.length != 0 && searchString
!= "")
schObj.option("appointmentSettings", { dataSource: result });
else
schObj.option("appointmentSettings", { dataSource:
schObj._currentAppointmentData });
}
</script>
```

Customize the Default Appointment Window

Apart from the custom appointment window, it is possible to customize the default appointment window by adding/removing the required number of fields into it. This can be achieved through the Create event of the scheduler.

The following code example depicts the way to achieve the customization of default appointment window.

RAZOR

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ShowCurrentTimeIndicator(false)
.ScheduleClientSideEvents(event =>
event.AppointmentWindowOpen("onAppointmentOpen"))
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

JS

```
// This function executes before the appointment window gets opened.
function onAppointmentOpen(args) {
// to add custom element in default appointment window
if (this._appointmentAddWindow.find(".custom-fields").length == 0) {
var customDesign = "<tr class='custom-fields'><td class='e-
textlabel'>Event Type</td><td><input class='app-type'
type='text'/></td><td class='e-textlabel'>Event Status </td><td><input
class='status' type='text'/></td></tr>";
$(customDesign).insertAfter(this._appointmentAddWindow.find("." +
this._id + "arrow"));
}
if (!ej.isNullOrUndefined(args.appointment)) {
// if double clicked on the appointments, retrieve the custom field
values from the appointment object and fills it in the appropriate
fields.                this._appointmentAddWindow.find(".app-
type").val(args.appointment.AppointmentType);
this._appointmentAddWindow.find(".status").val(args.appointment.Status);
} else {
// if double clicked on the cells, clears the field values.
this._appointmentAddWindow.find(".app-type").val("");
this._appointmentAddWindow.find(".status").val("");
}
}
```

SignalR Implementation

To implement SignalR concept in Scheduler, add and refer the appropriate SignalR scripts in your project and then create a hub for initiating the action. The SignalR implementation can be achieved with the following code example.

RAZOR

Copyright © 2001 - 2020 Syncfusion Inc.

```
@using MyProject.Models; // Here MyProject defines your project name to
access the model class
@{
<!-- Datasource for Appointments -->
List<ScheduleFields> Appoint = new List<ScheduleFields>();
Appoint.Add(new ScheduleFields { Id = "1", Subject = "Meeting", StartTime
= new DateTime(2015, 11, 10, 10, 00, 00), EndTime = new DateTime(2015,
11, 10, 11, 00, 00), Description = "", AllDay = false, Recurrence =
false, RecurrenceRule = "" });
}
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 5))
.ScheduleClientSideEvents(d => {
d.BeforeAppointmentCreate("actionComplete");
d.Navigation("actionComplete");
d.BeforeAppointmentRemove("actionComplete");
d.BeforeAppointmentChange("actionComplete"); })
.AppointmentSettings(fields => fields.Datasource(Appoint)
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

HTML

```
<script src="~/Scripts/jquery.signalR-1.1.4.min.js"></script>
<script src="@Url.Content("~/signalr/hubs")"></script>
<script type="text/javascript">
$(function () {
window.signal = $.connection.scheduleHub;
window.signal.client.modify = function (action, data) {
if (data != null) {
var id = data.Id != null ? data.Id : data[0].Id;
var subject = data.Subject;
var startTime = new Date(data.StartTime);
var endTime = new Date(data.EndTime);
var description = data.Description;
var allDay = data.AllDay;
var recurrence = data.Recurrence;
var recurrenceRule = data.RecurrenceRule;
var object = { Id: id, Subject: subject, StartTime: startTime, EndTime:
endTime, Description: description, AllDay: allDay, Recurrence:
recurrence, RecurrenceRule: recurrenceRule };
var schedule = $("#Schedule1").data("ejSchedule");
if (action == "appointmentSaved") {
new ej.DataManager(schedule._currentAppointmentData).insert(object);
schedule._appointmentProcessing(object);
schedule._renderAppointmentAll();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
else if (action == "appointmentEdited") {
new ej.DataManager(schedule._currentAppointmentData).update("Id",
object);
new ej.DataManager(schedule._processed).remove("Id", object.Id);
schedule._appointmentProcessing(object);
schedule._renderAppointmentAll();
}
else if (action == "appointmentDeleted") {
var appointment = new
ej.DataManager(schedule._processed).executeLocal(new
ej.Query().where("Id", ej.FilterOperators.equal, id));
new ej.DataManager(schedule._currentAppointmentData).remove("Id",
appointment[0].Id);
new ej.DataManager(schedule._processed).remove("Id", appointment[0].Id);
schedule._renderAppointmentAll();
}
}
};
$.connection.hub.start().done(function () {
window.actionComplete = function (args) {
if(args.methodType=="public")
args.appointment=null;
var appointmentDetails = args.appointment;
if (args.type == "appointmentSaved" || args.type == "appointmentEdited"
|| args.type == "appointmentDeleted") {
window.signal.server.modify(args.type, appointmentDetails);
}
};
});
});
</script>
```

Create a Hub file and add the following action for accessing the client details.

C#

```
public void Modify(string action, Object data)
{
Clients.Others.modify(action, data);
}
```

Synchronize the Schedule with Outlook

Schedule appointments can be synchronized with Outlook and vice versa, by making use of the Microsoft Outlook 12/15 Object library.

The following code example depicts the way to synchronize the Schedule with Outlook.

RAZOR

```
@(Html.EJ().Schedule("Schedule1")
.Width("100%")
.Height("525px")
.CurrentDate(new DateTime(2015, 11, 12))
.AppointmentSettings(fields => fields.Datasource(dataSource =>
dataSource.URL("/Home/GetApp").CrudURL("/Home/Batch").Adaptor("UrlAdaptor
"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Id("Id")
.Subject("Subject")
.StartTime("StartTime")
.EndTime("EndTime")
.Description("Description")
.AllDay("AllDay")
.Recurrence("Recurrence")
.RecurrenceRule("RecurrenceRule"))
)
```

Schedule control is not directly compatible with the Outlook calendar object, as it returns the COM object. Therefore, in order to bind the schedule control with those data retrieved from outlook, then it is necessary to convert the COM object into the schedule acceptable object format. To do so, add the following code example in your code behind.

C#

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;
using System.Web.Mvc;
using System.ComponentModel;
using System.Configuration;
using System.Data;
using System.Data.SqlClient;
using System.Collections;
using Microsoft.Office.Interop.Outlook; // required Microsoft Assembly
using System.Web.Script.Serialization;
using System.Web.UI;
using System.Web.UI.WebControls;
using ScheduleCRUD.Models;
namespace ScheduleCRUD.Controllers
{
public class HomeController : Controller
{
DataClasses1DataContext db = new DataClasses1DataContext();
public ActionResult Index()
{
return View();
}
public JsonResult GetApp() // function to display the outlook
appointments in Schedule initially
{
IEnumerable data = GetData();
return Json(data, JsonRequestBehavior.AllowGet);
}
public List<ScheduleData> GetData() // function to return the outlook
appointments
{
Microsoft.Office.Interop.Outlook.Application oApp = new
Microsoft.Office.Interop.Outlook.Application();
Microsoft.Office.Interop.Outlook.NameSpace mapNamespace =
oApp.GetNamespace("MAPI");
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Microsoft.Office.Interop.Outlook.MAPIFolder CalendarFolder =
mapNamespace.GetDefaultFolder(Microsoft.Office.Interop.Outlook.OlDefaultF
olders.olFolderCalendar);
Microsoft.Office.Interop.Outlook.Items outlookCalendarItems =
CalendarFolder.Items;
List<Microsoft.Office.Interop.Outlook.AppointmentItem> appointmentList =
new List<Microsoft.Office.Interop.Outlook.AppointmentItem>();
foreach (Microsoft.Office.Interop.Outlook.AppointmentItem item in
outlookCalendarItems)
{
appointmentList.Add(item);
}
List<ScheduleData> newApp = new List<ScheduleData>();
// converting COM object into IEnumerable object
for (var i = 0; i < appointmentList.Count; i++)
{
ScheduleData app = new ScheduleData();
app.Id = i;
app.Subject = appointmentList[i].Subject;
app.AllDay = appointmentList[i].AllDayEvent;
app.StartTime = Convert.ToDateTime(appointmentList[i].Start.ToString());
string endTime = appointmentList[i].End.ToString();
DateTime appEndDate = Convert.ToDateTime(endTime);
if (endTime.Contains("12:00:00 AM") && app.AllDay == true)
app.EndTime = appEndDate.AddMinutes(-1);
else
app.EndTime = appEndDate;
app.Recurrence = false;
app.RecurrenceRule = null;
newApp.Add(app);
}
return newApp;
}
public JsonResult Batch(EditParams param)
{
if (param.action == "insert" || (param.action == "batch" && param.added
!= null)) // this block of code will execute while inserting the
appointments
{
var value = param.action == "insert" ? param.value : param.added[0];
int intMax = db.ScheduleDatas.ToList().Count > 0 ?
db.ScheduleDatas.ToList().Max(p => p.Id) : 1;
DateTime startTime = Convert.ToDateTime(value.StartTime);
DateTime endTime = Convert.ToDateTime(value.EndTime);
ScheduleData appoint = new ScheduleData()
{
Id = value.Id,
StartTime = startTime,
EndTime = endTime,
StartTimeZone=value.StartTimeZone,
EndTimeZone=value.EndTimeZone,
Subject = value.Subject,
Description = value.Description,
Recurrence = value.Recurrence,
CategoryId = value.CategoryId,
AllDay = value.AllDay,
RecurrenceRule = value.RecurrenceRule,
```

```
};
db.ScheduleDatas.InsertOnSubmit(appoint);
db.SubmitChanges();
Microsoft.Office.Interop.Outlook.Application outlookApp = new
Microsoft.Office.Interop.Outlook.Application();
Microsoft.Office.Interop.Outlook.AppointmentItem newAppointment = null;
newAppointment =
(Microsoft.Office.Interop.Outlook.AppointmentItem)outlookApp.CreateItem(M
icrosoft.Office.Interop.Outlook.OlItemType.olAppointmentItem);
newAppointment.Start =
Convert.ToDateTime(value.StartTime).ToUniversalTime();
newAppointment.End = Convert.ToDateTime(value.EndTime).ToUniversalTime();
newAppointment.Subject = value.Subject.ToString();
newAppointment.Save();
}
IEnumerable data = new DataClasses1DataContext().ScheduleDatas.Take(500);
// new.Appointment.Take(5);
return Json(data, JsonRequestBehavior.AllowGet);
}
}
}
```

Note: In order to achieve the above scenario, need to refer the Microsoft assembly (Microsoft Outlook 12/15 Object library [Microsoft.Office.Interop.Outlook]) in your application and refer it in the controller page as shown above.

Scroller

Overview

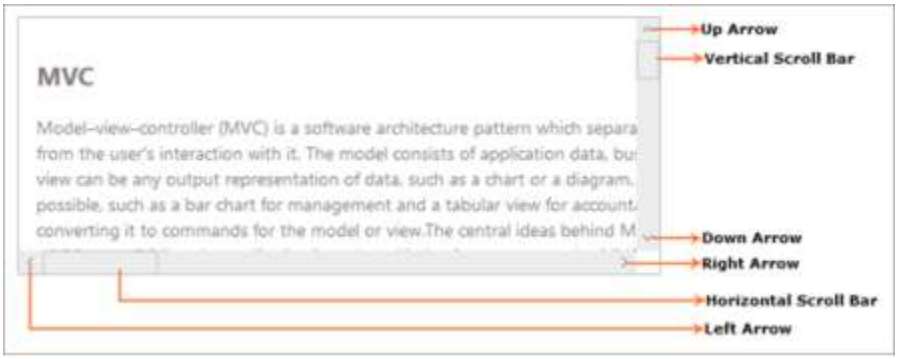
The Essential ASP.NET MVC Scroller control has a sliding document whose position corresponds to a value. The document has text, HTML content or images. You can also customize the Scroller control by resizing the scrolling bar and changing the theme.

Key Features

- Height and Width—Set the height and width of the scroll panel.
- Button Size—Customize the width and height of the buttons (UP, DOWN, RIGHT and LEFT).
- Scroller Size—Customize the scrollbar width and height.
- Step Increment—Set the number of pixels to be moved on pressing the ARROW key.
- RTL Support—Sets the alignment of the horizontal Scroller to the right, the reading order to right-to-left and the layout of the control to flow from right to left.
- Theme—Essential ASP.NET MVC controls consists of 12 built in themes (6 – flat and 6 – gradient effects), and also supports custom skins to set user-defined themes.

Copyright © 2001 - 2020 Syncfusion Inc.

Control Structure



Getting Started

This section explains briefly about how to create a Scroller in your ASP.NET MVC application.

Create your first Scroller in MVC

ASP.NET MVCScroller control allows you to slide document whose position corresponds to a value. The document has text, HTML content or images. Refer the following guidelines to create a Scroller control for horizontal and vertical Scrolling.

Add Scroller Control to your MVC Application

Essential Studio ASP.NET MVC Scroller control has a built-in feature to customize the resizing and changing the Scrollbar theme.

1. Create an MVC Project and add required assemblies, scripts, and styles to it. Refer MVC-Getting Started Documentation.
2. Add the following code example to the corresponding view page to render the Scroller.

ASPX-CS

```
<div id="scrollContent">
<div> @* Wrapper div for Scroller.*@
<div class="inner-content"> @* Content div*@
<h3> MVC </h3>
<p>
Model–view–controller (MVC) is a software architecture pattern which
separates the representation of information from the user's interaction
with it. The model consists of application data, business rules, logic,
and
functions. A view can be any output representation of data, such as a
chart
or a diagram.
</p>
</div>
</div>
</div>
@{ Html.EJ().Scroller("scrollContent").Height(150).Width(300).Render(); }
```

3. Add the following style in the view page to set the height and width of the Scroller.

CSS

Copyright © 2001 - 2020 Syncfusion Inc.

```
<style type="text/css" class="cssStyles">
.inner-content
{
width: 400px;
padding:15px;
}
</style>
```

4. Execute the above example code to get the following output.

Scroller Styles

The Essential ASP.NET MVCScroller control allows you to customize the look and function of scrollbars. You can vary it significantly by setting the scrollbar button size, scrollbar position, height and width of the Scroller control. This section describes you the custom styles to be used when creating Scroller.

Button Size

In Scroller control, it allows you to customize the scroll arrows width and height. In horizontal scroller the ButtonSize customizes the top and down arrow and in vertical scroller the ButtonSize customizes the left and right arrow.

Scroller Size

The ScrollerSize property is used to customize the scrollbar width and height. It is applicable for both horizontal and vertical scroller.

Scroll Top

The ScrollerTop property is used to move the Scroller content and scrollbars in top position with the specified value. It is used for only vertical scroller.

Scroll Left

The ScrollerLeft property is used to move the Scroller content and scrollbars in left position with the specified value. It is used for only horizontal scroller.

Height

The Height property is used to set the height for Scroller outer wrapper.

Width

The width property is used to set the Width for Scroller outer wrapper.

In the View page, add the Scroller helper to configure Scroller widget.

ASPX-CS

```
// In the CSHTML page, add a <div> element to configure Scroller widget
and initialize the control.
```

Copyright © 2001 - 2020 Syncfusion Inc.

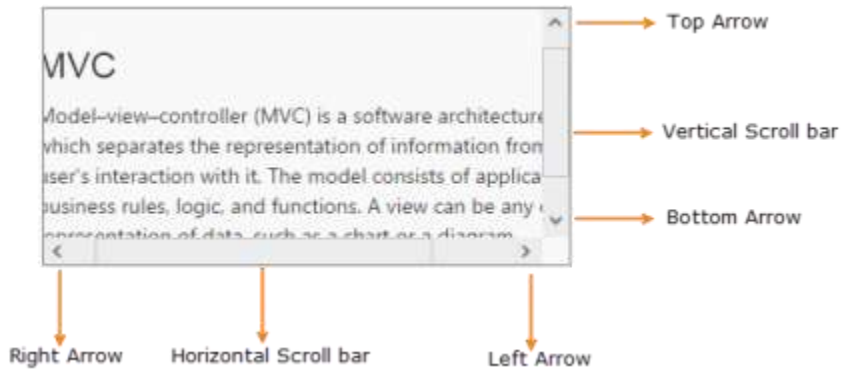
```
<div id="scrollContent">
<div> @*Wrapper div for Scroller.*@
<div class="inner-content"> @*Content div*@
<h3>MVC </h3>
<p>
Model-view-controller (MVC) is a software architecture pattern which
separates the representation of information from the user's interaction
with it. The model consists of application data, business rules, logic,
and
functions. A view can be any output representation of data, such as a
chart
or a diagram.
</p>
</div>
</div>
</div>
@{Html.EJ().Scroller("scrollContent").Height(170).Width(350).ScrollTop(10
).ScrollLeft(20).ButtonSize(20).Render();}
```

1. Configure the styles

CSS

```
<style type="text/css">
.inner-content
{
width: 400px;
padding: 15px;
}
#scrollContent {
border: 1px solid grey;
}
</style>
```

The following screenshot displays the Scroller control with basic styles



Scroller control rendered with basic styles

Copyright © 2001 - 2020 Syncfusion Inc.

Thumb Scrolling

Normally the scrollbar position can be changed by dragging the scrollbar handle or clicking the arrows. The Scroller control allows you for panning or dragging the scroll content area to drag by dragging inside the scroll content. To achieve this in your Scroller control, enable the EnableTouchScroll to true. By default the value forEnableTouchScroll is true. When you want to prevent the panning or dragging the scroll content area, set EnableTouchScroll as false.

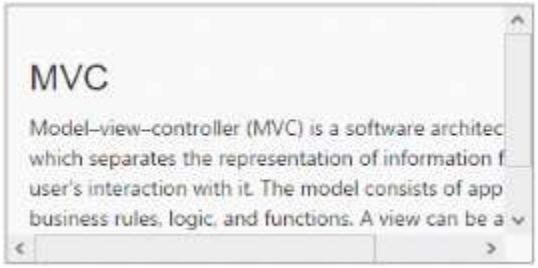
The following steps explains you the configuration of EnableTouchScroll property in Scroller.

1. In the View page, add a scroller helper to configure the EnableTouchScroll property.

ASPX-CS

```
// In the CSHTML page, add a <div> element to configure Scroller widget
and initialize the control.
<div id="scrollContent">
<div> @*Wrapper div for Scroller.*@
<div class="inner-content">  @*Content div*@
<h3>MVC </h3>
<p>
Model-view-controller (MVC) is a software architecture pattern which
separates the representation of information from the user's interaction
with it. The model consists of application data, business rules, logic,
and
functions. A view can be any output representation of data, such as a
chart
or a diagram.
</p>
</div>
</div>
</div>
@{Html.EJ().Scroller("scrollContent").Height(170).Width(350).EnableTouchS
croll(false).Render();}
```

The following screenshot displays Scroller control with disabled touch support.



Scroller control with disabled touch support

Customizing the scroll Step

The Scroller control allows you to specify the scroll movement step in a pixel value, this step value is added to the scrollbar position when you press the arrow key. Based on position value, the scrollbar moves in its corresponding orientation. You can achieve this by using ScrollOneStepBy.

The following steps explains you the configuration of ScrollOneStepBy property in Scroller.

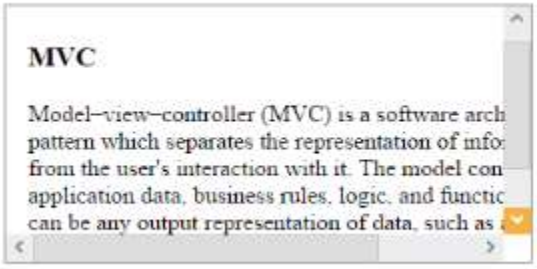
Copyright © 2001 - 2020 Syncfusion Inc.

1. In the View page, add a scroller helper to configure Scroller widget.

ASPX-CS

```
// In the CSHTML page, add a <div> element to configure Scroller widget
and initialize the control.
<div id="scrollContent">
<div>
@*Wrapper div for Scroller.*@
<div class="inner-content">
@*Content div*@
<h3>MVC </h3>
<p>
Model-view-controller (MVC) is a software architecture pattern which
separates the representation of information from the user's interaction
with it. The model consists of application data, business rules, logic,
and
functions. A view can be any output representation of data, such as a
chart or a diagram.
</p>
</div>
</div>
</div>
@{Html.EJ().Scroller("scrollContent").Height(170).Width(350).ScrollOneSte
pBy(50).Render();}
```

The following screenshot displays the Scroller control with scroll step value.



Scroller Control with scroll step value

RTL

EnableRTL API provides right-to-left functionality and features for languages that work in a right-to-left for selecting, editing. Arabic and Hebrew are written from right to left. If you have a working style from right to left, you can use this feature in scroller. You can achieve this in your Scroller by using EnableRTL property. Setting this property to true, the Scroller content text is displayed in the right to left format. The vertical scrollbar move to right to left side.

The following steps explains you the configuration of EnableRTL property in Scroller.

In the View page, add a scroller helper to configure Scroller widget.

ASPX-CS

```
// In the CSHTML page, add a <div> element to configure Scroller widget
and initialize the control.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div id="scrollcontent">
<div>  @*Wrapper div for Scroller.*@
<div class="inner-content"> @*Content div*@
<h3>MVC </h3>
<p>
Model-view-controller (MVC) is a software architecture pattern which
separates the representation of information from the user's interaction
with it. The model consists of application data, business rules, logic,
and
functions. A view can be any output representation of data, such as a
chart
or a diagram.
</p>
</div>
</div>
</div>
@{Html.EJ().Scroller("scrollContent").Height(170).Width(350).EnableRTL(tr
ue).Render();}
```

The following screenshot displays the Scroller control in RTL direction.

Scroller control in RTL direction

How to?

Render Scroller from Code behind

Scroller can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of Scroller properties in the controller.

C#

```
<div>
@* Wrapper div for Scroller.*@
<div class="inner-content" style="width:400px;padding:15px">
@* Content div*@
<h3> MVC </h3>
<p>
Model-view-controller (MVC) is a software architecture pattern which
separates the representation of information from the user's interaction
with it. The model consists of application data, business rules, logic,
and
functions. A view can be any output representation of data, such as a
chart
or a diagram.
</p>
</div>
```

```
</div>
</div>
//Namespace to get the JavaScript (Scroller) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class ScrollerController : Controller
{
// GET: Scroller
public ActionResult ScrollerFeatures()
{
//Initializing the Scroller model
ScrollerProperties ScrollerObj = new ScrollerProperties();
//Initializing the datasource and other properties
ScrollerObj.Height = 150;
ScrollerObj.Width = 300;
//Passing Scroller properties using the ViewData
ViewData["ScrollerModel"] = ScrollerObj;
return View();
}
}
}
```

Binding the Scroller properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().Scroller("scrollContent",(Syncfusion.JavaScript.Models.Scroller
Properties)ViewData["ScrollerModel"]).Render();
}
```

Signature

Overview

The Essential MVC Signature Plugin is used to capture or drawing the smooth signatures. It captures user's signature as vector outlines of strokes. Using Signature we can customize the background, stroke width and stroke color and also convert captured signature to an image format. It is also provided with Undo, Redo & Clear options.

Key Features

- **Height and Width** - Set the height and width of the signature canvas.

*** Stroke Color and Background Color** - Customize the stroke color and background color for the canvas

- **Background Image** - Sets the background image for the signature canvas.
- **Stroke Width** - Sets the stroke's minimum and maximum width for the drawing stroke.

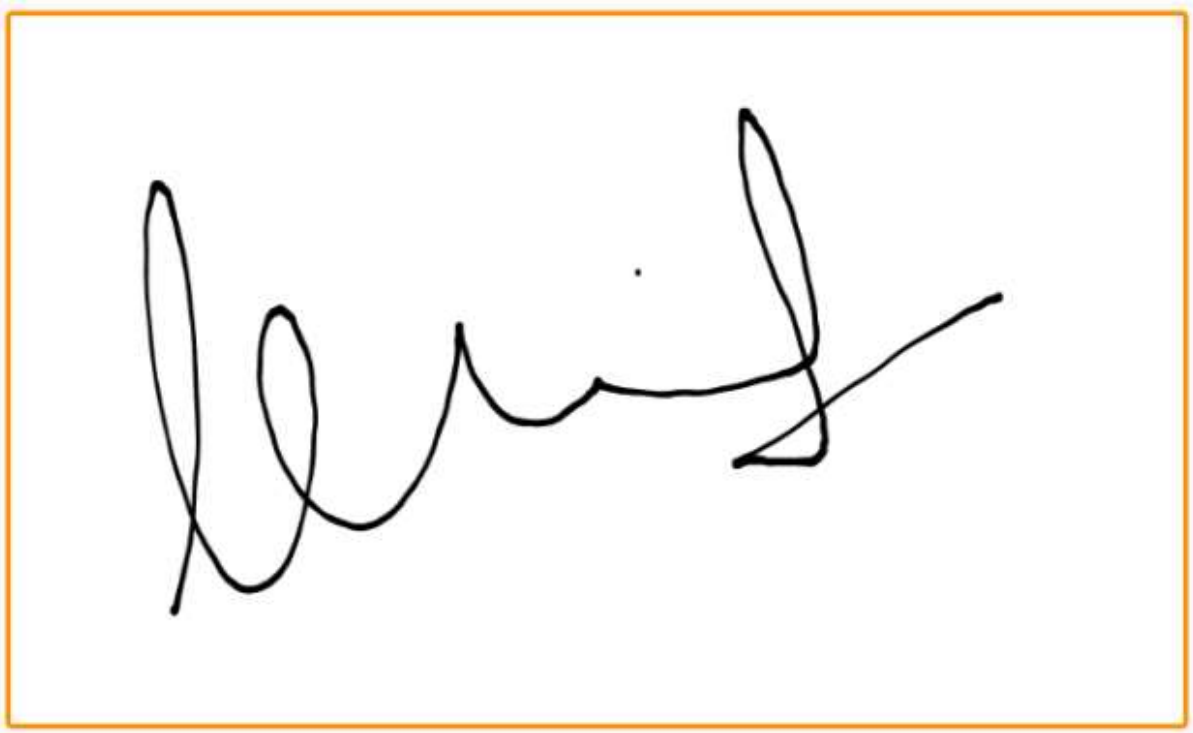
***Undo and Redo** – Undo and Redo the strokes in the signature, if wrongly drawn

Copyright © 2001 - 2020 Syncfusion Inc.

Getting Started

The Signature simplifies creation of a signature capture in a browser, allowing a user to draw a signature using mouse or touch.

This section explains briefly about how to create a **Signature** control in your application with ASP.NET MVC application by the step-by-step instructions. The following screenshot demonstrates the functionality of Signature widget.



Creating your first Signature in MVC application

Create an MVC Project and add necessary assemblies, scripts and CSS files given in MVC-Getting Started Documentation.

Add Signature control using the helper from EJ namespace.

RAZOR

```
@Html.EJ().Signature("mySign").Height("400px")
```

Execute the code to render a Signature widget as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

Adjusting Signature Size

We can customize the width and height of the Signature by width and height properties. These properties completely depend on signature canvas. The width and height are adjusted within the signature canvas.

The following code example is used to render the Signature control with customized width and height.

RAZOR

```
@Html.EJ().Signature("mySign").Height("500px").Width("200px")
```

The following screenshot illustrates signature with customized width and height.

Copyright © 2001 - 2020 Syncfusion Inc.

Signature Customization

Stroke color

Signature widget allows you to set the stroke color for the signature stroke using the **StrokeColor** property. When we set our required color, then the signature's stroke color will be changed.

The following example is used to render the Signature control with stroke color.

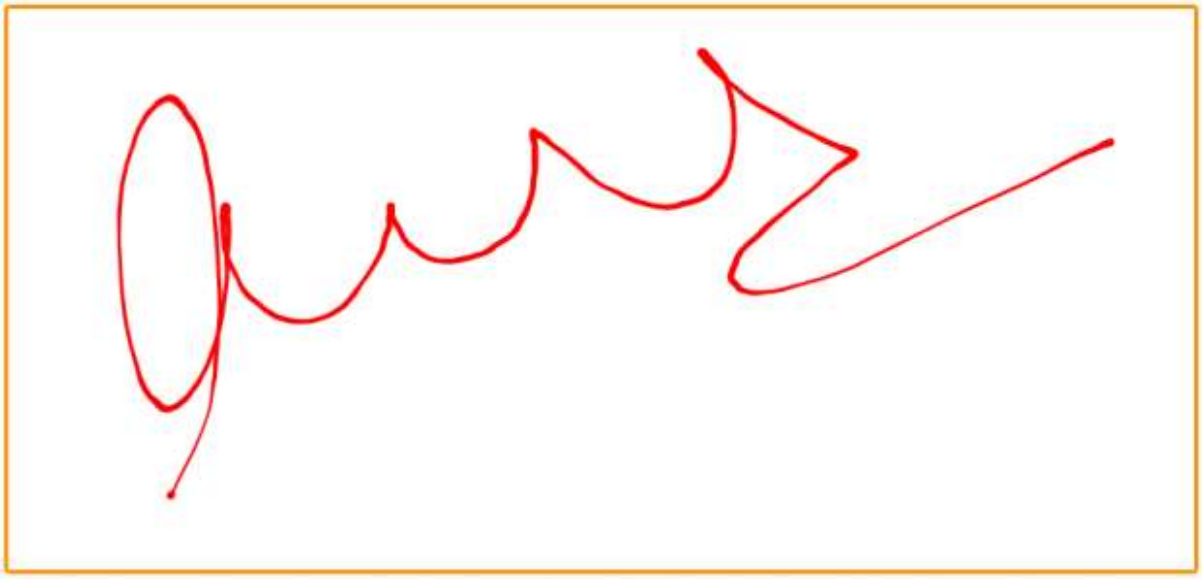
In the View page, define the following code.

RAZOR

```
@Html.EJ().Signature("mySignature").StrokeColor("red")
```

The following screenshot illustrates the Signature with custom defined stroke color.

Copyright © 2001 - 2020 Syncfusion Inc.



Stroke Width

Signature widget allows you to set the stroke width for the control using the **StrokeWidth** property. When we set our required width, then the signature's stroke width will be changed.

The following code example is used to render the Signature control with stroke width value.

In the View page, define the following code.

RAZOR

```
@Html.EJ().Signature("mySignature").StrokeWidth(5)
```

The following screenshot illustrates the Signature with custom defined stroke maximum value.

Background color

Signature widget allows you to set the background Color for the control using the **BackgroundColor** property. When we set our required background, then the signature's background color will be changed automatically.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example is used to render the Signature control with background color.

In the View page, define the following code.

RAZOR

```
@Html.EJ().Signature("mySignature").BackgroundColor("grey")
```

The following screenshot illustrates the Signature with custom defined background color

Background Image

Signature widget allows you to set the background image for the control using the **BackgroundImage** property. When we set our required background image, then the signature's canvas will be changed with the given image.

The following code example is used to render the Signature control with customized background image.

In the View page, define the following code.

RAZOR

```
@Html.EJ().Signature("mySignature").BackgroundImage("image.jpg")
```

The following screenshot illustrates the Signature with custom defined background image.

Copyright © 2001 - 2020 Syncfusion Inc.

How To

Save signature image with user defined format

By default, the downloaded image form the signature canvas will be in **png** format. We can define our own format to download the image with **SaveImageFormat** property. And we can also save the image along with the background by using the **SaveWithBackground** property.

In the View page, define the following code.

RAZOR

```
@Html.EJ().Signature("mySignature").Height("400px").StrokeWidth(3).Backgr
oundImage("../../Images/progressbar/water.png").IsResponsive(true).saveWi
thBackground(true)
@Html.EJ().Button("signSave").Text("Save").ShowRoundedCorner(true).Client
SideEvents(event => event.Click("onSave"))
```

Add the following script to define the download format for the canvas.

JS

```
<script type="text/javascript">
function onSave() {
var sign = $("#mySignature").ejSignature("instance");
sign.option("saveImageFormat", "jpg")
sign.save("mySignature");
}
</script>
```

The following screenshot illustrates the Signature with saving (downloading) the drawn image along with its background.

Copyright © 2001 - 2020 Syncfusion Inc.

To clear the Signature

To clear the signature, you can simply use the **clear()** method. This method will clear all the drawn strokes in the signature canvas and leaves it empty.

RAZOR

```
@Html.EJ().Signature("mySignature").Height("400px").StrokeWidth(3).IsResp
onsive(true)
@Html.EJ().Button("signClear").Text("Clear").ShowRoundedCorner(true).Clie
ntSideEvents(clientSideEvent => clientSideEvent.Click("onClear"))
```

JS

```
<script type="text/javascript">
function onClear() {
var sign = $("#mySignature").ejSignature("instance");
sign.clear();
}
</script>
```

Make signature as responsive

When the signature control is resized or even the window is resized the strokes drawn in the signature will be disappeared. To make the strokes visible even after resizing the window, we must set the **IsResponsive** property as true.

In the View page, define the following code to render signature with responsive.

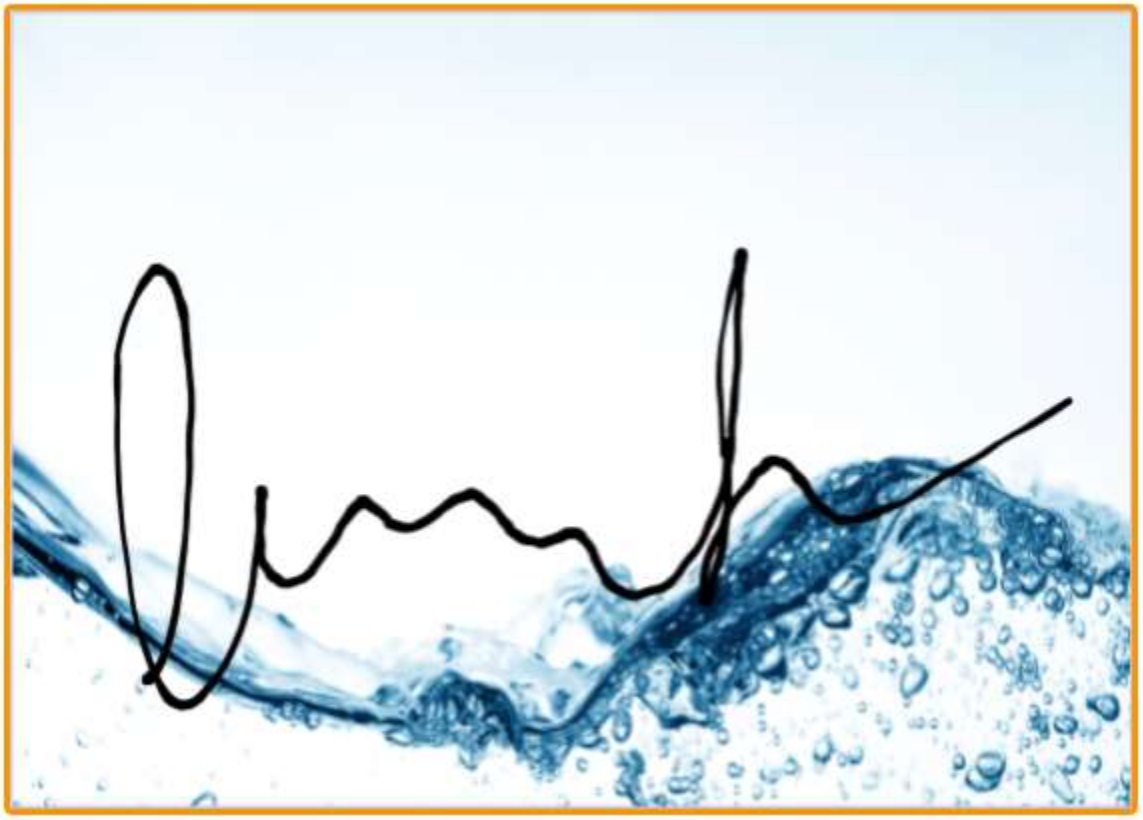
RAZOR

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().Signature("mySign").IsResponsive(true)
```

The following screenshot illustrates the Signature with responsiveness.

Before Responsiveness:



After giving the Responsiveness:

To check whether any input to the signature control since render

We can detect whether not there has been any input to the signature control since render. To detect we can use the storeSnap public variable, which is an array that stores all the canvas inputs. At initial rendering this array is empty and we can use this variable to check for the drawn strokes.

JS

```
<script type="text/javascript">
var sign = $("#signature").ejSignature("instance");
if (ej.isNullOrUndefined(sign.storeSnap)) {
//Something
}
</script>
```

Render Signature from Code behind

Signature can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side

The following code illustrates the initialization of Signature properties in the controller.

C#

```
//Namespace to get the JavaScript (Signature) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class SignatureController: Controller
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult SignatureFeatures()
{
//Initializing the Signature model
SignatureProperties signObj = new SignatureProperties();
//Initializing the other properties
signObj.Height = "200px";
signObj.IsResponsive = true;
signObj.StrokeWidth = 5;
//Passing Signature properties using the ViewData
ViewData["SignModel"] = signObj;
return View();
}
}
}
```

Binding the Signature properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().Signature("sign1",
(Syncfusion.JavaScript.Models.SignatureProperties)ViewData["SignModel"]).
Render();
}
```

Slider

Slider

The Essential ASP.NET MVC Slider provides support to select a value from a particular range as well as selects a range value. The Slider has a sliding base on which the handles are moved. There are three types of Sliders such as default Slider, min-range Slider and range Slider.

Key Features

- Orientation—Slider control is displayed in horizontal or vertical direction.
- Animation—Supports for handle movement with animation.
- Tooltip—Supports to display a tooltip to display the currently selected value.
- Range Slider—Supports to select a range of values.
- Scale—Supports to display a scale with small and big ticks.
- Persist—Supports for state maintenance while refreshing a page.
- Customizable—Easily customizable.
- RTL Support—Sets the alignment to the right, the reading order to right-to-left and the layout of the control to flow from right to left.
- Themes—Essential JavaScript controls consist of 12 built-in themes (6 – flat and 6 – gradient effects), and also support custom skins to set user-defined themes.

Getting Started

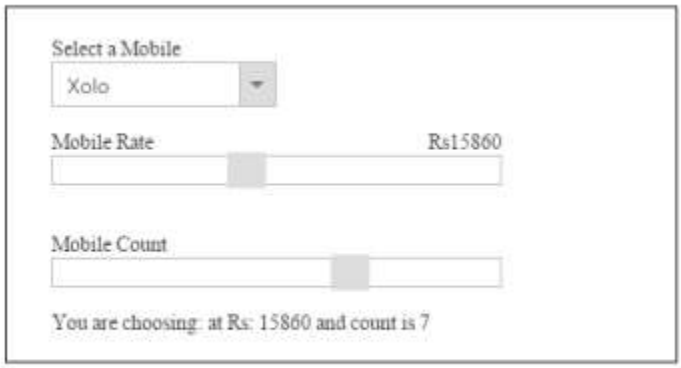
This section explains briefly about how to create a Slider in your application with ASP.NET MVC.

Copyright © 2001 - 2020 Syncfusion Inc.

Create your first Slider in MVC

ASP.NET MVC Slider provides support to display a Slider within the web page. The following section explains you on how to use Sliders in a real-time application to select a mobile model within specified range in Mobile Purchase.

The following screenshot illustrates the functionality of Slider control. You can select a mobile model in the dropdown to purchase it at any rate specified in the Mobile RateSlider and you can also specify the number of mobiles you need by selecting the Mobile CountSlider. Simultaneously, you can observe the change in mobile rate and count using Sliders.



Create a Slider

ASP.NET MVC Slider control allows you to switch between different ranges of input. The basic Slider is horizontal and has a single handle that can be moved with the mouse or by using the arrow keys. You can easily create the Slider control using @Html.helper as follows.

1. Create an MVC Project and add necessary assembly, scripts, and styles to it.

Refer MVC-Getting Started

2. Add the following code example for Slider to the corresponding view page.

ASPX-CS

```
<div class="frame">
<div class="inner">
<div class="control-label">
Select a Mobile
</div>
@Html.EJ().DropDownList("selectMobile").TargetID("mobileList").Width("150
px")
<div id="mobileList">
<ul>
<li>Nokia Lumia</li>
<li>Nokia Asha</li>
<li>Xolo</li>
<li>Samsung Galaxy</li>
<li>Moto G</li>
</ul>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</div>
<span class="column-left">
<span>Mobile Rate</span>
</span>
<span class="column-right">
<span>Rs </span><span class="value"></span>
</span>
@Html.EJ().Slider("rateSlider").Height("20px").Value("100").MinValue(5000
).MaxValue(30000).IncrementStep(20).ClientSideEvents(event =>
event.Change("onChange").Slide("onChange"))
<span class="Columnleft">
<span>Mobile Count</span>
</span>
@Html.EJ().Slider("countSlider").Height("20px").Value("1").MinValue(1).Ma
xValue(10).IncrementStep(1).ClientSideEvents(event =>
event.Change("onChange").Slide("onChange"))
You are choosing:
<span id="EventLog"></span>
</div>
</div>
```

3. Add the following styles for Sliders.

CSS

```
<style>
.frame
{
width:400px;
height:200px;
border:1px solid black;
margin-right:100px;
}
.control-label, .loan
{
font-weight:bold;
}
.column-right
{
font-weight:bold;
float:right;
}
.inner
{
width:300px;
height:150px;
padding:20px 40px 20px 30px;
}
.mobileList
{
display:block;
}
</style>
```

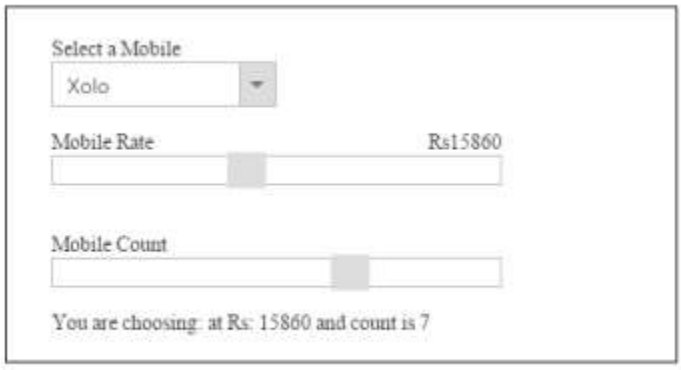
Copyright © 2001 - 2020 Syncfusion Inc.

4. Add the following script to the Slider.

JS

```
<script>
var mobileObj, rateObj, countObj;
function onChange(args) {
$('#' + args.id).parent().prev().find('.value').html(args.value)
show();
}
function show() {
selectObj = $('#selectMobile').data('ejDropDownList');
rateObj = $('#rateSlider').data('ejSlider');
countObj = $('#countSlider').data('ejSlider');
var x = selectObj.getValue();
var y = rateObj.getValue();
var z = countObj.getValue();
$('#EventLog').html("\n" + x + "\n" + "at Rs: " + y + "\n" + "and count
is " + z);
}
</script>
```

5. The following screenshot displays the final output in Slider creation.



EMI Calculator

This section explains how to use the Slider control for EMI Calculation. The final result of EMI amount is calculated automatically based on the loan amount, interest rate and tenure amount based on the amount you choose using Slider.

1. You can create an MVC Project and add necessary and script to it. Refer MVC-Getting Started Documentation.
2. Add the following code for Slider to the corresponding view page.

ASPX-CS

```
<div class="frame">
<div class="inner">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div id="loanHeading">
Details of Loan
</div>
<span class="column-left">
<span>Loan Amount</span>
</span>
<span class="column-right">
<span>Rs </span><span class="value">25000</span>
</span>
@Html.EJ().Slider("loanSlider").Height("16px").Value("25000").MinValue(10
000).MaxValue(1000000).IncrementStep(10).ClientSideEvents(event =>
event.Change("onChange").Slide("onChange"))
<span class="column-left">
<span>Interest Rate</span>
</span>
<span class="column-right">
<span class="value"></span><span>% pa</span>
</span>
@Html.EJ().Slider("interestSlider").Height("16px").Value("4").MinValue(1)
.MaxValue(20).IncrementStep(1).ClientSideEvents(event =>
event.Change("onChange").Slide("onChange"))
<span class="column-left">
<span>Tenure</span>
</span>
<span class="column-right">
<span class="value"></span><span>Years</span>
</span>
@Html.EJ().Slider("tenureSlider").Height("16px").Value("3").MinValue(1).M
axValue(20).IncrementStep(1).ClientSideEvents(event =>
event.Change("onChange").Slide("onChange"))
Your Monthly EMI Amount is
<span id="EventLog"></span>
</div>
</div>
</div>
```

3. Include the following styles for Slider.

CSS

```
<style>
.frame
{
width:350px;
height:200px;
border:1px solid black;
}
.inner
{
width:250px;
height:150px;
padding:20px 30px;
}
#loanHeading
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
font-weight:bold;
}
.column-left
{
font-weight:bold;
}
.column-right
{
float:right;
font-weight:normal;
}
</style>
```

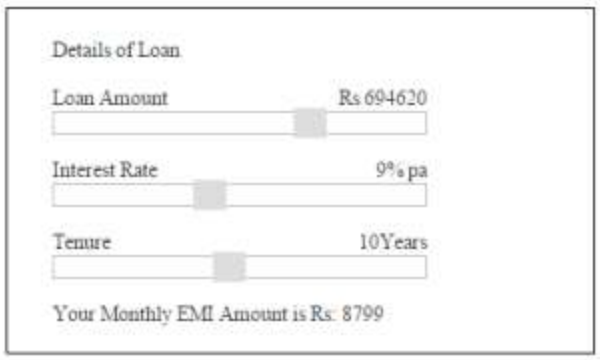
4. Include the following script to calculate the EMI amount.

ASPX-CS

```
<script type="text/javascript">
var loanObj, interestObj, tenureObj;
function onChange(args)
{
$('#' + args.id).parent().prev().find('.value').html(args.value)
calculate();
}
function calculate()
{
loanObj = $('#loanSlider').data('ejSlider');
interestObj = $('#interestSlider').data('ejSlider');
tenureObj = $('#tenureSlider').data('ejSlider');
var loan = loanObj.getValue(), interest = interestObj.getValue(), tenure
= tenureObj.getValue();
var P = loan;
var y = interest / 1200;
var tenureAmount = tenure * 12;
//actual processing
var top = y * (Math.pow((1 + y), tenureAmount));
var bottom = (Math.pow((1 + y), tenureAmount)) - 1;
var ans = top / bottom;
var final = P * ans;
var z = Math.round(final);
$('#EventLog').html("Rs: " + z);
}
</script>
```

The following screenshot displays the calculated EMI amount using Slider.

Copyright © 2001 - 2020 Syncfusion Inc.



The Slider component lets you to select a value such as number, percentage by moving the slider handle. It also allows you to specify a range of values between its minimum and maximum values. You can use Slider to influence other object. For example, Slider can be associated with a picture so that the picture enlarges or shrinks based upon the value in the slider.

The Slider has horizontal orientation by default. You can also change the orientation as vertical. Also, the Slider contains features like enabling slider of different types, enabling scale in the slider etc.

Behavior Settings

Height

By default, Slider renders with a height of 14px. You can change the Slider height using Height property. Specify the value for this property in string format.

Width

By default, Slider widget renders with 100% width. You can customize the width of the Slider using Width property. Specify the value for this property in string format.

The following steps explains you on how to configure the Height and Width of the Slider.

1. In an VIEW page, add a helper element to render it as a Slider widget.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("BasicSlider").Height("20").Width("500"))
```

Execute the above code example to render the following output.

IncrementStep

This property sets the incremental step value for the Slider. When the Slider handle slides through mouse or keyboard, it increments / decrements the value based on the step value. By default, when the

slider handle is moved, single value increments / decrements. Using IncrementStep property you can change the increment step value. Data type of this property is number.

The following steps explains you on how to configure the IncrementStep property.

1. In an VIEW page, add a helper element to render it as a Slider widget.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("BasicSlider").Height("20").Width("500").IncrementStep
(5))
```

Execute the above code example to render the following output.

In the above example, value for IncrementStep property is specified as “5” therefore, when you move the Slider handle, value “5” increments/decrements from the current Slider value.

ReadOnly

This feature prevents you from interacting with the Slider. That is you can only view the Slider value and cannot change it.

The following steps explains you on how to enable the ReadOnly property.

1. In an VIEW page, add a helper element to render it as a Slider widget.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("BasicSlider").Height("20").Width("500").ReadOnly(true
))
```

After you execute the above code example, the Slider values cannot be changed in any ways.

Persistence Support

This feature supports you to save current model value to browser cookies for state maintenance. When you refresh the web page, the Slider control retains the model value apply from browser cookies. The data type of EnablePersistence is Boolean type.

Copyright © 2001 - 2020 Syncfusion Inc.

The following steps explains you on how to enable the EnablePersistence property.

1. In an VIEW page, add a helper element to render it as a Slider widget.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("BasicSlider").Height("20").Width("500").EnablePersist
ence(true))
```

After execute the code, Increase the value and reload the page. The state is maintained in the Slider control.

Orientation

This property is used to set the Slider in either horizontal or vertical direction. By default, Slider renders in horizontal direction. Data type of this property is “Enum”.

Possible Slider orientations are as follows,

Property Table for MVC

Property	Allowed values	Description
Orientation	Vertical	Displays the Slider in vertical direction
	Horizontal (default value)	Displays the Slider in horizontal direction

The following steps explains you on how to configure the Orientation property.

1. In an VIEW page, add a helper element to render it as a Slider widget.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("BasicSlider").Height("150").Width("20").Orientation(O
rientation.Vertical))
```

Execute the above code example to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Slider in vertical Orientation

Slider Types

This feature allows you to specify the type of Slider. There are three different types of Slider, Default Slider, Min-Range Slider and Range Slider. By default, Default Slider renders. You can use the SliderType property to choose the type of Slider. Data type of this property is “Enum”

Both Default Slider and Min-Range Slider have same behavior that is used to select a single value. In Min-Range Slider, a shadow is considered from the start value to current handle position. But Range Slider contains two handles that is used to select a range of values and a shadow is considered in between the two handles.

Possible Slider types are as follows,

Property Table for MVC

Property	Allowed values	Description
SliderType	Default (default value)	It is the default Slider type. It helps to select a single value.
	MinRange	Use this Slider to select a single value; Displays shadow from the start value to the current value.
	Range	Use this Slider to select a range of values; Displays shadow in-between the selection range.

The following steps explains you on how to configure the SliderType property to display Range Slider and MinRange Slider.

1. In an VIEW page, specify the helper elements to render the RangeSlider and MinRangeSlider.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("minSlider").SliderType(SlideType.MinRange).Value("60"
).Width("500"))
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("30,
60").Width("500"))
```

Execute the above code example to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Shows different Slider types (Range and Min-Range sliders)

Updating slider value

Slider widget includes an option to specify/update its value. And also you can specify the starting and ending value for the Slider using the MinValue and MaxValue properties.

Value

This property is used to set the value in the “Default” and “Min-Range” Sliders. By default its value is null when no value is specified. Data type of this property is “Number”. You can get/set the value in the slider handle by using getValue and setValue methods.

Also change event will be triggered whenever **Slider** value is changed.

Values

This property is used to set the value in “Range Slider”. By default range values is from 0 to 100. This property is of “Array” data type.

The following steps explains you the configuration of “Value” and “Values” property.

1. In an VIEW page, specify the helper elements to render the “Range Slider” and “Default Slider”.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").SliderType(SlideType.Default).Value("
50").Width("500"))
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("20,
80").Width("500"))
```

Execute the above code example to render the following output.

MinValue

To set the minimum/starting value of the Slider, you can use the MinValue property. By default its value is 0. Data type of this property is “number”.

Copyright © 2001 - 2020 Syncfusion Inc.

MaxValue

To set the maximum/ending value of the Slider, you can use the MaxValue property. By default its value is 100. Data type of this property is “Number”.

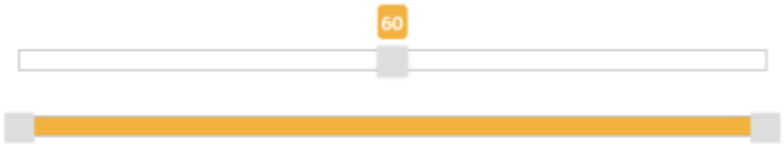
The following steps explains you on how to configure MinValue and MaxValue property.

1. In an VIEW page, specify the helper elements to render the Default Slider and Range Slider.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").Value("60").Width("500").MinValue(40)
.MaxValue(80))
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("10,
90")
.MinValue(10).MaxValue(90).Width("500"))
```

Execute the above code example to render the following output.



In the above example, for Default Slider the slider value starts from “40” (min value) and ends in “80” (max value), so the slider handle is placed at the center of the Slider while specifying the value as “60”.

For Range Slider, the value starts from “10” (min value) and ends in “90” (max value). The range shadow occupies the entire Slider, since the range (values) is specified as “[10, 90]”.

Buttons

Slider includes the button support for increment or decrement the values of the slider.

Enabling Buttons

Use the ShowButtons property to enable the button support. By default this property is disabled. Data type of this property is “Boolean”.

The following steps explains you on how to enable button support in Slider.

1. In an VIEW page, specify the helper elements to render the Range Slider.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("30,
60")
.Width("500").ShowButtons(true))
```

Copyright © 2001 - 2020 Syncfusion Inc.

Execute the above code example to render the following output.

Scale Settings

Slider widget includes option to display the scale on the Slider. Scale in Slider supports you to easily identify the current value/values of the Slider. Scale contains “small ticks” and “large ticks”. Values of the Slider is displayed above each large ticks.

Show Scale

This property enables the scale in the Slider. By default, its value is “false”. Data type of this property is “Boolean”.

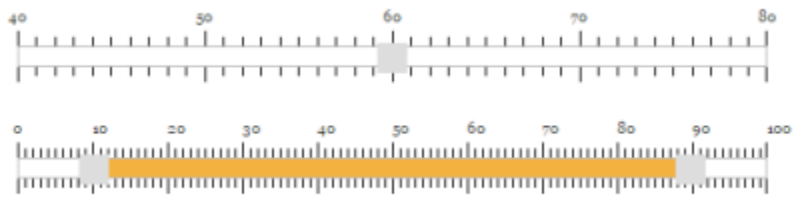
The following steps explains you the configuration of ShowScale property.

1. In an VIEW page, specify the helper elements to render the “Default Slider” and “Range Slider”.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").Value("60").Width("500").MinValue(40)
.MaxValue(80).ShowScale(true))
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("10,
90")
.ShowScale(true))
```

Execute the above code example to render the following output.



Enable Small Ticks

Slider widget provides you an option to enable/disable the small ticks present in the scale. By default, when you enable “ShowScale” property, small ticks is displayed in the scale. Use the ShowSmallTicks property to disable the small ticks present in the scale. Data type of this property is “Boolean”. The renderingTicks event will be triggered while creating each slider scale tick.

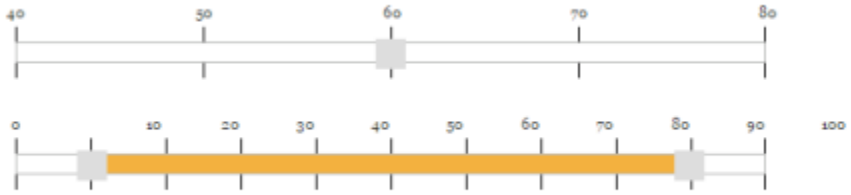
The following steps explains you on how to disable the small ticks in Slider.

1. In an VIEW page, specify the helper elements to render the “Default Slider” and “Range Slider”.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").Value("60").Width("500").MinValue(40)
.MaxValue(80)
.ShowScale(true).ShowSmallTicks(false))
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("10,
90")
.ShowScale(true).ShowSmallTicks(false))
```

Execute the above code example to render the following output.



Small step

This property specifies the distance between the two small ticks present in the scale and the position of the small ticks in the Slider scale. Data type of this property is “Number”.

Large step

This property specifies the distance between the two small ticks present in the scale and the position of the large ticks in the Slider scale. Data type of this property is “Number”.

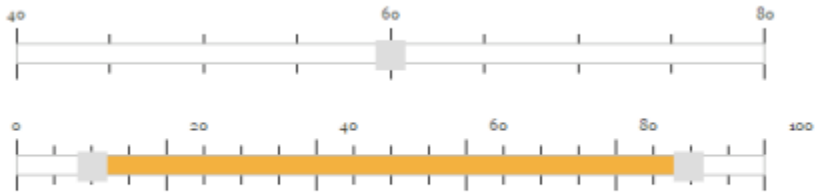
The following steps explains you on how to configure the SmallStep and LargeStep property in Slider scale.

1. In an VIEW page, specify the helper elements to render the “Default Slider” and “Range Slider”

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").Value("60").Width("500").MinValue(40)
.MaxValue(80)
.ShowScale(true).SmallStep(5).LargeStep(20))
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("10,
90")
.ShowScale(true).SmallStep(5).LargeStep(20))
```

Execute the above code example to render the following output.



Copyright © 2001 - 2020 Syncfusion Inc.

In the above example, for “Default Slider” the “SmallStep” value is specified as “5”, so for each 5 values from the starting value, small ticks is enabled. Also, “LargeStep” value is specified as “20”, so for each 20 values from the starting value, large ticks is enabled.

Similarly for “Range Slider”, “SmallStep” value is specifies as “5”, so for each 5 values from the starting value, small ticks is enabled. Also, “LargeStep” value is specified as “25” so, for each 25 values large ticks is enabled.

Appearance and Styling

Slider widget looks sleek and enriched with good UI appearance. It is included with both metro (flat) theme and gradient theme support. Totally twelve built-in themes are provided including six flat themes and six gradient themes. The themes include three color variations such as “Azure”, “Lime” and “Saffron”. The themes supported by the Slider widgets are as follows,

- default-theme
- flat-azure-dark
- flat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

In order to apply different themes, you can refer the “ej.widgets.all.min.css” file from the corresponding theme folders. This file is a combination of two style sheets “ej.widgets.core.min.css” and “ej.theme.min.css”. Instead of including “ej.widgets.all.min.css” file you can also refer the “ej.widgets.core.min.css” and “ej.theme.min.css” files separately.

The following steps explains you on how to apply “flat-lime-dark” theme to the Slider widget

1. In an VIEW page, specify the desired “ej.widgets.all.min.css” file to load the corresponding theme.

ASPX-CS

```
//In _Layout page, specify the desired
“ej.widgets.all.min.css” file to load the corresponding theme.
<head>
<title>Slider</title>
<!--Flat-saffron theme-->
<link href="http://cdn.syncfusion.com/13.1.0.21/js/web/flat-saffron-
dark/ej.web.all.min.css" rel="stylesheet" />
<!--scripts-->

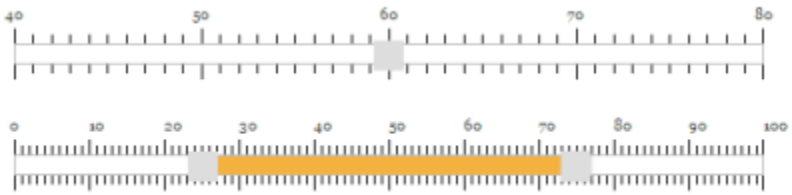
pt>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</head></td><td>
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").Value("60").Width("500").MinValue(40)
.MaxValue(80)     .ShowScale(true).SmallStep(5).LargeStep(20))
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("10,
90")     .ShowScale(true).SmallStep(5).LargeStep(20))
```

Execute the above code example to render the following output.



CSS Class

When you want to display the Slider widget in a different style based on the appearance of your application, you can use this CssClass property to apply custom theme for the Slider. Specify a class name as the value for CssClass property. The specified class is added to the wrapper of the Slider widget. Now, you can easily override the styles of the Slider widget by accessing the styles from the root level (using the CssClass specified).

The following steps explains you on how to configure the Slider with custom theme using the CssClass property. Here, a class name “purple” is specified for the CssClass.

1. In an VIEW page, specify the helper elements to render the “Default Slider” and “Range Slider”.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("25,
75")
.Width("500").CssClass("purple"))
```

2. Include the “CssClass” value before each style of the Slider widget and customize the styles as follows.

CSS

```
.purple.e-slider.e-widget
{
background-color: burlywood;
border-color: #bbbcbb;
}
.purple.e-tooltip
{
background: none repeat scroll 0 0 violet;
/* Old browsers */
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
border-color: #1b95cf;
color: white;
}
.purple.e-slider .e-handle.e-select
{
background-color: purple;
border-color: purple;
}
.purple.e-slider .e-handle.e-hover
{
background-color: purple;
border-color: purple;
}
.purple.e-slider .e-handle.e-focus
{
box-shadow: 0 0 2px rgba(0, 0, 0, 0.2);
}
.purple.e-slider .e-range
{
background: none repeat scroll 0 0 violet;
/* Old browsers */
}
.purple.e-scale .e-tick
{
background-image: url(images/dot.png);
}
```

Execute the above code example to render the following output.

Show Tooltip

Slider displays the tooltip to indicate the current value when you click on the Slider handle. By default, Slider displays the tooltip. Using the ShowTooltip option you can enable or disable the Tooltip. Data type of this property is “boolean”.

The following steps explains you on how to disable the tooltip in Slider.

1. In an VIEW page, specify the helper elements to render the Default Slider.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").Value("60").Width("500").ShowTooltip(
false))
```

Copyright © 2001 - 2020 Syncfusion Inc.

Show Rounded Corner

This property is used to display the Slider and its handle with rounded corners. By default ShowRoundedCorner is in disabled state. Data type of this property is “Boolean”.

The following steps explains you on how to disable the tooltip in Slider.

1. In an VIEW page, specify the helper elements to render the “Default Slider”.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").Value("60").Width("500").ShowRoundedC
orner(true))
```

Execute the above code example to render the following output.

Default Slider

Animation

This feature includes the animation effect for the Slider when moving the Slider handle.

Enabling Animation

By default, animation is enabled in the Slider. Using the EnableAnimation property you can enable/disable the animation effects. Data type of this property is “Boolean”.

The following steps explains you on how to disable the animation effect in Slider.

1. In an VIEW page, specify the helper elements to render the “Default Slider”.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").Value("60").Width("500").EnableAnimat
ion(false))
```

Customizing Animation speed

Animation speed of the Slider indicates the speed at which the slider handle can be moved. Higher the value specified for this property decreases the rate of speed at which the Slider handle can be moved.

Copyright © 2001 - 2020 Syncfusion Inc.

You can customize the animation speed of the Slider using the AnimationSpeed property. Default value of this property is “500”.

The following steps explains you on how to customize the animation speed.

1. In an VIEW page, specify the helper elements to render the “Default Slider”.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").Value("60").Width("500").AnimationSpe
ed(600))
```

Enable/Disable the Slider

Slider widget includes an option to enable/disable it. When you disable the Slider, it is displayed in a blur state and you cannot perform any operations in it.

Enabled

Using this Enabled property you can enable/disable the Slider. Data type of this property is “Boolean”. Also you can enable/disable the **Slider** by using enable and disable methods.

The following steps explains you on how to disable the Slider.

1. In an VIEW page, specify the helper elements to render the Default Slider.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("defaultSlider").Value("60").Width("500").Enabled(fals
e))
```

Execute the above code example to render the following output.

RTL support

Slider includes the Right to Left alignment support. Operations in the Slider is performed from Right to Left.

Enabling RTL

Use the EnableRTL property to enable the RTL support. By default this property is disabled. Data type of this property is “Boolean”.

The following steps explains you on how to enable RTL support in Slider.

1. In an VIEW page, specify the helper elements to render the Range Slider.

ASPX-CS

```
// Add this code in your view page
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("25,
75")
.Width("500").EnableRTL(true))
```

Execute the above code example to render the following output.

Keyboard Interaction

You can use Keyboard shortcut keys as an alternative to the mouse for using the Slider widget. All options in the Slider can be accessed using keyboard shortcuts. The following table explains the keyboard shortcut keys and the operations that can be performed using the corresponding keys.

List of Keyboard shortcuts

Shortcut Key	Description
AltÂ + j	Focuses into the Slider handle
Up/Right	Increments the Slider value
Down/Left	Decrements the Slider value
Home	Slider handle moves to the start value
End	Slider handle moves to the end value
Esc	Focuses out from the Slider handle

Configure keyboard interaction

The following steps explains you on how to enable keyboard support in Slider.

1. In an VIEW page, specify the helper elements to render the Range Slider.

ASPX-CS

```
// Add this code in your view page
@(Html.EJ().Slider("rangeSlider").SliderType(SlideType.Range).Values("25,
75")
.Width("500").EnableRTL(true))
// In JavaScript, Focus the Slider control in document key down function
<script>
$(document).on("keydown", function (e)
{
if (e.altKey && e.keyCode === 74)
{
// j- key code.
$("#rangeSlider a")[0].focus();
```

```
}
});
</script>
```

Run the sample and press, Alt + j keys to set focus in the Slider handle and you can handle the Slider operations using the keyboard shortcut keys.

When clicked the Alt + J key, the slider was focused.

Slider with Keyboard Interaction.

SpellCheck

SpellCheck

The ASP.NET MVC SpellCheck component provides all the functionalities that is available in EJ SpellCheck, since it is a server side wrapper of EJ SpellCheck widget. The ASP.NET MVC SpellCheck control helps to find and highlight misspelled words from a given content, typically by comparing it with a stored list of dictionary words.

Key Features

Some of the key features of SpellCheck are as follows,

- Custom Dictionary - Custom dictionary file is used to store and maintain your custom words like technical terms, brand names etc.
- Ignore Settings - Ignore words composed of alphanumeric characters, mixed case words, uppercase words, URL links, and file path.
- Ignore Words - Ignore a specific collection of words from the error word consideration.
- Customize Menu Items - Adding the user defined menu items in the context menu to correct the error words.
- Misspell Word Style - Highlight the erroneous word based on the user-customized style.
- Maximum Suggestion Count - Display a number of suggestions based on the user-specified count.

Getting Started

This section explains briefly about how to create a SpellCheck Control in your application with ASP.NET MVC

Create your first SpellCheck in MVC

Create a ASP.NET MVC Project and add necessary assemblies, CSS and scripts with the help of the given MVC-Getting Started documentation. After creating this project, you can create a SpellCheck in following ways.

SpellCheck Using Helper element

In the view page, add SpellCheck helper as shown below.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().SpellCheck("TextArea")
```

Service Reference

Assign the service method (CheckWords) path reference to the property dictionaryUrl, which is mandatory to check the spelling of the word.

The CheckWords method will perform the splitting of target sentence into separate words and check each word is that an erroneous or not. If the word is erroneous fetching the possible suggestions for it and returns those details as a result.

ASPX-CS

```
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords"))
```

Spell Checking

To spell check the content of the target element, you need to add one button and calling any one of the spell check method showInDialog or validate by clicking the button to highlight the error words.

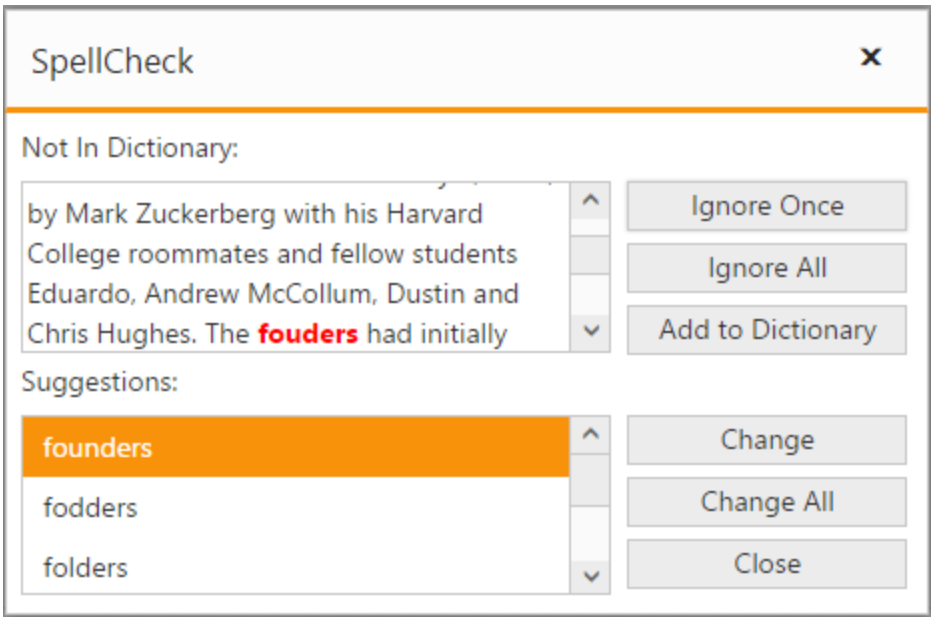
The following code example depicts that checking the spelling of the target element through the showInDialog method.

ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
Facebook is a social networking service headquartered in Menlo Park,
California. Its website was launched on February 4, 2004, by Mark
Zuckerberg with his Harvard College roommates and fellow students
Eduardo, Andrew McCollum, Dustin and Chris Hughes.
The founders had initially limited the websites membership to Harvard
students, but later expanded it to collages in the Boston area, the Ivy
League, and Stanford University. It gradually added support for students
at various other universities and later to high-school students.
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.showInDialog();
}
</script>
}
```

Once you have completed the above steps, you will get an output like below.

Copyright © 2001 - 2020 Syncfusion Inc.



Dependencies

To render the SpellCheck control, the following list of external dependencies are needed,

- jQuery - 1.7.1 and later versions

The other required internal dependencies are tabulated below,

File	Description/Usage
ej.core.min.js	Must be referred always first before using all the JS controls.
ej.data.min.js	Used to handle data operation and should be used while binding data to JS controls.
ej.spellcheck.min.js	spell check core script file.
ej.unobtrusive.min.js	Used to create our SpellCheck component with basic level HTML tag-like structure.
ej.scroller.js ej.button.js ej.dialog.js ej.menu.js ej.listbox.js ej.draggable.js	These files are referred for proper working of the sub-controls used within SpellCheck.

Copyright © 2001 - 2020 Syncfusion Inc.

ej.globalize.js	

Note: SpellCheck uses one or more sub-controls, therefore refer the ej.web.all.min.js (which encapsulates all the ej controls and frameworks in a single file) in the application instead of referring all the above specified internal dependencies.

To get the real appearance of the SpellChecker, the dependent CSS file ej.web.all.min.css (which includes styles of all the widgets) should also needs to be referred.

Dictionary

Essential ASP.NET MVC SpellCheck uses two different types of dictionary.

- Default Dictionary
- Custom Dictionary

Default Dictionary

The default dictionary is a primary dictionary file location to read the dictionary words for comparing it with the input words to identify its erroneous.

The following code example depicts the way to mention the default dictionary path and to read its content.

C#

```
SpellCheckController()
{
if (baseDictionary == null)
{
// Here you need to specify the corresponding file name (ex. Default.dic)
string filePath =
HttpContext.Current.Server.MapPath("~/App_Data/SpellCheck/Default.dic");
Stream stream = new FileStream(filePath, FileMode.Open, FileAccess.Read);
baseDictionary = new SpellCheckerBase(stream);
}
this.CustomFileRead();
}
```

Custom Dictionary

The custom dictionary is a collection of custom words that are used for spell checking (i.e. technical terms/words, company names, etc.,).

The following code example describes the way to mention the custom dictionary path to read its content.

C#

```
private readonly string _customFilePath =
HttpContext.Current.Server.MapPath("~/App_Data/SpellCheck/Custom.dic");
// Here you need to specify the corresponding custom dictionary file name
private void CustomFileRead()
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Stream stream1 = new FileStream(_customFilePath, FileMode.Open,
FileAccess.ReadWrite);
customDictionary = new SpellCheckerBase(stream1);
}
```

Note: The custom words will be displayed within the custom dictionary file line by line (i.e. one word per line).

Add a Word to Custom dictionary

You can directly add the necessary words in the custom dictionary file or else by using the SpellCheck control public method addToDictionary to add the custom words one by one.

Operations

Essential SpellCheck provides two ways to perform the spell check operation(error correction). They are,

- Dialog Mode
- Context Menu Mode

Dialog Mode

Description

SpellCheck provides the dialog mode option to perform the following spell check operations.

- Ignore Once
- IgnoreAll
- Change
- ChangeAll
- Add to Dictionary

Open Dialog Mode

The following code snippet shows how to open the dialog to spell check the content.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.showInDialog();
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Handling Dialog Actions

To define the specific actions before the dialog window open, the client-side event dialogBeforeOpen can be used as depicted in the below code example.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords")).ClientSideEvents(event =>
event.DialogBeforeOpen("onDialogBeforeOpen"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.showInDialog();
}
function onDialogBeforeOpen(args) {
if (args.requestType == "dialogBeforeOpen")
{
alert("dialog before open event triggered");
}
}
</script>
```

The client-side event dialogOpen can be used to define the specific actions after the dialog window open as shown in the following code example.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords")).ClientSideEvents(event =>
event.DialogOpen("onDialogOpen"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.showInDialog();
}
function onDialogOpen(args) {
if (args.requestType == "dialogOpen")
{
alert(args.targetText);
} }
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example used to define some actions after the dialog closing by using the client-side event dialogClose.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords")).ClientSideEvents(event =>
event.DialogClose("onDialogClose"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.showInDialog();
}
function onDialogClose(args) {
if (args.requestType == "dialogClose")
{
alert(args.updatedText);
} }
</script>
```

It is possible to predict the error word details before starting the spell check operations through dialog mode by using the client side event start. The below code example describes the above behavior.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords")).ClientSideEvents(event =>
event.Start("onSpellCheckStart"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.showInDialog();
}
function onSpellCheckStart(args) {
if (args.requestType == "spellCheckDialog")
{
alert(args.errorWords);
} }
</script>
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

You can get the corrected text content details before updating it into target element with the help of the client side event complete as mentioned in the below code example.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords")).ClientSideEvents(event =>
event.Complete("onCheckComplete"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.showInDialog();
}
function onCheckComplete(args) {
if (args.requestType == "changeErrorWord")
{
alert(args.targetText);
} }
</script>
```

Context Menu Mode

SpellCheck provides default context menu options to perform the spell check operations. It also allows to define additional custom context menu options.

The options that are available under contextMenuSettings are as follows,

- enable - Enables/disables the context menu option in SpellCheck.
- menuItems - Contains the options to perform spell check operations.

Default Menu Options

The menu items contains the following options to perform the spell check operation.

- IgnoreAll
- Add to Dictionary

The following code snippet shows how to enable the context menu settings in SpellCheck and to make use of it with default available options.

ASPX-CS

```
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords")).ContextMenuSettings(items=>items.Enable(t
rue).MenuItems(menuItem=>menuItem.ID("IgnoreAll").Text("Ignore All")))
```

Copyright © 2001 - 2020 Syncfusion Inc.

Note: For default menu items, the id must be defined the same as mentioned in the above code example – as we have processed the menus based on this id within our source.

Custom Menu Options

Apart from the default available options, it is also possible to add custom menu options to the context-menu list.

The following code example depicts how to add the custom menu items into the context menu settings.

ASPX-CS

```
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords")).ContextMenuSettings(items=>items.Enable(t
rue).MenuItems(menuItem=>menuItem.ID("IgnoreAll").Text("Ignore All")))
```

Note: The id given for the custom menu items must be unique.

Handling Menu Actions

The client-side event contextClick can be used to define specific actions when a click made on the custom menu items. The following code example describes the above behavior.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords")).ContextMenuSettings(items =>
items.Enable(true).MenuItems(menuItem =>
menuItem.ID("IgnoreAll").Text("Ignore All"))).ClientSideEvents(events =>
events.ContextClick("onCustomMenuClick"))
}
@section ScriptSection{
<script type="text/javascript">
function onCustomMenuClick(args) {
if (args.selectedOption == "Ignore")
{
alert("Custom menu clicked");
} }
</script>
```

It is possible to predict the target (error word) on which the right click is made with the use of the event contextOpen. The below code example shows how to block the display of context menu, when right clicked on the word by setting args.cancel as true.

ASPX-CS

```
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords")).ContextMenuSettings(items =>
items.Enable(true).MenuItems(menuItem =>
menuItem.ID("IgnoreAll").Text("Ignore All"))).ClientSideEvents(events =>
events.ContextOpen("onContextOpen"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@section ScriptSection{
<script type="text/javascript">
function onContextOpen (args) {
if (args.selectedOption == "Ignore")
{
alert("Custom menu clicked");
} }
</script>
```

You can get the current spell check operation arguments details with the client-side event validating. The following code example describes the way to block the ignoreAll operation for the particular word.

ASPX-CS

```
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary  =>
dictionary
.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUrl("
../api/SpellCheck/CheckWords")).ContextMenuSettings(items =>
items.Enable(true).MenuItems(menuItem =>
menuItem.ID("IgnoreAll").Text("Ignore All"))).ClientSideEvents(events =>
events.Validating("onSpellChecking"))
@section ScriptSection{
<script type="text/javascript">
function onSpellChecking (args) {
if (args.selectedOption == "Ignore")
{
alert("Custom menu clicked");
} }
</script>
```

Functionalities

Check Spelling

The main functionality of the SpellCheck control is checking the spelling of a word and returns the suggestions for an error word.

For example, if you pass the sentence that contains misspell words as input, you can know the error words in this sentence and its suggestions (apt words to replace).

Ignore Words

The SpellCheck control provides the support to ignore the words from an error word consideration and also to ignore an error words whenever needed. Please refer the following options to ignore the words.

Ignore

The ignore option is used to ignore a specific word once from the given input string.

The following code example describes the above method implementation.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
@section ScriptSection{
<script type="text/javascript">
var target = 'The first <span class="errorspan e-
errorword">textarea</span> <span class="errorspan e-
errorword">sample</span> uses a dialog <span class="errorspan e-
errorword">textarea</span> to display the <span class="errorspan e-
errorword">sample</span> spell <span class="errorspan e-
errorword">textarea</span> errors';
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
var targetIgnoreContent = spellObj.ignore("textarea", target, null);
}
</script>
}
```

IgnoreAll

The ignoreAll option is used to ignore all the error word occurrences from the given input string.

The following code example describes the way of using ignore all method.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
var target = 'The first <span class="errorspan e-
errorword">textarea</span> <span class="errorspan e-
errorword">sample</span> uses a dialog <span class="errorspan e-
errorword">textarea</span> to display the <span class="errorspan e-
errorword">sample</span> spell <span class="errorspan e-
errorword">textarea</span> errors';
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
var targetIgnoreContent = spellObj.ignoreAll("textarea", target, null);
}
</script>
}
```

Word Collection to Ignore

The ignore words option is used to ignore the collection of words from an error word checking. You can pass the technical terms, brand names which is not present in the dictionary file to this property ignoreWords as shown in the following code example and then while checking the spelling these passed words are considered as a correct word.

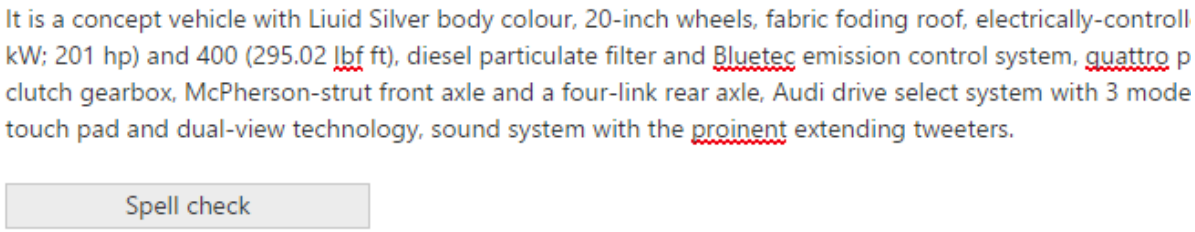
ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
It is a concept vehicle with Liquid Silver body color, 20-inch wheels,
fabric folding roof, electrically-controlled hood,
4-cylinder 2.0 TDI engine rated 204 PS (150 kW; 201 hp) and 400 (295.02
lbf ft), diesel particulate filter and Bluetech emission control system,
quattro permanent four-wheel drive system, Audi S tronic dual-clutch
gearbox, McPherson-strut front axle and a four-link rear axle, Audi drive
select system with 3 modes (dynamic, sport, efficiency),
MMI control panel with touch pad and dual-view technology, sound system
with the prominent extending tweeters JavaScript TypeScript .
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords")).ContextMenuSettings(context =>
context.Enable(true)).IgnoreWords(@ViewBag.datasource)
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check").ClientSideEvents(event => event.Click("contextMenu"))
}
@section ScriptSection{
<script type="text/javascript">
function contextMenu() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.validate();
}
</script>
}
public ActionResult ContextMenu()
{
string[] spellIgnoreWords = { "color", "Liquid", "folding" };
ViewBag.datasource = spellIgnoreWords;
return View();
}
```

Once you have run the above code, you get an output like below.



Ignore Settings

The ignore settings helps to ignore the uppercase, mixed case words, alphanumeric words, file path and email addresses from the error word checking. Ignore settings contains the following options to ignore the words based on their category.

Copyright © 2001 - 2020 Syncfusion Inc.

- ignoreAlphaNumericWords - ignoring the alpha numeric words from an error word consideration.
- ignoreUpperCase - ignoring the upper case words from an error word consideration.
- ignoreMixedCaseWords - ignoring the mixed case words from an error word consideration.
- ignoreFileNames - ignoring the file address path from an error word consideration.
- ignoreUrl - ignoring the url links from an error word consideration.
- ignoreEmailAddress - ignoring the email address from an error word consideration.

The following code example uses to enable the checking of all the words formed with alphanumeric, uppercase, mixed case words and file paths and email addresses.

ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
It is a concept vehicle with Liquid Silver body color, 20-inch wheels,
fabric folding roof, electrically-controlled hood,
4-cylinder 2.0 TDI engine rated 204 PS (150 kW; 201 hp) and 400 (295.02
lbf ft), diesel particulate filter and Bluetech emission control system,
quattro permanent four-wheel drive system, Audi S tronic dual-clutch
gearbox, McPherson-strut front axle and a four-link rear axle, Audi drive
select system with 3 modes (dynamic, sport, efficiency),
MMI control panel with touch pad and dual-view technology, sound system
with the prominent extending tweeters.
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords")).ContextMenuSettings(context =>
context.Enable(true)).IgnoreSettings(ignore=>ignore.IgnoreAlphaNumericWor
ds(false).IgnoreEmailAddress(false).IgnoreFileNames(false).IgnoreHtmlTags
(false).IgnoreMixedCaseWords(false).IgnoreUpperCase(false).IgnoreUrl(fals
e))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check").ClientSideEvents(event => event.Click("contextMenu"))
}
@section ScriptSection{
<script type="text/javascript">
function contextMenu () {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.validate();
}
</script>
}
```

Change Words

The SpellCheck control provides the support to change an error words from its possible suggestions. Please refer the following options to change an error word.

Change

The change option is used to replace an error word occurrences once from the given input string with the correct word.

The following code example describes the behavior of change method.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
var target = 'The first <span class="errorspan e-
errorword">textarea</span> <span class="errorspan e-
errorword">sample</span> uses a dialog <span class="errorspan e-
errorword">textarea</span> to display the <span class="errorspan e-
errorword">sample</span> spell <span class="errorspan e-
errorword">textarea</span> errors';
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
var targetChangeContent = spellObj.change("textarea", target,"text
area",null);
}
</script>
}
```

ChangeAll

The changeAll option is used to replace all the occurrences of an error word with the correct word(selected from the suggestions list) from the given inputs string.

The following code example uses to change all the error word occurrences.

ASPX-CS

```
@section ControlsSection{
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords"))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
var target = 'The first <span class="errorspan e-
errorword">textarea</span> <span class="errorspan e-
errorword">sample</span> uses a dialog <span class="errorspan e-
errorword">textarea</span> to display the <span class="errorspan e-
errorword">sample</span> spell <span class="errorspan e-
errorword">textarea</span> errors';
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
var targetChangeAllContent = spellObj.changeAll("textarea", target,"text
area", null);
}
</script>
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Custom Words

The SpellCheck control provides the support to add the custom words into the custom dictionary file.

The addToDictionary option is used to add the custom words into the custom dictionary file.

The following code example uses to add the custom word into the custom dictionary file.

ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
It is a concept vehicle with Liquid Silver body color, 20-inch wheels,
fabric folding roof, electrically-controlled hood,
4-cylinder 2.0 TDI engine rated 204 PS (150 kW; 201 hp) and 400 (295.02
lbf ft), diesel particulate filter and Bluetech emission control system,
quattro permanent four-wheel drive system, Audi S tronic dual-clutch
gearbox, McPherson-strut front axle and a four-link rear axle, Audi drive
select system with 3 modes (dynamic, sport, efficiency),
MMI control panel with touch pad and dual-view technology, sound system
with the prominent extending tweeters.
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords")).ContextMenuSettings(context =>
context.Enable(true)).IgnoreSettings(ignore=>ignore.IgnoreAlphaNumericWor
ds(false).IgnoreEmailAddress(false).IgnoreFileNames(false).IgnoreHtmlTags
(false).IgnoreMixedCaseWords(false).IgnoreUpperCase(false).IgnoreUrl(fals
e))
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.addToDictionary("Liquid");
}
</script>
}
```

You can also add the custom words into the custom dictionary file through the dialog mode or context menu mode add to dictionary option.

- Dialog Mode - Add To Dictionary button will be available in the dialog window, while checking the error in the given input string and clicking this button then the word will be added into the custom dictionary file.
- Context Menu Mode - Add To Dictionary option will be available in the context menu while right click on the error word in the target area and clicking this option then the word will be added into the custom dictionary file.

Checking content on typing

SpellCheck control provides support for checking the content, on pressing the Enter and Space key. The cursor position will also be properly retained, while processing the SpellCheck operations. If you enable “enableValidateOnType” property, the spellcheck operation will be carried out on typing.

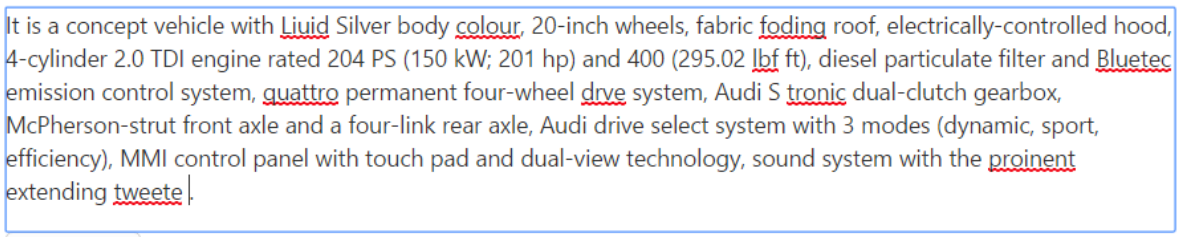
Copyright © 2001 - 2020 Syncfusion Inc.

The following code example describes the above behavior.

ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
It is a concept vehicle with Liquid Silver body color, 20-inch wheels,
fabric folding roof, electrically-controlled hood,
4-cylinder 2.0 TDI engine rated 204 PS (150 kW; 201 hp) and 400 (295.02
lbf ft), diesel particulate filter and Bluetech emission control system,
quattro permanent four-wheel drive system, Audi S tronic dual-clutch
gearbox, McPherson-strut front axle and a four-link rear axle, Audi drive
select system with 3 modes (dynamic, sport, efficiency),
MMI control panel with touch pad and dual-view technology, sound system
with the prominent extending tweeters.
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dic =>
dic.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUr
l("../api/SpellCheck/CheckWords")).ContextMenuSettings(context =>
context.Enable(true)).EnableValidateOnType(true)
}
```

The following screenshot displays the output for the above code



You can also validate the content within the IFrame element or IFrame element target text, by passing the IFrame element id or class name value to the controlsToValidate property.

Detailed information is given here

Suggestion Words

The getSuggestionWords option is used to retrieve the possible suggestion words for an error word which is provided to correct that spelling.

The following code example describes the above behavior.

ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
It is a concept vehicle with Liquid Silver body color, 20-inch wheels,
fabric folding roof, electrically-controlled hood,
4-cylinder 2.0 TDI engine rated 204 PS (150 kW; 201 hp) and 400 (295.02
lbf ft), diesel particulate filter and Bluetech emission control system,
quattro permanent four-wheel drive system, Audi S tronic dual-clutch
gearbox, McPherson-strut front axle and a four-link rear axle, Audi drive
select system with 3 modes (dynamic, sport, efficiency),
MMI control panel with touch pad and dual-view technology, sound system
with the prominent extending tweeters.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dic =>
dic.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUr
l("../api/SpellCheck/CheckWords"))
}
@section ScriptSection{
<script type="text/javascript">
$( document ).ready(function() {
var spellObj = $("#SpellCheck").data("ejSpellCheck");
spellObj.getSuggestionWords("textarea");
setTimeout(()=>{
alert(spellObj._suggestedWords);
},800);
});
</script>
}
```

Note: You can get the suggestion words after some time interval once this method is called. Since, AJAX request processing takes place in the background.

Synchronous request

On setting enableAsync option to false, enables the synchronous request to the server to perform SpellCheck operations.

The following code example describes the above behavior.

ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
It is a concept vehicle with Liquid Silver body color, 20-inch wheels,
fabric folding roof, electrically-controlled hood,
4-cylinder 2.0 TDI engine rated 204 PS (150 kW; 201 hp) and 400 (295.02
lbf ft), diesel particulate filter and Bluetech emission control system,
quattro permanent four-wheel drive system, Audi S tronic dual-clutch
gearbox, McPherson-strut front axle and a four-link rear axle, Audi drive
select system with 3 modes (dynamic, sport, efficiency),
MMI control panel with touch pad and dual-view technology, sound system
with the prominent extending tweeters.
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dic =>
dic.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").DictionaryUr
l("../api/SpellCheck/CheckWords")).EnableAsync(false).AjaxDataType("json"
)
}
```

Note: You need to set the ajaxDataType value as json to retrieve the synchronous request result properly.

Customization

The Essential ASP.NET MVC SpellCheck provides option to customize for the following scenarios.

- Misspell Word Appearance
- Restrict Suggestion Count

Copyright © 2001 - 2020 Syncfusion Inc.

Misspell Word Appearance

The SpellCheck control provide the support(misspellWordCss) to display the error word in user defined style. By default displaying the error words with the red underline.

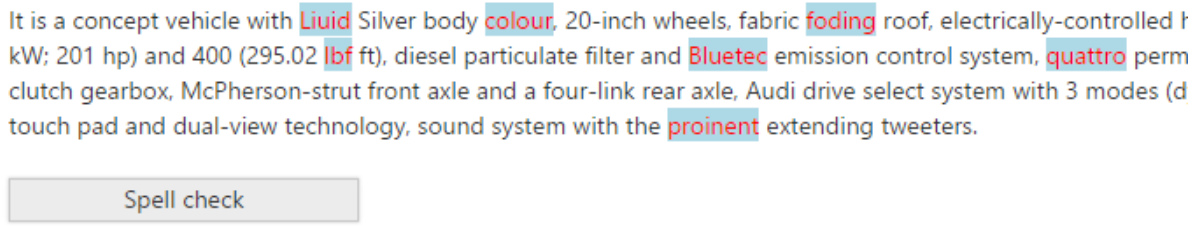
The following code example depicts the way to customize the error word highlight (displaying error word with red color font and lightblue background).

ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
It is a concept vehicle with Liquid Silver body color, 20-inch wheels,
fabric folding roof, electrically-controlled hood,
4-cylinder 2.0 TDI engine rated 204 PS (150 kW; 201 hp) and 400 (295.02
lbf ft), diesel particulate filter and Bluetech emission control system,
quattro permanent four-wheel drive system, Audi S tronic dual-clutch
gearbox, McPherson-strut front axle and a four-link rear axle, Audi drive
select system with 3 modes (dynamic, sport, efficiency),
MMI control panel with touch pad and dual-view technology, sound system
with the prominent extending tweeters.
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords")).MisspellWordCss("highlight")
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check").ClientSideEvents(event => event.Click("contextMenu"))
}
@section ScriptSection{
<script type="text/javascript">
function contextMenu () {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.validate();
}
</script>
}
@section StyleSection{
<style>
.highlight {
background-color: lightblue;
color: red;
}
</style>
}
```

Once you have run the above code, you get an output like below.

Copyright © 2001 - 2020 Syncfusion Inc.



Restrict Suggestion Count

The SpellCheck control provides option (maxSuggestionCount) to restrict the count that the number of items displayed in the suggestion list.

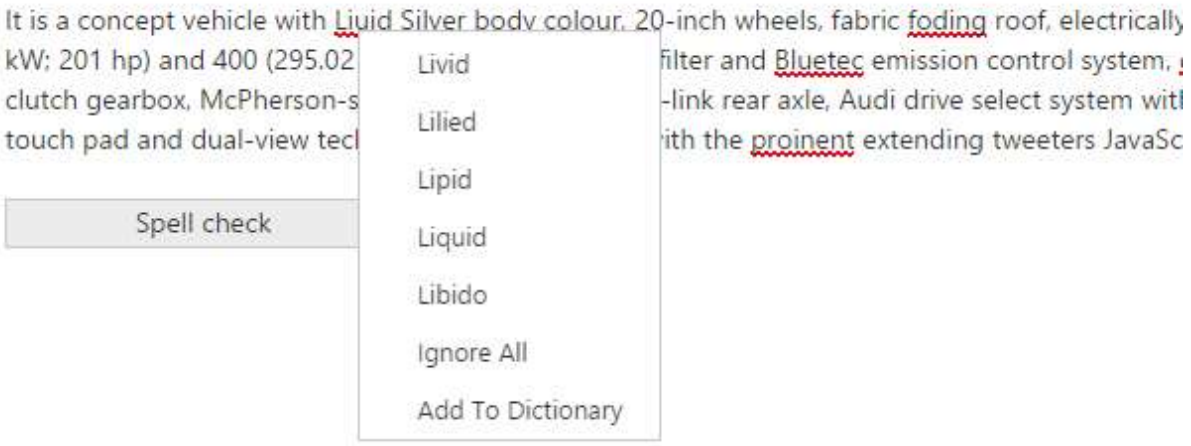
The following code example describes the way to control the suggestion count.

ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
It is a concept vehicle with Liquid Silver body color, 20-inch wheels,
fabric folding roof, electrically-controlled hood,
4-cylinder 2.0 TDI engine rated 204 PS (150 kW; 201 hp) and 400 (295.02
lbf ft), diesel particulate filter and Bluetech emission control system,
quattro permanent four-wheel drive system, Audi S tronic dual-clutch
gearbox, McPherson-strut front axle and a four-link rear axle, Audi drive
select system with 3 modes (dynamic, sport, efficiency),
MMI control panel with touch pad and dual-view technology, sound system
with the prominent extending tweeters.
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords")).MaxSuggestionCount(5)
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check").ClientSideEvents(event => event.Click("contextMenu"))
}
@section ScriptSection{
<script type="text/javascript">
function contextMenu () {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.validate();
}
</script>
}
```

Once you have run the above code, you get an output like below.

Copyright © 2001 - 2020 Syncfusion Inc.



Localization

SpellCheck dialog mode comes with default localization support which allows it to customize the display of text within the SpellCheck dialog in a user-specific culture and locale. The SpellCheck control can be localized in specific culture using the common API locale along with the collection of localized words defined for that culture using the ej.SpellCheck.Locale [**culture-code**].

By default, the SpellCheck control is localized in **en-US** culture. Please find the following table lists the default keywords and its localized text values for en-US culture.

Locale key words	Text
SpellCheckButtonText	SpellCheck
NotInDictionary	Not in Dictionary
SuggestionLabel	Suggestions
IgnoreOnceButtonText	Ignore Once
IgnoreAllButtonText	Ignore All
AddToDictionary	Add to Dictionary
ChangeButtonText	Change
ChangeAllButtonText	Change All
CloseButtonText	Close
CompletionPopupMessage	Spell check is complete
CompletionPopupTitle	Spell check alert
OK	OK

Copyright © 2001 - 2020 Syncfusion Inc.

NoSuggestionMessage	No suggestions available

To localize SpellCheck into any particular culture, it is necessary to refer the culture-specific script files in your application after the reference of **ej.web.all.min.js** file, which are available under the following location.

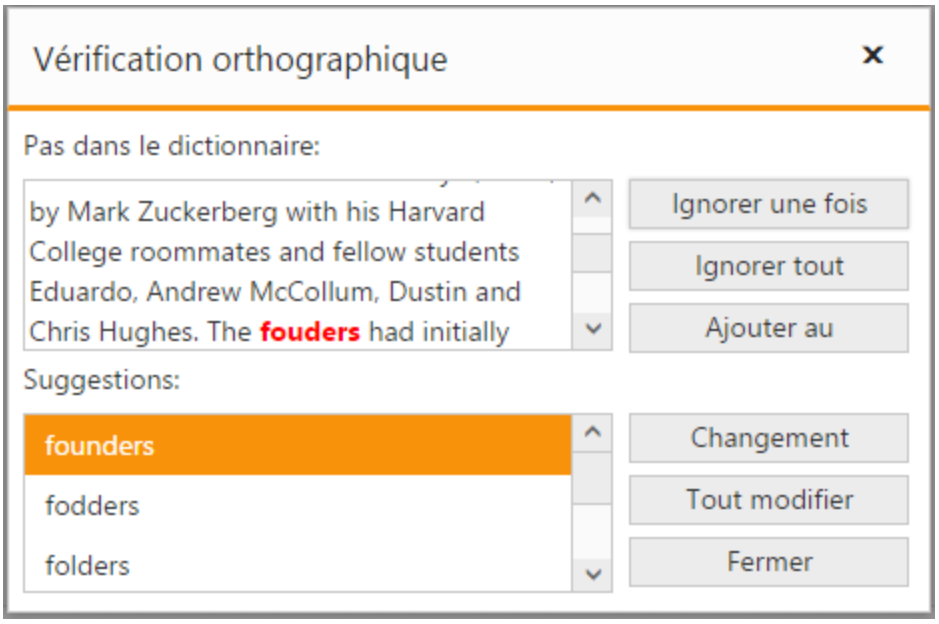
<Installed location>\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n

The following code example shows how to localize the SpellCheck control in **fr-FR** culture.

ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
Facebook is a social networking service headquartered in Menlo Park,
California. Its website was launched on February 4, 2004, by Mark
Zuckerberg with his Harvard College roommates and fellow students
Eduardo, Andrew McCollum, Dustin and Chris Hughes.
The founders had initially limited the websites membership to Harvard
students, but later expanded it to collages in the Boston area, the Ivy
League, and Stanford University. It gradually added support for students
at various other universities and later to high-school students.
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords")).Locale("fr-FR")
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
ej.SpellCheck.Locale["fr-FR"] = {
SpellCheckButtonText: "Vrification orthographique",
NotInDictionary: "Pas dans le dictionnaire",
SuggestionLabel: "Suggestions",
IgnoreOnceButtonText: "Ignorer une fois",
IgnoreAllButtonText: "Ignorer tout",
AddToDictionary: "Ajouter au dictionnaire",
ChangeButtonText: "Changement",
ChangeAllButtonText: "Tout modifier",
CloseButtonText: "Fermer",
CompletionPopupMessage: "Vrification orthographique est termine",
ErrorPopupMessage: "Vrification orthographique est pas termine",
CompletionPopupTitle: "Vrification orthographique alerte",
OK: "D'accord",
NoSuggestionMessage: "Aucune suggestion disponible",
};
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.showInDialog();
}
</script>
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Note: Refer the **ej.culture.fr-FR.min.js** file in your HTML application and also define the **locale** property for the SpellCheck control with the appropriate **culture-code** [**fr-FR**].

For further information on how to refer the required culture scripts into your application, refer here.

Localizing Specific Words

To customize or localize only some specific words in the default ej.SpellCheck.Locale["en-US"] collection, the words to be localized/customized can be defined in a separate variable and then extended to the original collection as depicted in the following code example.

ASPX-CS

```
@section ControlsSection{
<div id="TextArea" contenteditable="true" name="sentence">
Facebook is a social networking service headquartered in Menlo Park,
California. Its website was launched on February 4, 2004, by Mark
Zuckerberg with his Harvard College roommates and fellow students
Eduardo, Andrew McCollum, Dustin and Chris Hughes.
The founders had initially limited the websites membership to Harvard
students, but later expanded it to collages in the Boston area, the Ivy
League, and Stanford University. It gradually added support for students
at various other universities and later to high-school students.
</div><br />
@Html.EJ().SpellCheck("TextArea").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords")).Locale("fr-FR")
@Html.EJ().Button("SpellCheck").Width("200px").Height("25px").Text("Spell
check using dialog").ClientSideEvents(event => event.Click("showDialog"))
}
@section ScriptSection{
<script type="text/javascript">
var customizationMessage = { CompletionPopupMessage: "Completed", };
$.extend(ej.SpellCheck.Locale["en-US"], customizationMessage);
function showDialog() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.showInDialog();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
</script>
}
```

Multiple Targets

The SpellCheck control has support for multiple target HTML element's texts spelling and correct its error words. This can be achieved by passing the target HTML elements “id” values to the property “ControlsToValidate”.

You can spell check most of the HTML element’s texts such as div, span, textarea, input, address and article by using this property.

The multiple target HTML element supports in both the modes.

- Dialog Mode
- Context Menu Mode

The following code example describes the above behavior.

ASPX-CS

```
@section ControlsSection{
<div id="control1">
London, one of the most popular tourist destinations in the world for a
reason. A cultural and historical hub, London has an excellent public
transportation system that allows visitors to see all the fantastic
sights without spending a ton of money on a rental car.
London contains four World Heritage Sites.
</div><br />
<textarea id="control2" style="width:940px">
Paris, the city of lights and love - this short guide is full of ideas
for how to make the most of the romanticism that oozes from every one of
its beautiful corners.You couldn't possibly visit Rome, one of the
world's most fascinating cities. The old adage that Rome was not built in
a day - and that you won't see it in one or even in three - is true. For
the intrepid traveler who can keep pace, here is a list of must-sees.
But remember what the Romans say: Even a lifetime isn't enough to see
Rome.
</textarea><br />
<span id="control3">
Rome, one of the world's most fascinating cities. The old adage that Rome
was not built in a day - and that you won't see it in one or even in
three - is true. For the intrepid traveler who can keep pace, here is a
list of must-sees.
But remember what the Romans say: Even a lifetime isn't enough to see
Rome.
</span><br /><br />
@Html.EJ().SpellCheck("TextArea").ControlsToValidate("control1,control2,c
ontrol3").DictionarySettings(dictionary =>
dictionary.CustomDictionaryUrl("../api/SpellCheck/AddToDictionary").Dicti
onaryUrl("../api/SpellCheck/CheckWords"))
@Html.EJ().Button("SpellCheck").Text("Spell check using
dialog").ClientSideEvents(event => event.Click("showDialog"))
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Note: You need to pass the target HTML element's id value with the comma separator. For example, in the above code example passed id values of div(control1), textarea(control2) and span(control3) element.

Dialog Mode

If the user specifies multiple targets in ControlsToValidate property, the control must loop through the multiple HTML target elements one by one in the order which they are specified and process of every individual target' content.

ASPX-CS

```
@section ControlsSection{
<div id="control1">

function showContextMenu() {
var spellObj = $("#TextArea").data("ejSpellCheck");
spellObj.validate();
}
</script>
}
```

Note: We couldn’t highlight the error word in the target element itself, while checking the elements that doesn’t support the html or innerHTML value.

Responsiveness

The SpellCheck control has support for responsive behavior based on client browser’s width and height. To enable responsive, IsResponsive property should be true.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example describes the above behavior.

ASPX-CS

```
@section ControlsSection{<div id="TextArea" contenteditable="true"
name="sentence">
Facebook is a social networking service headquartered in Menlo Park,
California. Its website was launched on February 4, 2004, by Mark

SplitButton

SplitButton

The Split Button allows you to perform an action by clicking the button and choosing extra options from the dropdown button. The SplitButton can also display both text and images. By default the DropDown button is given to the right most corner of the button.

Key Features

- Trendy Look : Rich Appearance with Theme Support
- RTL : Supports for Right to Left alignment
- Text and Image : Supports both text and image as Split Button content
- Built-in Icon :Supports the built-in icon libraries
- Easy Customization: The customization of Split Button control to any form is made simple

Getting Started

This section explains briefly about how to create a Split Button in ASP.NET MVC application.

Copyright © 2001 - 2020 Syncfusion Inc.

Create your first Split Button in MVC

The HTML button element and the <UL>, <LI> can be easily configured as Essential ASP.NET MVC Split Button control. The basic rendering of Essential ASP.NET MVC Split Button is achieved by using default functionality. Initially the TargetID is a mandatory one, without this field it acts as normal button on two sides.

Create Split Button Control in MVC

Essential ASP.NET MVC Split Button control contains built-in features such as Click and different option choosing. You can easily create the Split Button control by using HTML helper as follows.

1. You can create an MVC Project and add necessary assemblies, styles and scripts to it. Refer MVC-Getting Started.
2. Add the following code to the corresponding View page to render Split Button.

ASPX-CS

```
@Html.EJ().SplitButton("splitButton").Text("Save").ShowRoundedCorner(true
).Size(ButtonSize.Large).TargetID("target")
```

3. Add the following

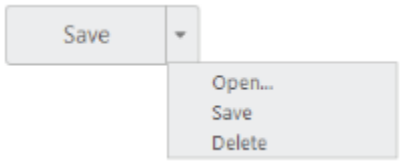
,

- elements to render Split Button with popup option.

ASPX-CS

```
<ul id="target">
<li><span>Open</span></li>
<li><span>Save</span></li>
<li><span>Delete</span></li>
</ul>
```

Output of the above scripts,



Easy customization

Split Button is used in many applications. Split Button Size, images and Content are varied according to each application. The following sections describes you some customizable options for Split Button that can perform easily.

Content for Split button

The TargetId is a mandatory one, without this field it acts as normal button on two sides. This TargetId property is used to specify the list of content for Split Button. The list of content is rendered as a vertical menu list. This vertical menu list is open, when you click on the down arrow of the Split Button.

Copyright © 2001 - 2020 Syncfusion Inc.

The following script explains you the details about rendering the Split Button with content.

1. In the VIEW page, add the following button elements to configure Split Button widget.

ASPX-CS

```
@*Add the code in the CSHTML page to configure and initialize the
control*@
@*Set the content for split button control as follows. *@
<div class="control">
<div class="spltspan">
@Html.EJ().SplitButton("splitButton").Text("login").Size(ButtonSize.Small
).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).PrefixIco
n("e-icon e-
login").ImagePosition(ImagePosition.ImageLeft).TargetID("Ul11")
<ul id="Ul11">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</div>
</div>
```

Execute the above code to render the following output.

Button Size

You can render the Split Button in different sizes by using Size property. The following table contains some predefined size option for rendering a Split Button in easiest way. Each size option has different height and width. Mainly it avoids the complexity in rendering Split Button with complex CSS class.

List of Button size

Normal	Creates split button with content size.
Mini	Creates split button with Built-in mini size height, width specified.
Small	Creates split button with Built-in small size height, width specified.
Medium	Creates split button with Built-in medium size height, width specified.
Large	Creates split button with Built-in large size height, width specified.

Apart from the above mentioned predefined size option, you can set your own width and height for Split Button using Height and Width property.

Copyright © 2001 - 2020 Syncfusion Inc.

The following steps explains you the details about rendering the Split Button with above mentioned Size options.

1. In the View page, add the following button elements to configure Split Button widget.

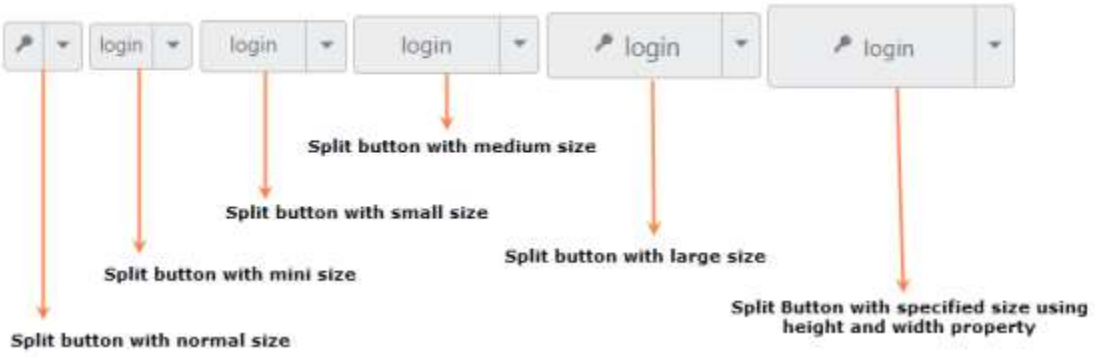
ASPX-CS

```
@*Add the code in the CSHTML page to configure and initialize the
control*@
@*Set the different size types for split button control as follows. *@
<div class="control">
<table>
<tr>
<td class="btnsht">
<div class="spltspan">
@Html.EJ().SplitButton("splitButton_normal").Text("login").ShowRoundedCor
ner(true).Size(ButtonSize.Normal).ContentType(ContentType.ImageOnly).Pref
ixIcon("e-icon e-login").TargetID("Ul11")
<ul id="Ul11">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</div>
</td>
<td>
@Html.EJ().SplitButton("splitButton_mini").Text("login").ShowRoundedCorne
r(true).Size(ButtonSize.Mini).TargetID("Ul21")
<ul id="Ul21">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_small").Text("login").ShowRoundedCorn
er(true).Size(ButtonSize.Small).TargetID("Ul31")
<ul id="Ul31">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_medium").Text("login").ShowRoundedCor
ner(true).Size(ButtonSize.Medium).TargetID("Ul41")
<ul id="Ul41">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_large").Text("login").ShowRoundedCorn
er(true).Size(ButtonSize.Large).ContentType(ContentType.TextAndImage).Pre
fixIcon("e-icon e-login").TargetID("Ul51")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<ul id="Ul51">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_customSize").Text("login").ShowRounde
dCorner(true).ContentType(ContentType.TextAndImage).PrefixIcon("e-icon e-
login").TargetID("Ul61").Height("50").Width("150")
<ul id="Ul61">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
</tr>
</table>
</div>
```

Execute the above code to render the following output.



ContentType

The content of the Split Button is mainly rendered as text and images. Instead of using complex CSS classes to render Split Button with different content types, you can use some predefined content type options listed in the following table. Using this ContentType property you can easily add different types of content for Split Button. Split Button supports the following content types.

List of content types

TextOnly	Supports only for text content only.
ImageOnly	Supports only for image content only
ImageBoth	Supports image for both ends of the button.
TextAndImage	Supports image with the text content.
ImageTextImage	Supports image with both ends and middle in text.

Copyright © 2001 - 2020 Syncfusion Inc.

Prefix and Suffix icons

Icons inside the Split Button is added easily using PrefixIcon and SuffixIcon property. Location of the icon in Split Button is a necessary thing. You can customize the location of Icon easily using the following mentioned options.

Split Button control also supports the Built-in icon libraries. The ej.widgets.core.min.css contains definitions for important icons that are used in Split Buttons. You can use these Built-in icons by mentioning the icon class name as value in PrefixIcon and SuffixIcon property. You can use any font icons that is defined in ej.widgets.core.min.css. It avoids the complexity in specifying icon using sprite image and CSS.

For example the following Built-in CSS classes are used to display the font icons that is used by media player.

- e-mediaback
- e-mediaforward
- e-medianext
- e-mediaprev
- e-mediaeject
- e-mediaclose
- e-mediapause
- e-mediaplay

Prefix Icon

It inserts the icon at the starting position of Split Button. After this prefix icon, you can use text or suffix icon.

Suffix Icon

It inserts the icon at the ending position of Split Button. Before this SuffixIcon, you can use Text or PrefixIcon.

The following steps explains you the details on rendering the Split Button with ContentType, PrefixIcon and SuffixIcon options

1. In the VIEW page, add the following button elements to configure Split Button widget.

ASPX-CS

```
//Add the code in the CSHTML page to configure and initialize the control
@*Set the different content types and use the necessary built-in icons
for split button control as follows.*@
<div class="control">
<table>
<tr>
<td class="btnsht">
<div class="spltspan">
@Html.EJ().SplitButton("splitButton_imageOnly").Text("login").Size(Button
Size.Medium).ShowRoundedCorner(true).ContentType(ContentType.ImageOnly).P
refixIcon("e-icon e-handup").TargetID("Ul11")
<ul id="Ul11">
<li><span>User</span></li>
<li><span>Guest</span></li>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<li><span>Admin</span></li>
</ul>
</div>
</td>
<td>
@Html.EJ().SplitButton("splitButton_textOnly").Text("login").Size(ButtonS
ize.Medium).ShowRoundedCorner(true).ContentType(ContentType.TextOnly).Tar
getID("Ul21")
<ul id="Ul21">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_imageBoth").Text("login").Size(Button
Size.Medium).ShowRoundedCorner(true).ContentType(ContentType.ImageBoth).P
refixIcon("e-icon e-handup").SuffixIcon("e-icon e-
palette").TargetID("Ul31")
<ul id="Ul31">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_textAndImage").Text("login").Size(But
tonSize.Medium).ShowRoundedCorner(true).ContentType(ContentType.TextAndIm
age).PrefixIcon("e-icon e-handup").TargetID("Ul41")
<ul id="Ul41">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_imageTextImage").Text("login").Size(B
uttonSize.Medium).ShowRoundedCorner(true).ContentType(ContentType.ImageTe
xtImage).PrefixIcon("e-icon e-handup").SuffixIcon("e-icon e-
palette").TargetID("Ul51")
<ul id="Ul51">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
</tr>
</table>
</div>
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

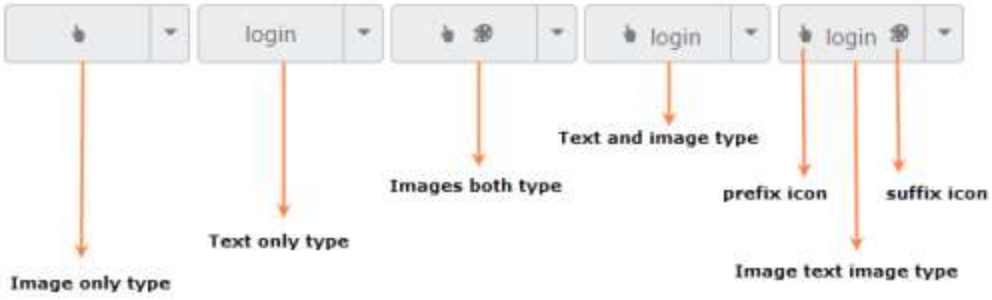


Image Position

To provide the best look and feel for Split Button, position of images in Split Button is important. Using ImagePosition property, you can easily customize the position of images inside Split Button without using any complex CSS. ImagePosition property is applicable only with the TextAndImage content type property. This property represent the position of images with respect to text.

ImageLeft	Support for aligning text in right and image in left.
ImageRight	Support for aligning text in left and image in right.
ImageTop	Support for aligning text in bottom and image in top.
ImageBottom	Support for aligning text in top and image in bottom.

The following steps explains you the details on rendering the Split Button with above mentioned ImagePosition property's options.

1. In the View page, add the following button elements to configure Split Button widget.

ASPX-CS

```
@*Add the code in the CSHTML page to configure and initialize the
control*@
<div class="control">
@*Set the different image position for split button control as follows.*@
<table>
<tr>
<td class="btnsht">
<div class="spltspan">
@Html.EJ().SplitButton("splitButton_normal_imageLeft").Text("login").Size
(ButtonSize.Normal).ShowRoundedCorner(true).ContentType(ContentType.TextA
ndImage).PrefixIcon("e-icon e-
handup").ImagePosition(ImagePosition.ImageLeft).TargetID("Ul11")
<ul id="Ul11">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</div>
</td>
<td>
@Html.EJ().SplitButton("splitButton_small_imageLeft").Text("login").Size(
ButtonSize.Small).ShowRoundedCorner(true).ContentType(ContentType.TextAnd
```

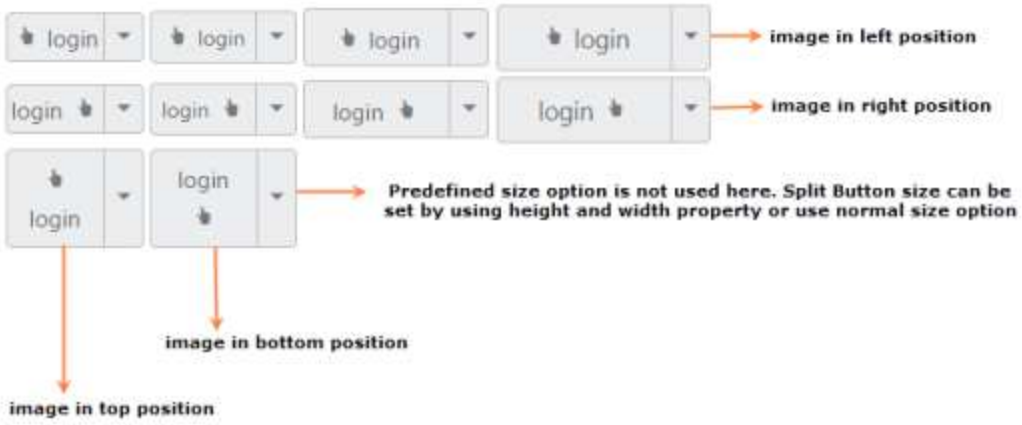
@Html.EJ().SplitButton("splitButton_medium_imageRight").Text("login").Size(ButtonSize.Medium).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).PrefixIcon("e-icon e-handup").ImagePosition(ImagePosition.ImageRight).TargetID("Ul71")
<ul id="Ul71">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_large_imageRight").Text("login").Size(ButtonSize.Large).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).PrefixIcon("e-icon e-handup").ImagePosition(ImagePosition.ImageRight).TargetID("Ul81")
<ul id="Ul81">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
</tr>
<tr>
<td class="btnsht">
<div class="spltspan">
@Html.EJ().SplitButton("splitButton_imageTop").Text("login").Size(ButtonSize.Normal).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).PrefixIcon("e-icon e-handup").ImagePosition(ImagePosition.ImageTop).TargetID("Ul91").Height("60")
<ul id="Ul91">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</div>
</td>
<td>
@Html.EJ().SplitButton("splitButton_imageBottom").Text("login").Size(ButtonSize.Normal).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).PrefixIcon("e-icon e-handup").ImagePosition(ImagePosition.ImageBottom).TargetID("Ul101").Height("60")
<ul id="Ul101">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
</tr>
</table>
</div>
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.



Theme support

You can control the style and appearance of Split Button based on CSS classes. In order to apply styles to the Split Button control, you can refer two files namely, ej.widgets.core.min.css and ej.theme.min.css. When you refer the ej.widgets.all.min.css file, then it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these two.

By default, there are 12 themes support available for Split Button control namely

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

Custom CSS

You can use the CSS class to customize the Split Button control appearance. Define a CSS class as per requirement and assign the class name to CssClass property.

The following steps explains you the details about rendering the Split Button with custom CSS.

1. In the VIEW page, add the following button elements to configure Split Button widget.

ASPX-CS

```
@*Add the code in the CSHTML page to configure and initialize the
control*@
<div class="control">
@*Set Custom CSS class for split button control as follows*@
<table>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<tr>
<td class="btnsht">
<div class="spltspan">
@Html.EJ().SplitButton("splitButton_customCSS1").Text("login").Size(Butto
nSize.Small).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage
).PrefixIcon("e-icon e-
handup").ImagePosition(ImagePosition.ImageLeft).TargetID("Ul11").CssClass
("customCss1")
<ul id="Ul11">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</div>
</td>
<td>
@Html.EJ().SplitButton("splitButton_customCSS2").Text("login").Size(Butto
nSize.Small).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage
).PrefixIcon("e-icon e-
handup").ImagePosition(ImagePosition.ImageLeft).TargetID("Ul21").CssClass
("customCss2")
<ul id="Ul21">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_customCSS3").Text("login").Size(Butto
nSize.Small).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage
).PrefixIcon("e-icon e-
handup").ImagePosition(ImagePosition.ImageLeft).TargetID("Ul31").CssClass
("customCss3")
<ul id="Ul31">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_customCSS4").Text("login").Size(Butto
nSize.Small).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage
).PrefixIcon("e-icon e-
handup").ImagePosition(ImagePosition.ImageLeft).TargetID("Ul41").CssClass
("customCss4")
<ul id="Ul41">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
<td class="btnsht">
@Html.EJ().SplitButton("splitButton_customCSS5").Text("login").Size(Butto
nSize.Small).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage
).PrefixIcon("e-icon e-
handup").ImagePosition(ImagePosition.ImageLeft).TargetID("Ul51").CssClass
("customCss5")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<ul id="Ul51">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</td>
</tr>
</table>
</div>
```

2. Configure the CSS styles to apply on buttons

CSS

```
<style type="text/css">
/* Customize the button background */
.e-split .customCss1
{
background-color: #121111;
}
.e-split .customCss2
{
background-color: #94bbd5;
}
.e-split .customCss3
{
background-color: #f3533c;
}
.e-split .customCss4
{
background-color: #d1eeed;
}
.e-split .customCss5
{
background-color: #deb66e;
}
/* Customize the button image & text color */
.e-split .customCss1.e-btn.e-select .e-icon, .e-split .customCss1.e-
btn.e-select .e-btntxt
{
color: #94bbd5;
}
.e-split .customCss2.e-btn.e-select .e-icon, .e-split .customCss2.e-
btn.e-select .e-btntxt
{
color: #121111;
}
.e-split .customCss3.e-btn.e-select .e-icon, .e-split .customCss3.e-
btn.e-select .e-btntxt
{
color: #cef6f7;
}
.e-split .customCss5.e-btn.e-select .e-icon, .e-split .customCss5.e-
btn.e-select .e-btntxt
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
color: #534f4f;
}
</style>
```

Execute the above code to render the following output.

Dropdown Button

You can change the Split Button as Dropdown Button that consists of a single button that when clicked displays a drop-down list of mutually exclusive items. You can achieve this by using default functionality of Split Button with ButtonMode as ButtonMode.Dropdown. Initially the TargetID is a mandatory one.

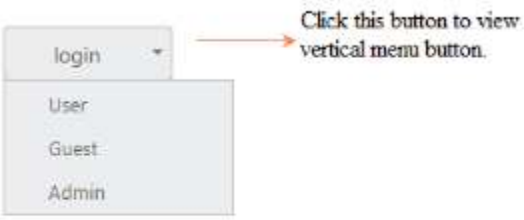
The following steps explain how to change the Split Button as Dropdown Button.

1. In the VIEW page, add the following button elements to configure Button widget.

ASPX-CS

```
@*Add the code in the CSHTML page to configure and initialize the
control*@
@Html.EJ().SplitButton("dropdownButton").Text("login").ShowRoundedCorner(
true).Size(ButtonSize.Medium).ContentType(ContentType.TextOnly).TargetID(
"menu1").ButtonMode(ButtonMode.Dropdown)
<ul id="menu1">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
```

2. Execute the above code to render the following output.



Arrow Position

To provide a good look and feel for Split Button, position of arrow in Split Button is important. Using ArrowPosition property, you can easily customize the position of arrow inside Split Button without using any complex CSS. ArrowPosition property is applicable for both Split Button and Dropdown Button. This property represent the position of arrow with menu content.

Copyright © 2001 - 2020 Syncfusion Inc.

List of arrow position

Left	Support for arrow in left.
Right	Support for arrow in right.Â
Top	Support for arrow in top.Â
Bottom	Support for arrow in bottom.

The following steps explain you the details on rendering the Split Button with above mentioned arrow position options.

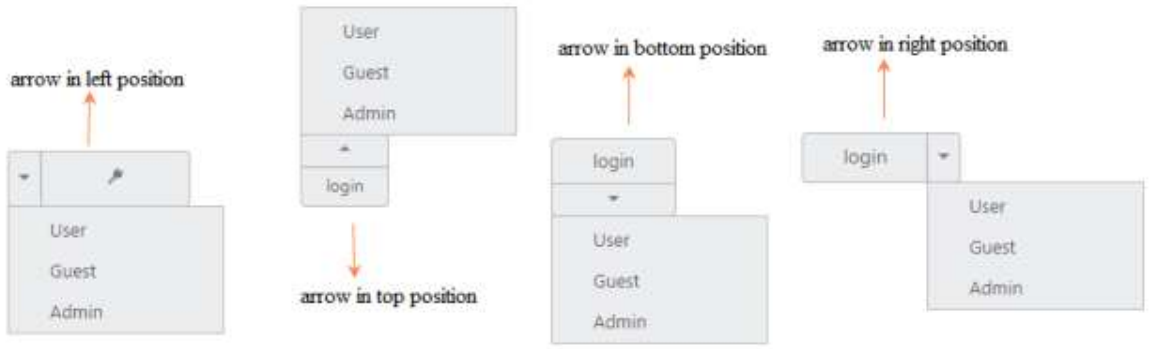
1. In the View page, add the following button elements to configure Split Button widget.

ASPX-CS

```
@*Add the code in the CSHTML page to configure and initialize the
control*@
@Html.EJ().SplitButton("spltbutton11").Text("login").ShowRoundedCorner(tr
ue).Size(ButtonSize.Large).ContentType(ContentType.ImageOnly).TargetID("U
l11").PrefixIcon("e-icon e-login").ArrowPosition(ArrowPosition.Left)
<ul id="Ul11">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
@Html.EJ().SplitButton("spltbutton21").Text("login").ShowRoundedCorner(tr
ue).Size(ButtonSize.Mini).ContentType(ContentType.TextOnly).TargetID("Ul2
1").ArrowPosition(ArrowPosition.Top)
<ul id="Ul21">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
@Html.EJ().SplitButton("spltbutton31").Text("login").ShowRoundedCorner(tr
ue).Size(ButtonSize.Small).ContentType(ContentType.TextOnly).TargetID("Ul
31").ArrowPosition(ArrowPosition.Bottom)
<ul id="Ul31">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
@Html.EJ().SplitButton("spltbutton41").Text("login").ShowRoundedCorner(tr
ue).Size(ButtonSize.Medium).ContentType(ContentType.TextOnly).TargetID("U
l41").ArrowPosition(ArrowPosition.Right)
<ul id="Ul41">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
```

2. Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.



RTL Support

In some cases it is necessary to use right to left alignment. RTL support is provided by using EnableRTL property. In RTL mode when there is more than one content (image/text, image/image) in Split Button, then the content is aligned in right to left format. For example, when text is in left and image is in right position, after applying right to left alignment these position are interchanged.

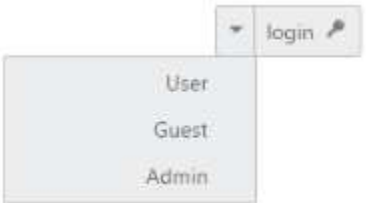
The following steps explains you the details about rendering the button with Right to left alignment support

1. In the VIEW page, add the following button elements to configure Split Button widget.

ASPX-CS

```
@*Add the code in the CSHTML page to configure and initialize the
control*@
@*Enable the alignment format for split button control as follows.*@
<div class="spltspan">
@Html.EJ().SplitButton("splitButton_rtl").Text("login").Size(ButtonSize.S
mall).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).Prefi
xIcon("e-icon e-
login").ImagePosition(ImagePosition.ImageLeft).TargetID("Ul11").EnableRTL
(true)
<ul id="Ul11">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</div>
```

Execute the above code to render the following output.



Copyright © 2001 - 2020 Syncfusion Inc.

Miscellaneous

Text

It is necessary to display the user defined text for Split Button. Using Text property, you can easily set text content for Split Button.

The following steps explains you the details about rendering the Split Button with specified text.

1. In the VIEW page, add the following button elements to configure Split Button widget

ASPX-CS

```
//Add the code in the CSHTML page to configure and initialize the control
@*Set the text for split button control as follows. *@
<div class="spltspan">
@Html.EJ().SplitButton("splitButton_text").Text("sign
in").Size(ButtonSize.Small).TargetID("Ul11")
<ul id="Ul11">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</div>
```

Execute the above code to render the following output.

ShowRoundedCorner

Specifies the corner of Split Button in rounded shape. By default, the edges of Split Button is not rounded. To set rounded corner, you can enable ShowRoundedCorner property.

The following steps explains you the details about rendering the Split Button with rounded corner.

1. In the VIEW page, add the following button elements to configure Split Button widget.

ASPX-CS

```
//Add the code in the CSHTML page to configure and initialize the control
@*Enable the rounded corner for split button control as follows.*@
<div class="spltspan">
@Html.EJ().SplitButton("splitButton_roundedCorner").Text("login").Size(Bu
ttonSize.Small).ShowRoundedCorner(true).TargetID("Ul11")
<ul id="Ul11">
<li><span>User</span></li>
<li><span>Guest</span></li>
<li><span>Admin</span></li>
</ul>
</div>
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

How to?

Render SplitButton from Code behind

SplitButton can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of SplitButton properties in the controller.

C#

```
<ul id="target">
<li><span>Open</span></li>
<li><span>Save</span></li>
<li><span>Delete</span></li>
</ul>
//Namespace to get the JavaScript (SplitButton) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class SplitButtonController : Controller
{
// GET: SplitButton
public ActionResult SplitButtonFeatures()
{
//Initializing the SplitButton model
SplitButtonProperties BtnObj = new SplitButtonProperties();
//Initializing the datasource and other properties
BtnObj.Text = "login";
BtnObj.Size= ButtonSize.Medium;
BtnObj.TargetID = "target";
BtnObj.ShowRoundedCorner=true;
//Passing SplitButton properties using the ViewData
ViewData["BtnModel"] = BtnObj;
return View();
}
}
}
```

Binding the SplitButton properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().SplitButton("searchCustomer",(Syncfusion.JavaScript.Models.Spli
tButtonProperties)ViewData["BtnModel"]).Render();
}
```

Splitter

Splitter

The Essential ASP.NET MVCSplitter is a layout control that enables you to divide a Web page into distinct areas by inserting resizable panes. You can create any number of Splitter panes and place them inside the Splitter control; the split bars are inserted automatically in between the adjacent panes.

Copyright © 2001 - 2020 Syncfusion Inc.

Key Features

- Expand or Collapse Panes—Support for expanding or collapsing panes by using the Expand or Collapse arrows.
- Animation—Supports for animating panes while expanding or collapsing the panes, and also setting the animation speed.
- Window Resizing—Supports for resizing the Splitter while resizing the window.
- RTL—Supports for right to left alignment of Splitter panes.
- Themes—Essential ASP.NET MVC controls consist of 12 built-in themes (6 – flat and 6 – gradient effects), and also support custom skins that enable to set user-defined themes.

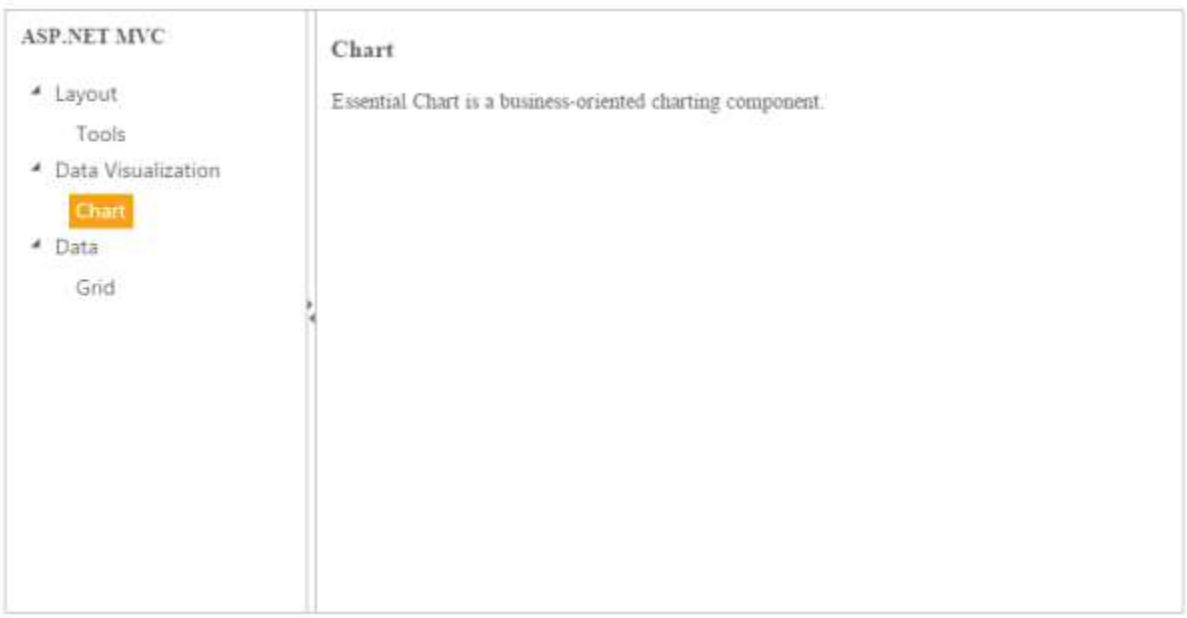
Getting Started

This section explains briefly about how to create a Splitter in ASP.NET MVC application.

Create your first Splitter in MVC

ASP.NET MVCSplitter control consists of movable split bar(s) that divides the container's display area into two or more resizable and collapsible panels. Refer the following guidelines to create a Splitter, add tree view in the Splitter and how to set actions to view the image that is used to split the document or image and also Expand or Collapse the Splitter.

The following screenshot illustrates a Splitter control.



Create a Splitter

Essential Studio ASP.NET MVC Splitter control has a built-in feature to split the display into horizontal and vertical order.

1. Create an MVC Project and add required assemblies, scripts, and styles to it. Refer MVC-Getting Started Documentation.
2. Add the following code example to the corresponding view page to render the Splitter. You can download the desired mobile and name it as galaxy.jpg. ‘ContentTemplate’ property is used to

Copyright © 2001 - 2020 Syncfusion Inc.

specify the HTML tags within the helper elements. Here we have used the contentTemplate property to specify the contents of the splitter control.

ASPX-CS

```
@{Html.EJ().Splitter("outerSplitter").PaneProperties(p =>
{
p.Add().ContentTemplate(
@<div class="cont">
<h3 class="h3">
ASP.NET MVC
</h3>
@*Add Tree Element here*@
</div>).PaneSize("200");
p.Add().ContentTemplate(
@<div class="cont">
<div class="_content">
Select any product from the tree to show the description.
</div>
<div class="tools des">
<h3>
Tools
</h3>
<p>
Essential Tools is an collection of user interface components used to
create interactive
ASP.NET MVC applications.
</p>
</div>
<div class="chart des">
<h3>
Chart
</h3>
<p> Essential Chart is a business-oriented charting component.</p>
</div>
<div class="grid des">
<h3>
Grid
</h3>
<p>
Essential MVC Grid offers full featured a Grid control with extensive
support for
Grouping and the display of hierarchical data.
</p>
</div>
</div>).PaneSize("200");
}).Height("400").Width("100%").Render();}
```

3. Add the following style in the view page to set the height and width of the Splitter.

CSS

```
<style type="text/css" class="cssStyles">
#outerSplitter
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
margin: 0 auto;
}
.cont #treeView_Container
{
margin-bottom: 0;
border: none;
}
.h3, ._content, p
{
font-size: 14px;
margin-top: 10px;
text-indent: 10px;
}
.des
{
display: none;
}
</style>
```

Configure Tree View

Add the following code example in the corresponding view page. 'HtmlAttributes' property is used to add HTML attributes like, id, class etc.. to the components. We need to use IDictionary<string, object> to specify the HTML attributes. Please check the below code.

ASPX-CS

```
@{IDictionary<string, object> htmlAttribute = new Dictionary<string,
object>();
htmlAttribute.Add("class", "_child");
}
@Html.EJ().TreeView("treeview").Items(items =>
{
items.Add().Text("Layout").Expanded(true).Children(child =>
{
child.Add().Id("tools").Text("Tools").HtmlAttributes(htmlAttribute);
});
items.Add().Text("Data Visualization").Expanded(true).Children(child =>
{
child.Add().Id("chart").Text("Chart").HtmlAttributes(htmlAttribute);
});
items.Add().Text("Data").Expanded(true).Children(child =>
{
child.Add().Id("grid").Text("Grid").HtmlAttributes(htmlAttribute);
});
}).ClientSideEvents(e => e.NodeSelect("treeClicked"))
```

Set Actions to Splitter control to view the image

Add the following code example in the view page to set action in Splitter control to view the image.

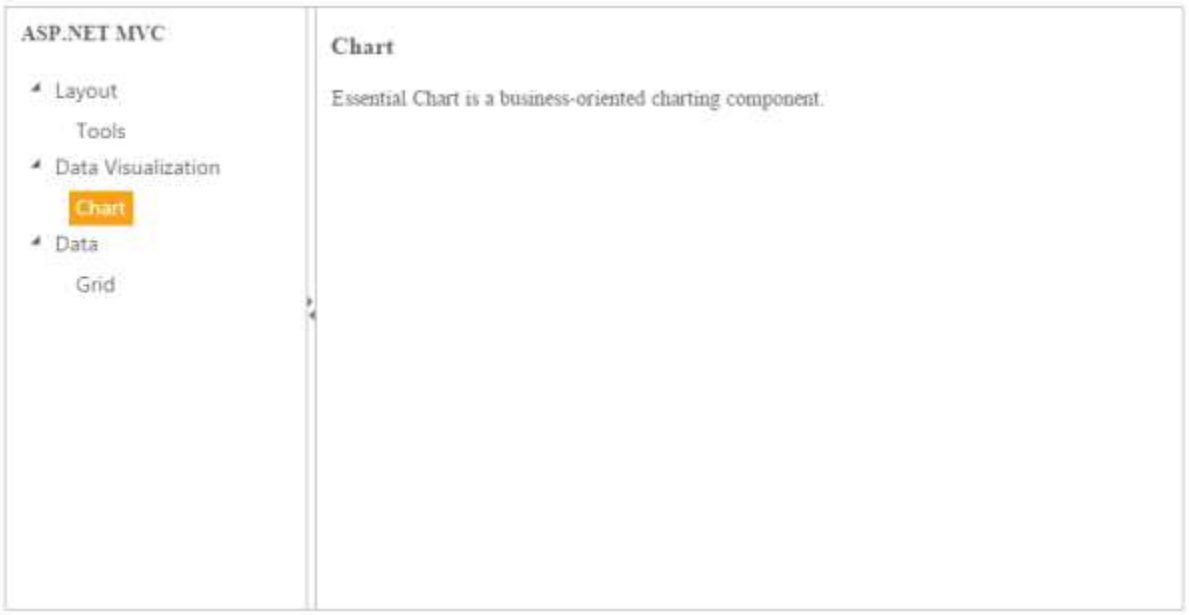
JS

```
<script type="text/javascript">
function treeClicked(sender, args)
{
if (sender.currentElement.hasClass('_child'))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
//nodeSelect event handle
var content = $('.' + sender.currentElement[0].id).html();
$('._content').html(content);
}
}
</script>
```

Execute the above code example to render the following output.



Enabling Collapsible

The Splitter provides you the option to enable or disable the pane collapse functionality. You can click the icon in Split bar to collapse or expand the corresponding pane element in Splitter. Setting the Collapsible property to “false” disables the pane collapse functionality in the Splitter widget.

Configure Collapsible

The following steps explain the implementation of the Collapsible option in Splitter.

1. In the View page, add the Splitter helper and configure the ‘Collapsible’ property as shown below. ‘ContentTemplate’ property is used to specify the HTML tags within the helper elements. Here we have used the contentTemplate property to specify the contents of the splitter control.

ASPX-CS

```
@Html.EJ().Splitter("Splitter").Height("280").Width("600").Orientation(Or
ientation.Horizontal).PaneProperties(
p =>
{
p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Tools </h3>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Essential Tools is an collection of user interface components used to
create interactive
ASP.NET MVC applications.
</div>
</div>).Collapsible(false);
p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Grid </h3>
Essential MVC Grid offers full featured a Grid control with extensive
support for
Grouping and the display of hierarchical data.
</div>
</div>);
})
```

The output for Splitter when collapsible is set to “true” is as follows.

The output for Splitter when collapsible is “false”.

Splitter Orientation

The Splitter supports both vertical and horizontal orientation of the pane. You can declare the orientation by using enum, ej.Orientation.Vertical or ej.Orientation.Horizontal, that have the corresponding value of vertical and horizontal as a string.

Copyright © 2001 - 2020 Syncfusion Inc.

Configure Splitter Orientation

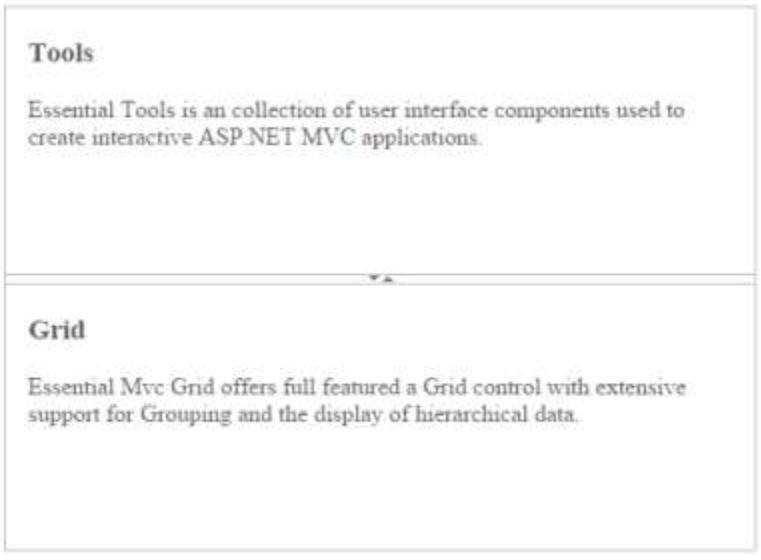
The following steps explain the implementation of Splitter orientation option.

1. In the View page, add the Splitter helper and configure the 'Orientation' property as shown below.

ASPX-CS

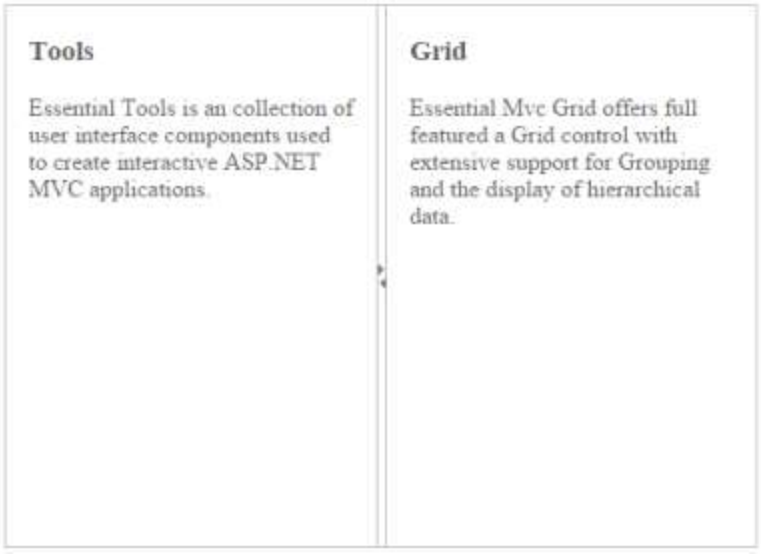
```
@{Html.EJ().Splitter("Splitter").Height("360").Width("500").Orientation(O
rientation.Vertical).PaneProperties(
p =>
{
p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Tools </h3>
Essential Tools is an collection of user interface components used to
create interactive
ASP.NET MVC applications.
</div>
</div>);
p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Grid </h3>
Essential MVC Grid offers full featured a Grid control with extensive
support for
Grouping and the display of hierarchical data.
</div>
</div>);
}).Render();}
```

The output for Splitter with ej.Orientation.Vertical.



The output for Splitter with ej.Orientation.Horizontal.

Copyright © 2001 - 2020 Syncfusion Inc.



Nested Splitter Support

The Splitter provides nested pane support that allows you to add a pane between two pane elements.

Configure Nested Splitter

The following steps explain the implementation of the “Nested Splitter” option.

1. In the View page, add the Splitter helper and configure the outer and inner splitters. As you can see we have specified a helper function to render the inner splitter. A helper is a reusable snippet of Razor syntax exposed as a method, and is intended for rendering HTML to the browse. To use helper within another helper we have specified as a separate function as shown below.

ASPX-CS

```
@{Html.EJ().Splitter("outerSplitter").Height("300").Width("600").Orientat
ion(Orientation.Vertical).PaneProperties(
p =>
{
p.Add().ContentTemplate(
@<div>
<div class="content" style="padding: 0px 15px;">
<h3 class="h3">
ASP.NET MVC
</h3>
</div>
</div>).PaneSize("60");
p.Add().ContentTemplate(
@<div style="height: 100%; width: 100%">
@innerSplitter()
</div>);
}).Render();}
@helper innerSplitter()
{
@Html.EJ().Splitter("innerSplitter").Width("600").PaneProperties(p1 =>
{
p1.Add().ContentTemplate(@<div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

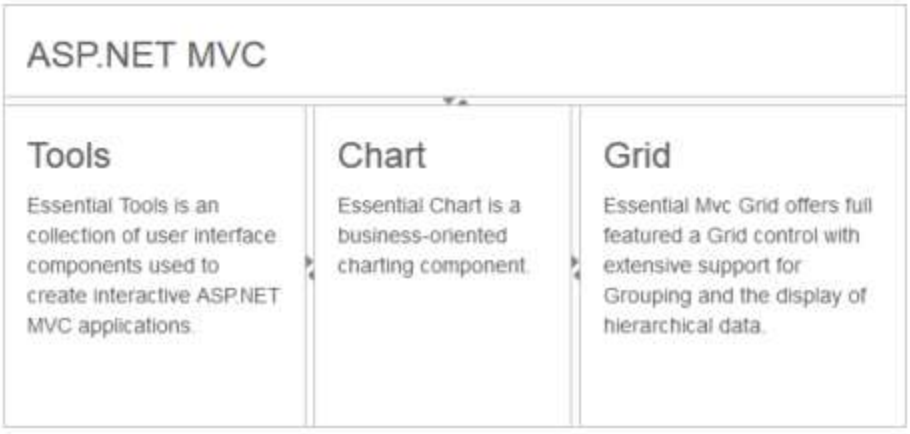
```
<div class="content">
<h3 class="h3">
Tools
</h3>
Essential Tools is an collection of user interface components used to
create interactive
ASP.NET MVC applications.
</div>
</div>).PaneSize("200");
p1.Add().ContentTemplate(@<div>
<div class="content">
<h3 class="h3">
Chart
</h3>
Essential Chart is a business-oriented charting component.
</div>
</div>).PaneSize("200");
p1.Add().ContentTemplate(@<div>
<div class="content">
<h3 class="h3">
Grid
</h3>
Essential MVC Grid offers full featured a Grid control with extensive
support for
Grouping and the display of hierarchical data.
</div>
</div>).PaneSize("200");
})
}
```

CSS

```
<style type="text/css" >
#outerSplitter
{
margin: 0 auto;
}
.h3
{
font-size: 14px;
}
#innerSplitter
{
border: 0 none;
}
.content
{
padding: 15px;
}
</style>
```

The output for nested Splitter.

Copyright © 2001 - 2020 Syncfusion Inc.



Splitter Integration

The Splitter allows you to use other Essential ASP.NET MVC products inside the pane. The integrated function of those widgets can be used in other panes of the Splitter.

Configuring other widgets in Splitter

The following steps explain the implementation of Splitter integration.

1. In the View page, add the Splitter helper and configure the elements within the split pane. The first pane has the TreeView content and the next one has some content that is related to TreeView.

ASPX-CS

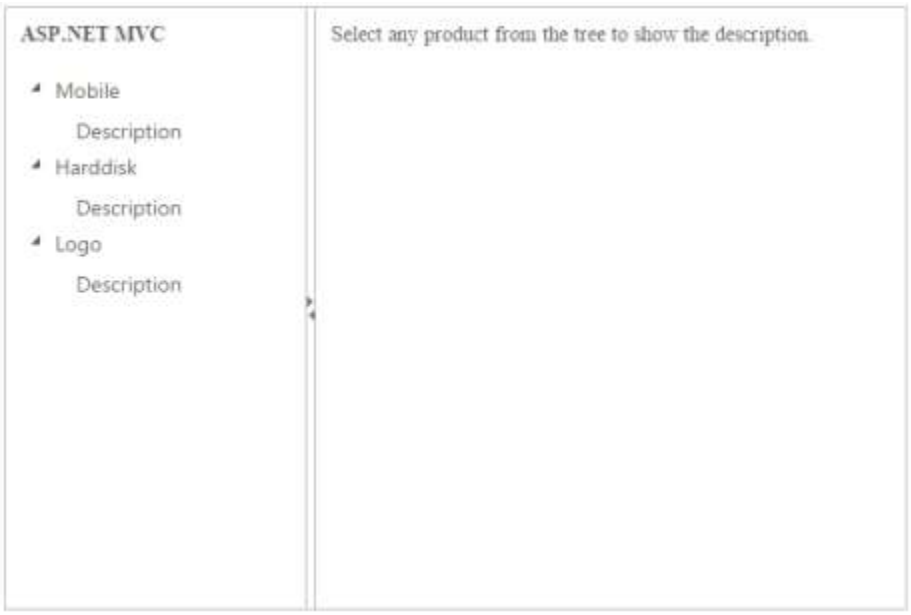
```
@{IDictionary<string, object> htmlAttribute = new Dictionary<string,
object>();
htmlAttribute.Add("class",
"_child");}@{Html.EJ().Splitter("outerSplitter").PaneProperties(p =>     {
p.Add().ContentTemplate(
@<div class="cont">
<h3 class="h3">
ASP.NET MVC
</h3>
@Html.EJ().TreeView("treeview").Items(items =>
{
items.Add().Text("Mobile").Expanded(true).Children(child =>
{
child.Add().Id("tools").Text("Galaxy").HtmlAttributes(htmlAttribute);
});
items.Add().Text("Hard Disk").Expanded(true).Children(child =>
{
child.Add().Id("chart").Text("Seagate").HtmlAttributes(htmlAttribute);
});
items.Add().Text("Logo").Expanded(true).Children(child =>
{
child.Add().Id("grid").Text("Amazon").HtmlAttributes(htmlAttribute);
});
}).ClientSideEvents(e=>e.NodeSelect("treeClicked"))
</div>).PaneSize("200");
p.Add().ContentTemplate(
@<div class="cont">
```

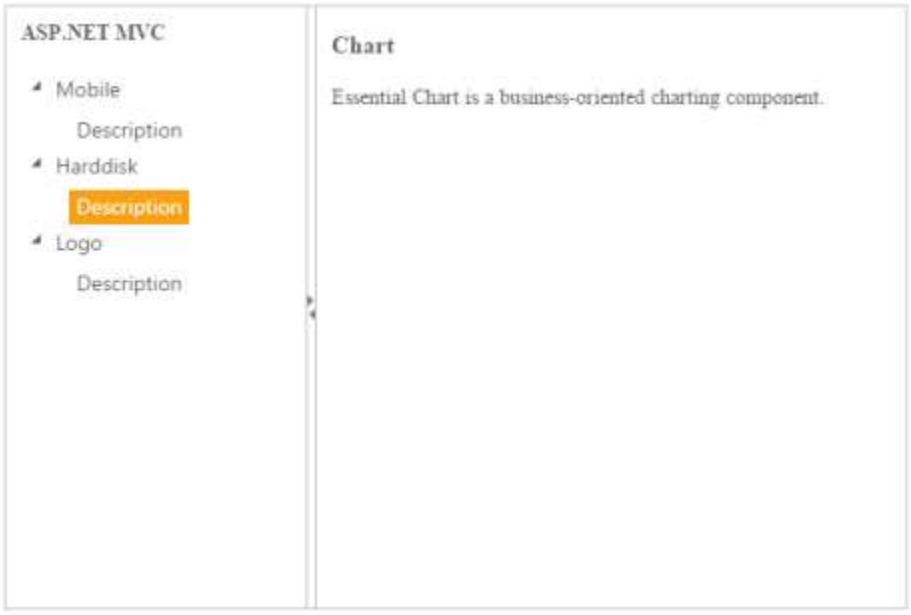
Copyright © 2001 - 2020 Syncfusion Inc.

```
<div class="_content">
Select any product from the tree to show the description.
</div>
<div class="tools des">
<h3>
Tools
</h3>
<p>
Essential Tools is an collection of user interface components used to
create interactive
ASP.NET MVC applications.
</p>
</div>
<div class="chart des">
<h3>
Chart
</h3>
<p> Essential Chart is a business-oriented charting component.</p>
</div>
<div class="grid des">
<h3>
Grid
</h3>
<p>
Essential MVC Grid offers full featured a Grid control with extensive
support for
Grouping and the display of hierarchical data.
</p>
</div>
</div>).PaneSize("200");
}).Height("400").Width("100%").Render();}<style type="text/css">
#outerSplitter {
margin: 0 auto;
}    .cont #treeView_Container {
margin-bottom: 0;
border: none;
}
.h3, ._content, p {
font-size: 14px;
margin-top: 10px;
text-indent: 10px;
}
.des {
display: none;
}
</style>
<script type="text/javascript">
function treeClicked(sender, args)
{
if (sender.currentElement.hasClass('_child'))
{
//nodeSelect event handle
var content = $('.' + sender.currentElement[0].id).html();
$('._content').html(content);
}
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

When the node is selected in TreeView, the integrated output is displayed in the second pane.





Appearance and Styling

Responsive

The EnableAutoResize option allows the Splitter control to adapt its rendering based on the parent container where it is actually placed. When this option is set to true, the Splitter control adjusts its height and width based on the outer container that contains it, and also the sub-elements within it adjust to its height, width and position, appropriately.

Enabling Auto Resize

The following steps explain the implementation of AutoResize option in the Splitter control.

Copyright © 2001 - 2020 Syncfusion Inc.

1. In the View page, add the Splitter helper and configure the ‘EnableAutoResize’ property.

ASPX-CS

```
@{Html.EJ().Splitter("outerSplitter").Height("280")
.Width("100%").Orientation(Orientation.Vertical).EnableAutoResize(true)
.PaneProperties(
p =>
{
p.Add().ContentTemplate(
@<div>
<div class="content" style="padding: 0px 15px;">
<h3 class="h3">
ASP.NET MVC
</h3>
</div>
</div>).PaneSize("60");
p.Add().ContentTemplate(
@<div style="height: 100%; width: 100%">
@innerSplitter()
</div>);
}).Render();}
@helper innerSplitter()
{
@Html.EJ().Splitter("innerSplitter").EnableAutoResize(true).PanePropertie
s(p1=>
{
p1.Add().ContentTemplate(@<div>
<div class="content">
<h3 class="h3">
Tools
</h3>
Essential Tools is an collection of user interface components used to
create interactive
ASP.NET MVC applications.
</div>
</div>);
p1.Add().ContentTemplate(@<div>
<div class="content">
<h3 class="h3">
Grid
</h3>
Essential MVC Grid offers full featured a Grid control with extensive
support for
Grouping and the display of hierarchical data.
</div>
</div>);
});
}
```

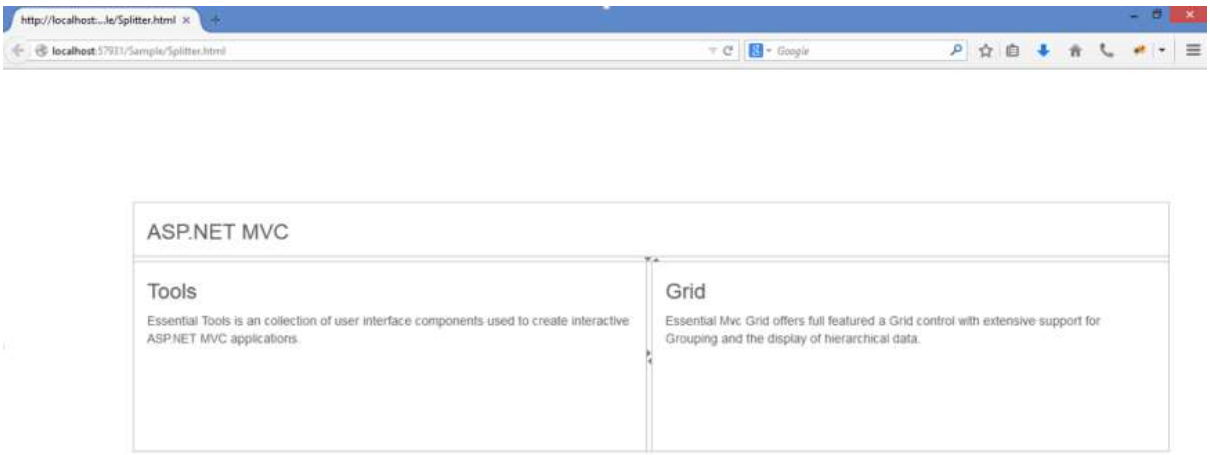
CSS

```
<style type="text/css">
#outerSplitter
{
margin: 0 auto;
```

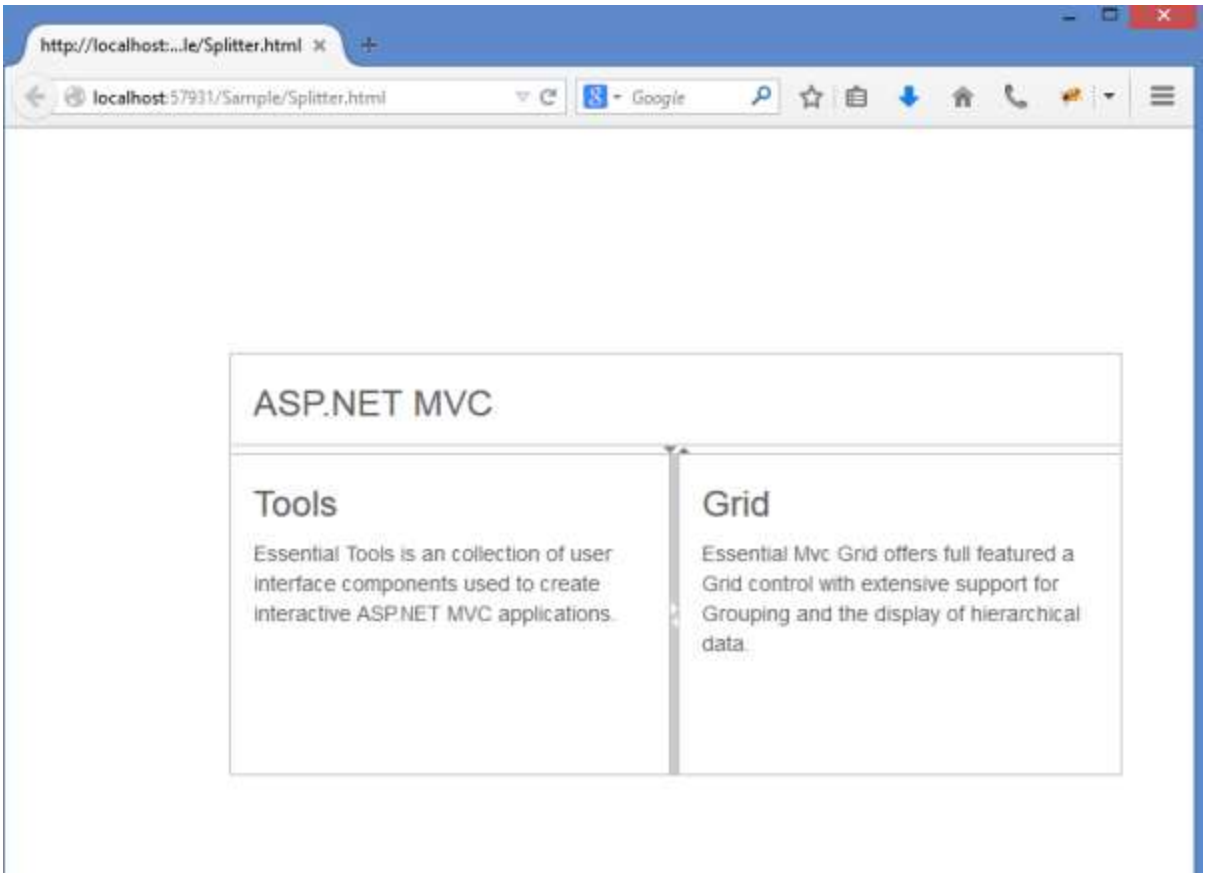
Copyright © 2001 - 2020 Syncfusion Inc.

```
}
.h3
{
font-size: 14px;
}
#innerSplitter
{
border: 0 none;
}
.content
{
padding: 15px;
}
</style>
```

The output for Splitter when EnableAutoResize is “true”.



Copyright © 2001 - 2020 Syncfusion Inc.



Animation Support

The Splitter provides you animation support when you expand or collapse the pane. The animation speed can be modified by using the AnimationSpeed property, that has values in milliseconds.

Enabling Animation with Animation speed

The following steps explain the implementation of EnableAnimation option in the Splitter widget.

1. In the View page add the Splitter helper to customize the Splitter appearance.

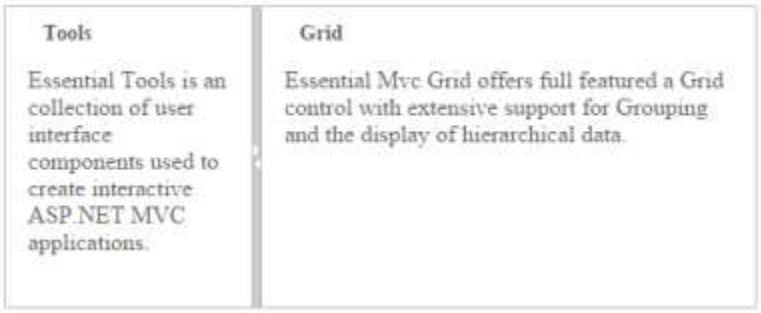
ASPX-CS

```
@{Html.EJ().Splitter("Splitter").Height("200").Width("500").EnableAnimati
on(true).AnimationSpeed(300).PaneProperties(
p =>
{
p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Tools </h3>
Essential Tools is an collection of user interface components used to
create interactive
ASP.NET MVC applications.
</div>
</div>);
p.Add().ContentTemplate(
@<div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div style="padding: 0px 15px;">
<h3 class="h3">Grid </h3>
Essential MVC Grid offers full featured a Grid control with extensive
support for
Grouping and the display of hierarchical data.
</div>
</div>);
}).Render();}
```

The output for Splitter when EnableAnimation is “true”. Expanding or collapsing the outer pane in the Splitter produces the animation effect with the animation speed.



Adjusting Splitter Size

Height

The height of Splitter can be modified by using the Height property. The default value for Height property is null in Splitter. You can set the Height property by pixel or percentage values.

Width

The width of Splitter can be modified by using the Width property. The default value for Width property is null in Splitter. You can set the Width property by pixel or percentage values.

Max Size

Defines the maximum resizable size of the pane when you resize the Splitter widget. The default value of MaxSize is null in Splitter. You can set the MaxSize property by pixel values.

Min Size

Defines the minimum resizable size of the pane when you resize the Splitter widget. The default value of MinSize is 10 in Splitter. You can set the MinSize property by pixel values.

Pane Size

Defines the pane size in the Splitter widget. The default value of PaneSize is 0px in Splitter. You can set the PaneSize property by pixel or percentage values.

Resizable

Defines whether the pane in the Splitter is resizable or not. Setting the resizable property as “false” disables the resize option to the pane. The default value of Resizable property is true in Splitter.

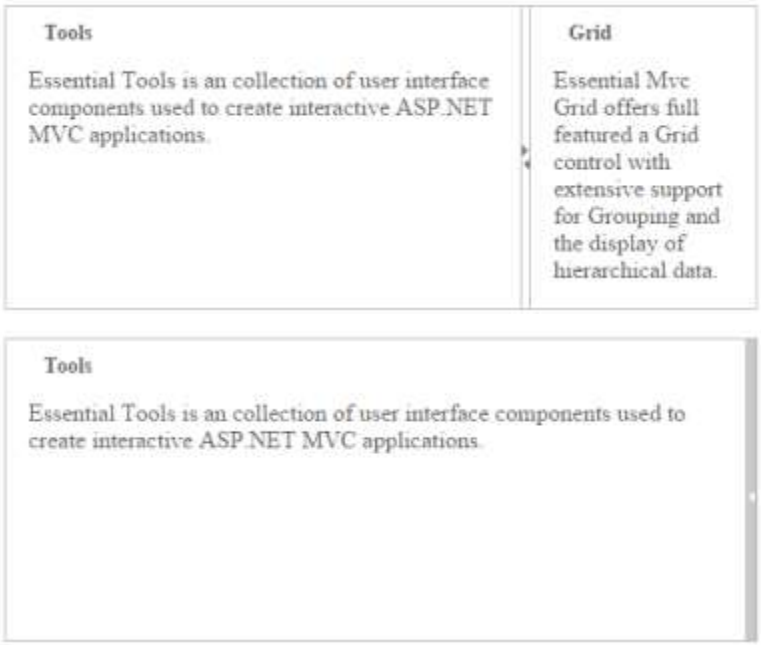
The following steps explain the implementation of Splitter properties.

1. In the View page add Splitter helper and configure resizable property of the split pane.

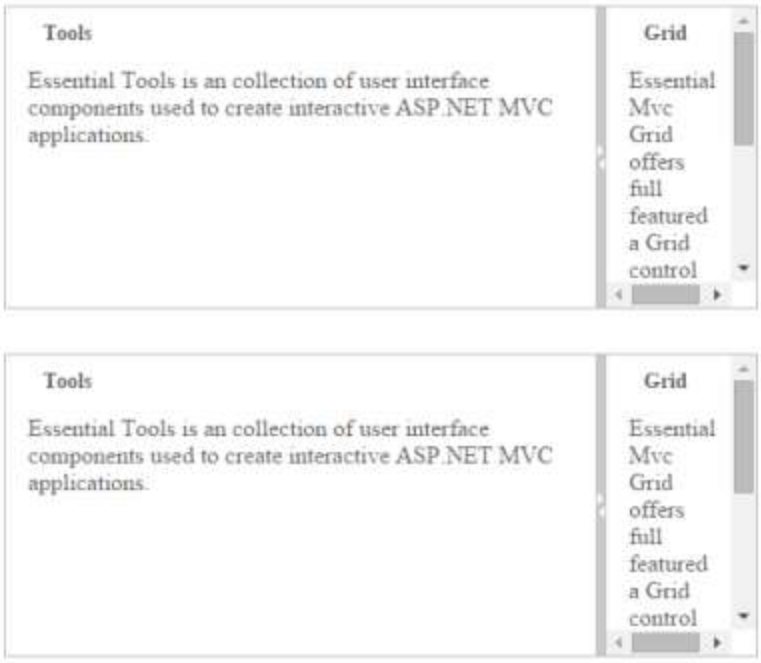
ASPX-CS

```
@{Html.EJ().Splitter("Splitter").Height("200").Width("500").PaneProperties(
p =>
{
p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Tools </h3>
Essential Tools is an collection of user interface components used to create interactive
ASP.NET MVC applications.
</div>
</div>);
p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Grid </h3>
Essential MVC Grid offers full featured a Grid control with extensive support for
Grouping and the display of hierarchical data.
</div>
</div>).Collapsible(true).MinSize("100").MaxSize("150").PaneSize("150").Resizable(true);
}).Render();}
```

The output for Splitter after adding the properties.



Copyright © 2001 - 2020 Syncfusion Inc.



Theme

Splitter control's style and appearance can be controlled based on CSS classes. In order to apply styles to the Splitter control, refer 2 files namely: ej.widgets.core.min.css and ej.theme.min.css. If the file ej.widgets.all.min.css is referred, then it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these two.

By default, there are 12 themes support available for Autocomplete control namely

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

CSS Class

The CSS properties can be customized by using CssClass in the Splitter widget. The following steps explain the implementation of CssClass option in the Splitter widget.

In the View page add the Splitter helper and customize the Splitter appearance.

ASPX-CS

```
@{Html.EJ().Splitter("Splitter").Height("200").Width("500").CssClass("cus
tomCSS").PaneProperties(
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
p =>
{
p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Tools </h3>
Essential Tools is an collection of user interface components used to
create interactive
ASP.NET MVC applications.
</div>
</div>);
p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Grid </h3>
Essential MVC Grid offers full featured a Grid control with extensive
support for
Grouping and the display of hierarchical data.
</div>
</div>).Collapsible(true).MinSize("100").Resizable(true);
}).Render();}
```

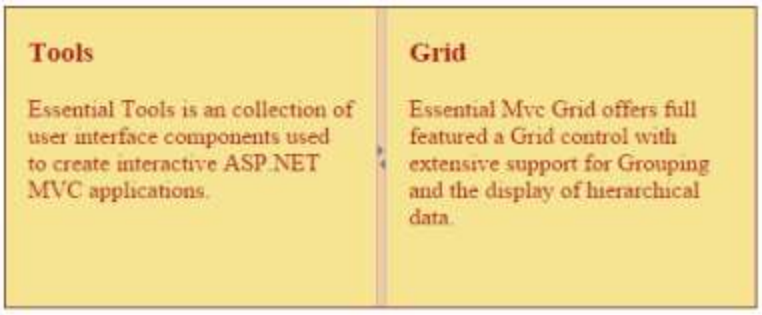
1. Customize the CSS class by setting CSS properties.

CSS

```
<style>
.customCSS
{
border-color: #661e19;
}
/*Customize Splitbar*/
.customCSS .e-splitbar
{
background-color: #f9c89f;
}
/*Customize Splitter pane*/
.customCSS .e-pane
{
color: #b21010;
background-color: #f6e492;
}
</style>
```

The output for Splitter after customizing the CSS class.

Copyright © 2001 - 2020 Syncfusion Inc.



Keyboard Navigation

With the keyboard navigation enabled in the Splitter control, it is possible to control the actions of the Splitter with the provided shortcut keys. Almost all the Splitter actions that are done by mouse can be controlled with shortcut keys.

The various keyboard shortcuts available within the Splitter control are discussed in the following table.

Keyboard Shortcuts

Shortcut Key	Description
Left	Moves the Split bar left.
Right	Moves the Split bar right.
Ctrl + Left	Collapses the left pane.
Ctrl + Right	Collapses the right pane.
Up	Moves the Split bar up.
Down	Moves the Split bar down.
Ctrl + Up	Collapses the top pane.
Ctrl + Down	Collapses the bottom pane.
Enter	Resize the pane to the current Split bar position.
Esc	Focuses out from the Split bar.

Configuring Keyboard Navigation

The following steps explain to enable keyboard interaction for Splitter widget.

1. In the View page add Splitter helper to render the control.

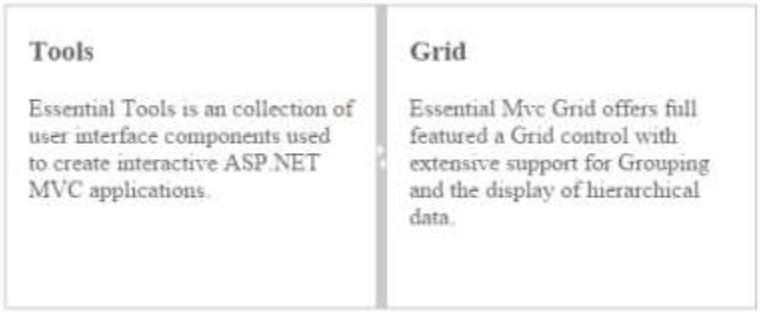
ASPX-CS

```
@{Html.EJ().Splitter("Splitter").Height("200").Width("500").PaneProperties(
p =>    {        p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Tools </h3>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Essential Tools is an collection of user interface components used to
create interactive
ASP.NET MVC applications.
</div>
</div>);
p.Add().ContentTemplate(
@<div>
<div style="padding: 0px 15px;">
<h3 class="h3">Grid </h3>
Essential MVC Grid offers full featured a Grid control with extensive
support for
Grouping and the display of hierarchical data.
</div>
</div>);
}).Render();}
<script type="text/javascript">
//Control focus key
$(document).on("keydown", function (e) {
if (e.altKey && e.keyCode === 74) { // j- key code.
$("#Splitter .e-splitbar")[0].focus();
}
});
</script>
```

1. Run the sample and press Alt + J to focus the Splitter widget. We can fully utilize the functionality of the splitter control by using keyboard shortcuts.



RTL Support

The Splitter provides you with RTL (Right-To-Left) support. The alignment of Splitter can be changed from Left-To-Right to Right-To-Left.

Enable RTL

The following steps explain enabling the right-to-left property for Splitter widget.

In the View page add the Splitter helper to enable the RTL functionality.

ASPX-CS

```
@{Html.EJ().Splitter("outerSplitter").Height("300").Width("600").Orientat
ion(Orientation.Vertical).EnableRTL(true)
.PaneProperties(
p =>
{
p.Add().ContentTemplate(
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@<div>
<div class="content" style="padding: 0px 15px;">
<h3 class="h3">
ASP.NET MVC
</h3>
</div>
</div>).PaneSize("60");
p.Add().ContentTemplate(
@<div style="height: 100%; width: 100%">
@innerSplitter()
</div>);
}).Render();}
@helper innerSplitter()
{
@Html.EJ().Splitter("innerSplitter").Width("600").PaneProperties(p1 =>
{
p1.Add().ContentTemplate
(@<div>
<div class="content">
<h3 class="h3">
Tools
</h3>
Essential Tools is an collection of user interface components used to
create interactive
ASP.NET MVC applications.
</div>
</div>).PaneSize("200");
p1.Add().ContentTemplate
(@<div>
<div class="content">
<h3 class="h3">
Chart
</h3>
Essential Chart is a business-oriented charting component.
</div>
</div>).PaneSize("200");
p1.Add().ContentTemplate
(@<div>
<div class="content">
<h3 class="h3">
Grid
</h3>
Essential MVC Grid offers full featured a Grid control with extensive
support for
Grouping and the display of hierarchical data.
</div>
</div>).PaneSize("200");
})
}
```

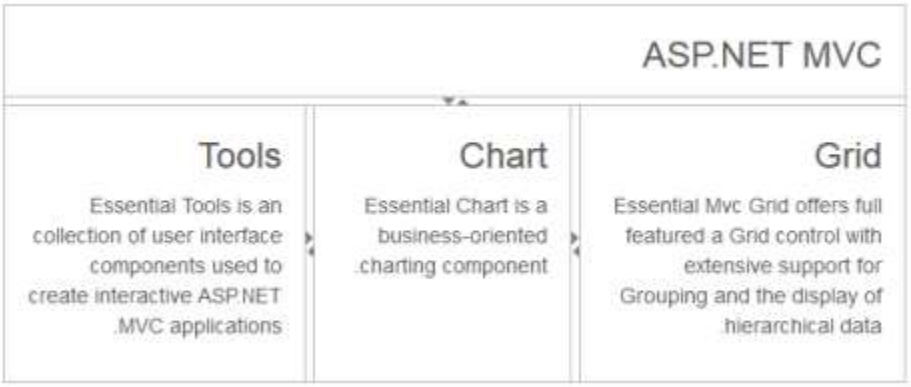
CSS

```
<style type="text/css">
#outerSplitter
{
margin: 0 auto;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
.h3
{
font-size: 14px;
}
#innerSplitter
{
border: 0 none;
}
.content
{
padding: 15px;
}
</style>
```

The output for Splitter when EnableRTL is “true”.



How To?

Change Expand/Collapse icons

By default, you are provided with collapse/expand icons in **Split bar** to collapse or expand the splitter panes. We have provided template support to replace existing expand/collapse icons.

- **expanderTemplate** Specifies HTML element string to replace template with existing expand/collapse icons.
- **clickOnExpander** event is triggered when we click on the template icon.`

ASPX-CS

```
<div id="outterSplitter">
@Html.EJ().Splitter("innerSplitter").PaneProperties(p1 =>
{
p1.Add().ContentTemplate(@<div>
<div class="cont">
Pane 1
</div>
</div>);
p1.Add().ContentTemplate(@<div>
<div class="cont">
Pane 2
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</div>
</div>);
}).Height("250").Width("80%").ExpanderTemplate("<img class='eimg'
src='../Content/basketball.png' alt='employee'/>").ClientSideEvents(cs =>
cs.ClickOnExpander("onClick"))
</div>
```

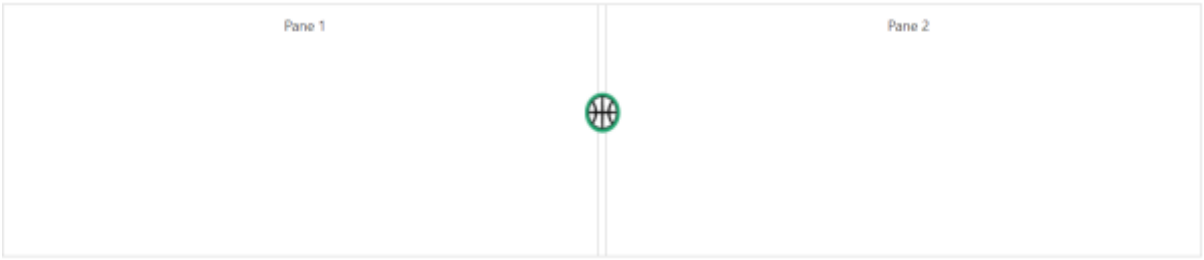
JS

```
<script type="text/javascript">
var flag = true;
function onClick(args) {
if (flag) { this.collapse(0); flag = false; }
else { this.expand(0); flag = true; }
}
</script>
```

CSS

```
.cont {
padding: 10px 0 0 10px;
text-align: center;
}
.eimg {
height:40px;
width:35px;
margin-left: -13px;
}
.e-splitter .e-splitbar .e-splitter-h-template {
top: 15%;
}
```

The output for Splitter with **Template support**.



Copyright © 2001 - 2020 Syncfusion Inc.

Change the splitter pane size dynamically

Splitter pane size can be changed by updating model property of paneSize and by refreshing the control using refresh public method. As shown in the below code, based on the selected dropdown list value, pane size of splitter is changed.

RAZOR

```
@Html.EJ().DropDownList("customersList").Datasource((IEnumerable<Customer
s>)ViewBag.datasource).DropDownListFields(df =>
df.ID("id").Text("text").Value("text")).Value("50").ClientSideEvents(e=>e
.Change("change"))
@Html.EJ().Splitter("Splitter").PaneProperties(
p =>
{
p.Add().ContentTemplate(
@<div>
<div class="content">
<h3 class="h3">
Pane 1
</h3>
</div>
</div>);
p.Add().ContentTemplate(
@<div>
<h3 class="h3">Pane 2</h3>
</div>);
}).Height("350")
```

C#

```
List<Customers> customer = new List<Customers>();
public ActionResult SplitterFeatures()
{
customer.Add(new Customers { id = "1", text = "25" });
customer.Add(new Customers { id = "2", text = "50" });
customer.Add(new Customers { id = "3", text = "75" });
ViewBag.datasource = customer;
return View();
}
public class Customers
{
public string id { get; set; }
public string text { get; set; }
}
```

CSS

```
<style type="text/css" class="cssStyles">
.cont
{
padding: 10px 0 0 10px;
text-align: center;
}
#inner
{
border:0 none;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
#Splitter
{
margin: 0 auto;
}
</style>
```

JAVASCRIPT

```
<script>
function change(args) {
var obj = $("#Splitter").data("ejSplitter");
obj.model.properties[0].paneSize = args.value + "%";
obj.refresh();
}
</script>
```

Render Splitter from Code behind

Splitter can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side

The following code illustrates the initialization of Splitter properties in the controller.

C#

```
//Namespace to get the JavaScript (Splitter) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class SplitterController: Controller
{
public ActionResult SplitterFeatures()
{
//Initializing the splitter model
SplitterProperties splitterObj = new SplitterProperties();
//Initializing the split panes and other properties
splitterObj.PaneProperties.Add(new PaneProperties() { Collapsible = true,
Expandable = true, ContentTemplate = new
Syncfusion.JavaScript.MvcTemplate<PaneProperties> { RazorViewTemplate =
(data) => { return "Pane 1"; } } });
splitterObj.PaneProperties.Add(new PaneProperties() { Collapsible = true,
Expandable = true, ContentTemplate = new
Syncfusion.JavaScript.MvcTemplate<PaneProperties> { RazorViewTemplate =
(data) => { return "Pane 2"; } } });
```

```
splitterObj.Orientation = Syncfusion.JavaScript.Orientation.Vertical;
splitterObj.Height = "300px";
splitterObj.Width = "500px";
//Passing Splitter properties using the ViewData
ViewData["SplitterModel"] = splitterObj;
return View();
}
}
}
```

Binding the Splitter properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().Splitter("Splitter",
(Syncfusion.JavaScript.Models.SplitterProperties)ViewData["SplitterModel"
]).Render();
}
```

Spreadsheet

Overview

The Spreadsheet control is a Microsoft Excel-like Spreadsheet component for web. It provides editing experience that is very similar to that of excel and it is able to import and export Excel workbook files. The Spreadsheet control includes all the important features of Microsoft Excel like editing, sorting, filtering, formulas, data validation, formatting, table, charts, import and export.

Key Features

The key features of Spreadsheet control for ASP.NET MVC are:

- **Editing** - Provides support to edit the cell content.
- **Sorting** - Helps you to visualize and figure out your data better, organize and find the data quickly that you want.
- **Filtering** - Offers Excel-like filtering to filter data.
- **Formulas** - Allows you to handle calculations in cells.
- **Table** - Allows you to manage and analyze a group of related data.
- **Formatting** - Provides various formatting support like cell formatting, number formatting, text formatting.
- **Data Validation** - Helps you to restrict the users to enter the valid data in a range.
- **Conditional Formatting** - Allows you to highlight range of cells with a certain colors, depending on the provided conditions.
- **Chart** – Allows you to have graphical representation of data.
- **Fill Series** - Allows you to drag fill data based on adjacent cell data.
- **Printing** – Allows you to print whole sheet / selected range of data.
- **Import and Export** - Allows you to import excel files to view and export Spreadsheet as excel files.

Copyright © 2001 - 2020 Syncfusion Inc.

Getting Started

This section explains briefly about how to create Spreadsheet in your ASP.NET MVC application and also how to populate the Spreadsheet with data, formats and how to export Spreadsheet data as excel file.

Initialize Spreadsheet

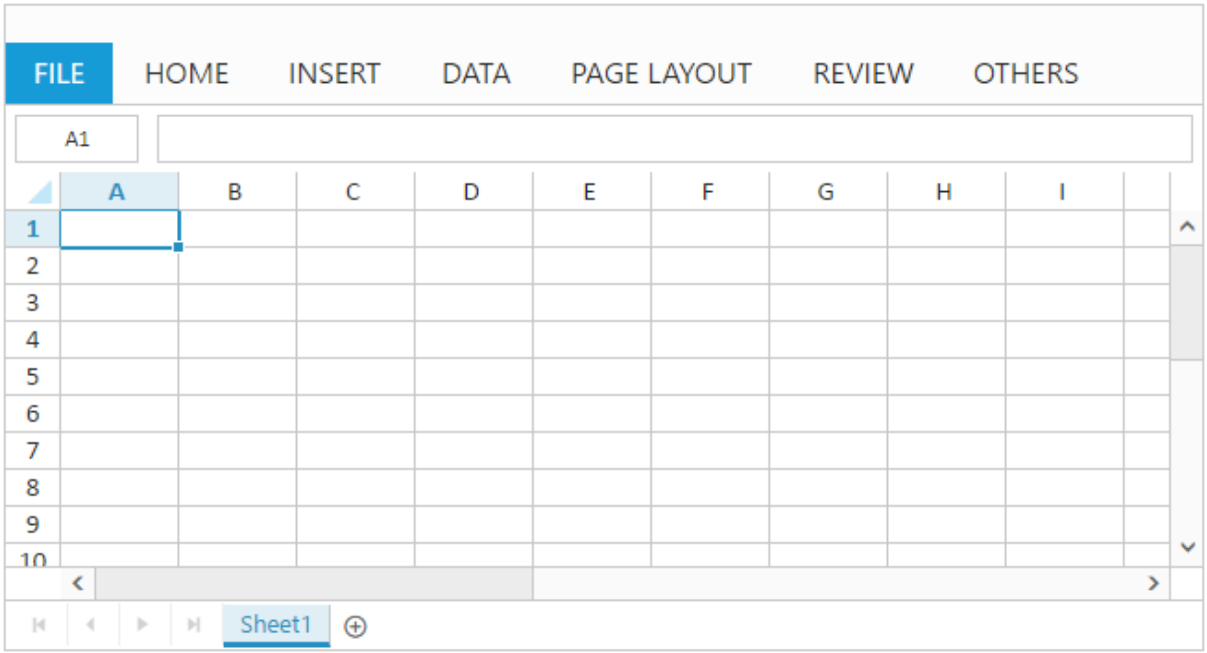
The following steps explains how to create spreadsheet,

1. Create Syncfusion ASP.NET MVC application. You can refer MVC Getting started documentation to create new project and add necessary dll's and script files.
2. Add the following code example in view page to render Spreadsheet control. Spreadsheet is rendered with default height and width. You can also customize Spreadsheet dimension by setting Height and Width property in ScrollSettings.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet"))
```

Now, the Spreadsheet is rendered with default row and column count.



Populate Spreadsheet with Data

Now, this section explains how to populate JSON data to the Spreadsheet. You can set DataSource property in Sheets settings to populate JSON data in Spreadsheet.

1) Create datasource for Spreadsheet control.

CSHARP

```
public ActionResult Index()
{
var DataSource = GetAllItemDetails().ToList();
ViewBag.Datasource = DataSource;
return View();
```

```
}
public IEnumerable<object> GetAllItemDetails()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
lItems.Add(new ItemDetail() { ItemName = "Sneakers", Date = new
DateTime(2014, 07, 22), Time = new DateTime(2014, 07, 22, 10, 55, 53),
Quantity = 40, Price = 20, Amount = 800, Discount = 13, Profit = 66 });
lItems.Add(new ItemDetail() { ItemName = "Running Shoes", Date = new
DateTime(2014, 02, 04), Time = new DateTime(2014, 02, 04, 03, 44, 34),
Quantity = 20, Price = 10, Amount = 200, Discount = 3, Profit = 14 });
lItems.Add(new ItemDetail() { ItemName = "Loafers", Date = new
DateTime(2014, 11, 30), Time = new DateTime(2014, 11, 30, 03, 12, 52),
Quantity = 31, Price = 10, Amount = 310, Discount = 6, Profit = 29 });
lItems.Add(new ItemDetail() { ItemName = "Cricket Shoes", Date = new
DateTime(2014, 07, 09), Time = new DateTime(2014, 07, 09, 11, 32, 14),
Quantity = 41, Price = 30, Amount = 1210, Discount = 12, Profit = 166 });
lItems.Add(new ItemDetail() { ItemName = "T-Shirts", Date = new
DateTime(2014, 10, 31), Time = new DateTime(2014, 10, 31, 12, 01, 44),
Quantity = 50, Price = 10, Amount = 500, Discount = 9, Profit = 55 });
return lItems;
}
public class ItemDetail
{
public string ItemName { get; set; }
public DateTime Date { get; set; }
public DateTime Time { get; set; }
public int Quantity { get; set; }
public int Price { get; set; }
public int Amount { get; set; }
public int Discount { get; set; }
public int Profit { get; set; }
}
```

2) Initialize Spreadsheet with datasource.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
```

```
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
)
```

	A	B	C	D	E	F	G
1	Item Name	Date	Time	Quantity	Price	Amount	Discount
2	Casual Shoes	2/14/2014	11:34:32 AM	10	20	200	1
3	Sports Shoes	6/11/2014	5:56:32 AM	20	30	600	5
4	Formal Shoes	7/27/2014	3:32:44 AM	20	15	300	7
5	Sandals & Floaters	11/21/2014	6:23:54 AM	15	20	300	11
6	Flip- Flops & Slippers	6/23/2014	12:43:59 AM	30	10	300	10
7	Sneakers	7/22/2014	10:55:53 AM	40	20	800	13
8	Running Shoes	2/4/2014	3:44:34 AM	20	10	200	3
9	Loafers	11/30/2014	3:12:52 AM	31	10	310	6
10	Cricket Shoes	7/9/2014	11:32:14 AM	41	30	1210	12

Apply Conditional formatting

Conditional formatting helps you to apply formats to a cell or range with certain color based on the cells values. You can use AllowConditionalFormats property to enable/disable Conditional formats.

To apply conditional formats for a range use CFormatRule property.The following code example illustrates this behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).CFormatRule(formatRule =>
{
formatRule.Action(SpreadsheetCFormatRuleAction.GreaterThan).Inputs(new
List<string>() { "10"
}).Color(SpreadsheetCFormatHighlightColor.RedFill).Range("D2:D8").Add();
}).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

	A	B	C	D	E	F	G
1	Item Name	Date	Time	Quantity	Price	Amount	Discount
2	Casual Shoes	2/14/2014	11:34:32 AM	10	20	200	1
3	Sports Shoes	6/11/2014	5:56:32 AM	20	30	600	5
4	Formal Shoes	7/27/2014	3:32:44 AM	20	15	300	7
5	Sandals & Floaters	11/21/2014	6:23:54 AM	15	20	300	11
6	Flip- Flops & Slippers	6/23/2014	12:43:59 AM	30	10	300	10
7	Sneakers	7/22/2014	10:55:53 AM	40	20	800	13
8	Running Shoes	2/4/2014	3:44:34 AM	20	10	200	3
9	Loafers	11/30/2014	3:12:52 AM	31	10	310	6
10	Cricket Shoes	7/9/2014	11:32:14 AM	41	30	1210	12

Export Spreadsheet as Excel File

The Spreadsheet can save its data, style, format into an excel file. To enable save option in Spreadsheet set AllowExporting option in ExportSettings as true. Since Spreadsheet uses server side helper to save documents set ExcelUrl in ExportSettings option. The following code example illustrates this behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
//...
.ExportSettings(export =>
{
export.ExcelUrl("ExportToExcel");
}
)
//...
)
```

CSHARP

```
[AcceptVerbs(HttpVerbs.Post)]
//...
public void ExportToExcel(string sheetModel, string sheetData, string
password)
{
if (String.IsNullOrEmpty(password))
Spreadsheet.Save(sheetModel, sheetData, "sample", ExportFormat.XLSX,
ExcelVersion.Excel2013);
else
Spreadsheet.Save(sheetModel, sheetData, "sample", ExportFormat.XLSX,
ExcelVersion.Excel2013, password);
}
//...
```

Copyright © 2001 - 2020 Syncfusion Inc.

Use shortcut Ctrl + S to save Spreadsheet as excel file.

Note: 1. For more details about Export refer following link

2. For more details about Client dependencies refer the following link

3. For more details about Server dependencies refer the following link

Worksheet

Worksheet is a collection of cells organized in the form of rows and columns that allow us to store, format, manipulate and display data in grid format. You can create multiple sheets in Spreadsheet and use sheet tab for switching between those worksheets. By default, Spreadsheet creates single worksheet since default SheetCount value is 1.

List of Sheet Operations

You can perform following operations in worksheet,

- Add
- Remove
- Rename
- Move and Copy

Add

The Spreadsheet has support for inserting new sheet. You can insert sheet into two ways.

- Add a new sheet as last sheet.
- Insert a new sheet before the active sheet.

Add Sheet

You can dynamically add a sheet by one of the following ways,

- Click the new sheet button in the Spreadsheet sheet tab.
- Using addNewSheet method.

Insert Sheet

You can dynamically insert a sheet by one of the following ways,

- Right clicking on the worksheet in the sheet tab and then click Insert option in the context menu.
- Click OTHERS tab in the ribbon and select Insert Sheet option in Insert dropdown button.
- Using insertSheet method.

The following code example describes the above behavior

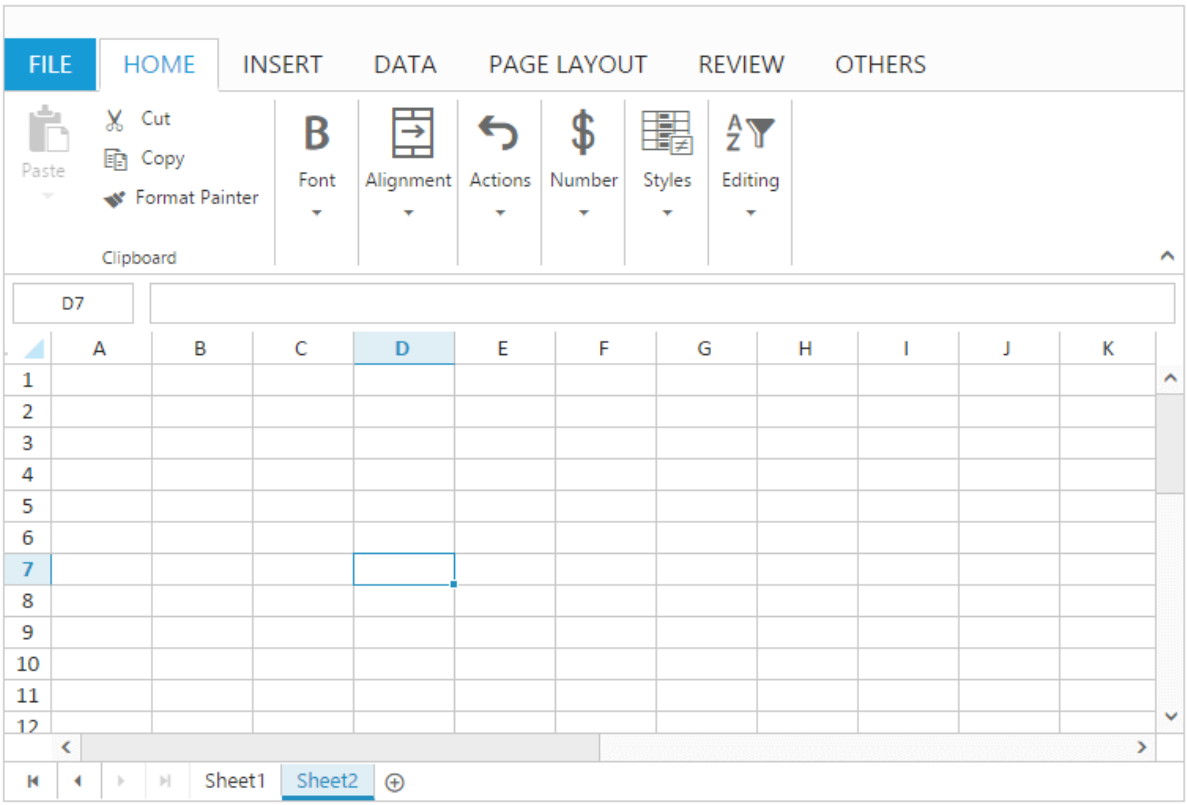
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
if (!this.isImport) {
this.addNewSheet(); //To add as a last sheet.
//this.insertSheet(); // To insert a sheet before the active sheet.
}
}
</script>
```

The following output is displayed as a result of the above code example.



Copy

The Spreadsheet provides support to create a copy of an existing worksheet. You can dynamically copy a worksheet by using one of the following ways,

- Right clicking on the worksheet in the sheet tab and then click Move or Copy in the context menu. Check the “Create a copy” checkbox in the “Move or Copy” dialog.
- Copy an existing worksheet using copySheet method.

The following code example describes the above behavior

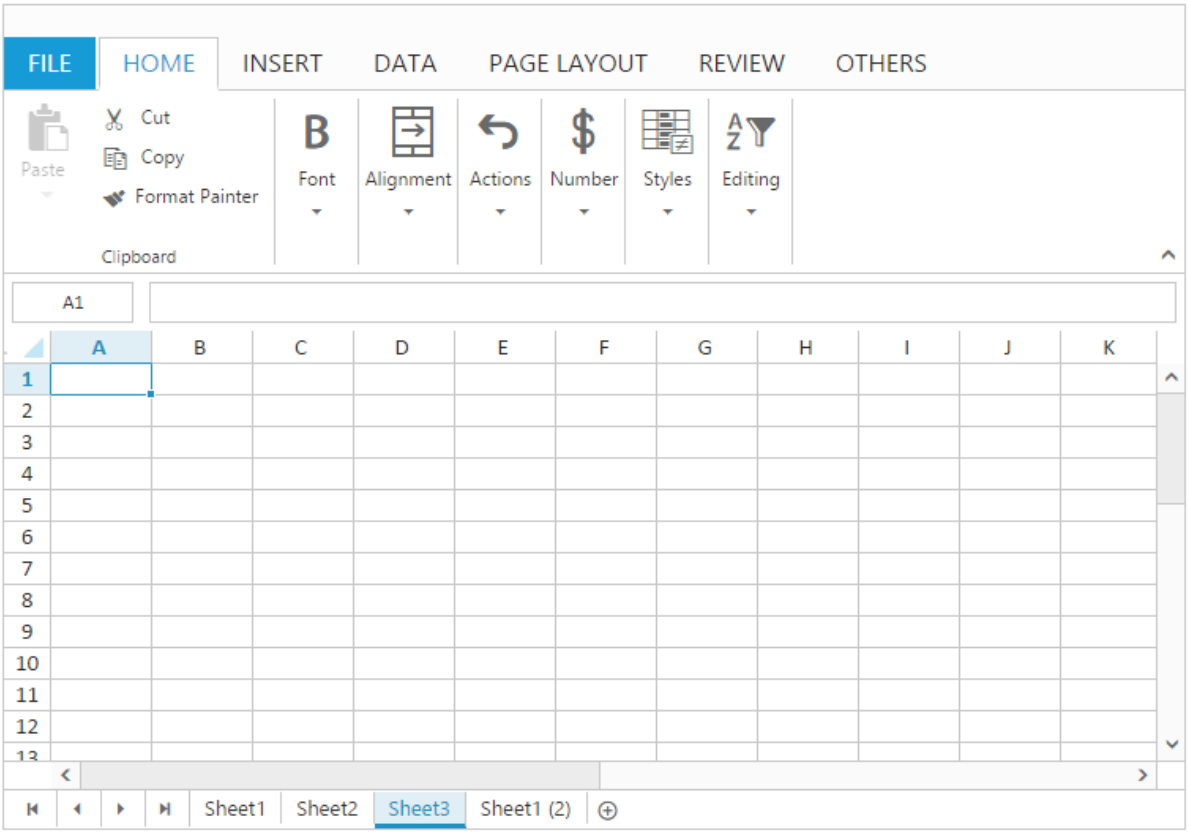
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.SheetCount(3)
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
if (!this.isImport) {
this.copySheet(1, 3, true); //arg1- from index, arg2 -to index, arg3 -
isCopySheet
}
}
</script>
```

The following output is displayed as a result of the above code example.



Move

The Spreadsheet provides support to move an existing worksheet. You can dynamically move a worksheet by using one of the following ways,

- Right clicking on the worksheet in the sheet tab and then click Move or Copy in the context menu. Select the sheet that you have to move in the “Move or Copy” dialog.
- Move an existing worksheet using copySheet method.

The following code example describes the above behavior

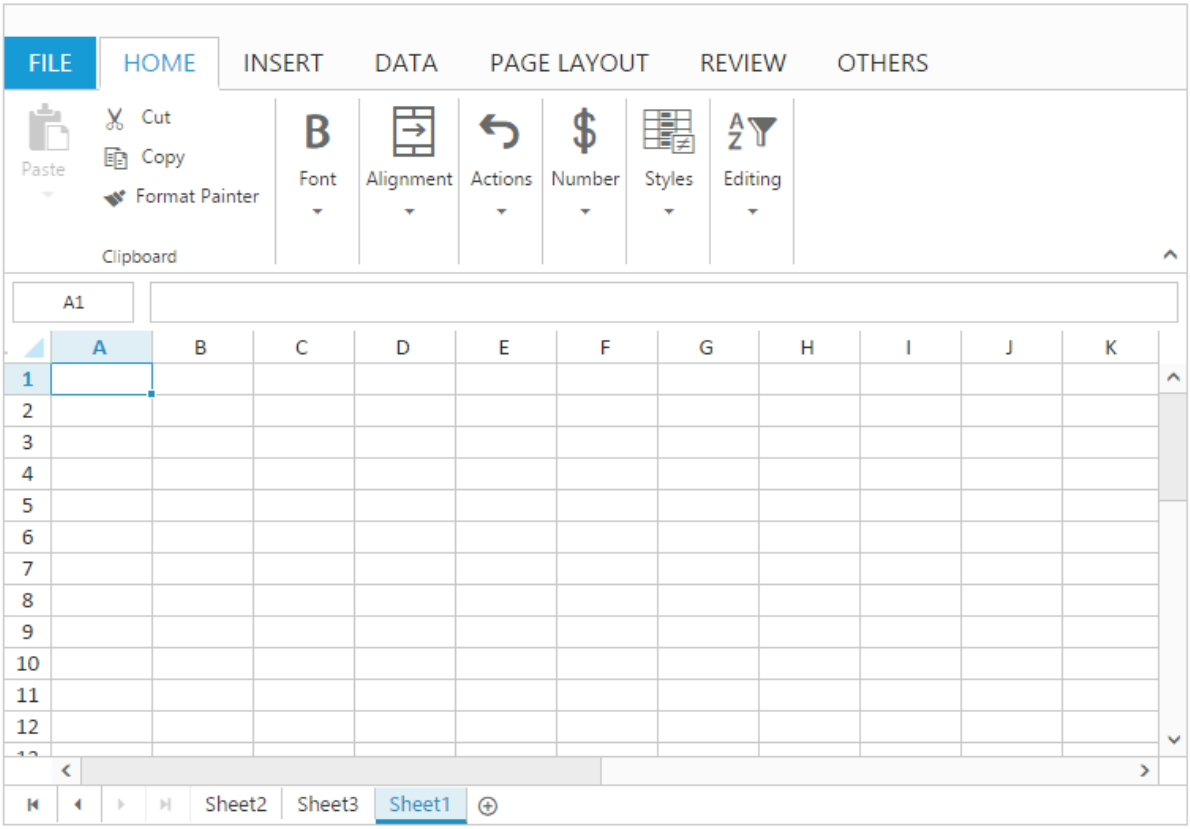
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.SheetCount(3)
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
if (!this.isImport) {
this.copySheet(1, 3, false); //arg1- from index, arg2 -to index, arg3 -
isCopySheet
}
}
</script>
```

The following output is displayed as a result of the above code example.



Remove

The Spreadsheet has support for removing an existing worksheet. You can dynamically remove the existing sheet by following ways,

- Right click on the worksheet in the sheet tab and then click Delete option in the context menu.
- Select the existing worksheet, click OTHERS tab in the ribbon and select Delete dropdown button. Then click Delete Sheet.

You can also remove an active worksheet using deleteSheet method.

The following code example describes the above behavior

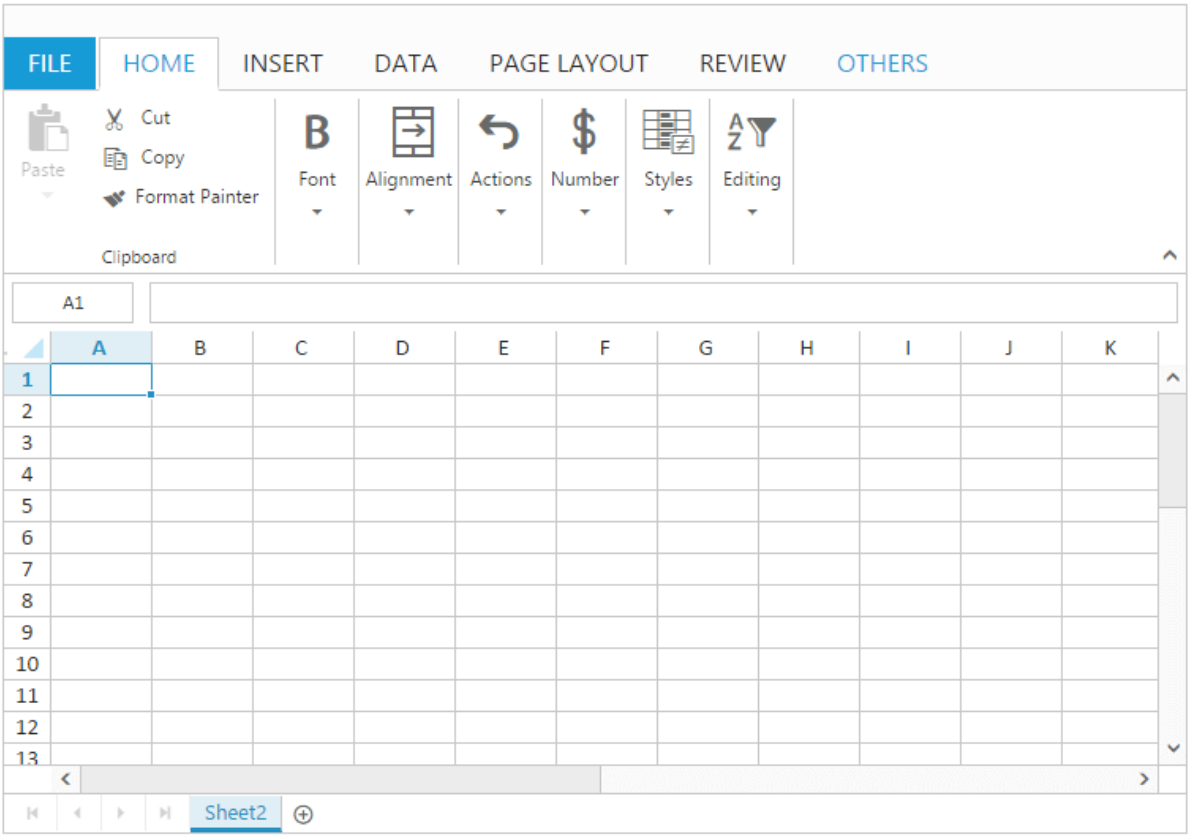
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.SheetCount(2)
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script type="text/javascript">
function loadComplete(args) {
if (!this.isImport) {
this.deleteSheet();
}
}
</script>
```

The following output is displayed as a result of the above code example.



Rename

The Spreadsheet has support for renaming an existing worksheet. You can dynamically rename worksheet by using one of the following ways,

- Right clicking on the worksheet in the sheet tab and then click Rename option in the context menu.
- Rename an active worksheet using sheetRename method.

The following code example describes the above behavior

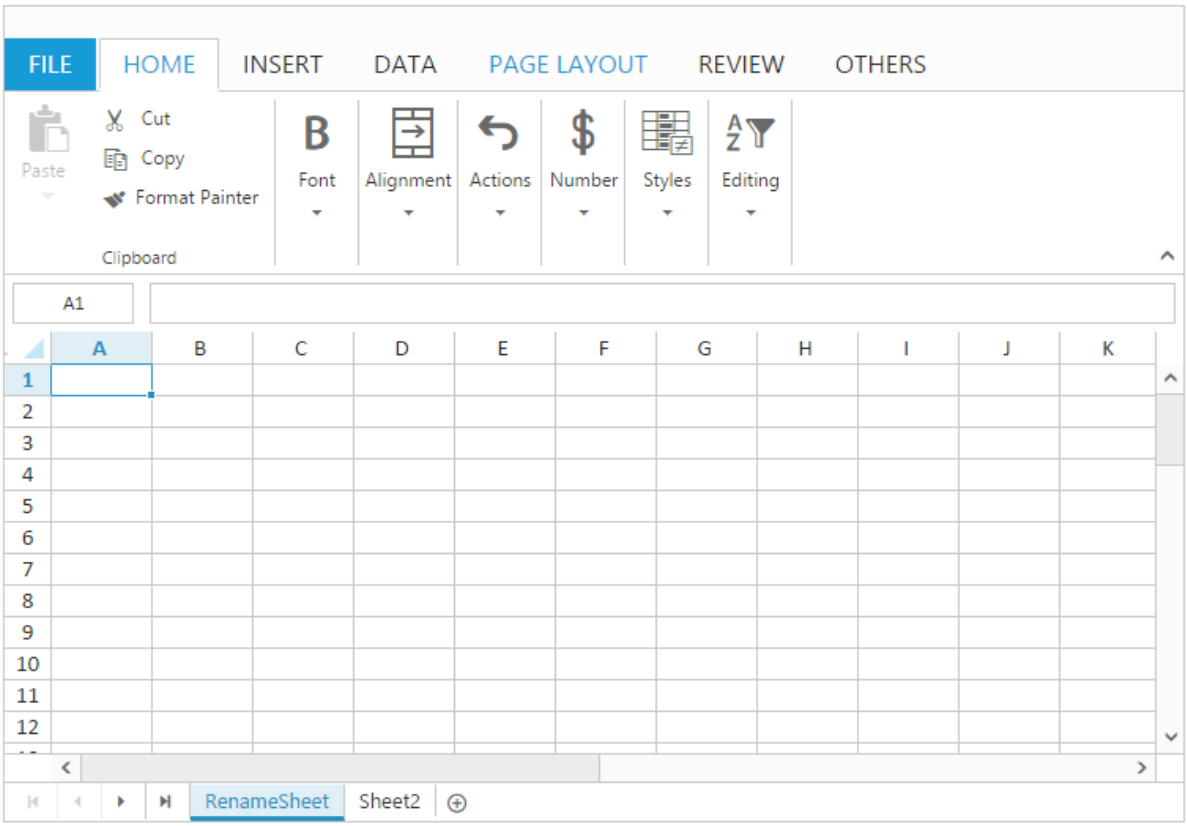
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.SheetCount(2)
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script type="text/javascript">
function loadComplete(args) {
if (!this.isImport) {
this.sheetRename("RenameSheet")
}
}
</script>
```

The following output is displayed as a result of the above code example.



Headers

Headers in the Spreadsheet are numbered rows and lettered columns in worksheets. It makes ease of view and reference to your data. You can dynamically show/hide worksheet header by using one of the following ways,

- Select PAGE LAYOUT tab in the ribbon and then check or uncheck Headings in the Show group.
- Show/Hide the worksheet headers using ShowHeadings property and showHeadings method.

The following code example describes the above behavior

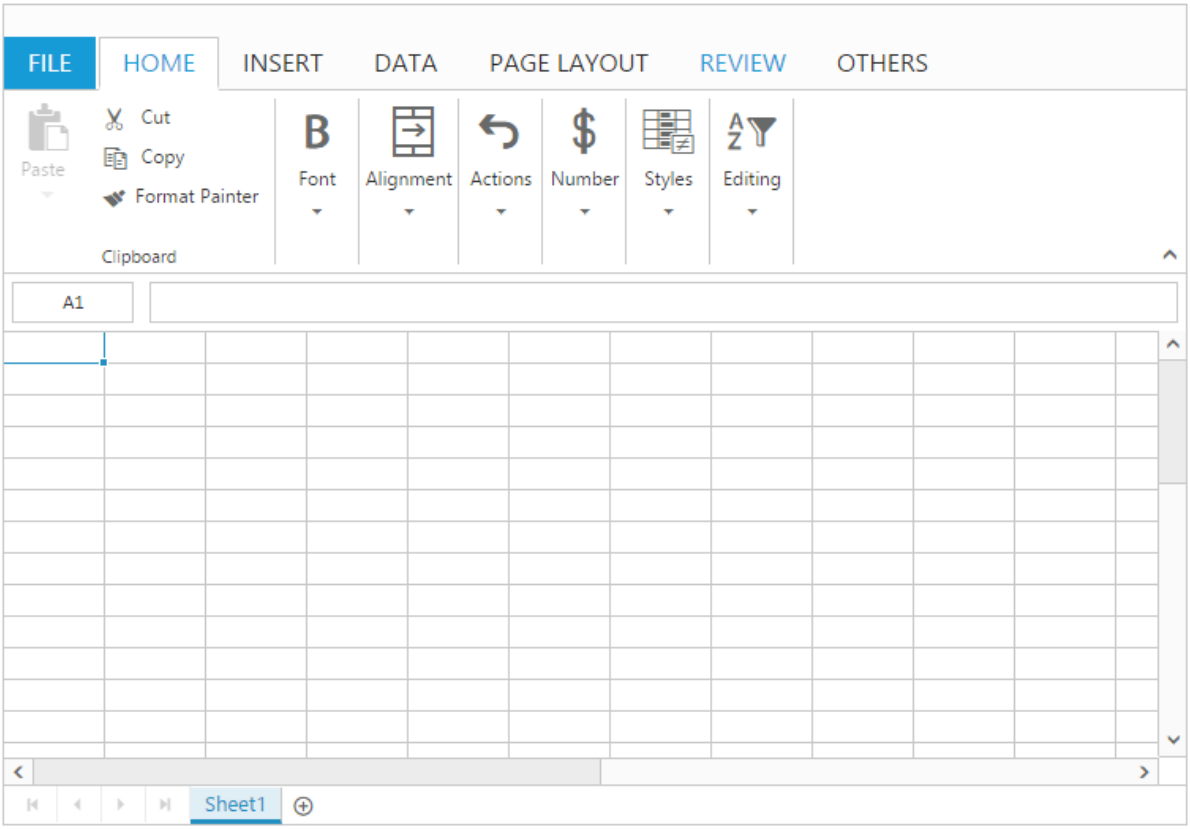
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.ShowHeadings(false).Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

The following output is displayed as a result of the above code example.



Show / Hide Sheets

You can dynamically show/hide worksheet by using one of the following ways,

- Right clicking on the worksheet in the sheet tab and then click Hide or Unhide in the context menu
- Hide the sheet using hideSheet method.
- Show the hidden sheet using unhideSheet method.

The following code example describes the above behavior

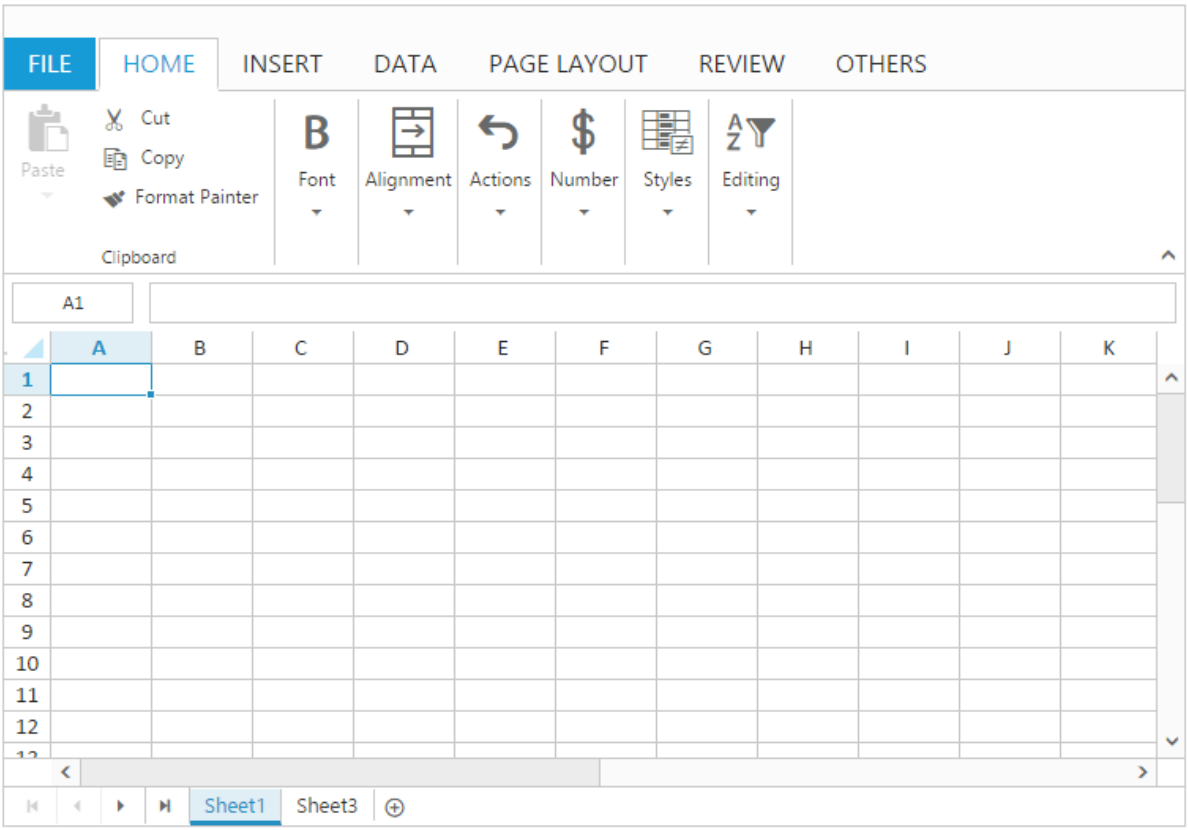
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.SheetCount(3)
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if (!this.isImport) {
this.hideSheet(1);
this.hideSheet(2);
this.unhideSheet(1);
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
</script>
```

The following output is displayed as a result of the above code example.



Show / Hide Gridlines

Gridlines act as a border like appearance of cells. They are used to distinguish cells on the worksheet. You can dynamically show/hide gridlines by using one of the following ways,

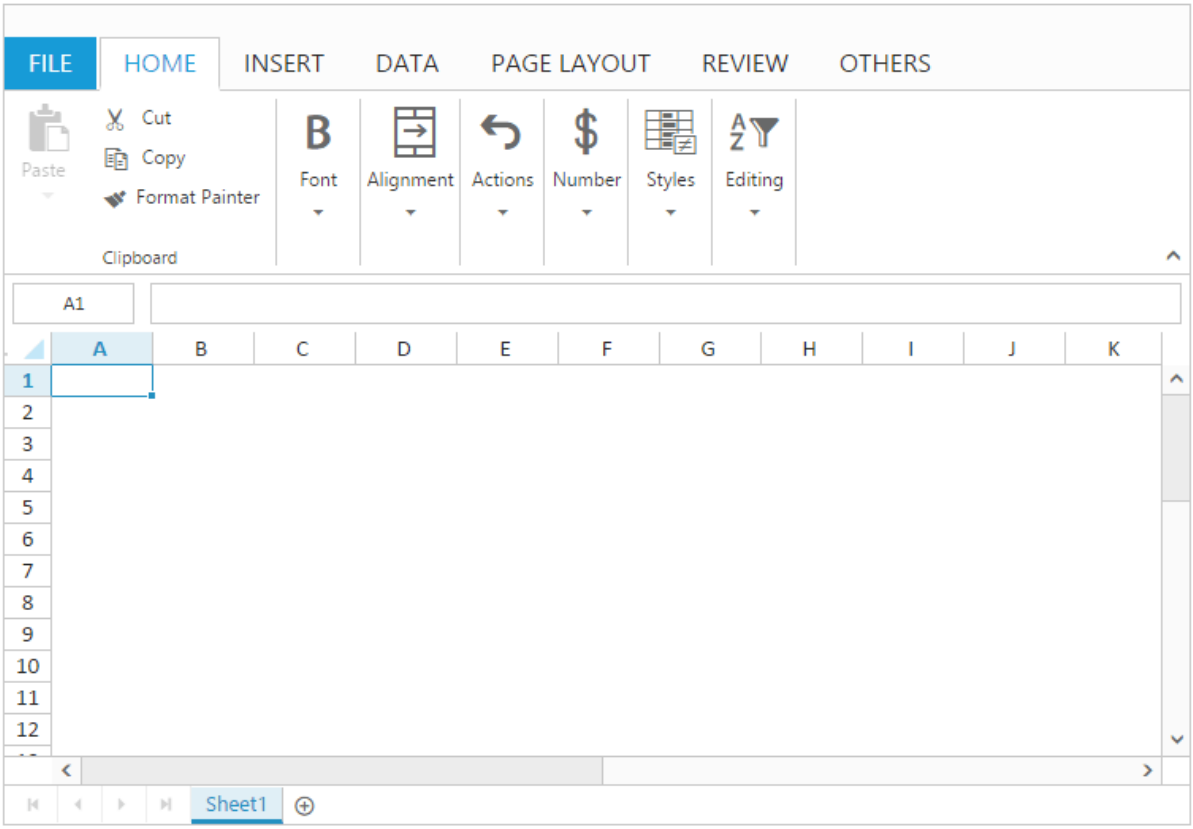
- Select PAGE LAYOUT tab in the ribbon and then check or uncheck Gridlines in the Show group.
- Show/Hide gridlines in a worksheet using ShowGridlines property and showGridlines method.

The following code example describes the above behavior

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.ShowGridlines(false).Add();
})
)
```

The following output is displayed as a result of the above code example.



Rows and Columns

Spreadsheet is a tabular format consisting of rows and columns. Rows and columns are used to represent the editing area in Spreadsheet. The intersection point of rows and columns are called as cells. In that you can perform editing. You have RowCount and ColCount in sheets property for defining the rows and columns count. By default, Spreadsheet creates 20 rows and 21 columns. Based on this grid content will be created.

Rows

Rows are a collection of cells that run horizontally. Each row is identified by the row number in the row header.

Columns

Columns are a collection of cells that run vertically. Each column is identified by column heading in the column header.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).RowCount(50).ColCount(36).Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

List of operations

You can perform the following list of operations in rows and columns,

- Insert
- Delete
- Show and Hide
- Resizing

Insert

You can insert blank cells, rows or columns based on the selection in a worksheet. You have to enable the AllowInsert property to perform the insert operation. You can perform insert operation through,

- OTHERS tab in ribbon.
- Context menu

Note: In the header context menu you can insert only rows or columns.

Copyright © 2001 - 2020 Syncfusion Inc.

Insert Shift Bottom

You can dynamically insert blank cells to the top of the selected range and shift the selected cells to down by following ways,

- Click Insert in the context menu and select “Shift Cells Down” option in Insert dialog.
- Select Insert Cells option in Insert button of OTHERS tab in Ribbon and select “Shift Cells Down” option in Insert dialog.

You can also perform insert shift bottom using insertShiftBottom method.

Insert Shift Right

You can dynamically insert blank cells to the left of the selected range and shift the selected cells to right by following ways,

- Click Insert in the context menu and select “Shift Cells Right” option in Insert dialog.
- Select Insert Cells option in Insert button of OTHERS tab in Ribbon and select “Shift Cells Right” option in Insert dialog.

You can also perform insert shift right using insertShiftRight method.

Insert Entire Row

You can dynamically insert the selected number of blank rows to the top of the selected range by following ways,

- Click Insert in the context menu and select “Entire Row” option in Insert dialog.
- Select Insert Cells option in Insert button of OTHERS tab in Ribbon and select “Entire Row” option in Insert dialog.
- Select Insert Sheet Rows option in Insert button of OTHERS tab in Ribbon.
- Click Insert option in row header context menu.

You can also perform insert entire row using insertEntireRow method.

Insert Entire Column

You can dynamically insert the selected number of blank columns to the left of the selected range by following ways,

- Click Insert in the context menu and select “Entire Column” option in Insert dialog.
- Select Insert Cells option in Insert button of OTHERS tab in Ribbon and select “Entire Column” option in Insert dialog.
- Select Insert Sheet Columns option in Insert button of OTHERS tab in Ribbon.
- Click Insert option in column header context menu.

You can also perform insert entire column using insertEntireColumn method.

Delete

You can delete a range of cells, rows or columns based on the selection in worksheet. You have to enable the AllowDelete property to perform delete operation.

You can perform delete operation through,

Copyright © 2001 - 2020 Syncfusion Inc.

- OTHERS tab in Ribbon
- Context menu

Note: In header Context menu you can delete only rows or columns.

Delete Shift Up

You can dynamically delete the selected range of cells and shift the other cells to top by following ways,

- Click Delete in the context menu and select “Shift Cells Up” option in Delete dialog.
- Select Delete Cells option in Delete button of OTHERS tab in Ribbon and select “Shift Cells Up” option in Delete dialog.

You can also perform delete shift up using deleteShiftUp method.

Delete Shift Left

You can dynamically delete the selected range of cells and shift the other cells to left by following ways,

- Click Delete in the context menu and select “Shift Cells Left” option in Delete dialog.
- Select Delete Cells in Delete button of OTHERS tab in Ribbon and select “Shift Cells Left” option in Delete dialog.

You can also perform delete shift left using deleteShiftLeft method.

Delete Entire Row

You can dynamically delete the selected rows and shift the other rows to top by following ways,

- Click Delete in the context menu and select “Entire Row” option in Delete dialog.
- Select Delete Cells option in Delete button of OTHERS tab in Ribbon and select “Entire Row” option in Delete dialog.
- Select Delete Sheet Rows option in Delete button of OTHERS tab in Ribbon.
- Click Delete option in row header context menu.

You can also perform delete entire row using deleteEntireRow method.

Delete Entire Column

You can dynamically delete a selected columns and shift other columns to left by following ways,

- Click Delete in the context menu and select “Entire Column” option in Delete dialog.
- Select Delete Cells option in Delete button of OTHERS tab in Ribbon and select “Entire Column” option in Delete dialog.
- Select Delete Sheet Columns option in Delete button of OTHERS tab in Ribbon.
- Click Delete option in column header context menu.

You can also perform delete entire column using deleteEntireColumn method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if (!this.isImport) {
this.insertEntireRow(2, 2);
this.insertEntireColumn(2, 2);
this.deleteEntireRow(4, 4);
this.deleteEntireColumn(4, 4);
this.insertShiftBottom({ rowIndex: 4, colIndex: 4 }, { rowIndex: 4,
colIndex: 4 });
this.insertShiftRight({ rowIndex: 3, colIndex: 4 }, { rowIndex: 3,
colIndex: 4 });
this.deleteShiftUp({ rowIndex: 4, colIndex: 6 }, { rowIndex: 4, colIndex:
6 });
this.deleteShiftLeft({ rowIndex: 3, colIndex: 6 }, { rowIndex: 3,
colIndex: 6 });
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

Show and Hide

You can show or hide the rows and columns in Spreadsheet using methods and context menu.

Hide Row

You can hide the rows dynamically by using one of the following ways,

- Click “Hide” option in row header context menu.
- Hide the rows using hideRow method.

Hide Column

You can hide the columns dynamically by using one of the following ways,

- Click “Hide” option in column header context menu.
- Hide the columns using hideColumn method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
```

```
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if (!this.isImport) {
this.hideRow(2);
this.hideColumn(2);
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

Sheet1

Show Row

You can show the hidden rows dynamically by using one of the following ways,

- Click “Unhide” option in row header context menu.
- Show the hidden rows using showRow method.

Show Column

You can show the hidden columns dynamically by using one of the following ways,

- Click “Unhide” option in column header context menu.
- Show the hidden columns using showColumn method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
```

12								

Resizing

You can change ColumnWidth and RowHeight with the specified value. You have to enable AllowResizing property to perform resizing.

You can perform resizing using one of the following ways,

- Resize option in column header and row header.
- Set the column width by using setColWidth method or ColumnWidth property.
- Set the row height by using setRowHeight method or RowHeight property.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ScrollSettings(scroll =>
{
scroll.Height(510);
})
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.RowHeight(20)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.ColumnWidth(64)
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if (!this.isImport) {
this.XLResize.setColWidth(2, 100);
this.XLResize.setRowHeight(2, 40);
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });

Freeze Pane

Freeze pane allows you to keep a portion of the sheet visible, while scrolling through the rest of the worksheet.

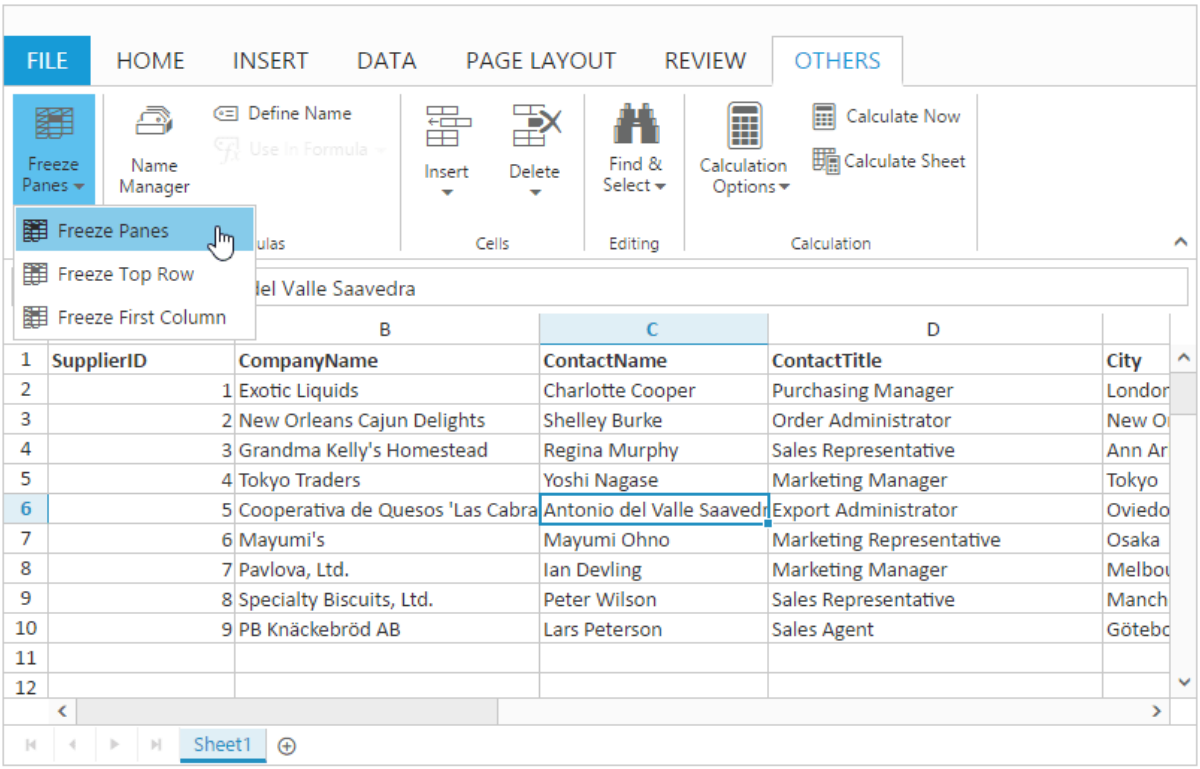
The freeze pane can be applied in a following ways,

1. User Interface
2. Initial Load
3. Method

User Interface

Select any cell and on OTHERS tab click Freeze Panes in Freeze Panes dropdown list.

Copyright © 2001 - 2020 Syncfusion Inc.



Initial Load

You can use AllowFreezing property to enable or disable freeze pane in Spreadsheet.

To specify number of rows and columns to be frozen, use FrozenRows and FrozenColumns property in sheets.

The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
.AllowFreezing(true)
.Sheets(sheet =>
{
sheet.Datasource((IEnumerable<object>)ViewBag.Datasource).FrozenRows(5).F
rozenColumns(2).Add();
})
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<PersonDetail> lItems = new List<PersonDetail>();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
lItems.Add(new PersonDetail() { SupplierID = 1, CompanyName = "Exotic
Liquids", ContactName = "Charlotte Cooper", ContactTitle = "Purchasing
Manager", City = "London", PostalCode = "EC1 4SD", Country = "UK" });
lItems.Add(new PersonDetail() { SupplierID = 2, CompanyName = "New
Orleans Cajun Delights", ContactName = "Shelley Burke", ContactTitle =
"Order Administrator", City = "New Orleans", PostalCode = "70117",
Country = "USA" });
lItems.Add(new PersonDetail() { SupplierID = 3, CompanyName = "Grandma
Kelly's Homestead", ContactName = "Regina Murphy", ContactTitle = "Sales
Representative", City = "Ann Arbor", PostalCode = "48104", Country =
"USA" });
lItems.Add(new PersonDetail() { SupplierID = 4, CompanyName = "Tokyo
Traders", ContactName = "Yoshi Nagase", ContactTitle = "Marketing
Manager", City = "Tokyo", PostalCode = "100", Country = "Japan" });
lItems.Add(new PersonDetail() { SupplierID = 5, CompanyName =
"Cooperativa de Quesos 'Las Cabras'", ContactName = "Antonio del Valle
Saavedra", ContactTitle = "Export Administrator", City = "Oviedo",
PostalCode = "33007", Country = "Spain" });
lItems.Add(new PersonDetail() { SupplierID = 6, CompanyName = "Mayumi's",
ContactName = "Mayumi Ohno", ContactTitle = "Marketing Representative",
City = "Osaka", PostalCode = "545", Country = "Japan" });
lItems.Add(new PersonDetail() { SupplierID = 7, CompanyName = "Pavlova,
Ltd.", ContactName = "Ian Devling", ContactTitle = "Marketing Manager",
City = "Melbourne", PostalCode = "3058", Country = "Australia" });
lItems.Add(new PersonDetail() { SupplierID = 8, CompanyName = "Specialty
Biscuits, Ltd.", ContactName = "Peter Wilson", ContactTitle = "Sales
Representative", City = "Manchester", PostalCode = "M14 GSD", Country =
"UK" });
lItems.Add(new PersonDetail() { SupplierID = 9, CompanyName = "PB
Knäckebröd AB", ContactName = "Lars Peterson", ContactTitle = "Sales
Agent", City = "Göteborg", PostalCode = "S-345 67", Country = "Sweden"
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

Note: The default value of AllowFreezing property is true.

Method

You can freeze rows or columns using freezePanes method.

The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if (!this.isImport)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
this.XLFreeze.freezePanes(5,2);
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<PersonDetail> lItems = new List<PersonDetail>();
lItems.Add(new PersonDetail() { SupplierID = 1, CompanyName = "Exotic
Liquids", ContactName = "Charlotte Cooper", ContactTitle = "Purchasing
Manager", City = "London", PostalCode = "EC1 4SD", Country = "UK" });
lItems.Add(new PersonDetail() { SupplierID = 2, CompanyName = "New
Orleans Cajun Delights", ContactName = "Shelley Burke", ContactTitle =
"Order Administrator", City = "New Orleans", PostalCode = "70117",
Country = "USA" });
lItems.Add(new PersonDetail() { SupplierID = 3, CompanyName = "Grandma
Kelly's Homestead", ContactName = "Regina Murphy", ContactTitle = "Sales
Representative", City = "Ann Arbor", PostalCode = "48104", Country =
"USA" });
lItems.Add(new PersonDetail() { SupplierID = 4, CompanyName = "Tokyo
Traders", ContactName = "Yoshi Nagase", ContactTitle = "Marketing
Manager", City = "Tokyo", PostalCode = "100", Country = "Japan" });
lItems.Add(new PersonDetail() { SupplierID = 5, CompanyName =
"Cooperativa de Quesos 'Las Cabras'", ContactName = "Antonio del Valle
Saavedra", ContactTitle = "Export Administrator", City = "Oviedo",
PostalCode = "33007", Country = "Spain" });
lItems.Add(new PersonDetail() { SupplierID = 6, CompanyName = "Mayumi's",
ContactName = "Mayumi Ohno", ContactTitle = "Marketing Representative",
City = "Osaka", PostalCode = "545", Country = "Japan" });
lItems.Add(new PersonDetail() { SupplierID = 7, CompanyName = "Pavlova,
Ltd.", ContactName = "Ian Devling", ContactTitle = "Marketing Manager",
City = "Melbourne", PostalCode = "3058", Country = "Australia" });
lItems.Add(new PersonDetail() { SupplierID = 8, CompanyName = "Specialty
Biscuits, Ltd.", ContactName = "Peter Wilson", ContactTitle = "Sales
Representative", City = "Manchester", PostalCode = "M14 GSD", Country =
"UK" });
lItems.Add(new PersonDetail() { SupplierID = 9, CompanyName = "PB
Knäckebröd AB", ContactName = "Lars Peterson", ContactTitle = "Sales
Agent", City = "Göteborg", PostalCode = "S-345 67", Country = "Sweden"
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above behavior.

Note: When we apply freeze pane by selecting cell “A1”, rows and columns are frozen based on the middle cell in the worksheet.

Freeze Rows

It allows you to keep the certain number of rows visible while scrolling through the rest of the worksheet.

The freeze rows can be applied in a following ways,

1. Initial Load
2. Method

Initial Load

You can freeze rows using `FrozenRows` property in sheets.

The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Datasource((IEnumerable<object>)ViewBag.Datasource).FrozenRows(3).A
dd();
})
)
```

C#

Open and Save

The native data format for Spreadsheet is JSON. You can load and store JSON data with Spreadsheet. In Spreadsheet we have saveAsJSON and loadFromJSON method which is used to save Spreadsheet as JSON and same JSON used to render Spreadsheet.

JAVASCRIPT

```
function saveAsJSON() {
var excelObj = $("#Spreadsheet").data("ejSpreadsheet");
window.excelData = excelObj.saveAsJSON();
}
function loadFromJSON() {
var excelObj = $("#Spreadsheet").data("ejSpreadsheet");
excelObj.loadFromJSON(window.excelData);
}
```

When you open excel file, it need to be read and converted to client side Spreadsheet model. The converted client side Spreadsheet model is sent as JSON which is used to render Spreadsheet. Similarly, when you save the Spreadsheet, the client Spreadsheet model is sent to the server as JSON for processing and saved. Server configuration is used for this process.

Open

The Spreadsheet can open excel documents as like excel application with its data, style, format. To enable open option in Spreadsheet set AllowImport option to true. Since Spreadsheet uses a server side helper to open document, set ImportMapper in ImportSettings to map server action.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.AllowImport(true)
.ImportSettings(import =>
{
import.ImportMapper("Import");
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
return View();
}
[AcceptVerbs(HttpVerbs.Post)]
public ActionResult Import(ImportRequest importRequest)
{
return importRequest.SpreadsheetActions();
}
}
}
```

Following file types can be opened in Spreadsheet

- XLS
- XLSX
- CSV

Click here to view online demo sample. You can open excel documents in following ways

1. Initial settings
2. Methods
3. User Interface

Initial settings

The Spreadsheet can load excel documents initially. The document can be specified either from client side or in server side. To load excel documents initially from client side, set ImportUrl in ImportSettings. The code snippets for document initial load on client side are as follows,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ImportSettings(import =>
{
import.ImportMapper("Import").ImportUrl("http://mvc.syncfusion.com/Spread
sheet/LargeData.xlsx");
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
return View();
}
[AcceptVerbs(HttpVerbs.Post)]
public ActionResult Import(ImportRequest importRequest)
{
return importRequest.SpreadsheetActions();
}
}
}
```

To load excel documents initially from server side, set ImportOnLoadas true and assign document stream or URL in the server. The code snippets for document initial load from server side are as follows,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ImportSettings(import =>
{
import.ImportOnLoad(true).ImportMapper("Import");
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
return View();
}
[AcceptVerbs(HttpVerbs.Post)]
public ActionResult Import(ImportRequest importRequest)
{
importRequest.Url =
"http://mvc.syncfusion.com/Spreadsheet/LargeData.xlsx";
return importRequest.SpreadsheetActions();
}
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

14	10260	OTTIK	4	1	7/19/1996	$5

Sheet1

Methods

To open an excel document, import method should be called with import options as a parameter. The Spreadsheet can open excel document as a stream or file URL.

Stream

Spreadsheet can open excel document as a stream and the document stream was either from the client side or it can be specified in server side. The code snippets to open excel document as a stream from client side are as follows,

JAVASCRIPT

```
function fileOpen(args) {
var excelObj = $("#Spreadsheet").data("ejSpreadsheet"),
stream = args.files[0]; // file stream from ejUploadbox
excelObj["import"]({ file: stream });
}
```

The Code snippets to specify excel document as stream in server side are as follows,

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
var DataSource = new OrderItemsDataContext().GetAllItemDetails.ToList();
ViewBag.Datasource = DataSource;
return View();
}
[AcceptVerbs(HttpVerbs.Post)]
public ActionResult Import(ImportRequest importRequest)
{
importRequest.FileStream = getFileStream(); // assign file stream
return importRequest.SpreadsheetActions();
}
}
}
```

File URL

Spreadsheet can open excel document from specified URL. The URL can be specified either from client side or in server side. The code snippets to open excel document as URL from client side are as follows,

JAVASCRIPT

```
function fileOpen() {
var excelObj = $("#Spreadsheet").data("ejSpreadsheet");
excelObj["import"]({Url:
"http://mvc.syncfusion.com/Spreadsheet/LargeData.xlsx"});
}
```

The Code snippets to specify excel document as URL in server side are as follows,

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
return View();
}
[AcceptVerbs(HttpVerbs.Post)]
public ActionResult Import(ImportRequest importRequest)
{
importRequest.Url =
"http://mvc.syncfusion.com/Spreadsheet/LargeData.xlsx";
return importRequest.SpreadsheetActions();
}
}
}
```

User Interface

You can dynamically open excel document by clicking the file menu in ribbon and choose Open to upload excel file.

Copyright © 2001 - 2020 Syncfusion Inc.

Save

The Spreadsheet can save its data, style, format into an excel file. To enable save option in Spreadsheet set AllowExporting option in ExportSettings as true. Since Spreadsheet uses server side helper to save documents set ExcelUrl in ExportSettings option.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ExportSettings(export =>
{
export.AllowExporting(true).ExcelUrl("ExportToExcel").CsvUrl("ExportToCSV
").PdfUrl("ExportToPDF");
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
return View();
}
[AcceptVerbs(HttpVerbs.Post)]
public void ExportToExcel(string sheetModel, string sheetData, string
password)
{
if (String.IsNullOrEmpty(password))
Spreadsheet.Save(sheetModel, sheetData, "sample", ExportFormat.XLSX,
ExcelVersion.Excel2013);
else
Spreadsheet.Save(sheetModel, sheetData, "sample", ExportFormat.XLSX,
ExcelVersion.Excel2013, password);
}
[AcceptVerbs(HttpVerbs.Post)]
public void ExportToCsv(string sheetModel, string sheetData)
{
Spreadsheet.Save(sheetModel, sheetData, "sample", ExportFormat.CSV);
}
[AcceptVerbs(HttpVerbs.Post)]
public void ExportToPdf(string sheetModel, string sheetData)
{
Spreadsheet.Save(sheetModel, sheetData, "sample", ExportFormat.PDF);
}
}
}
```

Note: To export as Stream skip file name parameter in Save method. For more details refer below code snippets,

Stream stream = Spreadsheet.Save(sheetModel, sheetData, ExportFormat.XLSX, ExcelVersion.Excel2013);

Copyright © 2001 - 2020 Syncfusion Inc.

You can save Spreadsheet contents with following file types,

- XLS
- XLSX
- CSV
- PDF

Click here to view online demo sample. You can save excel documents in following ways

1. Methods
2. User Interface

Methods

To save Spreadsheet document as excel file, export method should be called with file type as parameter. The code snippets to save Spreadsheet document are as follows,

JAVASCRIPT

```
function saveAsFile() {
var excelObj = $("#spreadsheet").data("ejSpreadsheet");
excelObj.XLExport["export"](ej.Spreadsheet.exportType.Excel);
}
```

User Interface

You can dynamically save Spreadsheet by clicking file menu in ribbon and choose SaveAs option.

Server dependencies

Import and Export Helper functions are available in the assembly Syncfusion.EJ.Export, which is available in Essential Studio and Essential JavaScript builds. The full list of assemblies needed for Spreadsheet import and export are as follows.

1. Syncfusion.EJ
2. Syncfusion.EJ.Export
3. Syncfusion.Linq.Base
4. Syncfusion.Compression.Base
5. Syncfusion.DocIO.Base
6. Syncfusion.XlsIO.Base
7. Syncfusion.PDF.Base

Note: 1. The above mentioned assemblies will be available in below location after Essential Studio build installation.

2. C:\Program Files (x86)\Syncfusion\Essential Studio\x.x.x.x\precompiledassemblies\x.x.x.x\y.y.

3. x.x.x.x defines build version of Essential Studio and y.y defines .NET Framework version.

Data Binding

Spreadsheet can be populated with external datasource using DataSource property. The DataSource property can be assigned either with the instance of DataManager or JSON data array collection. Spreadsheet supports three different kinds of Data binding.

Copyright © 2001 - 2020 Syncfusion Inc.

- Local Data
- Remote Data
- HTML Table Data

Local Data

To bind local data to the Spreadsheet, you can assign a JSON array to the worksheet DataSource property. The following code illustrates how to bind local data to the Spreadsheet,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).ShowHeader(fals
e).Add();
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<OrderDetail> lItems = new List<OrderDetail>();
lItems.Add(new OrderDetail() { OrderID = 10248, CustomerID = "VINET",
EmployeeID = 5, ShipCity = "Reims", ShipCountry = "France" });
lItems.Add(new OrderDetail() { OrderID = 10249, CustomerID = "TOMSP",
EmployeeID = 6, ShipCity = "Münster", ShipCountry = "Germany" });
lItems.Add(new OrderDetail() { OrderID = 10250, CustomerID = "HANAR",
EmployeeID = 4, ShipCity = "Rio de Janeiro", ShipCountry = "Brazil" });
lItems.Add(new OrderDetail() { OrderID = 10251, CustomerID = "VICTE",
EmployeeID = 3, ShipCity = "Lyon", ShipCountry = "France" });
lItems.Add(new OrderDetail() { OrderID = 10252, CustomerID = "SUPRD",
EmployeeID = 4, ShipCity = "Charleroi", ShipCountry = "Belgium" });
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code snippets.

Copyright © 2001 - 2020 Syncfusion Inc.

	A	B	C	D	E
1	10248	VINET	5	Reims	France
2	10249	TOMSP	6	Münster	Germany
3	10250	HANAR	4	Rio de Janeiro	Brazil
4	10251	VICTE	3	Lyon	France

13	10260	OTTIK	4	Köln	Germany
14	10261	QUEDE	4	Rio de Janeiro	Brazil
15	10262	RATTC	8	Albuquerque	USA

Sheet1

Remote Data

To bind remote data to the Spreadsheet, you can assign a service data as an instance of DataManager to the worksheet DataSource property. The following code illustrates how to bind remote data to the Spreadsheet,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Datasource("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders"
)
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight'])
.take(50)").Add();
})
)
```

The following output is displayed as a result of the above code snippets.

Sheet1

Offline Mode

To avoid sending post back request to server on every action, Spreadsheet allows user to create, update and delete data on client side. To enable this, set Offline property of DataManager as true to fetch all data from server on initial rendering of Spreadsheet and perform all operation on client side.

The following code illustrates Offline data binding for Spreadsheet,

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").URL("http://mvc.syncfusion.com/Servic
es/Northwnd.svc/Orders/").Offline(true)))
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.DataManagerID("FlatData")
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipName',  'ShipAddress'])")
.PrimaryKey("OrderID").Add();
})
)
```

The following output is displayed as a result of the above code snippets.

15	10262	RATTC	8	Rattlesnake Ca	2817 Milton D

Sheet1

Note: For further reference about Offline property in DataManager refer following link

HTML Table Data

An HTML Table element can also be used as the data source of Spreadsheet. To use HTML Table as data source, the table element should be passed to worksheet DataSource property of Spreadsheet as an instance of the DataManager. The following code illustrates how to bind HTML Table data to the Spreadsheet,

ASPX-CS

```
@(Html.EJ().DataManager("FlatData").Table("#_table1"))
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.DataManagerID("FlatData").Add();
})
)
<script id="_table1" type="text/template">
<table id="Table1">
<thead>

Ways to bind data in Spreadsheet

You can bind data to Spreadsheet in following ways,

- Cell binding
- Range binding
- Sheet binding

Cell Binding

Spreadsheet can bind data for individual cells in a sheet. The data may contain value, style, format, comment and hyperlink. The individual cell properties are listed below,

Properties	Description
Index	To specify particular cell
Value	To specify value. It may be string, integer, formula etc.
Style	To specify style in the cell
Format	To specify number format in the cell
Comment	To specify comment in the cell
Hyperlink	To specify hyperlink in the cell

The individual row properties are listed below,

Properties	Description

Copyright © 2001 - 2020 Syncfusion Inc.

Index	To specify particular row
Height	To specify height in the row

You can specify particular row with Index property and its height with Height property in the Rows property collection. The following code illustrates cell binding in Spreadsheet,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ScrollSettings(scroll =>
{
scroll.Height(510);
})
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
rows.Height(30).Cells(cells =>
{
cells.Value("Item Name").Style(style =>
{
style.FontWeight("bold").Color("#FFFFFF").BackgroundColor("#428bca");
}).Add();
cells.Value("Quantity").Style(style =>
{
style.FontWeight("bold").Color("#FFFFFF").BackgroundColor("#428bca");
}).Add();
cells.Value("Price").Style(style =>
{
style.FontWeight("bold").Color("#FFFFFF").BackgroundColor("#428bca");
}).Add();
cells.Value("Amount").Style(style =>
{
style.FontWeight("bold").Color("#FFFFFF").BackgroundColor("#428bca");
}).Add();
cells.Value("Stock Details").Style(style =>
{
style.FontWeight("bold").Color("#FFFFFF").BackgroundColor("#428bca");
}).Add();
cells.Value("Website").Style(style =>
{
style.FontWeight("bold").Color("#FFFFFF").BackgroundColor("#428bca");
}).Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("Casual Shoes").Comment(comment =>
{
comment.Value("Casual Footwears with wide variety of colors.");
}).Add();
cells.Value("10").Add();
cells.Value("20").Format(format =>
{
format.Type("currency");
```

Copyright © 2001 - 2020 Syncfusion Inc.

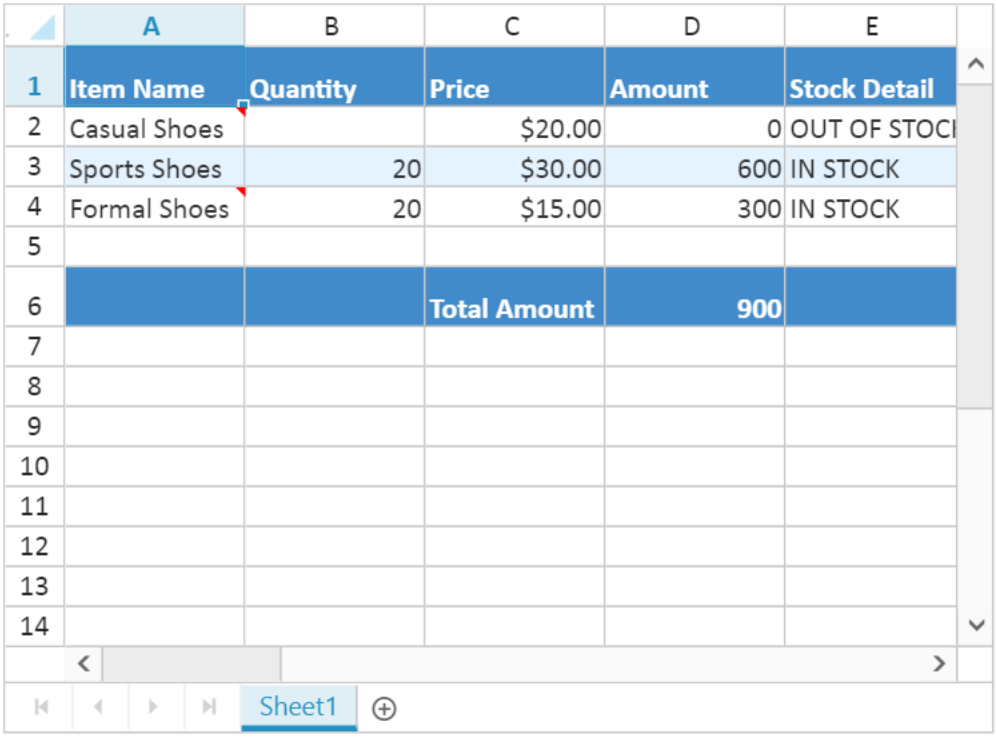
```
}).Add();
cells.Value("=B2*C2").Add();
cells.Value("OUT OF STOCK").Add();
cells.Value("Amazon").Hyperlink(hyperlink =>
{
hyperlink.WebAddr("www.amazon.com");
}).Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("Sports Shoes").Style(style =>
{
style.BackgroundColor("#E5F3FF");
}).Add();
cells.Value("20").Style(style =>
{
style.BackgroundColor("#E5F3FF");
}).Add();
cells.Value("30").Format(format =>
{
format.Type("currency");
}).Style(style =>
{
style.BackgroundColor("#E5F3FF");
}).Add();
cells.Value("=B3*C3").Style(style =>
{
style.BackgroundColor("#E5F3FF");
}).Add();
cells.Value("IN STOCK").Style(style =>
{
style.BackgroundColor("#E5F3FF");
}).Add();
cells.Value("AliExpress").Hyperlink(hyperlink =>
{
hyperlink.WebAddr("www.aliexpress.com");
}).Style(style =>
{
style.BackgroundColor("#E5F3FF");
}).Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("Formal Shoes").Comment(comment =>
{
comment.Value("Formal Footwears with wide range of sizes.");
}).Add();
cells.Value("20").Add();
cells.Value("15").Format(format =>
{
format.Type("currency");
}).Add();
cells.Value("=B4*C4").Add();
cells.Value("IN STOCK").Add();
cells.Value("Amazon").Hyperlink(hyperlink =>
{
hyperlink.WebAddr("www.amazon.com");
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}).Add();
}).Add();
rows.Height(30).Cells(cells =>
{
cells.Style(style =>
{
style.BackgroundColor("#428bca");
}).Add();
cells.Style(style =>
{
style.BackgroundColor("#428bca");
}).Add();
cells.Value("Total Amount").Index(2).Style(style =>
{
style.FontWeight("bold").Color("#FFFFFF").BackgroundColor("#428bca");
}).Add();
cells.Value("=Sum(D2:D4)").Style(style =>
{
style.FontWeight("bold").Color("#FFFFFF").BackgroundColor("#428bca");
}).Add();
cells.Style(style =>
{
style.BackgroundColor("#428bca");
}).Add();
cells.Style(style =>
{
style.BackgroundColor("#428bca");
}).Add();
}).Add();
}).Add();
})
)
```

The following output is displayed as a result of the above code snippets.

Copyright © 2001 - 2020 Syncfusion Inc.



Range Binding

Spreadsheet can bind data for one or more range in a sheet using RangeSettings. The individual range properties are listed below,

Properties	Description
DataSource	To specify JSON or DataManager
Query	To specify query for DataManager
StartCell	To specify start cell of a range
PrimaryKey	To specify data source primary key
ShowHeader	To show data source header
HeaderStyles	To specify header styles

The following code illustrates range binding in Spreadsheet

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).StartCell("C2")
.ShowHeader(true).Add();
}).Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

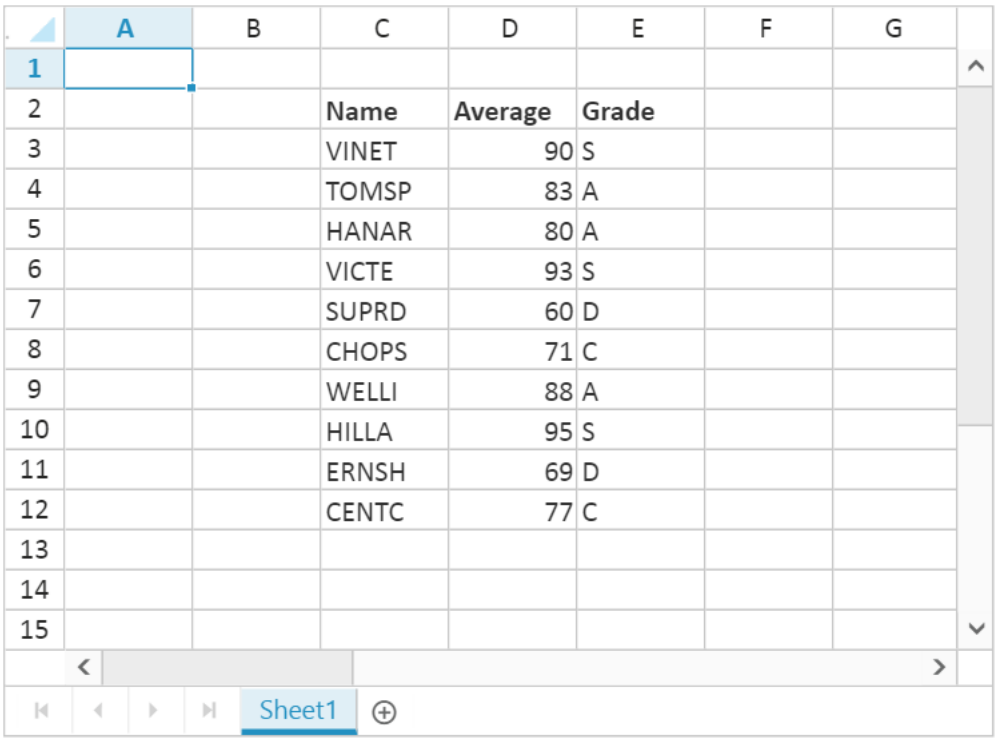
```
)
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<MarkDetail> lItems = new List<MarkDetail>();
lItems.Add(new MarkDetail() { Name = "VINET", Average = 90, Grade = "S"
});
lItems.Add(new MarkDetail() { Name = "TOMSP", Average = 83, Grade = "A"
});
lItems.Add(new MarkDetail() { Name = "HANAR", Average = 80, Grade = "A"
});
lItems.Add(new MarkDetail() { Name = "VICTE", Average = 93, Grade = "S"
});
lItems.Add(new MarkDetail() { Name = "SUPRD", Average = 60, Grade = "D"
});
lItems.Add(new MarkDetail() { Name = "CHOPS", Average = 71, Grade = "C"
});
lItems.Add(new MarkDetail() { Name = "WELLI", Average = 88, Grade = "A"
});
lItems.Add(new MarkDetail() { Name = "HILLA", Average = 95, Grade = "S"
});
lItems.Add(new MarkDetail() { Name = "ERNSH", Average = 69, Grade = "D"
});
lItems.Add(new MarkDetail() { Name = "CENTC", Average = 77, Grade = "C"
});
lItems.Add(new MarkDetail() { Name = "OTTIK", Average = 95, Grade = "S"
});
lItems.Add(new MarkDetail() { Name = "RATTC", Average = 85, Grade = "A"
});
lItems.Add(new MarkDetail() { Name = "FOLKO", Average = 90, Grade = "A"
});
lItems.Add(new MarkDetail() { Name = "BLONP", Average = 97, Grade = "S"
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code snippets.

Copyright © 2001 - 2020 Syncfusion Inc.



Sheet Binding

Spreadsheet can bind data for a sheet. The individual sheet properties are listed below,

Properties	Description
DataSource	To specify JSON or DataManager
Query	To specify query for DataManager
StartCell	To specify start cell of a range
PrimaryKey	To specify data source primary key
ShowHeader	To show data source header
HeaderStyles	To specify header styles
FieldAsColumnHeader	To show data source fields in column header

The following code illustrates sheet binding in Spreadsheet

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Datasource("http://mvc.syncfusion.com/Services/Northwnd.svc/Orders"
)
.Query("new ej.Query().select(['OrderID', 'CustomerID', 'EmployeeID',
'ShipCity', 'Freight'])
.take(50)").FieldAsColumnHeader(true).PrimaryKey("OrderID").Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
)
```

The following output is displayed as a result of the above code snippets.

	OrderID	CustomerID	EmployeeID	ShipName	ShipAddress
1	10248	VINET	1	SURINDER	OLDTOWN
2	10249	TOMSP	6	SURINDER	CENTRAL ST
3	10250	HANAR	9	SURINDER	Hamilton
4	10251	VICTE	3	SURINDER	Khreschatik

Sheet1

Cell Range

A Cell Range is a collection of cells in a sheet. It represents single cell or selection of cells. When cells have been selected, they are surrounded by border.

You have following features in Cell Range,

- Comment
- Cell Navigation
- Data Validation
- Drag and Drop
- Auto Fill
- Hyperlink
- Merge Cell

Comment

Comment is used to give additional information for an individual cell about the data it contains. When a cell has a comment, a red indicator appears in the corner of the cell. When mouse hover on the cell, the comment will appear. You can use `AllowComments` property to enable/disable comments.

Copyright © 2001 - 2020 Syncfusion Inc.

To insert a Comment

You can insert a comment by using one of the following ways,

- Using "New" button under Comments group of REVIEW Tab in ribbon.
- Using context menu to select "Insert Comment" option in "Comment".
- Using setComment method.

To remove a Comment

You can remove a comment by using one of the following ways,

- Using "Delete" button under Comments group of REVIEW Tab in ribbon.
- Using context menu to select "Delete Comment" option in "Comment".
- Using deleteComment method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.XLComment.setComment("A2", " Casual Foot wears with wide variety of
colors.", false);
this.XLComment.setComment("A4", " Formal Foot wears with wide variety of
sizes.", true); // If true comment is in Editing mode.
//To Remove a Comment
this.XLComment.deleteComment ("A2");
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

	A	B	C	D	E	F	G	H
1	Item Name	Date	Time	Quantity	Price	Amount	Discount	Profit
2	Casual Shoes	2/14/2014	11:34:32 AM	10	20	200	1	10
3	Sports Shoes	6/11/2014	5:56:32 AM	20	30	600	5	50
4	Formal Shoes		AM	20	15	300	7	27
5	Sandals & Floaters		AM	15	20	300	11	67

7	Sneakers		AM	40	20	800	13	66
8	Running Shoes	2/4/2014	3:44:34 AM	20	10	200	3	14
9	Loafers	11/30/2014	3:12:52 AM	31	10	310	6	29
10	Cricket Shoes	7/9/2014	11:32:14 AM	41	30	1210	12	166
11	T-Shirts	10/31/2014	12:01:44 AM	50	10	500	9	55

Cell Navigation

Cell navigation is used to navigate through the cells using keyboard. You can use `AllowKeyboardNavigation` property to enable/disable cell navigation. The following list of keys used for cell navigation are,

Keys	Description
Ctrl + Home	Go to first cell in the first row.

Copyright © 2001 - 2020 Syncfusion Inc.

Ctrl + End	Go to last cell in the last row.
Up Arrow	Go to previous cell in the same column
Down Arrow	Go to next cell in the same column
Right Arrow	Go to next cell in the same row
Left Arrow	Go to previous cell in the same row
Page Down	Go to next block
Page Up	Go to previous block
Home	Go to first cell of the same row
End	Go to last cell of the same row
Enter	Save the current cell changes and navigate to the next row.
Tab	Go to next cell
Shift + Tab	Go to previous cell
Shift + Up Arrow	Go to previous row or previous row cell with selection
Shift+ Down Arrow	Go to next row or next row cell with selection
Shift + Right Arrow	Go to next cell within the same row with selection
Shift + Left Arrow	Go to previous cell within the same row with selection
Ctrl + Up Arrow	Go to next cell from the first empty cell in upwards.
Ctrl + Down Arrow	Go to previous cell from the first empty cell in downwards.
Ctrl + Left Arrow	Go to next cell from the first empty cell in leftwards.
Ctrl+ Right Arrow	Go to previous cell from the first empty cell in rightwards.

Note: In the above table, "Ctrl + Home" and "Ctrl + End" is based on the used range.

Data Validation

Data Validation is used to restrict the user to enter the invalid data. You can use `AllowDataValidation` property to enable/disable data validation.

Note: The below validation script files are needed for validation.

* jquery.validate.min.js

* jquery.validate.unobtrusive.min.js

To apply validation.

You can apply data validation by using one of the following ways,

Copyright © 2001 - 2020 Syncfusion Inc.

- Using "Data Validation" option in Data Validation button under Data Tools group of DATA Tab in ribbon, Data Validation dialog will be opened in that you can perform Validation.
- Using applyDVRules method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.XLValidate.applyDVRules("G2:G12", ["Greater", 6], "number", true,
true);
//the last two boolean values used to ignore blank value and error alert.
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
}
```

To clear validation

You can clear data validation rule by one of the following ways,

- Using "Clear Validation" option in Data Validation button under Data Tools group of DATA Tab in ribbon.
- Using clearDV method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.XLValidate.applyDVRules("G2:G12", ["Greater", 6], "number", true,
true);
//the last two boolean values used to ignore blank value and error alert.
this.XLValidate.clearDV("G2:G12");
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

To format invalid data

You can highlight the invalid data by using following ways,

- Using "Format Invalid Data" option in Data Validation button under Data Tools group of DATA Tab in ribbon.
- Using highlightInvalidData method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.XLValidate.applyDVRules("G2:G12", ["Greater", 6], "number", true,
true);
//the last two boolean values used to ignore blank value and error alert.
this.XLValidate.highlightInvalidData ("G2:G12");
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

	A	B	C	D	E	F	G	H
1	Item Name	Date	Time	Quantity	Price	Amount	Discount	Profit
2	Casual Shoes	2/14/2014	11:34:32 AM	10	20	200	1	10
3	Sports Shoes	6/11/2014	5:56:32 AM	20	30	600	5	50
4	Formal Shoes	7/27/2014	3:32:44 AM	20	15	300	7	27
5	Sandals & Floaters	11/21/2014	6:23:54 AM	15	20	300	11	67

Drag and Drop

Drag and drop is used to pick a selected cells and drop it into a new place on the worksheet. You can use `AllowDragAndDrop` property to enable/disable drag and drop.

Copyright © 2001 - 2020 Syncfusion Inc.

You can do this by one of the following ways,

- Using mouse drag and drop.
- Using moveRangeTo Method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport)
this.XLDragDrop.moveRangeTo([1, 6, 4, 7], [1, 9, 4, 10]);
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

Auto Fill

Auto Fill is used to fill the cells with data based on adjacent cells. It also follows a pattern from adjacent cells if available. There is no need to enter the repeated data manually. You can use `AllowAutoFill` property to enable/disable the auto fill support. You can also use `ShowFillOptions` property to enable/disable the fill option and `FillType` property to change the default auto fill option which is available in `AutoFillSettings`.

You can do this by one of the following ways,

- Using “AutoFillOptions” menu which is open, while drag and drop the cell using fill handle element.
- Using autoFill method.

In Auto Fill we have following options,

- Copy Cells
- Fill Series
- Fill Formatting Only
- Fill Without Formatting
- Flash Fill

Copyright © 2001 - 2020 Syncfusion Inc.

Note: The default auto fill option is "fillSeries" which can be referred from FillType property.

Copy Cells

To copy the selected cell content to the adjacent cells. You can do this by one of the following ways,

- Using fill handle to select the adjacent cell range and "Copy Cells" option in "AutoFillOptions" menu to fill the adjacent cells.
- Using "copyCells" as fill type in autoFill method to fill the adjacent cells.

Fill Series

To fill the series of numbers, characters, or dates based on selected cell content to the adjacent cells with their formats.

You can do this by one of the following ways,

- Using fill handle to select the adjacent cell range and "Fill Series" option in "AutoFillOptions" menu to fill the adjacent cells.
- Using "fillSeries" as fill type in autoFill method to fill the adjacent cells.

Fill Formatting Only

To fill the cell style and number formatting based on the selected cell content to the adjacent cells without their content.

You can do this by one of the following ways,

- Using fill handle to select the adjacent cell range and "Fill Formatting Only" option in "AutoFillOptions" menu to fill the adjacent cells.
- Using "fillFormattingOnly" as fill type in autoFill method to fill the adjacent cells.

Fill Without Formatting

To fill series of numbers, characters, or dates based on the selected cells to the adjacent cells without their formats.

You can do this by one of the following ways,

- Using fill handle to select the adjacent cell range and "Fill Without Formatting" option in "AutoFillOptions" menu to fill the adjacent cells.
- Using "fillWithoutFormatting" as fill type in autoFill method to fill the adjacent cells.

Flash Fill

To fill the column when it senses a pattern from adjacent column data based on what you type.

You can do this by one of the following ways,

- Using fill handle to select the adjacent cell range and "Flash Fill" option in "AutoFillOptions" menu to fill the adjacent cells.
- Using "flashFill" as fill type in autoFill method to fill the adjacent cells.

The following code example describes the above behavior.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(rangeSettings =>
{
rangeSettings.Datasource((IEnumerable<ItemDetail>)ViewBag.Datasource).Add
();
rangeSettings.Datasource((IEnumerable<SampleData>)ViewBag.SampleData).Sta
rtCell("I1").Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">

Hyperlink

Hyperlink is used to navigate to web links or cell reference within the sheet or to other sheets in Spreadsheet. You can use AllowHyperlink property to enable/disable Hyperlink.

To insert a Hyperlink

You can insert a hyperlink by one of the following ways,

- Using "Hyperlink" button under Links group of INSERT Tab in ribbon.
- Using context menu to select "Insert Hyperlink" option in "Hyperlink".
- Using setHyperlink method.

To remove a Hyperlink

You can remove a hyperlink by one of the following ways,

- Using context menu to select "Remove Hyperlink" option in Hyperlink.
- Using removeHyperlink method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.XLEdit.updateValue("I2", "amazon");
this.XLEdit.updateValue("J2", "flipkart");
this.setHyperlink("E3:E3", { "cellAddr": "A1:D2" }, 2);
this.setHyperlink("I2:I2", { "webAddr": "http://www.amazon.com" }, 1);
this.setHyperlink("J2:J2", { "webAddr": "http://www.flipkart.com" }, 1);
//To Remove a Hyperlink
this.removeHyperlink("J2:J2");
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{

Merge Cell

Merge cell is a single cell created by combining two or more individual cells together. You can use AllowMerging property to enable/disable merge cells. The cell reference for a merged cell is the cell in the upper left corner of the original selected range or group of cells.

You have following options in Merge Cell,

- Merge Cells
- Merge & Center
- Merge Across

Merge Cells

You can combine two or more cells located in the same row or column into a single cell. When cells with multiple values are merged, upper-left most cell's data will be the data of merged cell.

You can do this by one of the following ways,

- Using "Merge Cells" option in Merge & Center button under Alignment group of HOME Tab in ribbon.
- Using mergeCells method.

Merge & Center

You can combine two or more cells located in the same row or column into a single cell with center text align. When cells with multiple values are merged, upper-left most cell's data will be the data of the merged cell. You can do this by one of the following ways,

Copyright © 2001 - 2020 Syncfusion Inc.

- Using Merge & Center button under Alignment group of HOME Tab in ribbon.
- Using "Merge & Center" option in Merge & Center button under Alignment group of HOME Tab in ribbon.
- Using mergeCells method with mergeCenter property as true to enable the center alignment.

Merge Across

You can combine two or more cells located in the same row into a single cell. When cells with multiple values are merged, left most cell's data will be the data of the merged cell.

You can do this by one of the following ways,

- Using "Merge Across" option in Merge & Center button under Alignment group of HOME Tab in ribbon.
- Using mergeAcrossCells method.

The following code example describes the behavior of Merge Cells, Merge & Center and Merge Across.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.mergeCells("A2:B4", true);
this.mergeCenter = true;
this.mergeCells("D2:E4", true); // true is to prevent the alert message.
this.mergeAcrossCells("G2:H4", true); // true is to prevent the alert
message.
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

	A	B	C	D	E	F	G	H
1	Item Name	Date	Time	Quantity	Price	Amount	Discount	Profit
2			11:34:32 AM			200		1
3			5:56:32 AM			600		5
4	Casual Shoes		3:32:44 AM	10		300		7
5	Sandals & Floaters	11/21/2014	6:23:54 AM	15	20	300	11	67
6	Flip- Flops & Slippers	6/23/2014	12:43:59 AM	30	10	300	10	70
7	Sneakers	7/22/2014	10:55:53 AM	40	20	800	13	66
8	Running Shoes	2/4/2014	3:44:34 AM	20	10	200	3	14

11	T-Shirts	10/31/2014	12:01:44 AM	50	10	500	9	55
12								

Unmerge Cells

You can split the merged cell into multiple cells. You can do this by one of the following ways,

- Using "Unmerge cells" option in Merge & Center button under Alignment group of HOME Tab in ribbon.
- Using unMergeCells method.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.mergeCells("D2:E4", true); // true is to prevent the alert message.
this.unmergeCells("D2:E4");
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.

	A	B	C	D	E	F	G	H
1	Item Name	Date	Time	Quantity	Price	Amount	Discount	Profit

12								

Editing

You can edit the contents of a cell directly in the cell. You can also do this by typing in the formula bar. When you edit the cell, Spreadsheet is operating in edit mode. In this mode some of the options are unavailable. You can use `AllowEditing` property to enable/disable editing feature.

Note: By default `AllowEditing` property is set to true.

Edit cell content

You can perform this by one of the following ways,

- Double click on the cell to perform editing. This starts the edit mode and positions the cursor at the end of the cell.
- Press F2 Key to edit the active cell.
- Use Formula bar to perform editing.
- Use Backspace and Delete Key to delete the contents of a cell.
- Use "Alt + Enter" keys to perform multi line editing.
- Using editCell method.

Save cell content

You can do this by one of the following ways,

- Perform mouse click on any other cell other than the current editing cell.
- Perform Enter/Tab key press on the cell.
- Using saveCell method.

Copyright © 2001 - 2020 Syncfusion Inc.

Note: Edited cells are automatically formatted (right/left/center/Number Formatting) based on cell values.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.XLEdit.editCell(3, 0, true); //if true, it maintains the existing
data otherwise it clears the data.
//this.XLEdit.saveCell();
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.

	A	B	C	D	E	F	G	H	I

12									

Read-Only Cells

You can restrict/prevent the editing in the specified range. You can use AllowLockCell property to enable/disable the lock cells. You can do this by one of the following ways,

- Using lockCells method to lock the selected cells. Then you need to protect the sheet using protectSheet method to restrict the editing.
- Using "Lock Cells" option under Changes group of REVIEW tab in ribbon. Then Using "Protect Sheet" option under Changes group of REVIEW tab in ribbon to restrict editing.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.AllowLockCell(true)
.Sheets(sheet =>
{
sheet.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.protectSheet(false);
this.lockCells("A1:A5", true);
this.protectSheet(true);
```

```
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

Events

The following events will trigger when editing and saving the cell.

- cellEdit - Triggered when the cell is edited.
- cellSave - Triggered when save the edited cell.

Data binding

You can bind the data to Spreadsheet using data manager. You can refer Data Binding to know more about this. You can use saveBatchChanges method to update the changes in server.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().DataManager("DataManager").URL("Default").Adaptor(AdaptorType
.UrlAdaptor).BatchURL("BatchUpdate"))
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.DataManagerID("DataManager").PrimaryKey("ItemName").Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.XLEdit.updateValue("I2", "amazon");
```

```
this.XLEdit.updateValue("J2", "flipkart");
this.saveBatchChanges(this.getActiveSheetIndex());
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
public ActionResult BatchUpdate( List<ItemDetail> changed,
List<ItemDetail> added,  List<ItemDetail> deleted, string action, string
key)
{
//Save the batch changes
}
}
```

To save and retrieve the Spreadsheet data in the database, you can refer this Knowledge Base link.

You can update data dynamically in the Spreadsheet by using updateRange method.

Selection

Selection provides an interactive support to highlight cell, row, or column that you select. Selection can be done through Mouse, Touch or Keyboard interaction. To enable selection, set `AllowSelection` as `true`.

Copyright © 2001 - 2020 Syncfusion Inc.

Selection Modes

The mode of selection can be single or range selection. The default selection mode can be set using SelectionUnit in SelectionSettings.

The two types of selection mode are as follows

- Single - SpreadsheetSelectionUnit.Single
- Range - SpreadsheetSelectionUnit.Range

Selection Type

There are four types of selection in Spreadsheet,

1. Cell Selection
2. Row Selection
3. Column Selection
4. Sheet Selection

You can set default SelectionType in SelectionSettings.

Cell Selection

Cell selection is used to select a single or multiple cells. It can be performed using selectRange method.

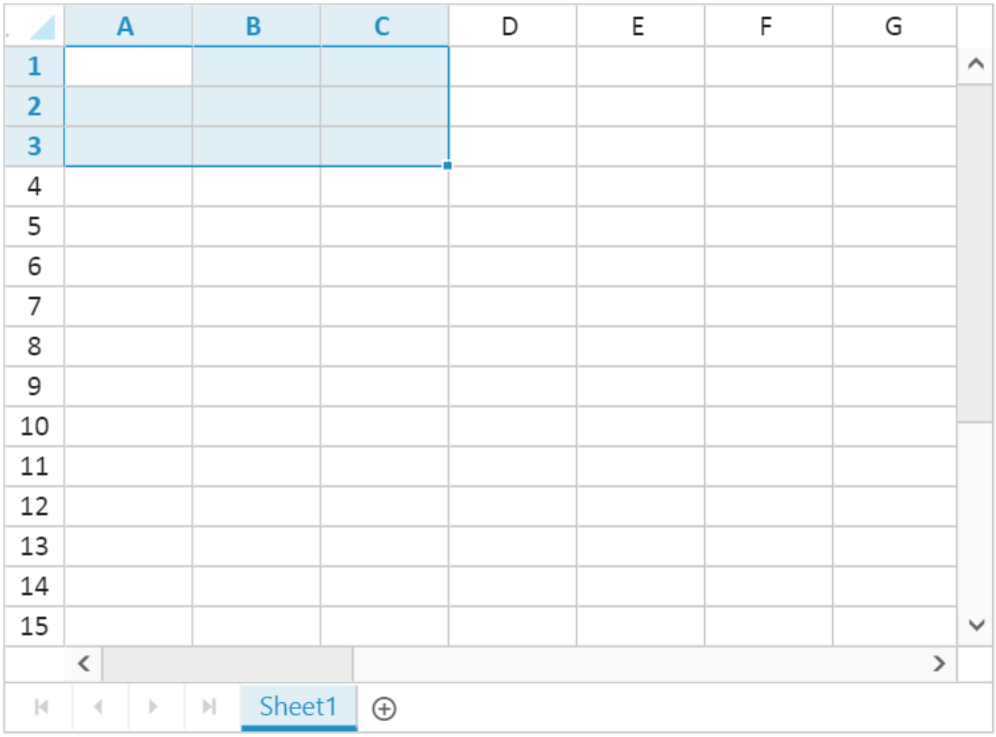
The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.XLSelection.selectRange("A1:C3");
this.XLDragFill.positionAutoFillElement();
}
}
</script>
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Row Selection

Row selection is used to select a single or multiple rows. It can be performed using selectRows method.

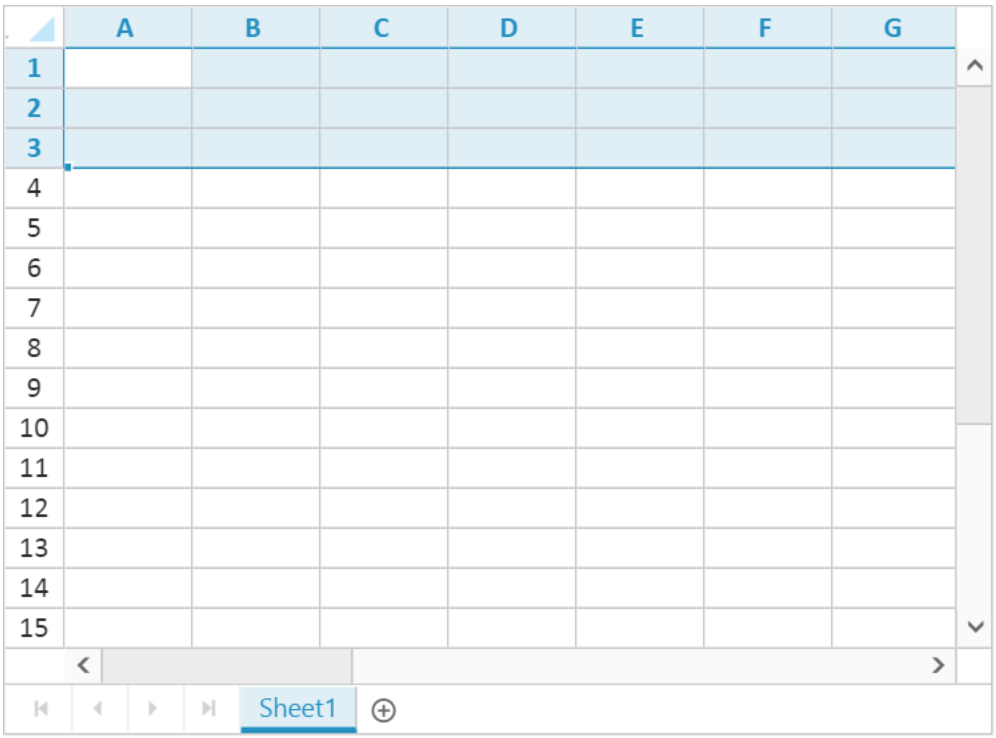
The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.XLSelection.selectRows(0,2);
this.XLDragFill.positionAutoFillElement();
}
}
</script>
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Note: This type can be set as default by setting SelectionType property in SelectionSettings as SpreadsheetSelectionType.Row

Column Selection

Column selection is used to select a single or multiple columns. It can be performed using selectColumns method.

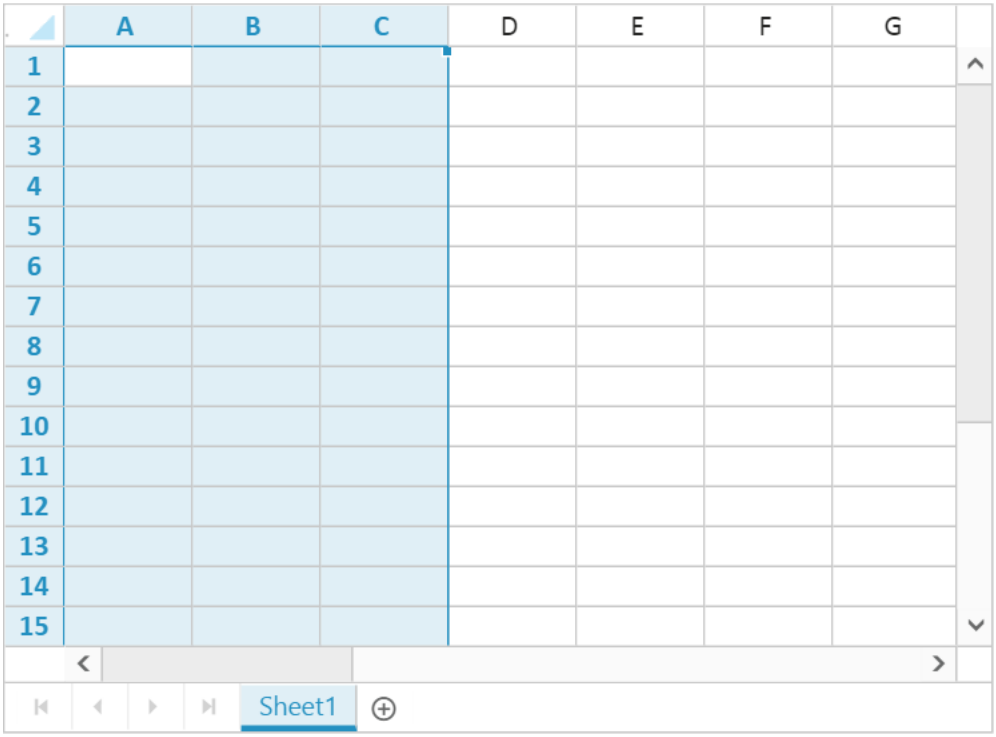
The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport) {
this.XLSelection.selectColumns(0,2);
this.XLDragFill.positionAutoFillElement();
}
}
</script>
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Note: This type can be set as default by setting SelectionType property in SelectionSettings as SpreadsheetSelectionType.Column

Sheet Selection

Sheet selection is used to select all cells in a worksheet. It can be performed using selectSheet method.

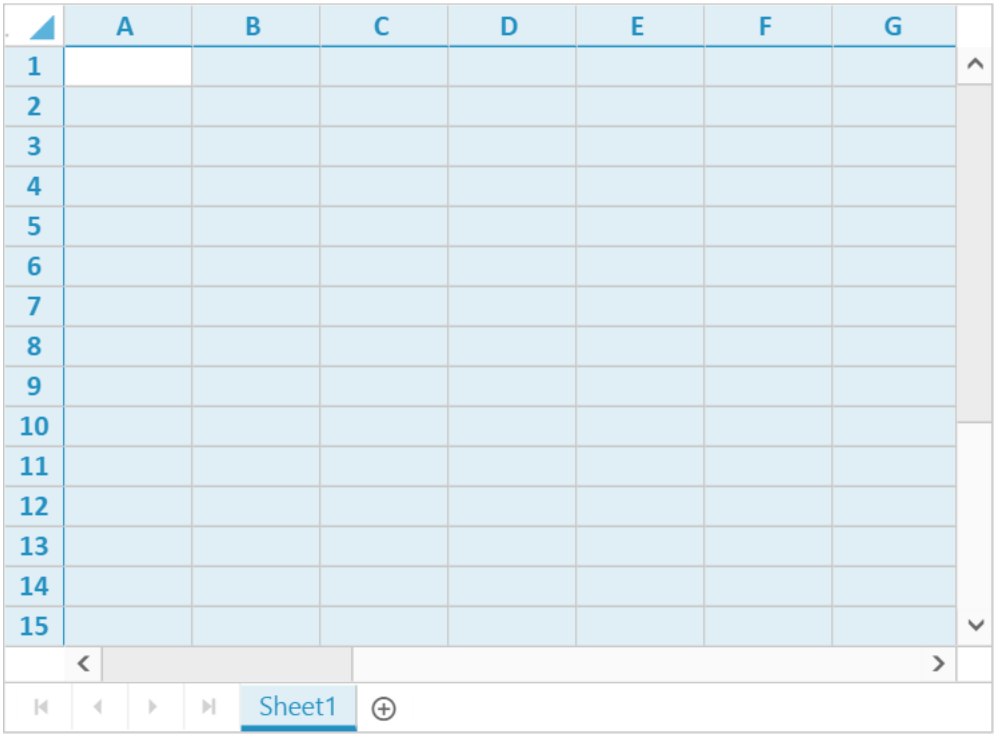
The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if(!this.isImport)
this.XLSelection.selectSheet();
}
</script>
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Context Menu

Context Menu is used to improve user interaction with Spreadsheet using popup menu. This will open when right clicking on Cell/Column Header/Row Header/Pager in Spreadsheet. You can use `EnableContextMenu` property to enable/disable context menu.

Default Context Menu items

Please find the below table for default context menu items and its actions.

Section	Context Menu items	Action
Row Cell	Cut	Cut the selected cells content to the clipboard, so that you can paste it somewhere else.
	Copy	Copy the selected cells content to the clipboard, so that you can paste it to somewhere else.
	Paste	Paste the content from clipboard to spreadsheet.
	Insert	Insert new cells or rows or columns to worksheet.
	Delete	Delete existing cells or rows or columns from worksheet.
	Sort	Perform sorting to the selected range of cells by ascending or descending.

Copyright © 2001 - 2020 Syncfusion Inc.

	Filter	Perform filtering to the selected cells based an active cell's value or active cell's color.
	Hyperlink	Create a link in the spreadsheet for quick access to webpages or worksheet reference.
	Comment	Add a note or extra information about the active cell.
	Format Cells	Apply number format to the selected cells.
	Clear Contents	Delete the contents in the selected cells.
Row Header / Column Header	Cut	Cut the selected cells content to the clipboard, so that you can paste it to somewhere else.
	Copy	Copy the selected cells content to the clipboard, so that you can paste it to somewhere else.
	Paste	Paste the content from clipboard to spreadsheet.
	Clear Contents	Delete the contents in the selected cells.
	Insert	Insert new cells or rows or columns to worksheet.
	Delete	Delete existing cells or rows or columns from worksheet.
	Hide	Hide the selected columns/rows.
	Unhide	Unhide the selected columns/rows.
Pager	Insert	Insert new worksheet to spreadsheet.
	Delete	Delete the selected worksheet from spreadsheet.
	Move or copy	Opens move or copy dialog to move worksheet or to create duplicate worksheet.
	Rename	Rename the selected worksheet.
	Protect Sheet	Prevent unwanted changes from others by limiting their ability to edit.
	Hide	Hide the selected worksheet.
	Unhide	Opens unhide dialog to unhide worksheet.

The following code example describes the above behavior.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.EnableContextMenu(true)
)
```

Data Presentation

Data presentation is helpful for proper representation of data in Spreadsheet. You have following features in Data Presentation.

- Cell types
- Chart
- Conditional formatting
- Filtering
- Picture
- Pivot table
- Sorting
- Table

Cell Type

You can insert the controls like Button, Checkbox, Dropdown list and Date picker. You can use `AllowCellType` property to enable/disable cell type operations.

To insert a Cell Type.

You can insert the cell type to the selected range of cells by one of the following ways

- Using `CellTypes` property in sheets.
- Using addCellTypes method.

To remove Cell Type

You can delete the cell type in the selected range of cells by using removeCellTypes method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.AllowCellType(true)
.Sheets(sheet =>
{
sheet.Datasource((IEnumerable<object>)ViewBag.Datasource)
.CellTypes(cellType =>
{
cellType.Range("A1").Setting(setting =>
{
setting.Type(CustomCellTypes.DropDownList).DataSourceRange("A2:A11");
}).Add();
cellType.Range("D1").Setting(setting =>
{
setting.Type(CustomCellTypes.Button).Text("BUTTON").BackgroundColor("gree
n");
}).Add();
cellType.Range("C1").Setting(setting =>
{
setting.Type(CustomCellTypes.DropDownList).DataSourceRange("A2:A11");
}).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
var excelCellType = this.XLCellType;
if (!this.isImport) {
excelCellType.addCellTypes("B1", {"type" :
ej.Spreadsheet.CustomCellType.DatePicker, 'value' : '2/12/2016'},  1);
excelCellType.addCellTypes("E1", {"type" :
ej.Spreadsheet.CustomCellType.CheckBox, "isChecked" : true },  1);
this.XLCellType.removeCellTypes("C1");
}
}
</script>
```

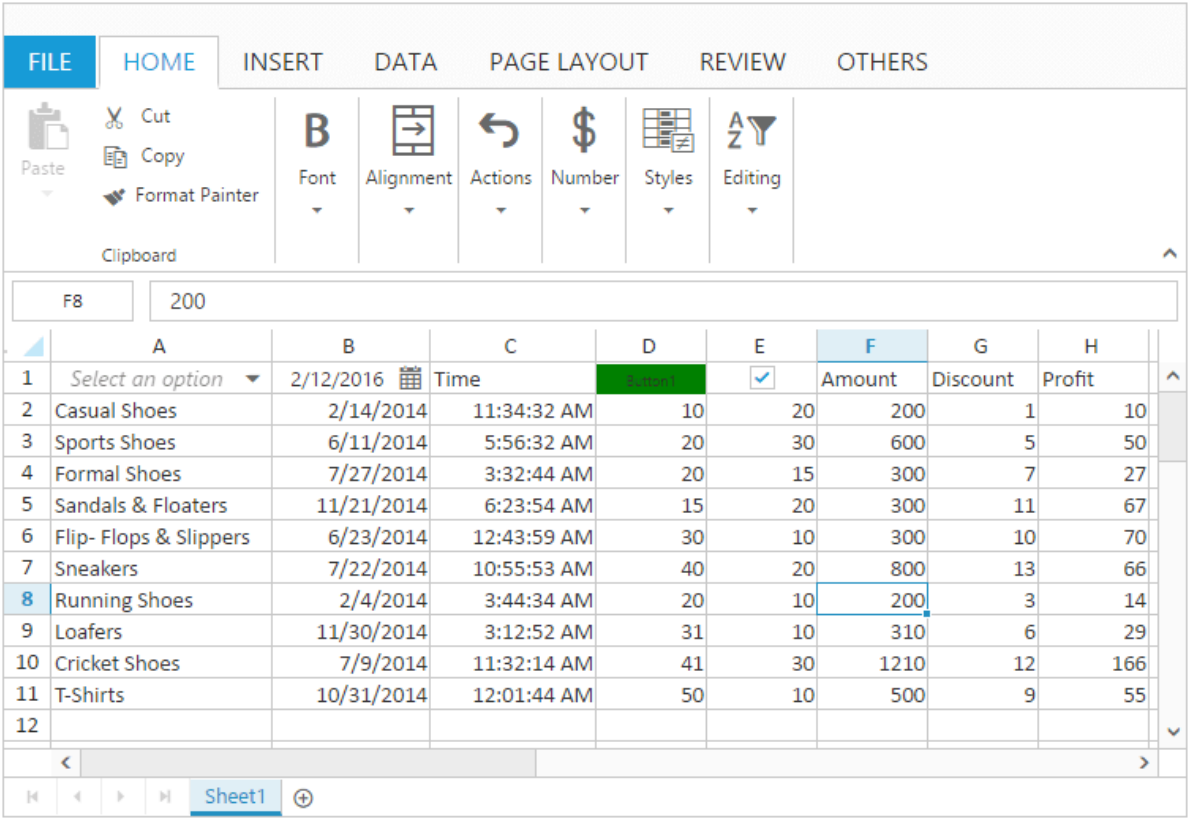
C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.



Chart

Chart is a graphical representation of data, that organizes and represents a set of numerical or qualitative data. It mostly displays the selected range of data in terms of x axis and y axis. You can use AllowCharts property to enable/disable chart operations.

Copyright © 2001 - 2020 Syncfusion Inc.

Types of Chart

The following types of charts are available in Spreadsheet.

- Area Chart
- Bar Chart
- Column Chart
- Line Chart
- Pie Chart
- Radar Chart
- Scatter Chart

You can create the Chart by one of the following ways,

- Using "Chart Type" button to Select the type of chart under Charts group of INSERT Tab in ribbon.
- Using createChart method to create the chart.

Chart Customization

You can perform the following customizations for chart. These are available in DESIGN Tab which is enabled while clicking the chart element.

Feature	Description
Add Chart Elements	You can add a chart element like chart axes, legends, chart title, axis title, data labels and grid lines.
Switch Row/Column	You can switch the row of the chart to column of the chart and vice versa.
Select Data	You can modify the data source of Chart.
Chart Type	You can change the type of the chart using Chart Type dialog.
Height and Width	You can change the height and width of the chart.
Chart Themes	You can change the theme of the chart. The available themes are saffron, lemon and azure in dark, light themes.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.AllowCharts(true)
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
```

```
<script type="text/javascript">
function loadComplete(args) {
if (!this.isImport) {
this.XLChart.createChart("D1:E6", { type: "column", enable3D: false,
marker: false, top: 40, left: 260, width: 340, height: 250 });
this.performSelection("E1");
this.XLChart.createChart("E1:F6", { type: "stackingcolumn", enable3D:
false, marker: { visible: false }, top: 40, left: 620, width: 340,
height: 250 });
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

Conditional Formatting

Conditional formatting helps you to apply formats to a cell or range with certain color based on the cells values. You can use AllowConditionalFormats property to enable/disable Conditional formats.

Condition Definition

You can define conditions such as greater than, less than, between, equal to, text contains and date occurring for selected cells and defining value for condition. It highlights the specified cell.

You can do this by one of the following ways,

- Using "Conditional Formatting" option in Conditional Formatting button of HOME Tab in ribbon to open the conditional formatting dialog.
- Using setCFRule method to define the condition.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.AllowConditionalFormats(true)
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
var conditionFormat = this.XLCFormat;
if (!this.isImport) {
conditionFormat.setCFRule({ "action": "greaterthan", "inputs": ["10"],
"color": "redft", "range": "G2:G11" });
conditionFormat.setCFRule({ "action": "lessthan", "inputs": ["20"],
"color": "yellowft", "range": "E1:E11" });
conditionFormat.setCFRule({ "action": "between", "inputs": ["300",
"600"], "color": "greenft", "range": "F2:F11" });
conditionFormat.setCFRule({ "action": "equalto", "inputs": ["20"],
"color": "redf", "range": "D2:D11" });
conditionFormat.setCFRule({ "action": "textcontains", "inputs":
["loafers"], "color": "redt", "range": "A1:A11" });
conditionFormat.setCFRule({ "action": "dateoccur", "inputs":
["02/04/2014"], "color": "redft", "range": "B1:B11" });
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new

Clear Rules

You can clear the defined rules by using one of the following ways,

- Using "Clear Rules" option in Conditional Formatting button of HOME Tab in ribbon to clear the rule.
- Using clearCF method to clear the defined rules.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {

Filtering

Filtering allows you to view specific rows in Spreadsheet, while hiding the other rows. When a filter is added to the header row, a drop-down menu appears in each cell of the header row. You can use `AllowFiltering` property to enable/disable filtering.

You can apply filtering by one of the following ways,

- Using "Filter" option in Sort & Filter button under Editing group of HOME Tab in ribbon.
- Using "Filter" button under Sort and Filter group of DATA Tab in ribbon.

You have following options in Filtering.

- Filter by Value.
- Filter by Color.
- Clear Filter.

Filter by Value

You can perform filtering by using number, string. The filtered rows are only visible in the Spreadsheet. All the other rows within the filtered range were hidden.

You can do this by one of the following ways,

- Using dropdown button in filter header to open the filter dialog.
- Using context menu to select "Filter by Selected Cell's Value" option in Filter.
- Using filterByActiveCell method.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.AllowFiltering(true)
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if (!this.isImport) {
this.performSelection("E2");
this.XLFilter.filterByActiveCell();
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

Filter by Color

You can perform filtering by the selected cell color or font color. The filtered rows are only visible in the Spreadsheet. You can do this by clicking "Filter by Color" option in filter dialog to select filter by cell color or font color.

Note: This option is only available if the selected range of cells having any color.

Clear Filter

You can clear the filtering to show all the filtered rows in the spreadsheet within the filtered range.

You can do this by one of the following ways,

- Using "Clear Filter" option in the filter dialog.
- Using context menu to select "Clear Filter" option in Filter.
- Using "Clear Filter" option in "Sort & Filter" button under Editing group of HOME Tab in ribbon.
- Using "Clear Filter" option under Sort and Filter group of DATA Tab in ribbon.
- Using clearFilter method to perform clear filtering.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.AllowFiltering(true)
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
```

```
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
var excelFilter = this.XLFilter;
if (!this.isImport) {
this.performSelection("E2");
excelFilter.filterByActiveCell();
excelFilter.clearFilter();
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{

Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

Picture

You can insert a picture by selecting the "Pictures" button under Illustrations group of INSERT Tab in ribbon.

Picture Customization

You can perform the following customizations for picture. These are available in DESIGN Tab which is enabled while clicking the picture element.

Feature	Description
Change Picture	You can change the picture with existing picture.
Reset Picture	You can reset the changes done in the picture such as border changes, height and width changes.
Picture Border	You can add border to the picture. You have Border Color, Border Type and Border weight options to draw a border.
Height and Width	You can change the height and width of the picture.

Pivot Table

Pivot table is a program tool that allows you to reorganize and summarize selected columns and rows of data to obtain a desired report. You can use `EnablePivotTable` property to enable/disable pivot table operations.

You can do this by one of the following ways,

Copyright © 2001 - 2020 Syncfusion Inc.

- Using "Pivot Table" option under Tables group of INSERT Tab in ribbon.
- Using createPivotTable method to create pivot table
- Using deletePivotTable method to remove the pivot table.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.EnablePivotTable(true)
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
if (!this.isImport) {
var settings = {
rows: [
{
fieldName: "Country",
},
{
fieldName: "State",
}
],
columns: [
{
fieldName: "Product",
}
],
values: [
{
fieldName: "Amount",
},
{
fieldName: "Quantity",
}
],
filters: [
{
fieldName: "Date",
}
]
};
this.XLPivot.createPivotTable("Sheet1!$A$1:$F$25", null, null, settings);
//this.XLPivot.deletePivotTable("name");
}
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<PivotData> data = new List<PivotData>();
data.Add(new PivotData() { Amount = 100, Country = "Canada", Date = "FY
2005", Product = "Bike", Quantity = 2, State = "Alberta" });
data.Add(new PivotData() { Amount = 200, Country = "Canada", Date = "FY
2006", Product = "Van", Quantity = 3, State = "British Columbia" });
data.Add(new PivotData() { Amount = 300, Country = "Canada", Date = "FY
2007", Product = "Car", Quantity = 4, State = "Brunswick" });
data.Add(new PivotData() { Amount = 150, Country = "Canada", Date = "FY

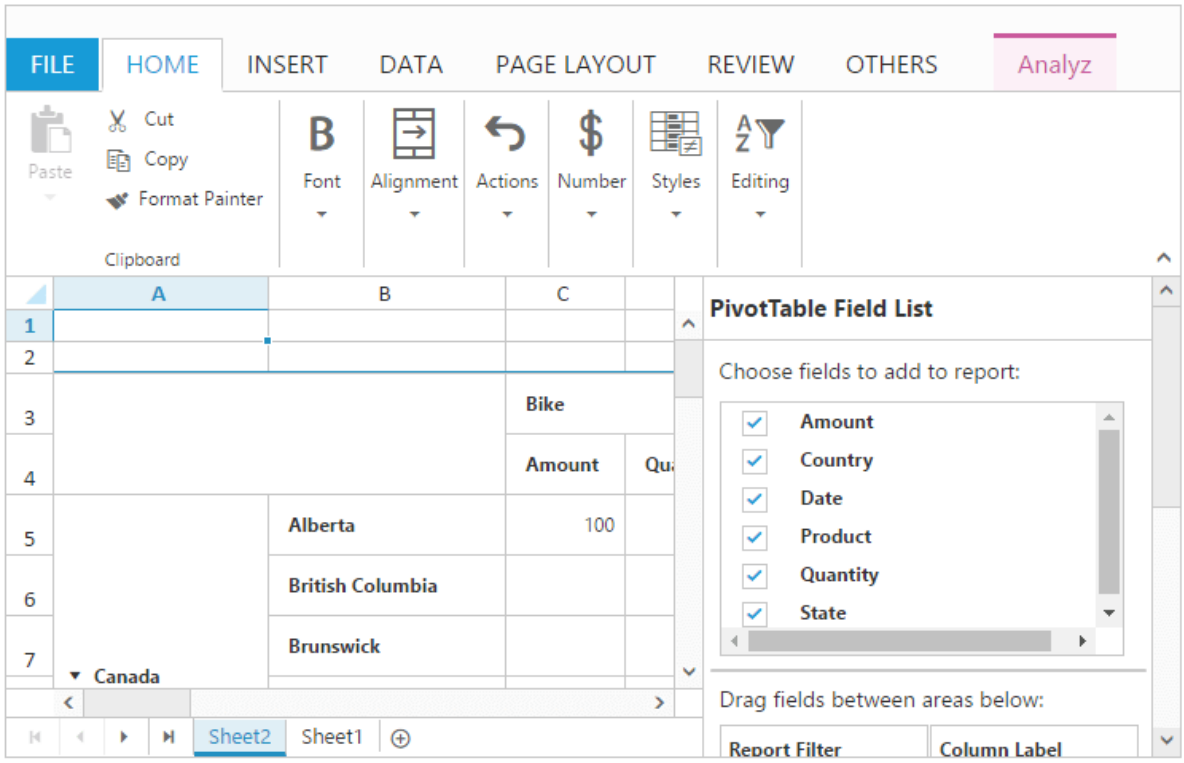
data.Add(new PivotData() { Amount = 150, Country = "Germany", Date = "FY
2008", Product = "Car", Quantity = 4, State = "Hamburg" });
data.Add(new PivotData() { Amount = 200, Country = "Germany", Date = "FY
2008", Product = "Bike", Quantity = 4, State = "Hessen" });
data.Add(new PivotData() { Amount = 150, Country = "Germany", Date = "FY
2007", Product = "Van", Quantity = 3, State = "Nordrhein-Westfalen" });
data.Add(new PivotData() { Amount = 100, Country = "Germany", Date = "FY
2005", Product = "Bike", Quantity = 2, State = "Saarland" });
data.Add(new PivotData() { Amount = 150, Country = "United Kingdom", Date
= "FY 2008", Product = "Bike", Quantity = 5, State = "England" });
data.Add(new PivotData() { Amount = 250, Country = "United States", Date
= "FY 2007", Product = "Car", Quantity = 4, State = "Alabama" });
data.Add(new PivotData() { Amount = 200, Country = "United States", Date
= "FY 2005", Product = "Van", Quantity = 4, State = "California" });
data.Add(new PivotData() { Amount = 100, Country = "United States", Date
= "FY 2006", Product = "Bike", Quantity = 2, State = "Colorado" });
data.Add(new PivotData() { Amount = 150, Country = "United States", Date
= "FY 2008", Product = "Car", Quantity = 3, State = "New Mexico" });
data.Add(new PivotData() { Amount = 200, Country = "United States", Date
= "FY 2005", Product = "Bike", Quantity = 4, State = "New York" });
data.Add(new PivotData() { Amount = 250, Country = "United States", Date
= "FY 2008", Product = "Car", Quantity = 3, State = "North Carolina" });
data.Add(new PivotData() { Amount = 300, Country = "United States", Date
= "FY 2007", Product = "Van", Quantity = 4, State = "South Carolina" });
```

```
ViewBag.Datasource = data;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.



Sorting

Sorting helps you to arrange the data to particular order in a selected range of cells. You can use AllowSorting property to enable/disable sorting.

You have following options in sorting.

- Sort by Ascending or Descending.
- Sort by Color.

Sort by Ascending and Descending

You can perform number sorting by ascending or descending and string sorting by A to Z or Z to A to arrange the data.

You can do this by one of the following ways,

- By choosing "Sort A to Z" or "Sort Z to A" in Sort & Filter button under Editing group of HOME Tab in ribbon.
- Using "Sort A to Z" or "Sort Z to A" button in Sort & Filter group of DATA Tab in ribbon.
- Using context menu to select "Sort A to Z" or "Sort Z to A" for strings and option in Sort.

Copyright © 2001 - 2020 Syncfusion Inc.

- Using "Sort A to Z" or "Sort Z to A" for strings an "Sort Smallest to Largest" or "Sort Largest to Smallest" for numbers in filter dialog.
- Using sortByRange method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.AllowSorting(true)
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
var excelSort = this.XLSort,excelFormat = this.XLFormat;
if (!this.isImport) {
excelSort.sortByRange("A2:A10", "A", "ascending");
excelSort.sortByRange("E2:E10", "E", "descending");
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
}
}
```

The following output is displayed as a result of the above code example.

	A	B	C	D	E	F	G
1	Item Name	Date	Time	Quantity	Price	Amount	Discount
2	Casual Shoes	2/14/2014	11:34:32 AM	10	30	200	
3	Cricket Shoes	6/11/2014	5:56:32 AM	20	30	600	
4	Flip- Flops & Slippers	7/27/2014	3:32:44 AM	20	20	300	
5	Formal Shoes	11/21/2014	6:23:54 AM	15	20	300	
6	Loafers	6/23/2014	12:43:59 AM	30	20	300	
7	Running Shoes	7/22/2014	10:55:53 AM	40	15	800	
8	Sandals & Floaters	2/4/2014	3:44:34 AM	20	10	200	
9	Sneakers	11/30/2014	3:12:52 AM	31	10	310	
10	Sports Shoes	7/9/2014	11:32:14 AM	41	10	1210	
11	T-Shirts	10/31/2014	12:01:44 AM	50	10	500	

Sort by Color

You can perform sort by color to arrange the data based on the selected cell's background color or font color. This option is only available if the selected range of cells having any color.

You can do this by one of the following ways,

- Using "Sort By Color" option in filter dialog to perform sorting by cell color or font color.
- Using context menu to select "Put Selected Cell Color To The Top" or "Put Selected Font Color To The Top" in Sort option.

Table

A table is a data structure that organizes information into rows and columns. You can use `AllowFormatAsTable` property to enable/disable table operations.

You can do this by one of the following ways,

- Using "Format As Table" under Styles group of HOME Tab in ribbon.
- Using Table option under Tables group of INSERT Tab in ribbon.
- Using createTable method to insert a table and removeTable to delete a table.

Copyright © 2001 - 2020 Syncfusion Inc.

Table Customization

You can perform the following customizations for table. These are available in DESIGN Tab which is enabled while clicking the table.

Feature	Description
Resize Table	You can add new rows to the table.
Convert to Range	You can convert the table to regular range of data without losing any table style format.
First Column	You can highlight the first column of the table.
Last Column	You can highlight the last column of the table.
Total Row	You can insert a new row in the bottom of the table to display the total value of the last column. You can toggle this by using checkbox.
Filter Button	You can able to hide or unhide the filter icons in the filter header of a table.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
var excelFormat = this.XLFormat;
if (!this.isImport) {
excelFormat.createTable({ "header": true, "formatName":
"TableStyleLight8" }, "A1:B4");
excelFormat.createTable({ "header": true, "formatName":
"TableStyleLight10" }, "D1:E4");
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<FormatData> formats = new List<FormatData>();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
formats.Add(new FormatData() { format1 = "Item Name", format2 =
"Quantity", format4 = "Item Name", format5 = "Quantity", format7 = "Item
Name", format8 = "Quantity" });
formats.Add(new FormatData() { format1 = "Casual Shoes", format2 = "10",
format4 = "Sandals & Floaters", format5 = "200", format7 = "Running
Shoes", format8 = "198" });
formats.Add(new FormatData() { format1 = "Sports Shoes", format2 = "20",
format4 = "Flip- Flops", format5 = "600", format7 = "Loafers", format8 =
"570" });
formats.Add(new FormatData() { format1 = "Formal Shoes", format2 = "20",
format4 = "Sneakers", format5 = "300", format7 = "T-Shirts", format8 =
"279" });
formats.Add(new FormatData());
formats.Add(new FormatData());
formats.Add(new FormatData());
formats.Add(new FormatData() { format1 = "Item Name", format2 =
"Quantity", format4 = "Item Name", format5 = "Quantity", format7 = "Item
Name", format8 = "Quantity" });
formats.Add(new FormatData() { format1 = "Casual Shoes", format2 = "10",
format4 = "Sandals & Floaters", format5 = "200", format7 = "Running
Shoes", format8 = "198" });
formats.Add(new FormatData() { format1 = "Sports Shoes", format2 = "20",
format4 = "Flip- Flops", format5 = "600", format7 = "Loafers", format8 =
"570" });
formats.Add(new FormatData() { format1 = "Formal Shoes", format2 = "20",
format4 = "Sneakers", format5 = "300", format7 = "T-Shirts", format8 =
"279" });
ViewBag.Datasource = formats;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

Formulas

Formulas are used for calculation of data in sheet. You can refer the formula cell reference in following ways,

1. Cell reference from same sheet
2. Cell reference from different sheets

You can set formula for a cell in following ways,

1. Initial Load
2. Method
3. User Interface

Initial Load

You can set formula for a cell by specifying Value property in cell data binding. The following code example describes the above behavior,

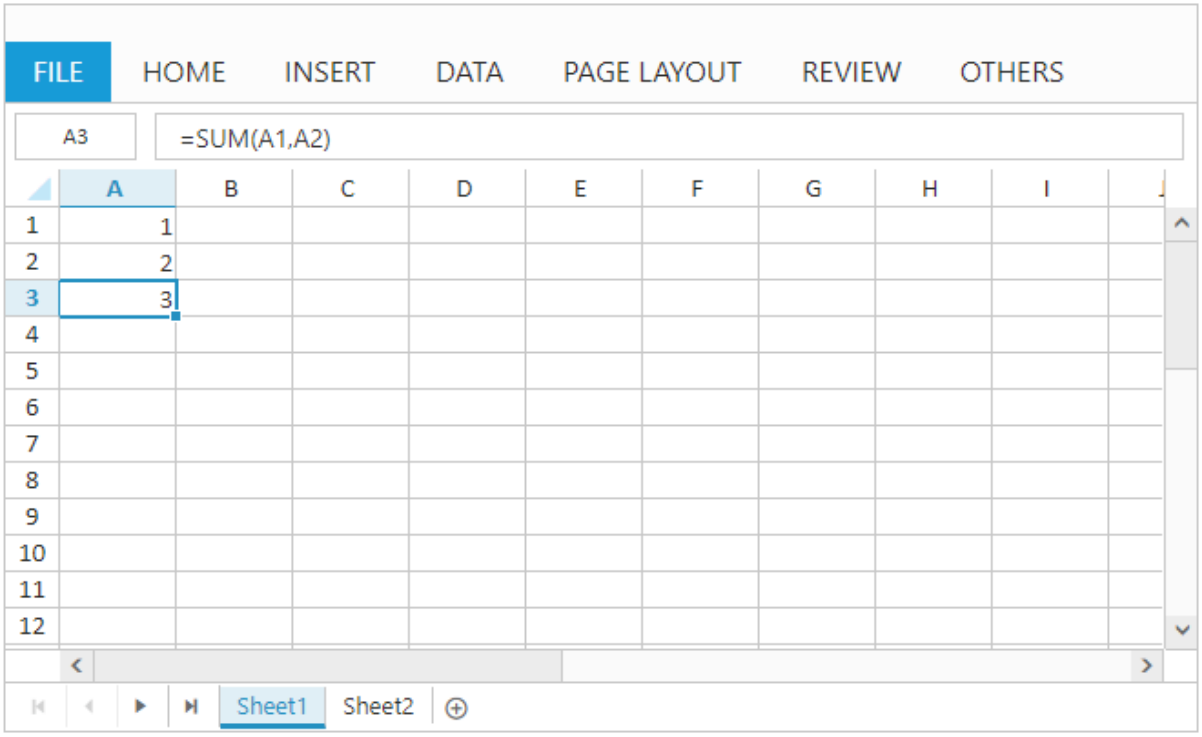
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
cells.Value("1").Add();
```

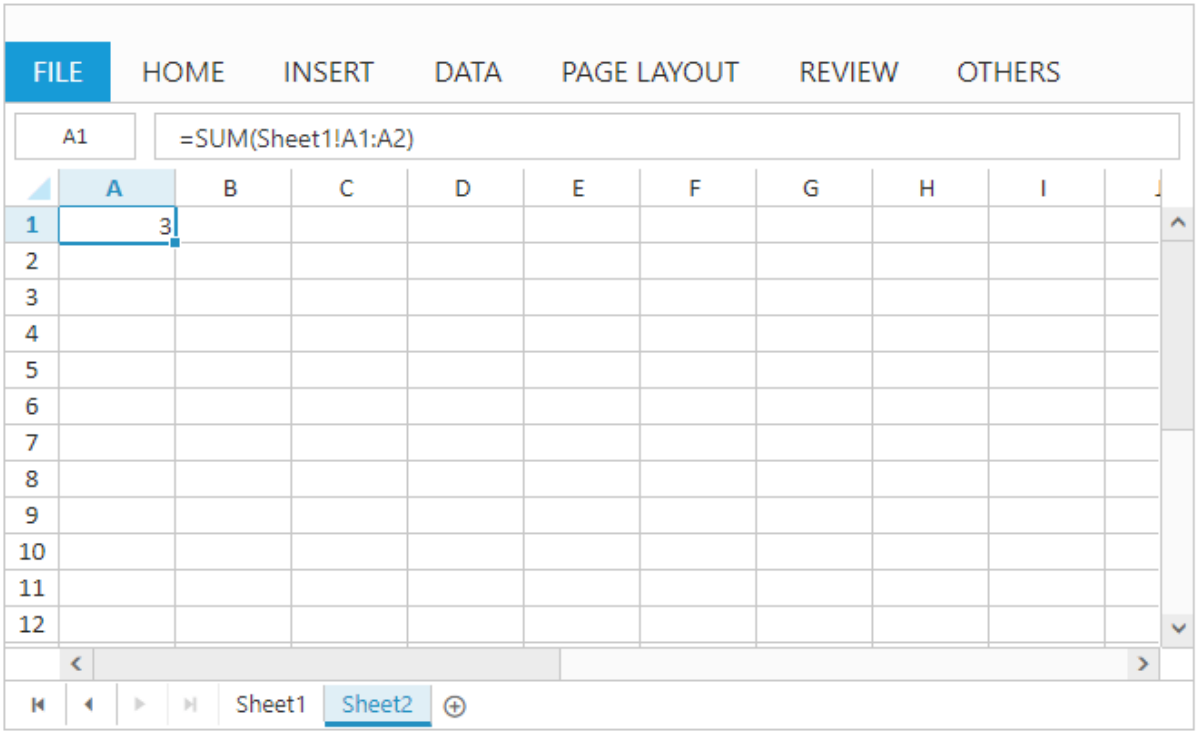
Copyright © 2001 - 2020 Syncfusion Inc.

```
}).Add();
rows.Cells(cells =>
{
cells.Value("2").Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("=SUM(A1,A2)").Add();
}).Add();
}).Add();
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
cells.Value("=Sheet1!A1:A2").Add();
}).Add();
}).Add();
})
)
```

The following output is displayed as a result of the above code example.



Cell Reference from Same sheet



Cell Reference from different sheets

Method

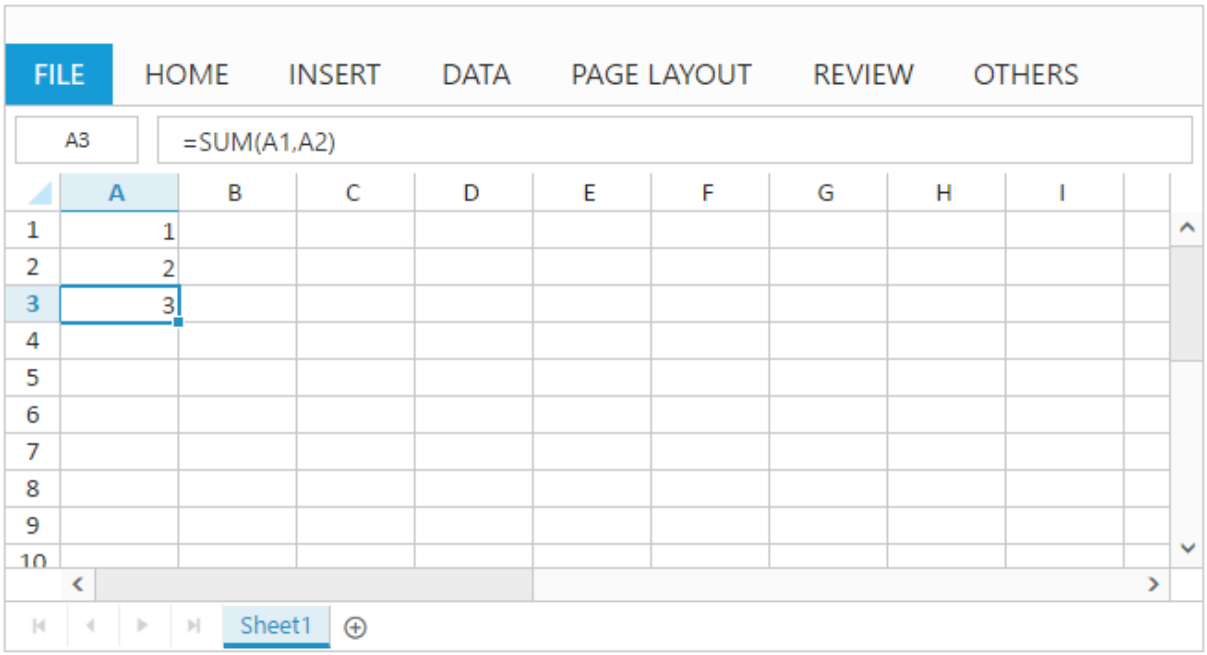
You can set formula for a cell using updateCellValue method. The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
cells.Value("1").Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("2").Add();
}).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script>
function loadComplete() {
this.XLEdit.updateCellValue({ rowIndex: 2, colIndex: 0 }, "=SUM(A1,A2)");
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following output is displayed as a result of the above code example.



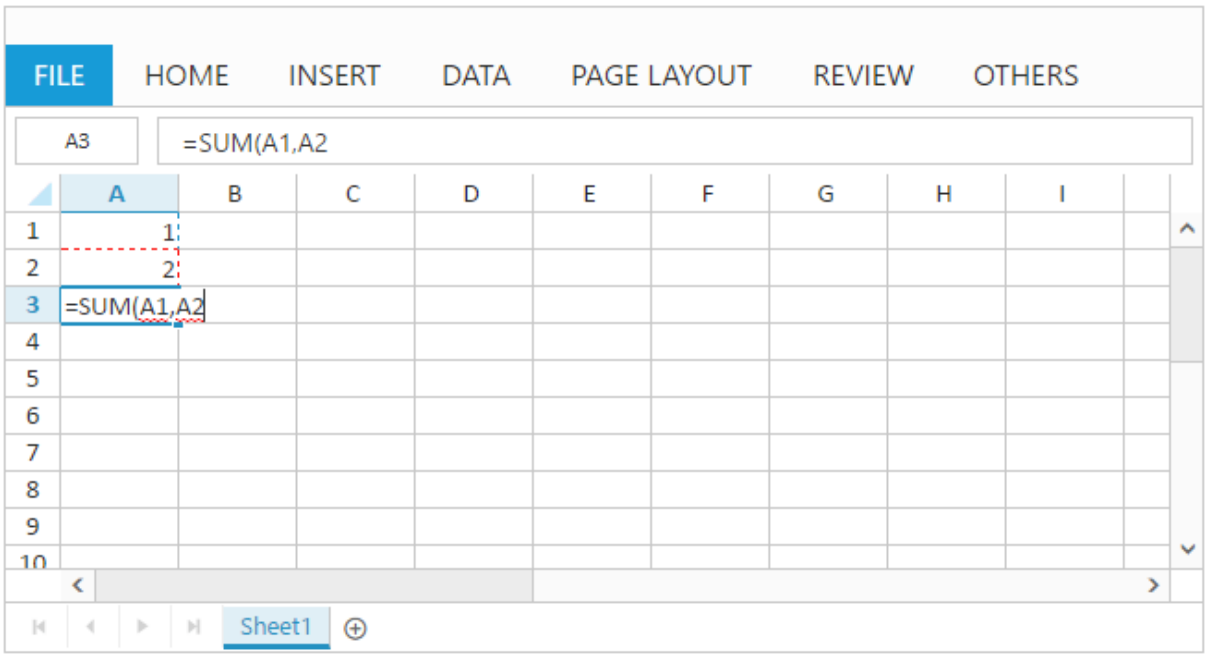
User Interface

You can set formula for a cell by edit and save a cell through user interface using Editing feature.

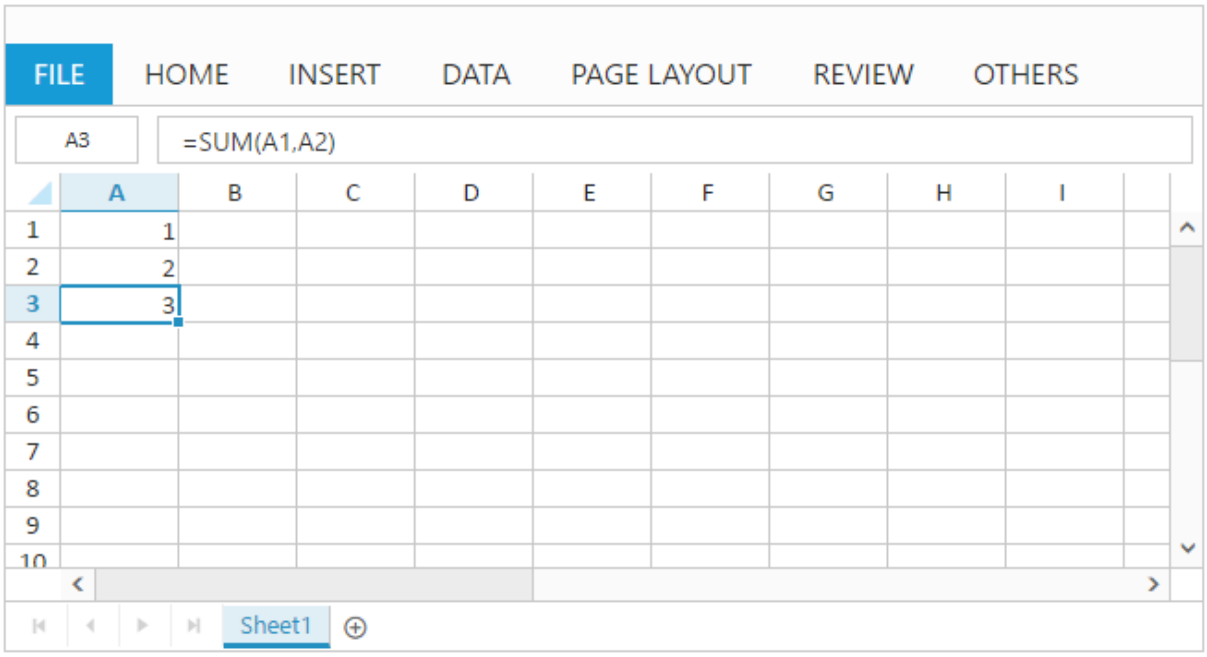
The following code example and screenshot describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
cells.Value("1").Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("2").Add();
}).Add();
}).Add();
})
)
```



The following output is displayed while saving edited cell with above code example.



Note: 1. The list of supported formulas can be find in following link

2. Constant values, cell references, formulas and named ranges can be passed as argument to formulas

3. Selection can be used to mention cell references within formula

User Defined Functions

The list of formulas supported in Spreadsheet is sufficient for most of your calculations. If not, you can create and use your own function using user defined function option. You can add user defined function to Spreadsheet in following ways,

Copyright © 2001 - 2020 Syncfusion Inc.

1. Initial Load
2. Method

Initial Load

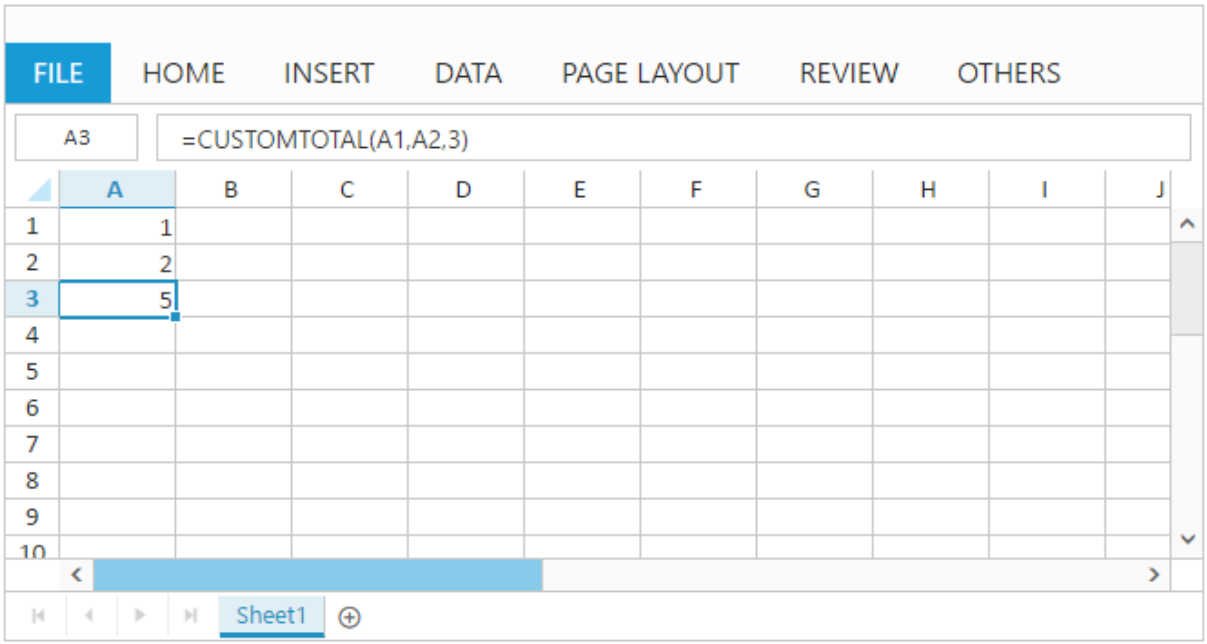
You can add your own function to Spreadsheet at initial load with CustomFormulas property. The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
cells.Value("1").Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("2").Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("=CUSTOMTOTAL(A1,A2,3)").Add();
}).Add();
}).Add();
})
.CustomFormulas(formula => {
formula.FormulaName("CUSTOMTOTAL").FunctionName("customTotal").Add(); })
)
<script>
function customTotal(args) {
var param1, param2, param3, value, excelObj =
$('#Spreadsheet').data("ejSpreadsheet"),
argument = excelObj.getValueFromFormulaArg(args);
param1 = argument["arg1"];
param2 = argument["arg2"];
param3 = argument["arg3"];
value = param1 * param2 + param3;
return value;
}
</script>
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Method

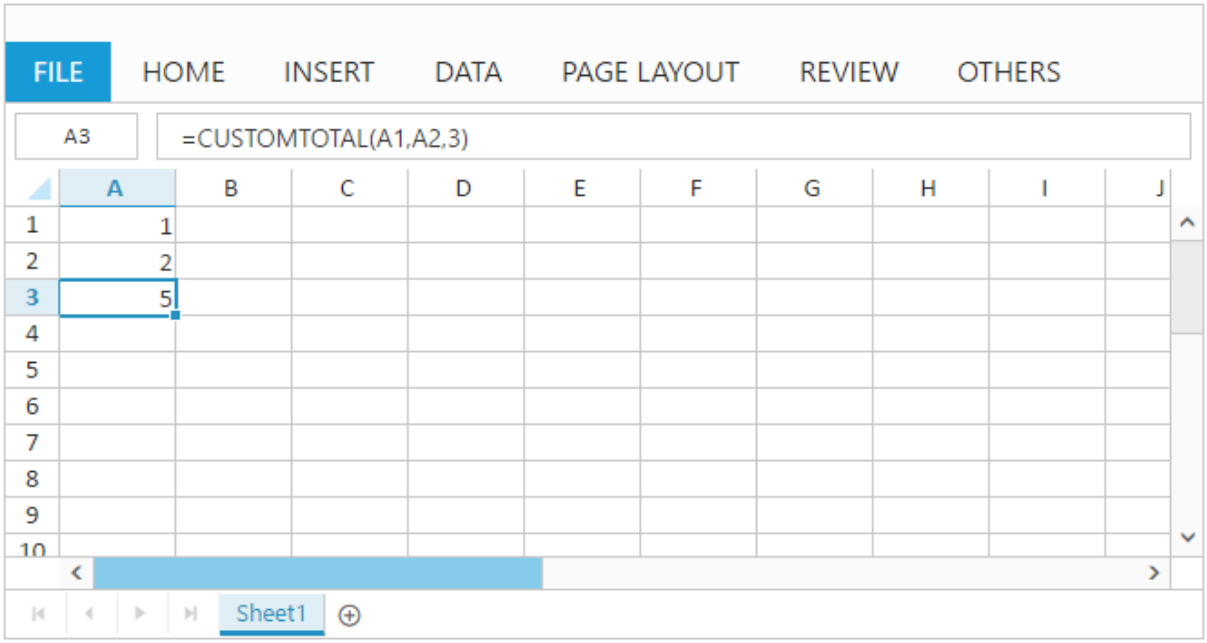
You can add your own function to Spreadsheet using addCustomFormula method. The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
cells.Value("1").Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("2").Add();
}).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script>
function loadComplete() {
this.addCustomFormula("CUSTOMTOTAL", "customTotal");
this.XLEdit.updateCellValue({ rowIndex: 2, colIndex: 0 },
"=CUSTOMTOTAL(A1,A2,3)");
}
function customTotal(args) {
var param1, param2, param3, value, excelObj =
$('#Spreadsheet').data("ejSpreadsheet"),
argument = excelObj.getValueFromFormulaArg(args);
param1 = argument["arg1"];
param2 = argument["arg2"];
```

```
param3 = argument["arg3"];
value = param1 * param2 + param3;
return value;
}
</script>
```

The following output is displayed as a result of the above code example.



To remove user defined function from Spreadsheet use removeCustomFormula method.

Named Ranges

To understand the purpose of cell reference or table, you can define a meaningful name using named ranges support. By using names, you can make your formula much easier to understand and maintain. You can add named ranges to Spreadsheet in following ways,

1. Initial Load
2. Method
3. User Interface

Initial Load

To add named ranges at initial load by using nameManager API, and also you can specify the name and address of the range by using name and refersto API. You can find the added named range list collection in Spreadsheet by accessing nameManager API.

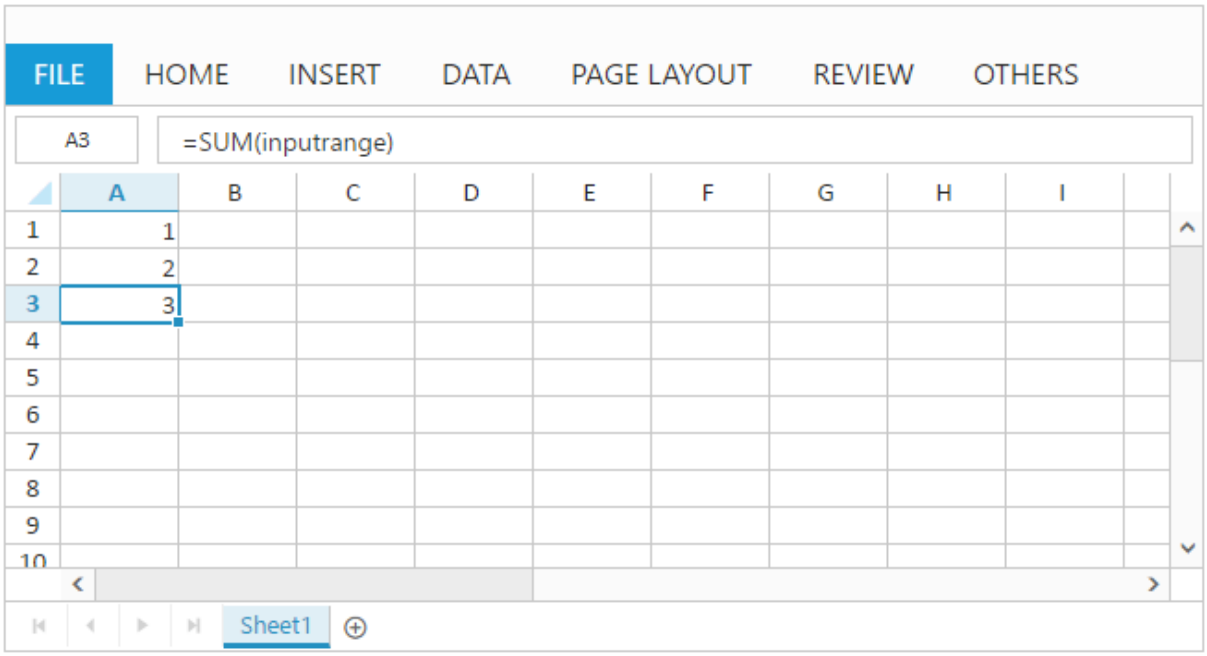
The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
```

```
rows.Cells(cells =>
{
cells.Value("1").Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("2").Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("=SUM(inputRange)").Add();
}).Add();
})
.NameManager(manager => {
manager.Name("inputRange").RefersTo("=Sheet1!$A$1:$A$2").Add(); })
)
```

The following output is displayed as a result of the above code example.



Method

You can add named range to Spreadsheet with addNamedRange method and it can be removed with removeNamedRange method.

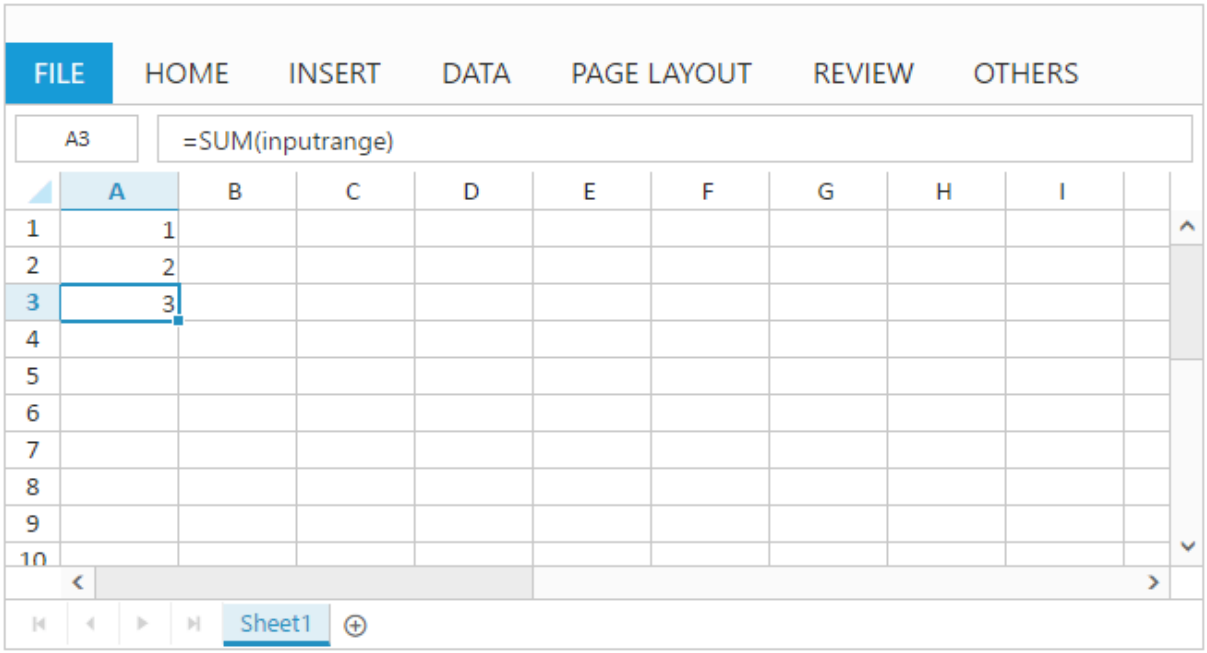
The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
```

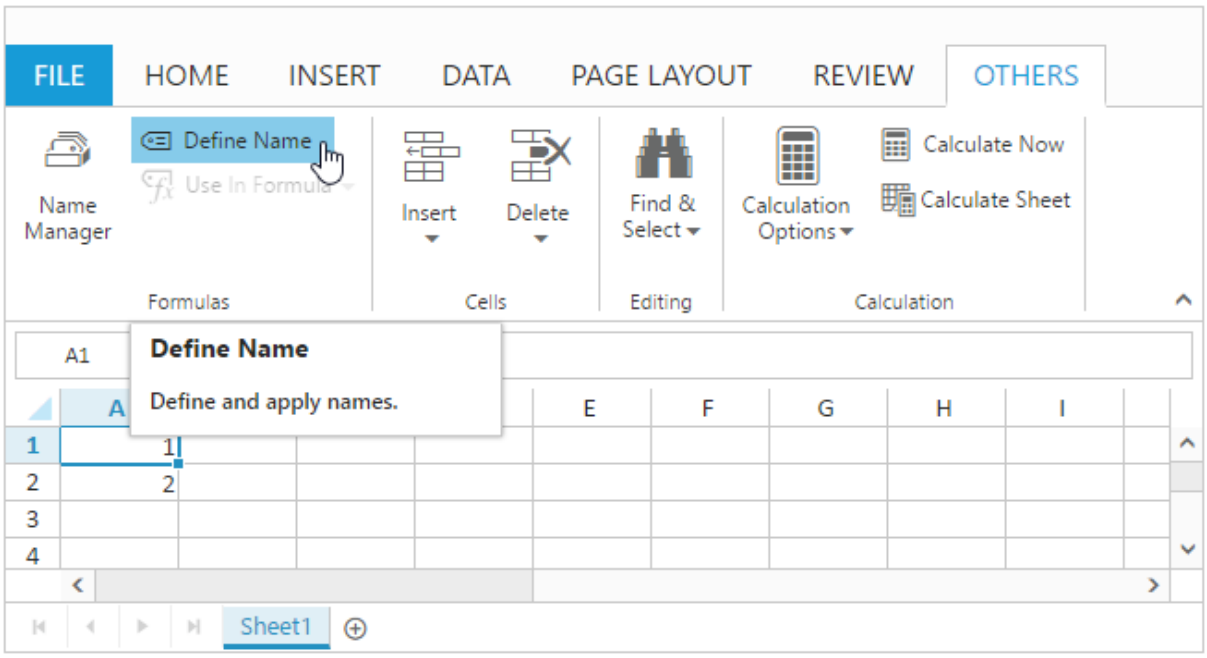
```
cells.Value("1").Add();
}).Add();
rows.Cells(cells =>
{
cells.Value("2").Add();
}).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script>
function loadComplete() {
this.XLRibbon.addNamedRange("inputRange", "=Sheet1!$A$1:$A$2", "named
range demo", this.getActiveSheetIndex());
this.XLEdit.updateCellValue({rowIndex: 2, colIndex: 0},
"=SUM(inputRange)");
}
</script>
```

The following output is displayed as a result of the above code example.



User Interface

You can define name for range of cells through user interface using Define Name option in OTHERS tab. The following screenshot describes the above behavior,



Note: 1. Defining name for cell reference or table will be accessible across all sheets.

2. Named Ranges will be displayed in Name Manger dialog box.

Formula Bar

Formula bar is used to edit or enter cell data in much easier way. To enable formula bar set `AllowFormulaBar` as `true`.

Auto Sum

To sum a row or column of data, select a cell next to the data you want to sum, click `AutoSum` on the `HOME` tab and press enter. To enable auto sum set `AllowAutoSum` API as `true`.

The auto sum options in ribbon is used to perform basic operations like sum, average, count, minimum, maximum etc.

Formatting

Spreadsheet supports many formatting options to make your data easier to view and understand. Use `AllowCellFormatting` property to enable / disable formatting option in Spreadsheet. The different types of formatting supported in Spreadsheet are,

1) Number Formatting 2) Text Formatting 3) Cell Formatting

Number Formatting

Number formatting is used to represent type for your data in Spreadsheet. The different types of number formatting supported in Spreadsheet are,

1) Number 2) Currency 3) Accounting 4) Percentage 5) Short Date 6) Long Date 7) Time 8) Scientific 9) Fraction

You can apply number format for a cell in following ways,

1) Initial Load 2) Method 3) User Interface

Copyright © 2001 - 2020 Syncfusion Inc.

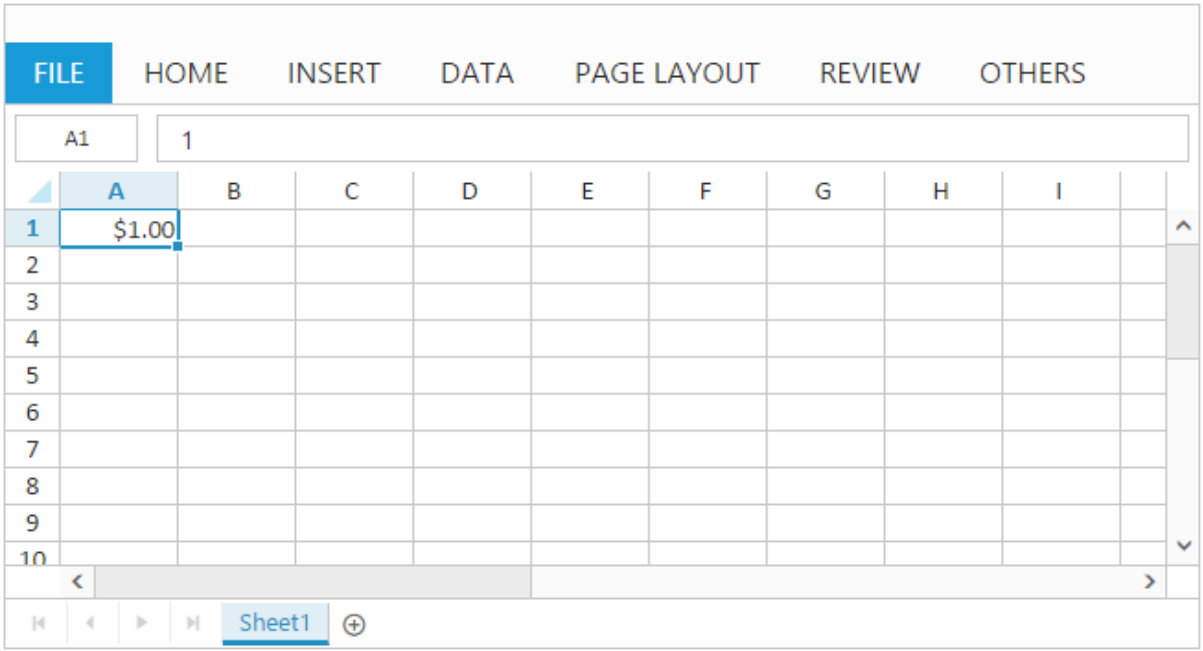
Initial Load

You can set number format for a cell by specifying Format property in cell data binding. The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
cells.Value("1").Format(format => {
format.Type("currency");
}).Add();
}).Add();
}).Add();
})
)
```

The following output is displayed as a result of the above code example.



Method

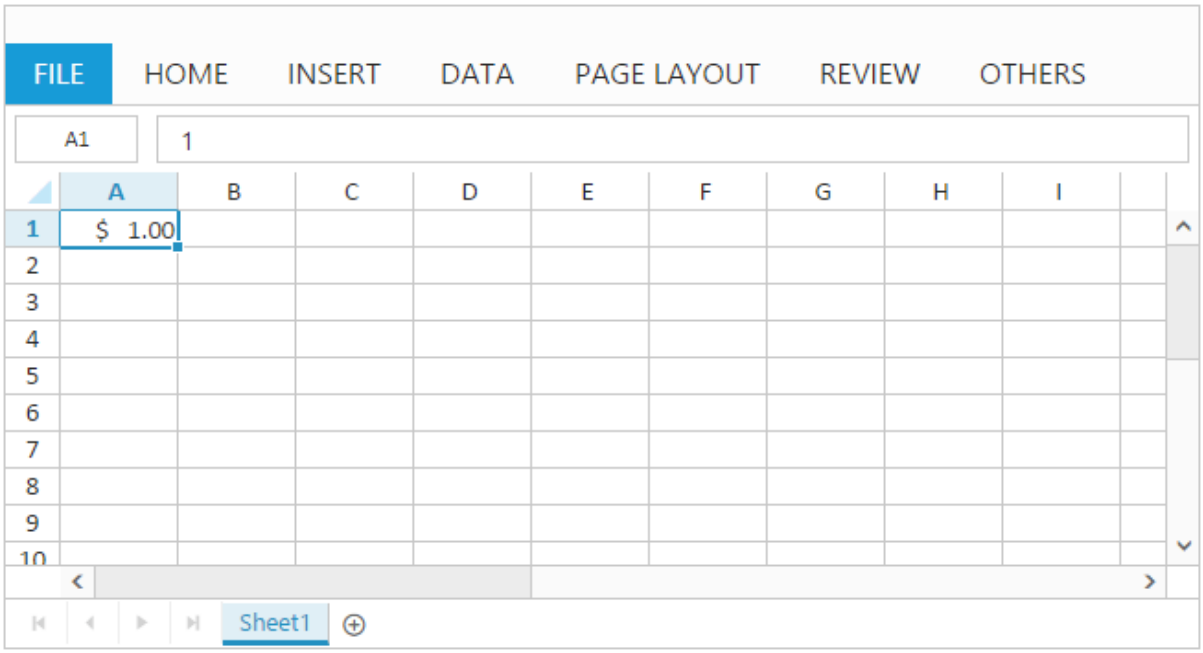
You can set number format for a cell using format method. The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
```

```
rows.Cells(cells =>
{
cells.Value("1").Add();
}).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script>
function loadComplete() {
this.XLFormat.format({ type: "accounting" }, "A1"); // applying
accounting type to cell A1
}
</script>
```

The following output is displayed as a result of the above code example.



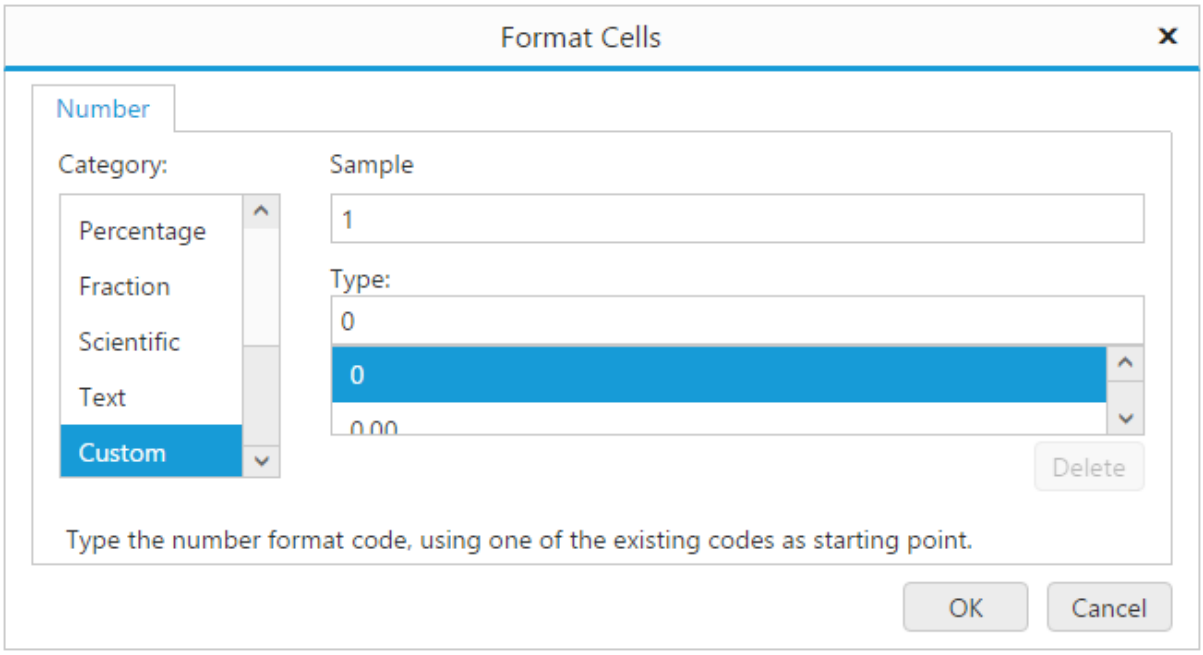
User Interface

You can set number format for a cell through number formatting options in ribbon HOME tab.

Custom Number Format

Spreadsheet supports many number format to display your data as currency, date, percentage and so on. If these pre-defined number formats do not meet your needs you can create and apply your own number formats using format cell dialog. The following screenshot illustrate this,

Copyright © 2001 - 2020 Syncfusion Inc.



Note: Spreadsheet supports basic number format customization and it doesn't have all functionality similar to excel

Text Formatting

To organize and easier to follow your financial, statistical or scientific data, you can apply text formats like font size, font color, text alignment etc. to a cell or range of cells.

Fonts

To distinguish your data from built-in font formats, you can apply different font formats like bold, italic, strike-through, color, font-family and size etc.

Text Alignment

To enhance the visual presentation of your data, you can align text in a cell vertically or horizontally. To align text vertically pick top, middle or bottom align and to align text horizontally pick left, center or right align.

Indents

To enhance the appearance of text in a cell, you can change the indentation of a cell content by increasing or decreasing text indent.

Applying Text Formatting

You can apply text format for a cell in following ways,

1) Initial Load 2) Method 3) User Interface

Initial Load

You can apply text format for a cell by specifying Style property in cell data binding. The following code example describes the above behavior,

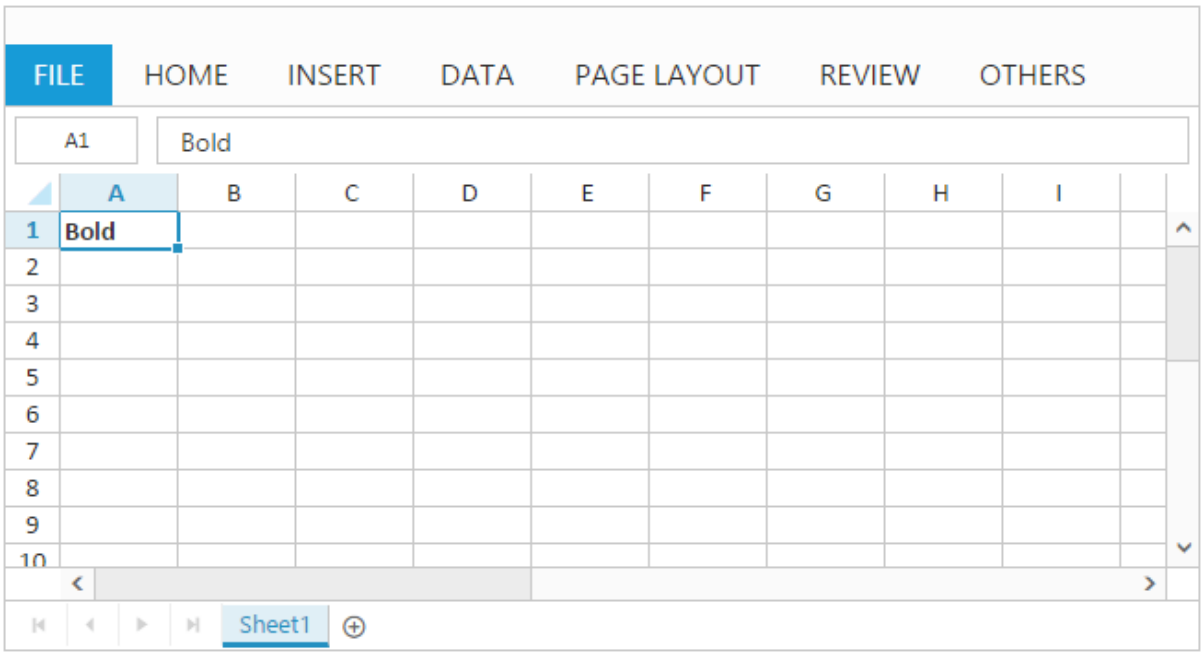
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
cells.Value("Bold").Style(style =>
{
style.FontWeight("bold");
}).Add();
}).Add();
}).Add();
})
)
```

The following output is displayed as a result of the above code example.



Method

You can apply text format for a cell or range of cells using format method. The following code example describes the above behavior,

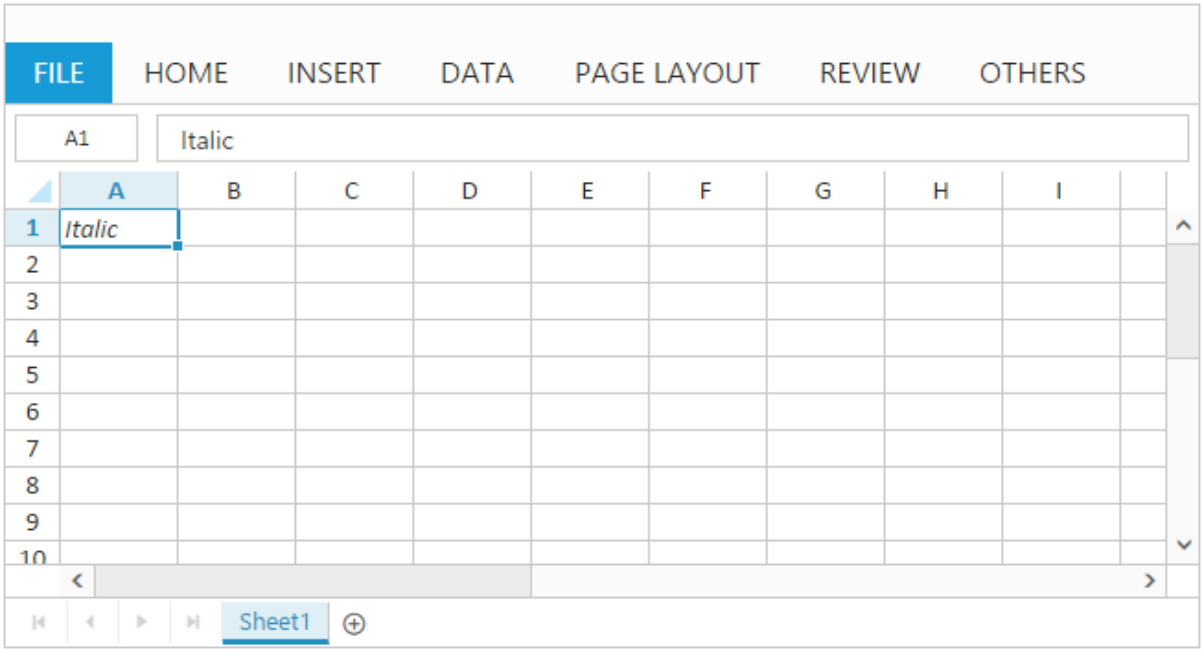
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
cells.Value("Italic").Add();
}).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script>
function loadComplete() {
this.XLFormat.format({ style: { "font-style": "italic" } }, "A1");
}
</script>
```

The following output is displayed as a result of the above code example.



User Interface

You can apply text format for a cell through text formatting options in ribbon HOME tab.

Wrap Text

To make text appearance on multiple lines in a cell, you can apply wrap text to the cell. So, that the text wraps automatically or you can enter a manual line break using ALT + ENTER key in edit mode. Use AllowWrap API to enable/disable wrap text. You can apply wrap text for a cell in following ways,

1) Method 2) User Interface

Method

You can wrap, text in a cell using wrapText method and it can be unwrap using unWrapText method. The following code example describes the wrapText behavior,

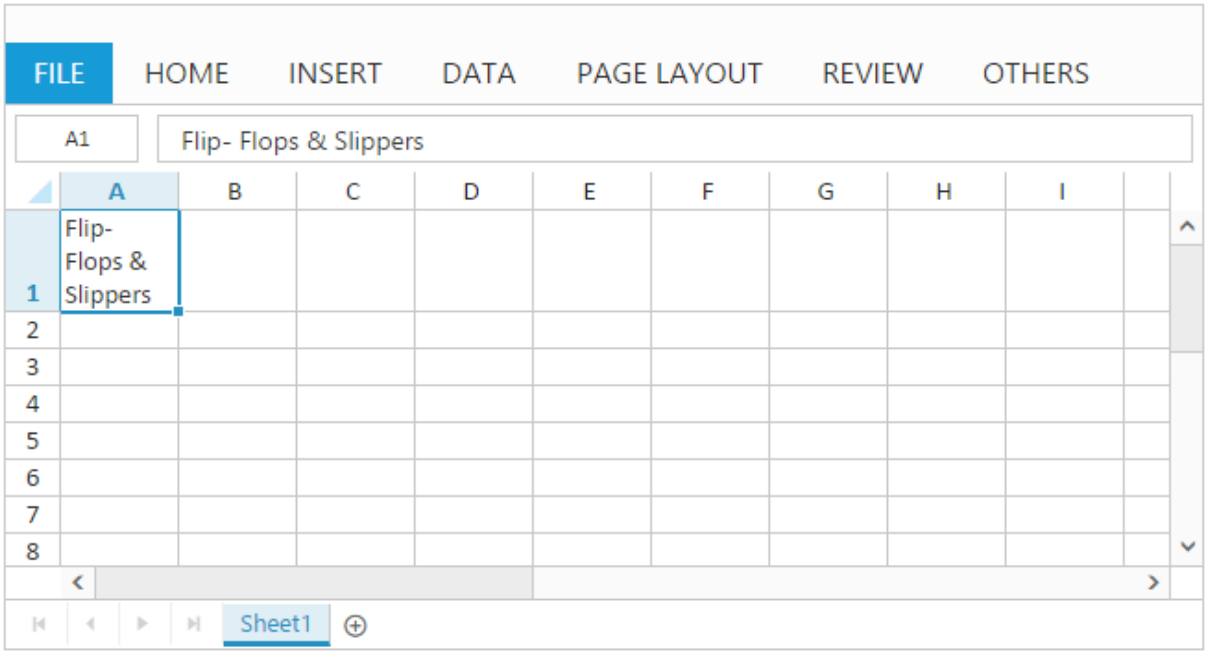
ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.Rows(rows =>
{
rows.Cells(cells =>
{
cells.Value("Flip-Flops & Slippers").Add();
}).Add();
}).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script>
function loadComplete() {
this.wrapText("A1");
//this.unWrapText("A1");
}
</script>
```

The following output is displayed as a result of the above code example.



User Interface

You can wrap or unwrap text in a cell using Wrap text option in ribbon HOME tab.

Cell Formatting

To highlight particular cell or section of cells from whole workbook you can use cell formatting options like borders, fill color etc.

Borders

You can add border around a cell or range of cells to define a section of worksheet or table. The different types of borders supported in Spreadsheet are,

1) Bottom Border 2) Top Border 3) Left Border 4) Right Border 5) All Borders 6) Outside Borders 7) Thick Box Border 8) Bottom Double Border 9) Thick Bottom Border 10) Top and Bottom Border 11) Top and Thick Bottom Border 12) Top and Bottom Double Border

You can apply border for a cell or range of cells through following ways,

1) Use format method to apply border via code 2) Apply border for a cell or range of cells using border options in ribbon HOME tab 3) Use Draw Border options in ribbon HOME tab

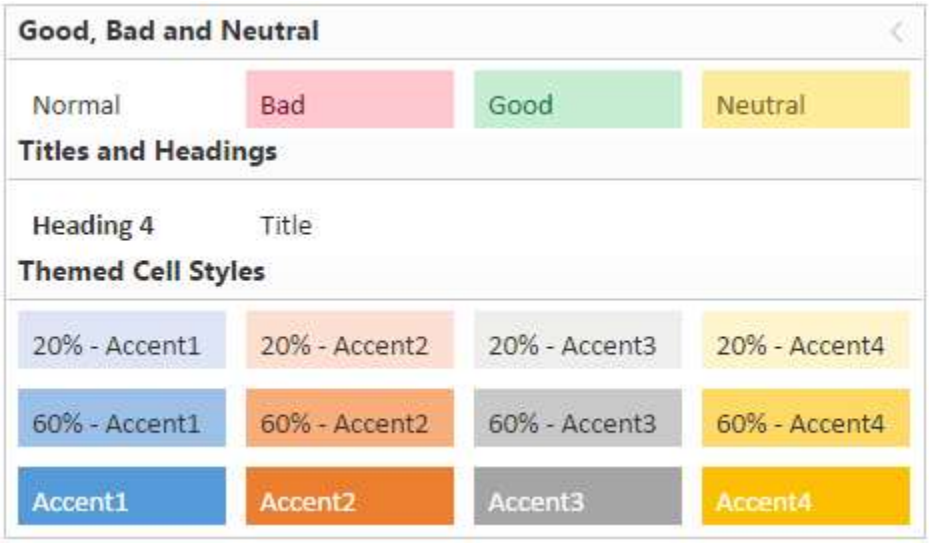
Copyright © 2001 - 2020 Syncfusion Inc.

Fill color

To highlight cell or range of cells from whole workbook you can apply background color for a cell using fill color option in Spreadsheet.

Cell Styles

Cell styles is a collection of pre-defined styles with multiple formatting characteristics to apply several formats in one step. You can apply cell style for a cell using Cell Styles option in ribbon HOME tab. The following screenshot illustrate this,



Format painter

The format painter lets you copy all of the formatting from a cell or range of cells and apply the same formatting to another cell or range of cells including font size, color, style etc.

Clear

Clear option is used to clear cell contents, formats or any attached comments from a cell or range of cells in worksheet. Use AllowClear API to enable/disable clear option in Spreadsheet.You have following clear options in Spreadsheet,

1) Clear All 2) Clear Formats 3) Clear Contents 4) Clear Comments 5) Clear Hyperlinks

Clear All

To clear content, format, comment, hyperlink etc. from a cell or range of cells, use Clear All option in Spreadsheet. Use clearAll method to clear cells via code.

Clear Formats

To clear formats in a cell or range of cells use Clear Formats option in Spreadsheet. Use clearAllFormat method to clear formats via code.

Clear Contents

To clear contents in a cell or range of cells use Clear Contents option in Spreadsheet. Use clearContents method to clear contents via code.

Clear Comments

To clear comment in a cell or range of cells use Clear Comments option in Spreadsheet. Use clearComments method to clear comments via code.

Copyright © 2001 - 2020 Syncfusion Inc.

Clear Hyperlinks

To clear hyperlink in a cell or range of cells use Clear Hyperlinks option in Spreadsheet. Use clearHyperlinks method to clear hyperlinks via code.

Scrolling

Scrolling helps you to move quickly to different areas of worksheet. Scrolling can be enabled by setting AllowScrolling as true in ScrollSettings.

You can scroll through worksheet using one of the following ways,

- Using the arrow keys
- Using the scroll bars
- Using the mouse

Set height and width for Scrolling

To set height and width in spreadsheet use Height and Width property in ScrollSettings. The default value for Height and Width is 100%.

The height and width can be set in percentage or pixel.

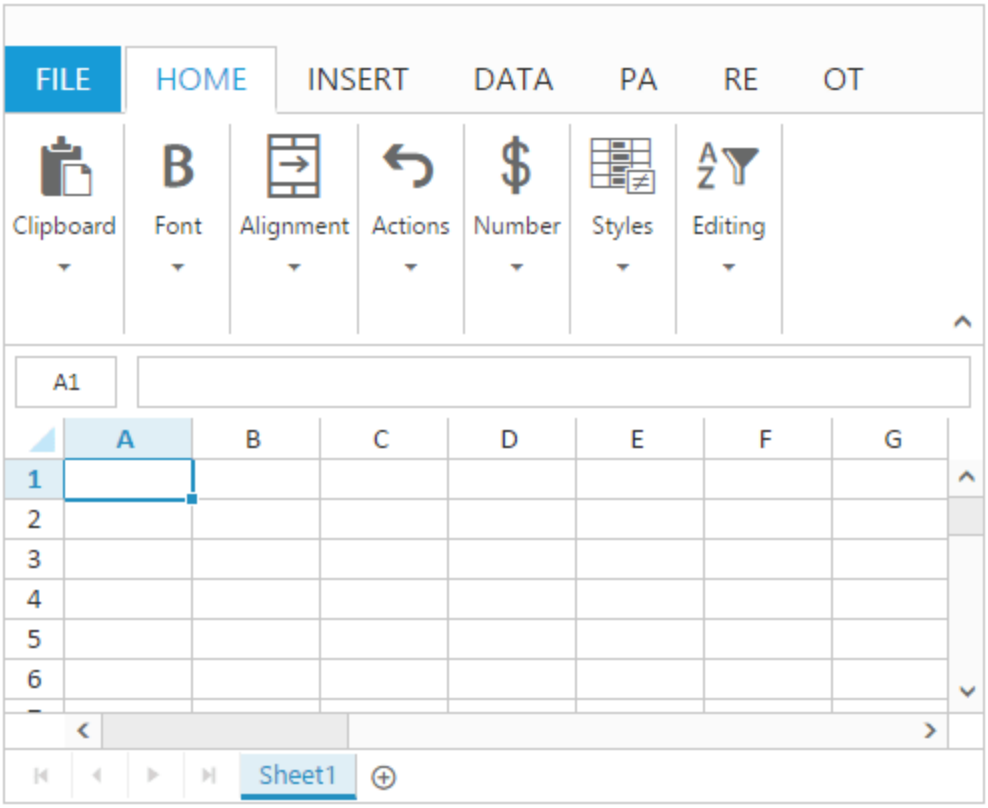
The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.ScrollSettings(scroll =>
{
scroll.AllowScrolling(true);
scroll.Height(400); // Height in pixel
scroll.Width("50%"); // Width in percentage
})
)
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Responsive

Spreadsheet has support for responsive behavior based on client browser's width and height. To enable responsive, set `IsResponsive` property in `ScrollSettings` as `true`. The three modes of responsive layout available in Spreadsheet based on client width are,

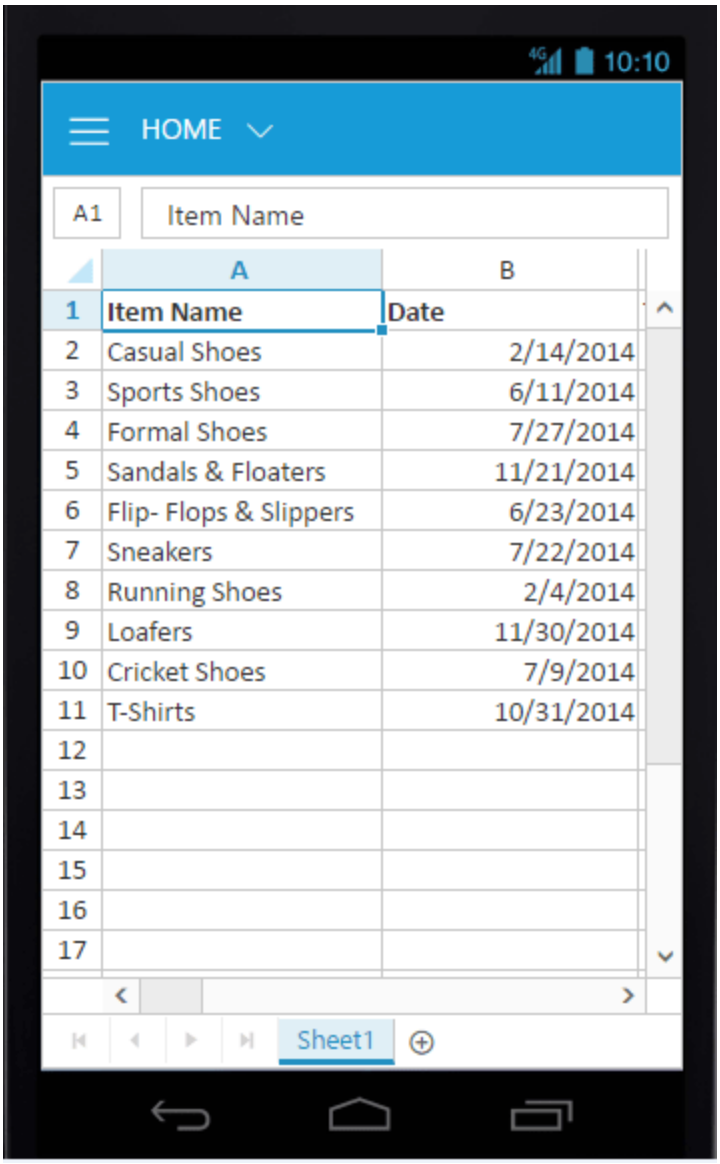
- Mobile(<420px)
- Tablet (420px to 617px)
- Desktop(>617px)

Note: Default value of `IsResponsive` property is `true`.

Mobile Mode

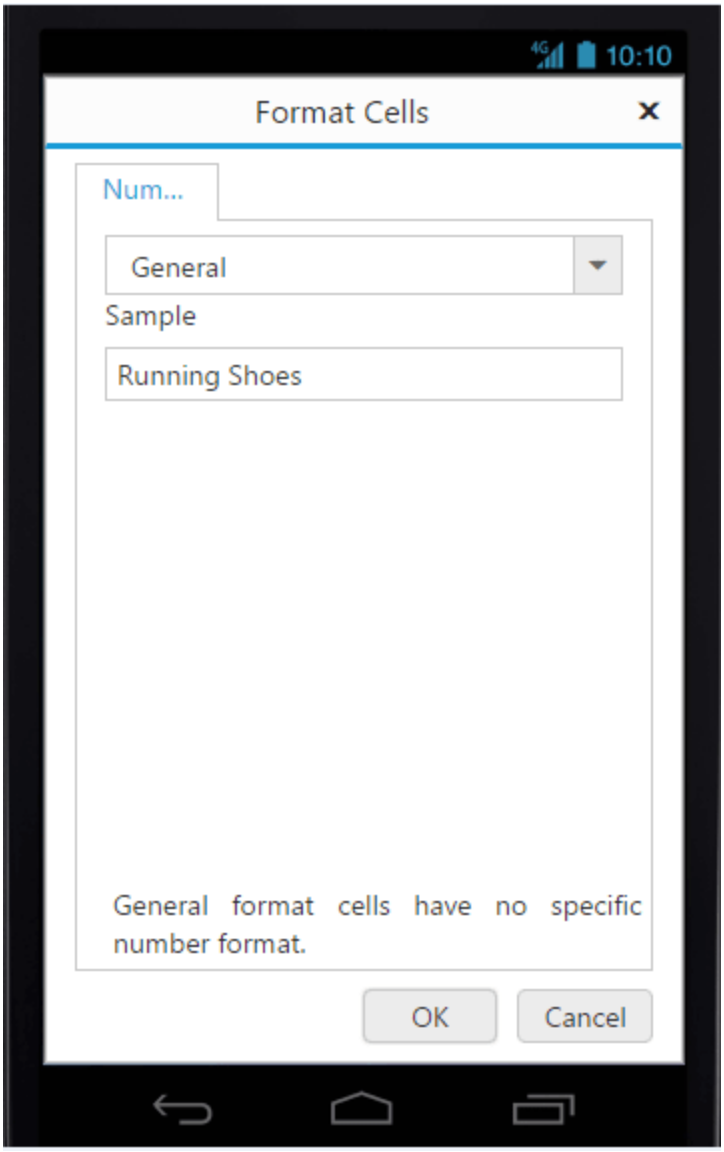
If client width is less than 420px, the spreadsheet will render in mobile mode. In which, you can see that spreadsheet user interface is customized and redesigned for best view in small screens. The customized feature includes filter dialog, format dialog, chart type dialog and ribbon.

Copyright © 2001 - 2020 Syncfusion Inc.



Ribbon in mobile layout

Copyright © 2001 - 2020 Syncfusion Inc.

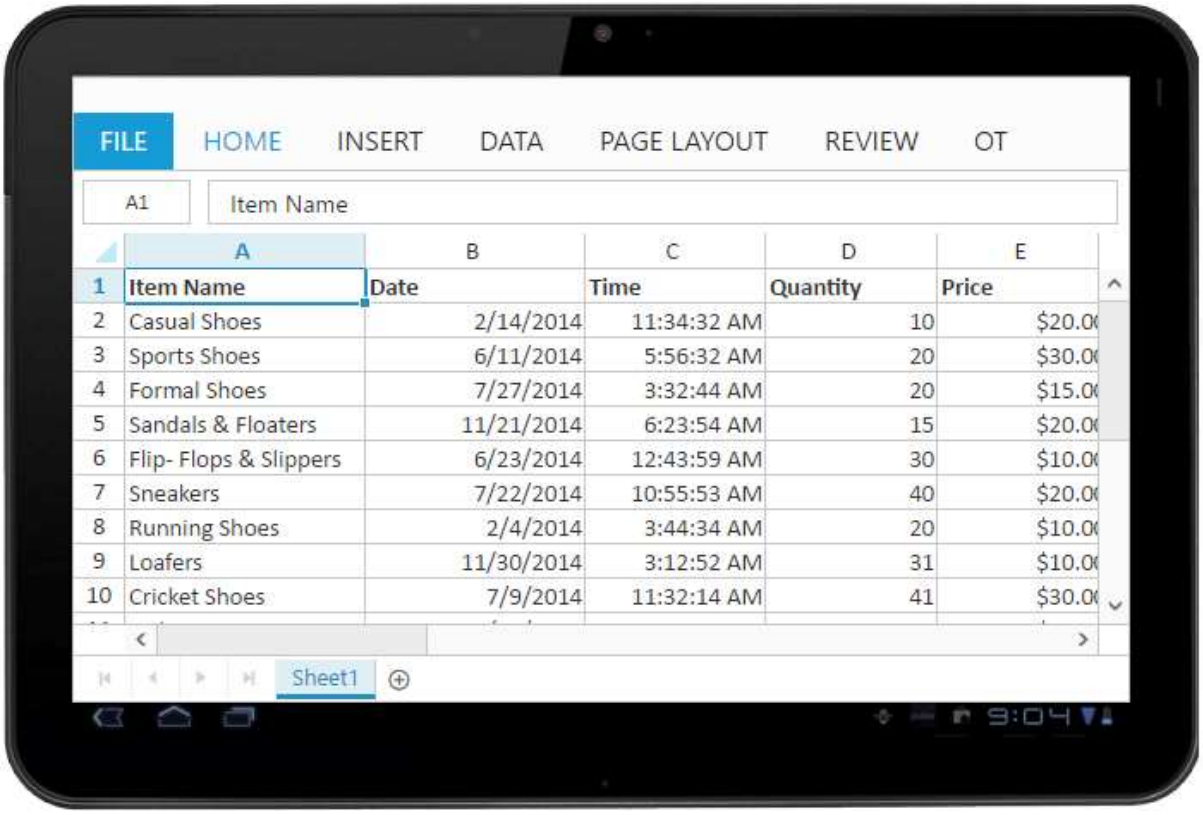


Format cell dialog in mobile layout.

Tablet Layout

If the client width is between 420px and 617px, then the spreadsheet will render in tablet mode. Also it has customized the dialogs to match tablet screen size.

Copyright © 2001 - 2020 Syncfusion Inc.



Ribbon in tablet layout.

Scroll Mode

Spreadsheet supports two type of modes in scrolling. You can use ScrollMode property in ScrollSettings to specify the mode of scrolling.

- Normal - This mode doesn't create new row/column when the scrollbar reaches the end.
- Infinite - This mode creates new row/column when the scrollbar reaches the end.

Note: Default value of ScrollMode property is Infinite mode.

Virtual Scrolling

Spreadsheet has support for virtual scrolling. This allows you to load data that you require (load data based on viewport size) without buffering the entire huge database. You can set AllowVirtualScrolling property in ScrollSettings as true to enable virtual scrolling.

Note: Default value of AllowVirtualScrolling property is true.

Clipboard

The Spreadsheet provides support for the clipboard operations (cut, copy, and paste). Clipboard operations can be enabled or disabled by setting AllowClipboard property in Spreadsheet.

By default AllowClipboard property is true.

Cut

This function cuts the selected range values and make it available in clipboard.

Copyright © 2001 - 2020 Syncfusion Inc.

You can do this by one of the following ways.

- Using "Ctrl + X" key.
- Using Cut button of HOME tab in ribbon to perform cut operation.
- Using Cut option in Context Menu.
- Using cut method.

Copy

This function copies the selected range values and make it available in clipboard.

You can do this by one of the following ways.

- Using "Ctrl + C" key.
- Using Copy button of HOME tab in ribbon to perform copy operation.
- Using Copy option in Context Menu.
- Using copy method.

Paste

This function pastes the clipboard content to newly selected range. If you perform cut paste, clipboard contents are cleared whereas in copy paste the clipboard contents are maintained.

You have following options in Paste.

- Paste Special - You can paste the values with formatting.
- Paste - You can paste only the values.

Note: The default paste option is Paste Special. This is working only within the current Spreadsheet. If you copy the content from other sources, it will paste only the values in the Spreadsheet.

You can do this by one of the following ways,

- Using "Ctrl + V" key.
- Using Paste button of HOME tab in ribbon to perform paste operation.
- Using Paste option in Context Menu.
- Using paste method.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.AllowClipboard(true)
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
```

Copyright © 2001 - 2020 Syncfusion Inc.

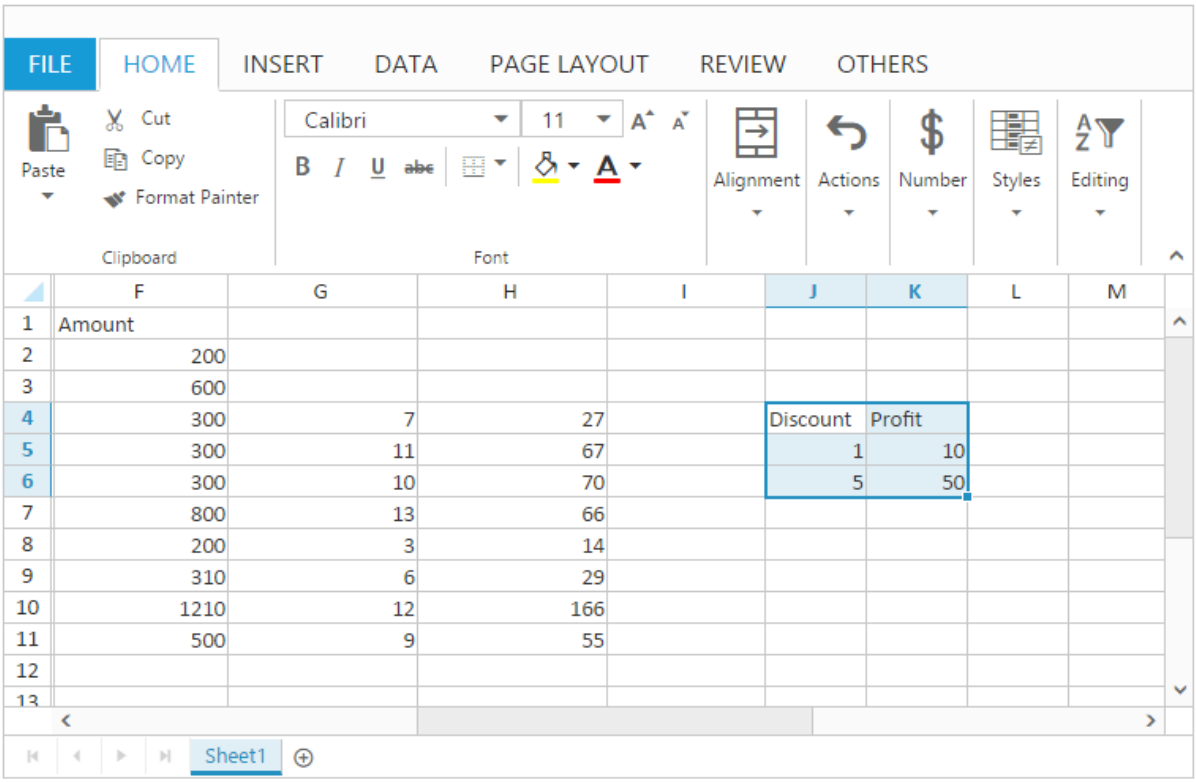
```
function loadComplete() {
var excelClip = this.XLClipboard;
this.performSelection("G1:H3");
excelClip.cut(); // Cut the selected cells
//excelClip.copy();//Copy the selected cells.
this.performSelection("J4");
excelClip.paste();
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Note: Similarly you can perform clipboard operations for shapes (Chart and Image).

Searching

This feature is used to search the contents in the Spreadsheet. You can use AllowSearching property to enable or disable this feature.

You have following options in Searching.

- Find
- Replace
- GoTo
- GoTo Special

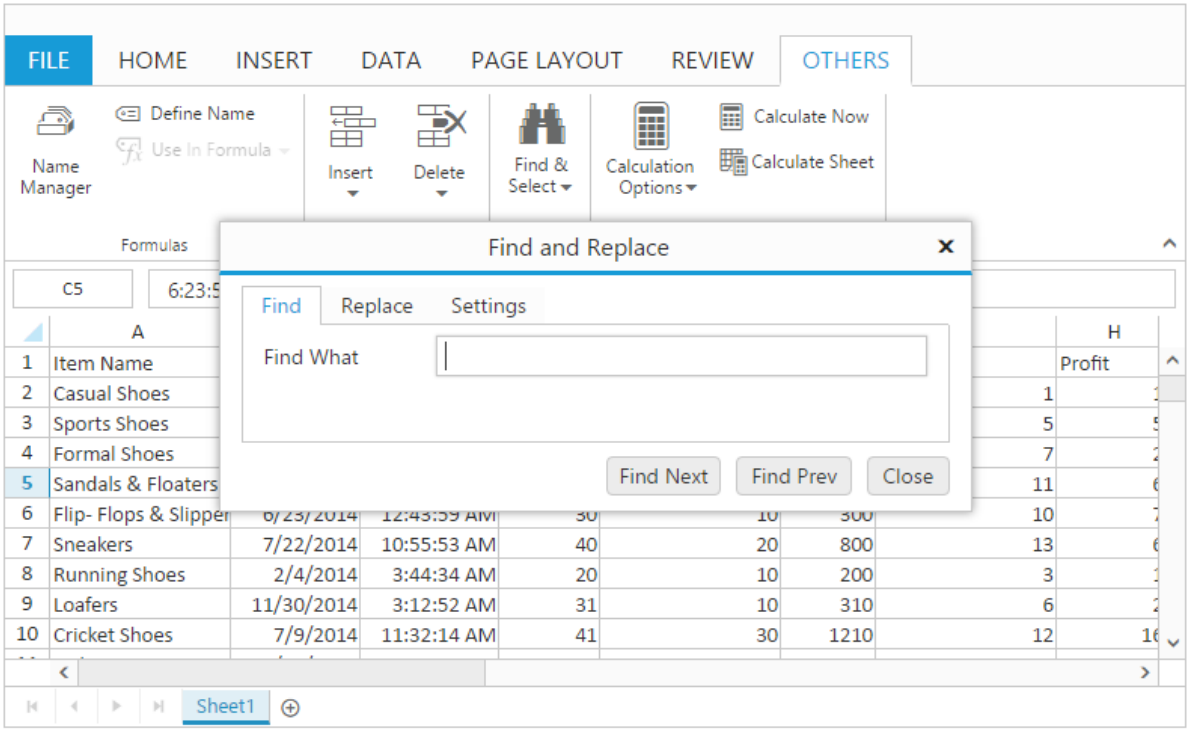
Find

This is used to search the contents of a cell. You can do this by one of the following ways,

- Using "Find" option in Find and Select button of OTHERS tab in ribbon to open the Find and Replace dialog.
- Using findNext and findPrevious methods to search the given value in workbook.
- Using "Ctrl + F" key to open the Find and Replace dialog with Find tab enabled.

The following output is displayed as a result of Find and Replace dialog with Find tab enabled.

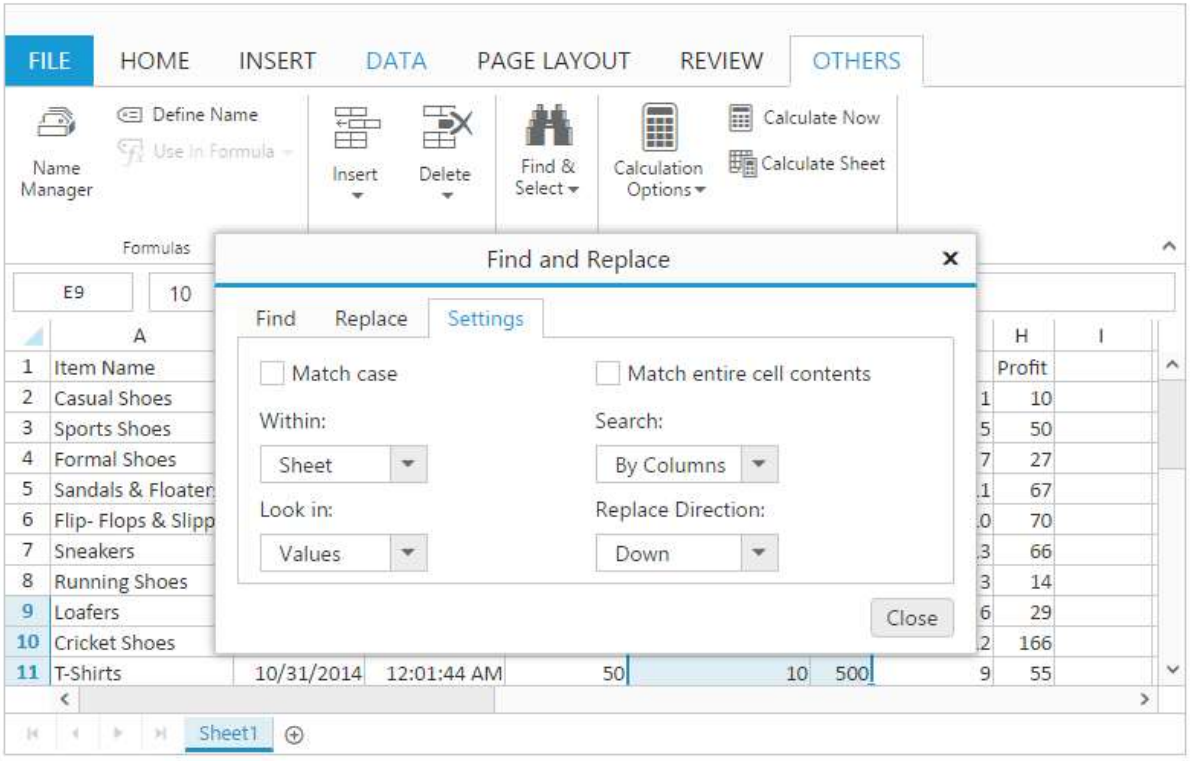
Copyright © 2001 - 2020 Syncfusion Inc.



You can customize the following settings in find option.

- Match Case - Search content should have same casing compared with the cell content.
- Match Entire Cell Content - Search content should match with entire cell content.
- Look in - You can search the contents by values, formulas and comments.
- Within - You can search the content within the sheet or workbook.
- Search - You can search the contents by rows or columns.
- Replace Direction - You can replace the contents by up or down direction.

Copyright © 2001 - 2020 Syncfusion Inc.



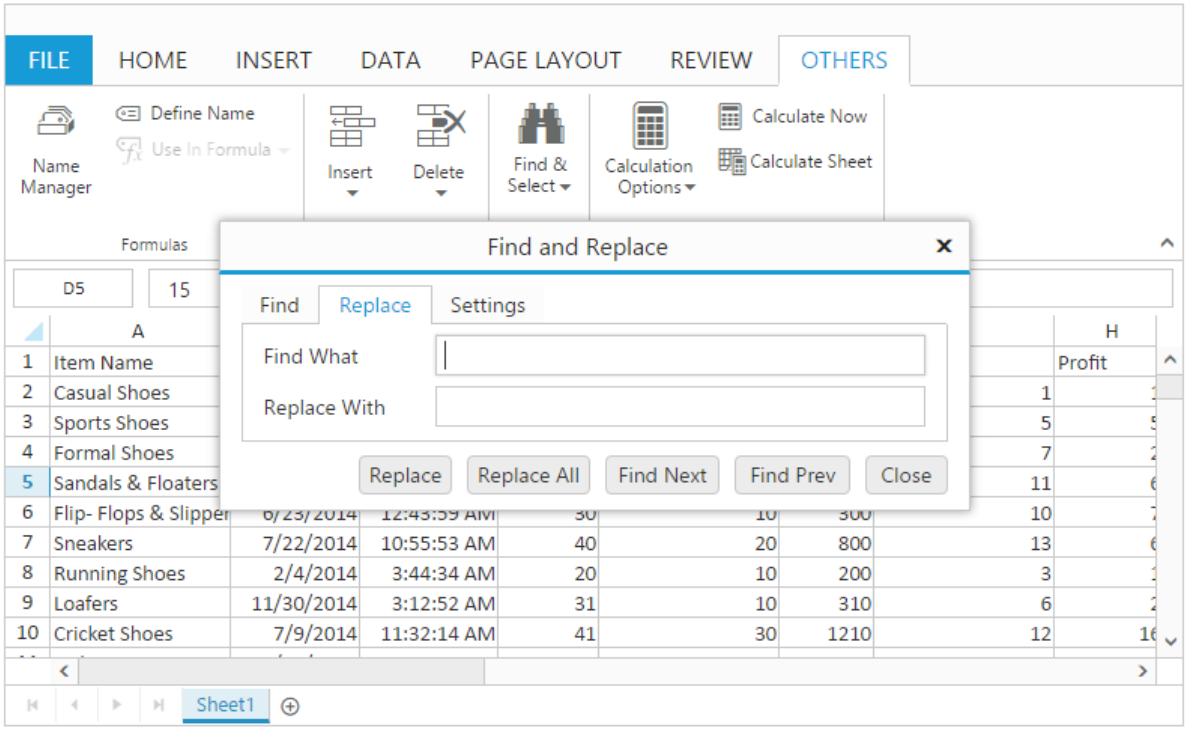
Find and Replace dialog with Settings tab

Replace

This is used to replace the contents of a cell. You can do this by one of the following ways.

- Using "Replace" option in Find and Select button of OTHERS tab in ribbon to open the Find and Replace dialog.
- Using replaceAllByBook or replaceAllBySheet method to replace the contents.
- Using "Ctrl + R" key to open the Find and Replace dialog with Replace tab enabled.

Copyright © 2001 - 2020 Syncfusion Inc.



Find and Replace dialog with Replace tab

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script type="text/javascript">
function loadComplete(args) {
var excelSearch = this.XLSearch;
if (!this.isImport) {
excelSearch.replaceAllBySheet("Shoes", "Slippers", true, false);
//excelSearch.replaceAllByBook("Shoes", "Slippers", true, false);
}
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
```

```
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

	A	B	C	D	E	F	G	H	I	J
1	Item Name	Date	Time	Quantity	Price	Amount	Discount	Profit		
2	Casual Slippers	2/14/2014	11:34:32 AM	10	20	200	1	10		
3	Sports Slippers	6/11/2014	5:56:32 AM	20	30	600	5	50		
4	Formal Slippers	7/27/2014	3:32:44 AM	20	15	300	7	27		
5	Sandals & Floaters	11/21/2014	6:23:54 AM	15	20	300	11	67		
6	Flip- Flops & Slippers	6/23/2014	12:43:59 AM	30	10	300	10	70

8	Running Slippers	2/4/2014	3:44:34 AM	20	10	200	3	14		
9	Loafers	11/30/2014	3:12:52 AM	31	10	310	6	29		
10	Cricket Slippers	7/9/2014	11:32:14 AM	41	30	1210	12	166		
11	T-Shirts	10/31/2014	12:01:44 AM	50	10	500	9	55		

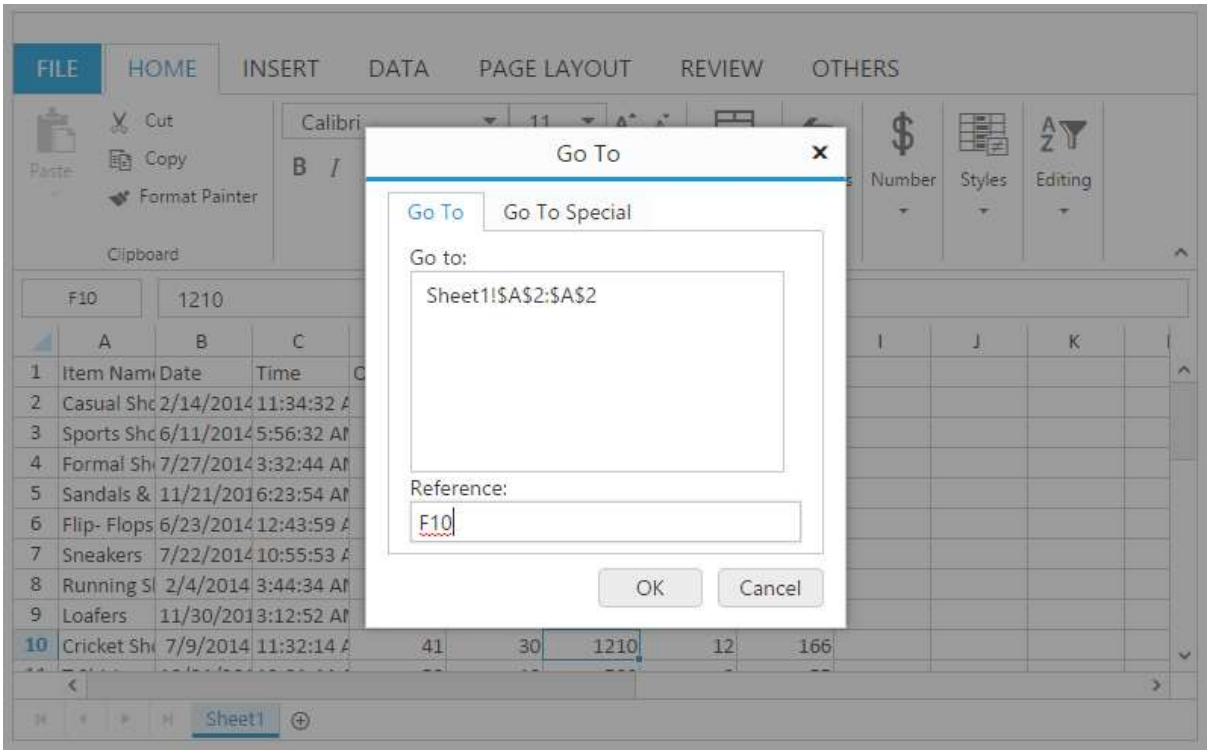
Go To

This feature is used to navigate to the particular cell in the worksheet or workbook.

Copyright © 2001 - 2020 Syncfusion Inc.

You can do this by one of the following ways,

- Using "Go To" option in Find and Select button of OTHERS tab in ribbon to open the Go To dialog.
- Using "Ctrl + G" key to open the Go To dialog.



Go To dialog

The following output is displayed as a result of goto to cell "F10".

	A	B	C	D	E	F	G	H
1	Item Name	Date	Time	Quantity	Price	Amount	Discount	Profit
2	Casual Shoes	2/14/2014	11:34:32 AM	10	20	200	1	1
3	Sports Shoes	6/11/2014	5:56:32 AM	20	30	600	5	5
4	Formal Shoes	7/27/2014	3:32:44 AM	20	15	300	7	2
5	Sandals & Floaters	11/21/2014	6:23:54 AM	15	20	300	11	6
6	Flip- Flops & Slipper	6/23/2014	12:43:59 AM	30	10	300	10	7
7	Sneakers	7/22/2014	10:55:53 AM	40	20	800	13	6
8	Running Shoes	2/4/2014	3:44:34 AM	20	10	200	3	1
9	Loafers	11/30/2014	3:12:52 AM	31	10	310	6	2
10	Cricket Shoes	7/9/2014	11:32:14 AM	41	30	1210	12	16

GoTo Special

This feature is used to quickly select cells of a specified type within the worksheet. You can do this by following ways,

- Using "Go to Special" option in Find and Select button of OTHERS tab in ribbon to open the Go To dialog.
- Using "Go to Formulas" option in Find and Select button of OTHERS tab in ribbon to highlight the cells, which contains formulas.
- Using "Go to Comments" option in Find and Select button of OTHERS tab in ribbon to highlight the cells, which contains comments.
- Using "Go to Conditional Formats" option in Find and Select button of OTHERS tab in ribbon to highlight conditional format applied cells.
- Using "Go to Data Validation" option in Find and Select button of OTHERS tab in ribbon to highlight the data validation applied cells.
- Using "Go to Constants" option in Find and Select button of OTHERS tab in ribbon to highlight the cells, which contains constant values.

The following output is displayed as a result of goto constants which selects the cells containing constant values.

Copyright © 2001 - 2020 Syncfusion Inc.

	A	B	C	D	E	F	G	H	I	J
1	Item Name	Date	Time	Quantity	Price	Amou	Discount	Profit

11	T-Shirts	10/31/	12:01:44	50	10	500	9	55		

Undo and Redo

Spreadsheet provides the support to perform undo and redo operations. You can set `AllowUndoRedo` property as `true` to enable undo redo feature. You can also use `UndoredoStep` property to limit the undo redo action.

Note: Default value of `UndoredoStep` property is 20. You can perform 20 undo or redo actions.

Undo the last action

Undo reverses the last action you performed with spreadsheet. You can do this by following ways.

- Use Undo button of HOME tab in ribbon.
- Use "Ctrl + Z" key.

Redo the action

Redo reverses the last undo action you performed with spreadsheet. You can do this by following ways.

- Use Redo button of HOME tab in ribbon.
- Use "Ctrl + Y" key.

Print

This feature is used to produce text and graphics from a computer screen or file into a sheet of paper. You can use `AllowPrinting` property in `PrintSettings` to enable/disable the print operation.

You have following options in printing.

- Print Sheet / Print Selected Area.

Copyright © 2001 - 2020 Syncfusion Inc.

- Print with Gridlines
- Print with Headers

Print Sheet / Print Selected Area

You can print the sheet or print the selected area by following ways,

- Using the Print button or Print Selected button under Print group of PAGE LAYOUT tab in ribbon.
- Using printSheet or printSelection method to print the spreadsheet.

The following code example describes the above behavior.

ASPX-CS

```
@Html.EJ().Button("btnPrint").Size(ButtonSize.Medium).ShowRoundedCorner(t
rue).Width("80").ClientSideEvents(e =>
e.Click("printClick")).Text("Print")
@Html.EJ().Button("btnPrintSel").Size(ButtonSize.Medium).ShowRoundedCorne
r(true).ClientSideEvents(e => e.Click("printSelClick")).Text("Print
Selected")
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.PrintSettings(printOption => {
printOption.AllowPrinting(true);
})
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).Add();
})
)
<script type="text/javascript">
function printClick(args) {
var excelObj = $("#Spreadsheet").ejSpreadsheet("instance");
excelObj.XLPrint.printSheet();
}
function printSelClick(args) {
var excelObj = $("#Spreadsheet").ejSpreadsheet("instance");
excelObj.XLPrint.printSelection();
}
</script>
```

C#

```
namespace MVCSampleBrowser.Controllers
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

The following output is displayed as a result of the above code example.

	A	B	C	D	E	F	G	H	I
1	Item Name	Date	Time	Quantity	Price	Amount	Discount	Profit	
2	Casual Shoes	2/14/2014	11:34:32 AM	10	20	200	1	10	
3	Sports Shoes	6/11/2014	5:56:32 AM	20	30	600	5	50	
4	Formal Shoes	7/27/2014	3:32:44 AM	20	15	300	7	27	
5	Sandals & Floaters	11/21/2014	6:23:54 AM	15	20	300	11	67	
6	Flip- Flops & Slippers	6/23/2014	12:43:59 AM	30	10	300	10	70	
7	Sneakers	7/22/2014	10:55:53 AM	40	20	800	13	66	
8	Running Shoes	2/4/2014	3:44:34 AM	20	10	200	3	14	
9	Loafers	11/30/2014	3:12:52 AM	31	10	310	6	29	
10	Cricket Shoes	7/9/2014	11:32:14 AM	41	30	1210	12	166	
11	T Shirts	10/21/2014	12:01:44 AM	50	10	500	9	55

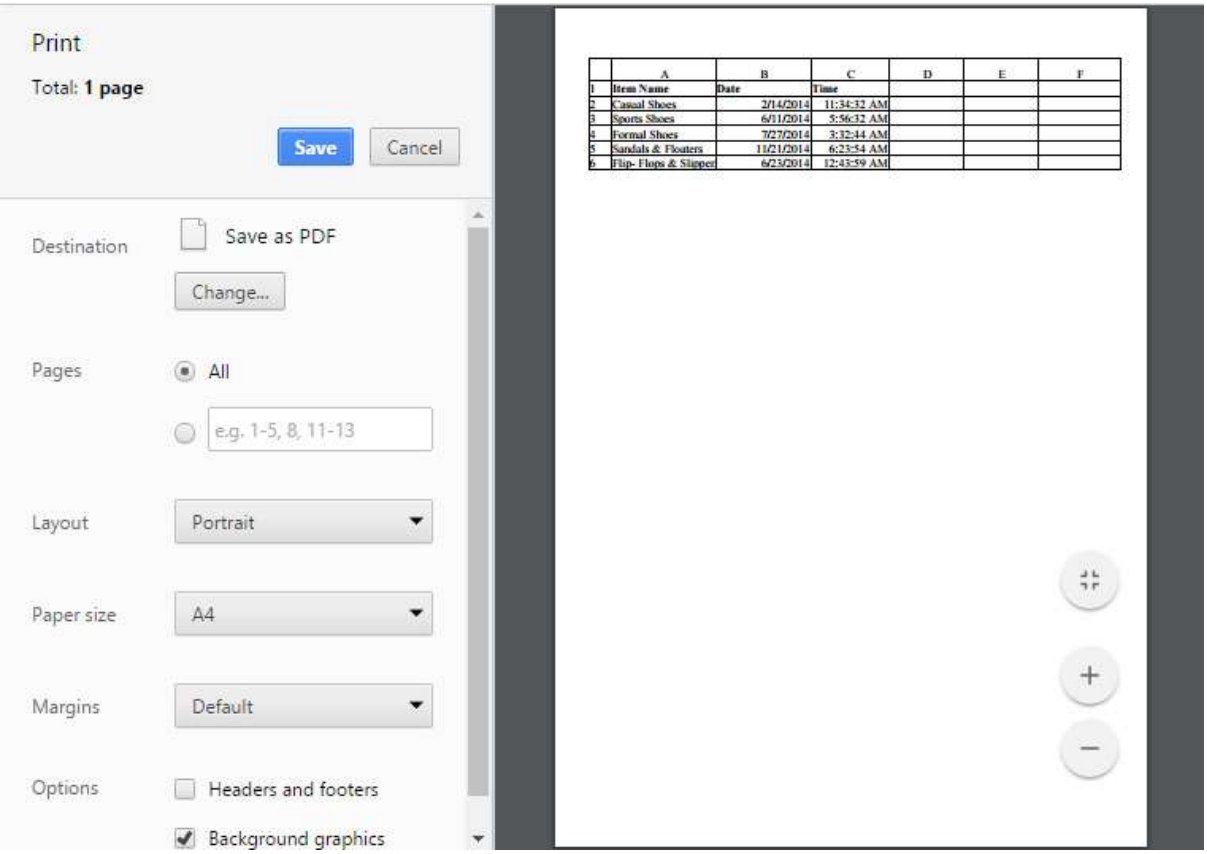
Print dialog with entire sheet in Chrome browser



Print dialog with selected area print in chrome browser

Print with Gridlines

You have an option to print the spreadsheet with gridlines or without gridlines. You can do this by one of the following ways,

- Check or uncheck the Gridlines option under Show group of PAGE LAYOUT tab in ribbon to print with Gridlines.
- Using ShowGridlines property to enable / disable the gridlines.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).ShowGridlines(false).Add();
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
```

```
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

Print dialog without gridlines in chrome browser

Print with Headings

You have an option to print the spreadsheet with headers or without headers. You can do this by one of the following ways,

- Check or uncheck the Headings option under Show group of PAGE LAYOUT tab in ribbon.
- Using ShowHeadings property to enable / disable showHeadings.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).Add();
}).ShowHeadings(false).Add();
})
)
```

C#

```
namespace MVCSampleBrowser.Controllers
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
public partial class SpreadsheetController : Controller
{
public ActionResult Default()
{
List<ItemDetail> lItems = new List<ItemDetail>();
lItems.Add(new ItemDetail() { ItemName = "Casual Shoes", Date = new
DateTime(2014, 02, 14), Time = new DateTime(2014, 02, 14, 11, 34, 32),
Quantity = 10, Price = 20, Amount = 200, Discount = 1, Profit = 10 });
lItems.Add(new ItemDetail() { ItemName = "Sports Shoes", Date = new
DateTime(2014, 06, 11), Time = new DateTime(2014, 06, 11, 05, 56, 32),
Quantity = 20, Price = 30, Amount = 600, Discount = 5, Profit = 50 });
lItems.Add(new ItemDetail() { ItemName = "Formal Shoes", Date = new
DateTime(2014, 07, 27), Time = new DateTime(2014, 07, 27, 03, 32, 44),
Quantity = 20, Price = 15, Amount = 300, Discount = 7, Profit = 27 });
lItems.Add(new ItemDetail() { ItemName = "Sandals & Floaters", Date = new
DateTime(2014, 11, 21), Time = new DateTime(2014, 11, 21, 06, 23, 54),
Quantity = 15, Price = 20, Amount = 300, Discount = 11, Profit = 67 });
lItems.Add(new ItemDetail() { ItemName = "Flip- Flops & Slippers", Date =
new DateTime(2014, 06, 23), Time = new DateTime(2014, 06, 23, 12, 43,
59), Quantity = 30, Price = 10, Amount = 300, Discount = 10, Profit = 70
});
ViewBag.Datasource = lItems;
return View();
}
}
}
```

Print dialog without headings in chrome browser

Keyboard Shortcuts

Shortcut	Description
Alt + Enter	In Cell editing mode, starts a new line in the same cell
Alt + F1	Creates a Chart from the selected cells
Alt + T	Opens create Table dialog box
Backspace	Clears content of the active cell. Deletes one character to the left in the Formula Bar. In Cell editing mode, it deletes one character to the left of the insertion point.
Ctrl + \	To apply go to row difference for selected cells
Ctrl + 1	Opens Format cell dialog box
Ctrl + 5	Applies or removes strikethrough
Ctrl + 8	Hides the selected columns
Ctrl + 9	Hides the selected rows

Copyright © 2001 - 2020 Syncfusion Inc.

Ctrl + A	Selects the entire worksheet.If worksheet has data, Ctrl + A will selects current region. Pressing Ctrl + A second time selects the entire worksheet.
Ctrl + B	Applies or removes bold formatting
Ctrl + C	Copies the selected cells
Ctrl + D	Uses the Fill Down command to copy the contents and format
Ctrl + F3	Opens name manager dialog box
Ctrl + I	Applies or removes italic formatting
Ctrl + K	Opens the Insert Hyperlink dialog box for new hyperlinks or the Edit Hyperlink dialog box for selected existing hyperlinks
Ctrl + O	Displays Open dialog box to open a file
Ctrl + P	Opens Print dialog box
Ctrl + R	Uses the Fill Right command to copy the contents and format
Ctrl + S	Saves the current workbook
Ctrl + Space Bar	Selects the entire column of selected cells in a worksheet
Ctrl + U	Applies or removes underlining
Ctrl + Shift + &	Applies the outline border to the selected cells
Ctrl + Shift + _	Removes the outline border from the selected cells
Ctrl + Shift + ~	Applies the General format
Ctrl + Shift + $	Applies the Currency format
Ctrl + Shift + %	Applies the Percentage format
Ctrl + Shift + ^	Applies the Scientific format
Ctrl + Shift + #	Applies the Short Date format
Ctrl + Shift + @	Applies the Time format
Ctrl + Shift + !	Applies the Number format with two decimal places
Ctrl + Shift + 8	To show hidden column within the selection
Ctrl + Shift + 9	To show hidden row within the selection
Ctrl + Shift + D	Opens Delete dialog box
Ctrl + Shift + Home	Extends the selection of cells to the beginning of the worksheet
Ctrl + Shift + I	Opens Insert dialog box
Ctrl + Shift + F2	To expand or collapse ribbon content

Copyright © 2001 - 2020 Syncfusion Inc.

Ctrl + Shift + O	Highlight all cells that contain comments
Ctrl + Shift + |	To apply go to column difference for selected cells
Ctrl + V	Inserts the content of the clipboard based on active cell and replaces any selection. It can be performed after you have cut or copied cell contents.
Ctrl + X	Cuts the selected cells
Ctrl + Y	Repeats the last action, if possible
Ctrl + Z	Reverses the last action or to delete the last entry
Delete	Delete selected cells
Esc	Cancel edit mode and discard changes.
F2	Start edit
Shift + F2	Adds or edits a cell comment
Shift + F11	Inserts a new worksheet
Shift + Spacebar	Selects the entire row of selected cells in a worksheet

Sparkline

Sparkline are easy to interpret and it conveys much more information to the user by visualizing the data in a small amount of space. Here sparkline were placed inside the cell. It creates the Sparkline based on the selected cell range's data. You can use AllowSparkline property to enable/disable Sparkline.

Types of Sparkline

The Following Types of Sparkline are available in Spreadsheet.

Column Line * Win/loss

You can create the Sparkline by one of the following ways,

Using the Sparkline Type button to select the type of Sparkline under Sparkline groups of INSERT Tab in ribbon. Using createSparkline method to create the Sparkline.

Sparkline Customization

You can perform the following customizations for Sparkline. These options are available in SPARKLINE DESIGN Tab which is enabled, while clicking the Sparkline element.

Feature	API	Description
Edit Data & Location Range	createSparkline	You can modify the data range, location range of Sparkline
Sparkline Type	changeType	You can change the type of sparkline by using sparkline type button.

Copyright © 2001 - 2020 Syncfusion Inc.

High Point, First Point, Last Point, Low Point, Negative Point, Sparkline Color and Marker Color	changePointColor	You can high light the high point, low point, first point, last point, negative point and Marker Color of sparkline .

The following code example describes the above behavior,

ASPX-CS

```
@(Html.EJ().Spreadsheet<object>("Spreadsheet")
.AllowSparkline(true)
.PageSettings(setting => setting.PageCount(1))
.Sheets(sheet =>
{
sheet.RangeSettings(range =>
{
range.Datasource((IEnumerable<object>)ViewBag.Datasource).StartCell("A1")
.Add();
}) Add();
})
.ClientSideEvents(events => events.LoadComplete("loadComplete"))
)
<script>
function loadComplete() {
var  xlSparkline = this.XLSparkline;
if(!this.isImport) {
this.sheetRename("Sparkline Chart");
this.mergeCells("F3:G4", true);
xlSparkline.createSparkline("A5:D5", "F3", "Column", {highPointColor:
"red", negativePointColor: "black", startPointColor: "green"} );
this.mergeCells("F8:G8", true);
xlSparkline.createSparkline("B2:B4", "F8", "Winloss");
this.mergeCells("F10:G11", true);
xlSparkline.createSparkline("C3:C5", "F10",  "Line",
{markerSettings:{visible:true},highPointColor: "red", negativePointColor:
"black", startPointColor: "green"} );
}
}
</script>
```

C#

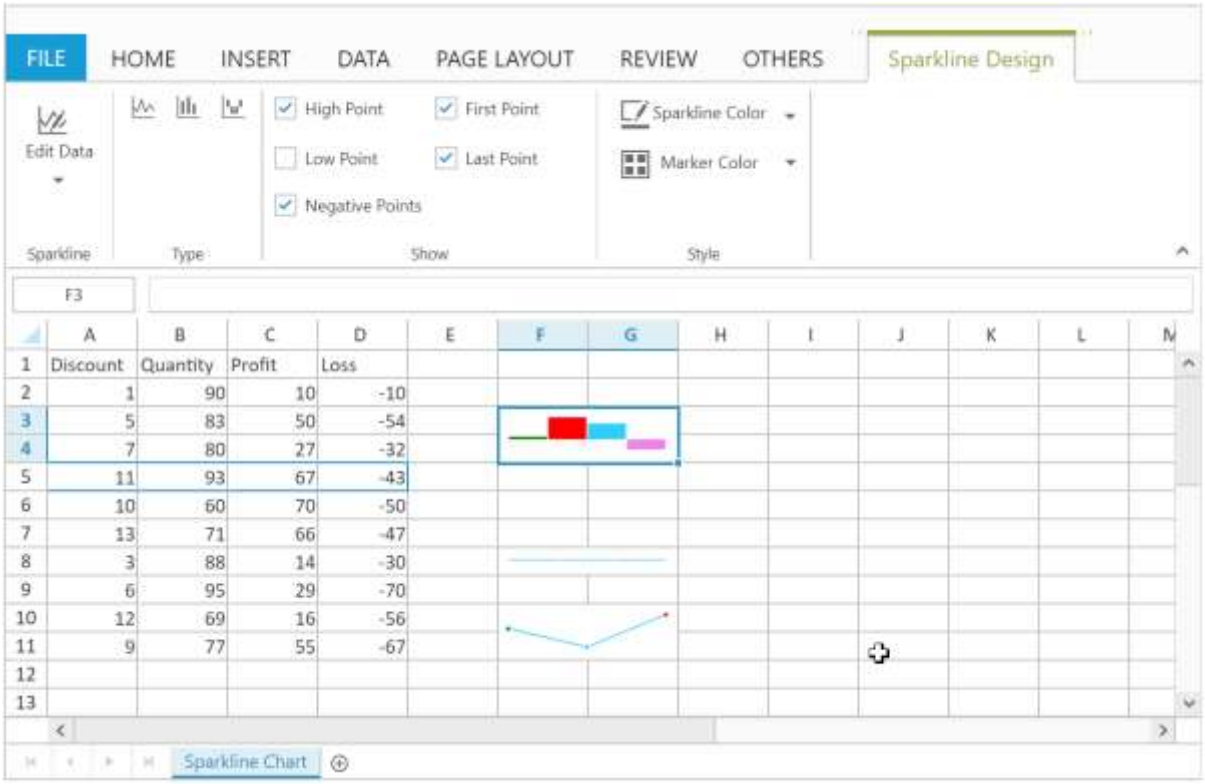
```
public ActionResult Index()
{
var dataSource = SparklineDetail.GetSparklineDetails.ToList();
ViewBag.DataSource = dataSource;
return View()
}
public IEnumerable<object> GetSparklineDetails
{
get
{
List<SparklineDetail> lItems = new List<SparklineDetail>();
lItems.Add(new SparklineDetail() { Discount = 1, Quantity = 90, Profit =
10, Loss = -10 });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
lItems.Add(new SparklineDetail() { Discount = 5, Quantity = 83, Profit =
50, Loss = -54 });
lItems.Add(new SparklineDetail() { Discount = 7, Quantity = 80, Profit =
27, Loss = -32 });
lItems.Add(new SparklineDetail() { Discount = 11, Quantity = 93, Profit =
67, Loss = -43 });
lItems.Add(new SparklineDetail() { Discount = 10, Quantity = 60, Profit =
70, Loss = -50 });
lItems.Add(new SparklineDetail() { Discount = 13, Quantity = 71, Profit =
66, Loss = -47 });
lItems.Add(new SparklineDetail() { Discount = 3, Quantity = 88, Profit =
14, Loss = -30 });
lItems.Add(new SparklineDetail() { Discount = 6, Quantity = 95, Profit =
29, Loss = -70 });
lItems.Add(new SparklineDetail() { Discount = 12, Quantity = 69, Profit =
16, Loss = -56 });
lItems.Add(new SparklineDetail() { Discount = 9, Quantity = 77, Profit =
55, Loss = -67 });
var itemCol =
from item in lItems
select new { item.Discount, item.Quantity, item.Profit, item.Loss };
return itemCol;
}
}
public class SparklineDetail
{
public int Discount { get; set; }
public int Quantity { get; set; }
public int Profit { get; set; }
public int Loss { get; set; }
}
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Sparkline

Overview

Sparklines are easy to interpret and also it conveys much more information to the user by visualizing the data in a small amount of space.

Some of the key features are,

- Consumes less amount of space for visualizing the data.
- Easy integration with grids.
- Five type of Sparkline available namely Line, Column, Area, Win-loss and Pie.
- Range Band to highlight selected start and end value region.
- Can customize markers for high, low, start, end and negative point.
- Trackball to get current mouse point to display tooltip.

Getting Started

This section explains you the steps required to populate the Sparkline with data. This section covers only the minimal features that you need to know to get started with the Sparkline.

Installation and Deployment

It describes you on how to configure the Syncfusion dependencies in your ASP.NET MVC application to create a Sparkline.

Referencing Syncfusion Assemblies

The following assemblies need to be referenced in your application for using Essential Sparkline MVC

Copyright © 2001 - 2020 Syncfusion Inc.

1. Syncfusion.EJ.dll
2. Syncfusion.EJ.MVC.dll

Follow the steps given below to deploy the application in the development server by referencing the assembly in **GAC**.

- Web.config file should be configured according to the referenced assemblies.
- To deploy your application, you have to ensure that the above referenced assemblies (in your web.config files) are present in the GAC.

```
<system.web>
  <compilation debug="true" targetFramework="4.5.1">
    <assemblies>
      <add assembly="Syncfusion.EJ, Version=13.3400.0.7, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
      <add assembly="Syncfusion.EJ.Mvc, Version=13.3400.0.7, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
    </assemblies>
  </compilation>
```

And, add Syncfusion namespace in the Web.config file of Views folder to generate SunburstChart builder code in View page.

```
<system.web.webPages.razor>
  <pages pageBaseType="System.Web.Mvc.WebViewPage">
    <namespaces>
      <add namespace="Syncfusion.JavaScript, Version=13.3400.0.7, Culture=neutral,
                                                PublicKeyToken=3d67ed1f87d44c89" />
      <add namespace="Syncfusion.JavaScript.DataVisualization, Version=13.3400.0.7,
                                                Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
      <add namespace="Syncfusion.MVC.EJ, Version=13.3400.0.7, Culture=neutral,
                                                PublicKeyToken=3d67ed1f87d44c89" />

    </namespaces>
  </pages>
</system.web.webPages.razor>
```

Note: If you are referring Syncfusion dll's manually from bin folder to create MVC SunburstChart, then remove Culture, Version and PublicKeyToken attributes used in all, and nodes.

Adding script reference

Add the below scripts references and Syncfusion **ScriptManager** to execute the script as mentioned in the following code snippet in layout page.

ASPX-CS

```
<!--  jquery script  -->
<script src="http://cdn.syncfusion.com/js/assets/external/jquery-
1.10.2.min.js"></script>
<!-- Essentialcshtml UI widget -->
<script
src="http://cdn.syncfusion.com/{{site.releaseversion}}/js/web/ej.web.all.
min.js"></script>
<!--Add Syncfusion Script Manager -->
@Html.EJ().ScriptManager()
```

To render the MVC Chart in unobtrusive mode refer **ej.unobtrusive.js** script file. Otherwise set false to **UnobtrusiveJavaScriptEnabled** in Web.config file.

In the above code, ej.web.all.min.js script reference has been added for demonstration purpose. It is not recommended to use this for deployment purpose, as its file size is larger since it contains all the

Copyright © 2001 - 2020 Syncfusion Inc.

widgets. Instead, you can use CSG utility to generate a custom script file with the required widgets for deployment purpose.

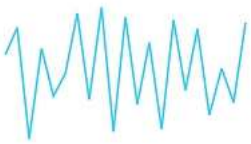
Initialize Sparkline

Add the following code in the index.cshtml file to create the Sparkline control in View page.

ASPX-CS

```
<div>
@(Html.EJ().Sparkline("sparklineContainer"))
</div>
```

Now, the Sparkline is rendered with some auto-generated random values and with default Line type Sparkline.



Working with Data

Local Data

1. You can bind the data to the Sparkline by using DataSourceproperty and then you need to map the **X** and **Y** value with XName and YName properties respectively.

C#

```
public class HomeController : Controller
{
public IActionResult Index()
{
//// Create dataSource to Sparkline
List<SparklineData> data = new List<SparklineData>();
data.Add(new SparklineData(0, 35));
data.Add(new SparklineData(1, 28));
data.Add(new SparklineData(2, 34));
data.Add(new SparklineData(3, 32));
data.Add(new SparklineData(4, 40));
data.Add(new SparklineData(5, 32));
data.Add(new SparklineData(6, 35));
data.Add(new SparklineData(7, 55));
data.Add(new SparklineData(8, 38));
data.Add(new SparklineData(9, 30));
data.Add(new SparklineData(10, 25));
data.Add(new SparklineData(11, 32));
///...
ViewBag.SparklineData = data;
return View();
}
}
public class SparklineData
{
public double Month;
```

```
public double Sales;
public SparklineData(double month, double sales)
{
this.Month = month;
this.Sales = sales;
}
}
```

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.DataSource((IEnumerable<object>)ViewBag.SparklineData)
.XName("Month").YName("Sales")
)
```

;

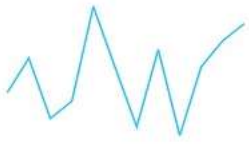
2. You can also bind an array of data to Sparkline by using DataSource property.

ASPX-CS

```
public class HomeController : Controller
{
public IActionResult Index()
{
Double[] y1 = { 2, 6, -1, 1, 12, 5, -2, 7, -3, 5, 8, 10};
ViewBag.SparklineData = y1;
return View();
}
}
```

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.DataSource((IEnumerable<object>)ViewBag.SparklineData)
)
```



;

Sparkline Dimensions

You can set the size directly on the Sparkline or to the container of the sparkline. When you do not specify the size, it takes 30px as the height and 50px as its width, by default.

Copyright © 2001 - 2020 Syncfusion Inc.

Set size for the container

You can customize the Sparkline dimension by setting the width and height for the container element.

HTML

```
<body>
<div id="container" style="width:820px;height:500px;"></div>
@(Html.EJ().Sparkline("container"))
</body>
```

Set size in pixels

You can also set the Height and Width for Sparkline by using the Size property of the Sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.Size(size=>size.Height("40").Width("60"))
)
```

Responsive Sparkline

To resize the Sparkline when the browser or the sparkline container is resized, set the IsResponsive property to **true**, where the sparkline adapts to the changes in size of the container.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.IsResponsive(true)
)
```

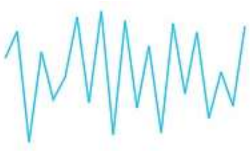
Sparkline Types

Line Type

To render a Line type Sparkline, set the Type as **line**. To change the color and width of the line, you can use the Fill and Width property.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
//To customize the  line type sparkline
.Width(3)
.Fill("#33ccff")
)
```



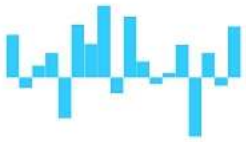
Copyright © 2001 - 2020 Syncfusion Inc.

Column Type

To render a Column Sparkline, set the type as **column** To change the color of the column, you can use the Fill property.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
//To customize the column type sparkline
.Type(SparklineType.Column)
.Fill("#33ccff")
)
```

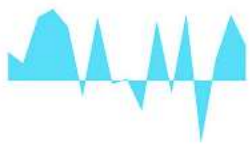


Area Type

To render an Area Sparkline, you can specify the type as **area**. To change the Area color, you can use the Fill property

ASPX-CS

```
@(Html.EJ().Sparkline("container")
//To customize the area type sparkline
.Type(SparklineType.Area)
.Fill("#69D2E7")
)
```

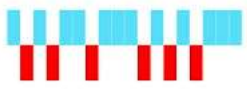


WinLoss Type

WinLoss Sparkline render as a column segment and it show the positive, negative and neutral values. You can customize the positive and negative color of the win-loss type.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
//To customize the area type sparkline
.Type(SparklineType.WinLoss)
.Fill("#69D2E7")
)
```



Copyright © 2001 - 2020 Syncfusion Inc.

Pie Type

You can create a pie type sparkline by setting the type as **pie**. Colors for the pie can be customize using Palette property.

ASPX-CS

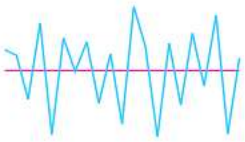
```
@(Html.EJ().Sparkline("container")
//To customize the area type sparkline
.Type(SparklineType.Pie)
.Palette(pl => { pl.Add("#ff3399"); pl.Add("#33ccff");  })
)
```

Axis Customize

The Sparkline axis can be collapsed using visible property in AxisLineSettings and this not applicable for win-loss. You can customize Color, Width and DashArray of axis line.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
//To customize the axis line of the sparkline
.AxisLineSettings(as => as.Visible(true).Color("#ff14ae"))
)
```

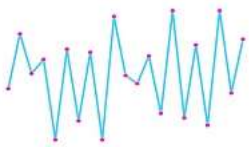


Marker Customization

You can customize markers by initializing the MarkerSettings property. The customization options allow you to change the Visibility, Fill, Width, Opacityand Border options Color, Width, Opacity for marker. This customization only applicable for line, column and area type Sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
//To customize the marker of the sparkline
.MarkerSettings(mr =>
mr.Visible(true).Fill("#ff14ae").Width(4).Border(br=> br.Width(1)))
)
```



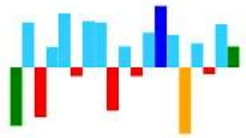
Copyright © 2001 - 2020 Syncfusion Inc.

Point Customization

You can customize points by initializing the point colors. The customization options allow you to differentiate the First, Last, Highest, Lowest, and Negative points. This customization only applicable for line, column and area type Sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
//To customize the point color of the sparkline
.NegativePointColor("Red")
.HighPointColor("Blue")
.LowPointColor("Orange")
.StartPointColor("Green")
.EndPointColor("Green")
)
```

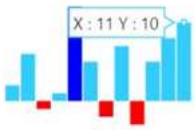


Tooltip

The Tooltip follows the pointer movement and is used to indicate the value of a point. This feature is applicable for line, column, pie, and area Sparkline. You can enable the tooltip by setting it's Visible property as true. You can customize the tooltip Fill, Border and Font.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.Tooltip(tooltip => tooltip.Visible(true))
)
```



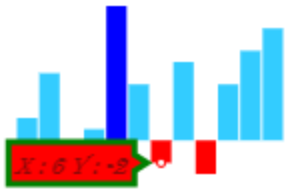
Tooltip Customization

You can customize the tooltip Fill, Border Color, Width and Font properties Color, FontFamily, FontStyle, FontWeight, Opacity and Size

ASPX-CS

```
@(Html.EJ().Sparkline("container")
// ...
.Tooltip(tooltip => tooltip
.Fill('red')
.Border(border=>border.Color('green').Width(3))
.Font(font=>font.Size('12px').FontFamily('Algerian').FontStyle('Italic').
FontWeight('Lighter').Opacity(0.5))
)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Tooltip Template

HTML elements can be displayed in the tooltip by using the Template option of the tooltip. The template option takes the value of the id attribute of the HTML element. You can use the **#point.x#** and **#point.y#** as place holders in the HTML element to display the x and y values of the corresponding point.

ASPX-CS

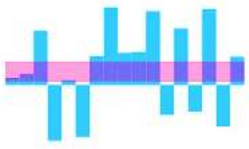
```
<div id="item" style="display: none;">
<div>
<div>#point.x#</div>
<div>#point.y#</div>
</div>
</div>
@(Html.EJ().Sparkline("container")
.Tooltip(tooltip => tooltip.Visible(true).Template("item"))
)
```

Range Band

The range band feature is used to highlight a particular range along the y-axis using StartRange and EndRange property. You can also customize the Color and Opacity of the RangeBandSettings.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
//To customize the range Band of the sparkline
.RangeBandSettings(range =>
range.StartRange(4).EndRange(30).Color("#ff14ae").Opacity(0.4))
)
```



Sparkline Customization

This section explains you the customization options available to make changes in the Sparkline for getting better appearance.

Copyright © 2001 - 2020 Syncfusion Inc.

Sparkline background

You can specify the background color for the Sparkline using Background property. When you don't specify the Background, it takes "transparent" as background color.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
//Specifies background color for sparkline
.Background("gray")
// ...
)
```

Stroke color and width

You can customize the series border color and width using Stroke and Width. This is applicable for Sparkline types line and area.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
// ...
//Specifies border color and width for line and area series
.Stroke("green")
.Width(3)
// ...
)
```

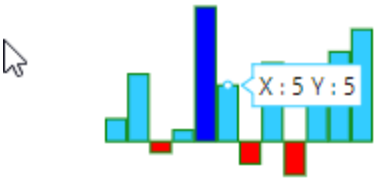
Sparkline border

You can customize the Border color and width of the Sparkline using Color and Height properties. This is applicable for column, win-loss and pie series.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
// ...
//Specifies border width and color for column, winLoss and pie series
.Border(border=>border.Color("green").Width(2))
// ...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Opacity

By default Opacity of the Sparkline is 1. You can specify the opacity value from 0 to 1. This is applicable for all types of series.

ASPX-CS

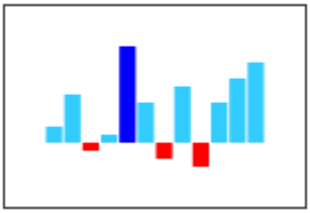
```
@(Html.EJ().Sparkline("container")
// ...
//Specifies the opacity of the sparkline
.Opacity(0.5)
// ...
)
```

Padding for Sparkline

Padding is used to specify the padding value between the container and Sparkline. By default padding value of the Sparkline is 5.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
// ...
//Padding for the sparkline
.Padding(20)
// ...
)
```



Canvas support

You can control whether Sparkline has to be rendered as SVG or Canvas. EnableCanvasRendering property supports all the functionalities supported in SVG rendering.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
// ...
//enables canvas rendering
.EnableCanvasRendering(true)
// ...
)
```

Themes

You can specify different Theme for Sparkline control.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
// ...
//theme for sparkline
.Theme(SparkTheme.FlatDark)
// ...
)
```

Methods and Events

Methods

redraw()

This methods redraws the entire sparkline. You can call redraw() whenever you update, add or remove points from the data source or whenever you want to refresh the UI.

ASPX-CS

```
@(Html.EJ().Sparkline("container"))
```

JS

```
// redraw method for sparkline
$("#container").ejSparkline("redraw");
```

Events

Load

The Load event is fired before loading the sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.Load("onLoad");
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
<script type="text/javascript">
function onLoad(sender) {
//Do something
}
</script>
```

Loaded

The Loaded event is fired after loaded the sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.Loaded("onLoaded");
)
```

JS

```
<script type="text/javascript">
function onLoaded(sender) {
//Do something
}
</script>
```

TooltipInitialize

Fires before rendering trackball tooltip. You can use TooltipInitialize event to customize the text displayed in trackball tooltip.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.TooltipInitialize("onTooltipInitialize")
)
```

JS

```
<script type="text/javascript">
function onTooltipInitialize(sender) {
//Do something
}
</script>
```

SeriesRendering

Fires before rendering a series. The SeriesRendering event is fired for each series in Sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.SeriesRendering("onSeriesRender")
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
<script type="text/javascript">
function onSeriesRender(sender) {
//Do something
}
</script>
```

PointRegionMouseMove

The PointRegionMouseMove event is fired when mouse is moved over a point.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.PointRegionMouseMove("onPointMouseMove")
)
```

JS

```
<script type="text/javascript">
function onPointMouseMove(sender) {
//Do something
}
</script>
```

PointRegionMouseClick

The PointRegionMouseClick event is fired on clicking a point in sparkline. You can use this event to handle clicks made on points.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.PointRegionMouseClick("onPointMouseClick")
)
```

JS

```
<script type="text/javascript">
function onPointMouseClick(sender) {
//Do something
}
</script>
```

SparklineMouseMove

The SparklineMouseMove is fired on moving mouse over the sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.SparklineMouseMove("onSparklineMouseMove")
)
```

JS

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script type="text/javascript">
function onSparklineMouseMove(sender) {
//Do something
}
</script>
```

SparklineMouseLeave

The SparklineMouseLeave event is fired on moving mouse outside the sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.SparklineMouseLeave("onSparklineMouseLeave")
)
```

JS

```
<script type="text/javascript">
function onSparklineMouseLeave(sender) {
//Do something
}
</script>
```

Click

The Click event is fired on clicking the sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.Click("onClick")
)
```

JS

```
<script type="text/javascript">
function onClick(sender) {
//Do something
}
</script>
```

DoubleClick

The DoubleClick event is fired on double clicking the sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.DoubleClick("onDoubleClick")
)
```

JS

```
<script type="text/javascript">
function onDoubleClick(sender) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Do something
}
</script>
```

RightClick

The RightClick event is fired on right clicking the sparkline.

ASPX-CS

```
@(Html.EJ().Sparkline("container")
.RightClick("onRightClick")
)
```

JS

```
<script type="text/javascript">
function onRightClick(sender) {
//Do something
}
</script>
```

SunburstChart

Overview

Sunburst chart is useful for visualizing hierarchical data. The center circle represents the root level in the hierarchy, with outer circles representing the higher levels of the hierarchy.

Some of the key features are,

- Visualize hierarchical data.
- Data label support for better readability.
- Interactively select or highlight segments.
- Interactive legend.
- Colors of the segments can be customized in the Sunburst Chart.

Getting Started

This section explains you the steps required to populate the SunburstChart , add data labels, tooltips and title to the SunburstChart. This section covers only the minimal features that you need to know to get started with the SunburstChart.

Installation and Deployment

It describes you on how to configure the Syncfusion dependencies in your ASP.NET MVC application to create a SunburstChart.

Referencing Syncfusion Assemblies

The following assemblies need to be referenced in your application for using Essential SunburstChart MVC

1. Syncfusion.EJ.dll
2. Syncfusion.EJ.MVC.dll

Copyright © 2001 - 2020 Syncfusion Inc.

Follow the steps given below to deploy the application in the development server by referencing the assembly in **GAC**.

- Web.config file should be configured according to the referenced assemblies.
- To deploy your application, you have to ensure that the above referenced assemblies (in your web.config files) are present in the GAC.

```
<system.web>
  <compilation debug="true" targetFramework="4.5.1">
    <assemblies>
      <add assembly="Syncfusion.EJ, Version=13.3400.0.7, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
      <add assembly="Syncfusion.EJ.Mvc, Version=13.3400.0.7, Culture=neutral, PublicKeyToken=3d67ed1f87d44c89"/>
    </assemblies>
  </compilation>
```

And, add Syncfusion namespace in the Web.config file of Views folder to generate SunburstChart builder code in View page.

```
<system.web.webPages.razor>
  <pages pageBaseType="System.Web.Mvc.WebViewPage">
    <namespaces>
      <add namespace="Syncfusion.JavaScript, Version=13.3400.0.7, Culture=neutral,
                                                PublicKeyToken=3d67ed1f87d44c89" />
      <add namespace="Syncfusion.JavaScript.DataVisualization, Version=13.3400.0.7,
                                                Culture=neutral, PublicKeyToken=3d67ed1f87d44c89" />
      <add namespace="Syncfusion.MVC.EJ, Version=13.3400.0.7, Culture=neutral,
                                                PublicKeyToken=3d67ed1f87d44c89" />

    </namespaces>
  </pages>
</system.web.webPages.razor>
```

Note: If you are referring Syncfusion dll's manually from bin folder to create MVC SunburstChart, then remove Culture, Version and PublicKeyToken attributes used in all, and nodes.

Adding script reference

Add the below scripts references and Syncfusion **ScriptManager** to execute the script as mentioned in the following code snippet in layout page.

ASPX-CS

```
<!--  jquery script  -->
<script src="http://cdn.syncfusion.com/js/assets/external/jquery-
1.10.2.min.js"></script>
<!-- Essentialcshtml UI widget -->
<script
src="http://cdn.syncfusion.com/{{site.releaseversion}}/js/web/ej.web.all.
min.js"></script>
<!--Add Syncfusion Script Manager -->
@Html.EJ().ScriptManager()
```

To render the MVC Chart in unobtrusive mode refer **ej.unobtrusive.js** script file. Otherwise set false to **UnobtrusiveJavaScriptEnabled** in Web.config file.

In the above code, ej.web.all.min.js script reference has been added for demonstration purpose. It is not recommended to use this for deployment purpose, as its file size is larger since it contains all the widgets. Instead, you can use CSG utility to generate a custom script file with the required widgets for deployment purpose.

Copyright © 2001 - 2020 Syncfusion Inc.

Initialize Sunburst Chart

Add the following code in the index.cshtml file to create the SunburstChart control in View page.

ASPX-CS

```
<div>
@(Html.EJ().SunburstChart("chartContainer"))
</div>
```

Populate Data source:

Now, let's see how to plot data source to the SunburstChart. First, let us generate a data source containing following fields in controller.

C#

```
public class DefaultData
{
public string Category { get; set; }
public string Country { get; set; }
public string JobDescription { get; set; }
public string JobGroup { get; set; }
public string JobRole { get; set; }
public int EmployeesCount { get; set; }
public static List<DefaultData> GetDefaultData()
{
List<DefaultData> data = new List<DefaultData>();
data.Add(new DefaultData() { Category = "Employees", Country = "USA",
JobDescription = "Sales",          JobGroup ="Executive",
EmployeesCount= 50});
data.Add(new DefaultData() { Category = "Employees", Country = "USA",
JobDescription = "Sales",          JobGroup = "Analyst",
EmployeesCount =40 });
data.Add(new DefaultData() { Category = "Employees", Country = "USA",
JobDescription = "Marketing",
EmployeesCount =40 });
data.Add(new DefaultData() { Category = "Employees", Country = "USA",
JobDescription = "Technical",      JobGroup = "Testers",
EmployeesCount =55 });
data.Add(new DefaultData() { Category = "Employees", Country = "USA",
JobDescription = "Technical",      JobGroup = "Developers", JobRole =
"Windows", EmployeesCount =175});
data.Add(new DefaultData() { Category = "Employees", Country = "USA",
JobDescription = "Technical",      JobGroup = "Developers", JobRole =
"Web",      EmployeesCount =70 });
data.Add(new DefaultData() { Category = "Employees", Country = "USA",
JobDescription = "Management",
EmployeesCount =40 });
data.Add(new DefaultData() { Category = "Employees", Country = "USA",
JobDescription = "Accounts",
EmployeesCount =60 });
data.Add(new DefaultData() { Category = "Employees", Country = "India",
JobDescription = "Technical",      JobGroup = "Testers",
EmployeesCount = 43 });
data.Add(new DefaultData() { Category = "Employees", Country = "India",
JobDescription = "Technical",      JobGroup = "Developers", JobRole =
"Windows", EmployeesCount = 125});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
data.Add(new DefaultData() { Category = "Employees", Country = "India",
JobDescription = "Technical",     JobGroup = "Developers", JobRole =
"Web",     EmployeesCount = 60 });
data.Add(new DefaultData() { Category = "Employees", Country = "India",
JobDescription = "HR Executives",
EmployeesCount = 70 });
data.Add(new DefaultData() { Category = "Employees", Country = "India",
JobDescription = "Accounts",
EmployeesCount = 45 });
data.Add(new DefaultData() { Category = "Employees", Country = "Germany",
JobDescription = "Sales",         JobGroup = "Executive",
EmployeesCount = 30 });
data.Add(new DefaultData() { Category = "Employees", Country = "Germany",
JobDescription = "Sales",         JobGroup = "Analyst",
EmployeesCount = 40 });
data.Add(new DefaultData() { Category = "Employees", Country = "Germany",
JobDescription = "Marketing",
EmployeesCount = 50  });
data.Add(new DefaultData() { Category = "Employees", Country = "Germany",
JobDescription = "Technical",     JobGroup = "Testers",
EmployeesCount = 40 });
data.Add(new DefaultData() { Category = "Employees", Country = "Germany",
JobDescription = "Technical",     JobGroup = "Developers", JobRole =
"Windows", EmployeesCount = 65 });
data.Add(new DefaultData() { Category = "Employees", Country = "Germany",
JobDescription = "Technical",     JobGroup = "Developers", JobRole =
"Web",     EmployeesCount = 27 });
data.Add(new DefaultData() { Category = "Employees", Country = "Germany",
JobDescription = "Management",
EmployeesCount = 33  });
data.Add(new DefaultData() { Category = "Employees", Country = "Germany",
JobDescription = "Accounts",
EmployeesCount = 55  });
data.Add(new DefaultData() { Category = "Employees", Country = "UK",
JobDescription = "Technical",     JobGroup = "Testers",
EmployeesCount = 45 });
data.Add(new DefaultData() { Category = "Employees", Country = "UK",
JobDescription = "Technical",     JobGroup = "Developers", JobRole =
"Windows", EmployeesCount = 96 });
data.Add(new DefaultData() { Category = "Employees", Country = "UK",
JobDescription = "Technical",     JobGroup = "Developers", JobRole =
"Web",     EmployeesCount = 55 });
data.Add(new DefaultData() { Category = "Employees", Country = "UK",
JobDescription = "HR Executives",
EmployeesCount = 60 });
data.Add(new DefaultData() { Category = "Employees", Country = "UK",
JobDescription= "Accounts",
EmployeesCount=30   });
data.Add(new DefaultData() { Category = "Employees", Country = "France",
JobDescription= "Technical",     JobGroup = "Testers",
EmployeesCount = 40 });
data.Add(new DefaultData() { Category = "Employees", Country = "France",
JobDescription= "Technical",     JobGroup = "Developers", JobRole =
"Windows", EmployeesCount = 65 });
data.Add(new DefaultData() { Category = "Employees", Country = "France",
JobDescription= "Technical",     JobGroup = "Developers", JobRole =
"Web",     EmployeesCount = 27 });
```

```
data.Add(new DefaultData() { Category = "Employees", Country = "France",
JobDescription="Marketing",
EmployeesCount= 50 });
return data;
}
}
```

Initialize Sunburst Chart with data

Now, bind the DefaultData to DataSource property of the Sunburst Chart. TheLevelsproperty determines the number of hierarchical levels. Each hierarchy level is formed based on the property specified in GroupMemberPath property, and each arc segment size is calculated using ValueMemberPath.

2. Add SunburstChart() action in SunburstChartController and add the following code.

C#

```
public ActionResult SunburstChart()
{
ViewData["defaultData"] = DefaultData.GetDefaultData();
return View();
}
```

3.Render the SunburstChart with the Datasource and Levels,the following code snippet is used

ASPX-CS

```
@{
var datasource = ViewData["defaultData"];
}
@(Html.EJ().SunburstChart("chartContainer")
.ValueMemberPath("EmployeesCount")
.DataSource(datasource)
.Levels(lv =>
{
lv.GroupMemberPath("Country").Add();
lv.GroupMemberPath("JobDescription").Add();
lv.GroupMemberPath("JobGroup").Add();
lv.GroupMemberPath("JobRole").Add();
}))
```

3. The final CSHTML file appears as follows

ASPX-CS

```
@using Syncfusion.JavaScript.DataVisualization
@{
var datasource = ViewData["datasource"];
}
<html xmlns="http://www.w3.org/1999/xhtml">
<head>
<!--  jquery script  -->
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script src="http://cdn.syncfusion.com/js/assets/external/jquery-
1.10.2.min.js"></script>
<!-- Essentialcshtml UI widget -->
<script src="http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/ej.web.all.min.js"></script>
<div>
@(Html.EJ().SunburstChart("chartContainer")
.ValueMemberPath("EmployeesCount")
.DataSource(datasource)
.Levels(lv =>
{
lv.GroupMemberPath("Country").Add();
lv.GroupMemberPath("JobDescription").Add();
lv.GroupMemberPath("JobGroup").Add();
lv.GroupMemberPath("JobRole").Add();
}))
</div>
@(Html.EJ().ScriptManager())
</body>
</html>
```

Add Title to the Sunburst Chart

The title of the Sunburst chart is used to provide quick information to the user about the data being plotted in the Sunburst Chart. You can add it by using the Text property of the **Title**

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//...Enable Text
.Title(ti => ti.Text("Employees Count"))
)
```

Enable Legend

You can enable or disable the legend by using the Visible property present inside the **Legend**

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//...Enable Legend
.Legend(li => li.Visible(true))
)
```

Add Data Labels

The data labels are used to improve the readability of the Sunburst chart. This can be achieved by enabling the visible property in the **DataLabelSettings**

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//...Enable DataLabel
.DataLabelSettings(dt => dt.Visible(true))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Now the Sunburst Chart is rendered along with the specified customizations

Click here to view the default sample of the Sunburst Chart.

Sunburst Elements

The Sunburst region represents the entire chart and all its elements. It includes all the chart elements like Legend, DataLabel, Levels etc. The major properties of the Sunburst Chart are as follows

datasource – Provides the data that are used to generate the chart.

valueMemberPath- Property based on the which the data segments are rendered in the chart

legend – displays the legend of the Sunburst Chart

levels- displays the hierarchical levels for the chart

data label– displays the data labels for the Sunburst Chart

Start and End Angle

Start and End Angle

You can change the start and end angle of Sunburst chart using **StartAngle** and **EndAngle** property as shown in below code

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.StartAngle(-90)
.EndAngle(90)
)
```

Sunburst Radius

The Radius of the Sunburst chart can be customized by using the **Radius** property. The default value of radius is 1 and its value ranges between 0 and 1

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.Radius(0.8)
)
```

;

Sunburst Inner Radius

The Inner Radius of the Sunburst chart can be customized by using the **InnerRadius** property. The default value of innerRadius is 0.4 and its value ranges between 0 and 1

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.InnerRadius(0.5)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

;

Levels

Sunburst chart is used to display hierarchical data. You can add more than one hierarchical data by using the **Levels** property of Sunburst chart. Each level of the hierarchy is represented by circle.

The following code snippet illustrates

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.Levels(
//.. to add the hierarchical levels
})
)
```

GroupMemberPath

It is the string property that is used to map the group category value in the dataSource .

You can define the levels as shown in the below code example

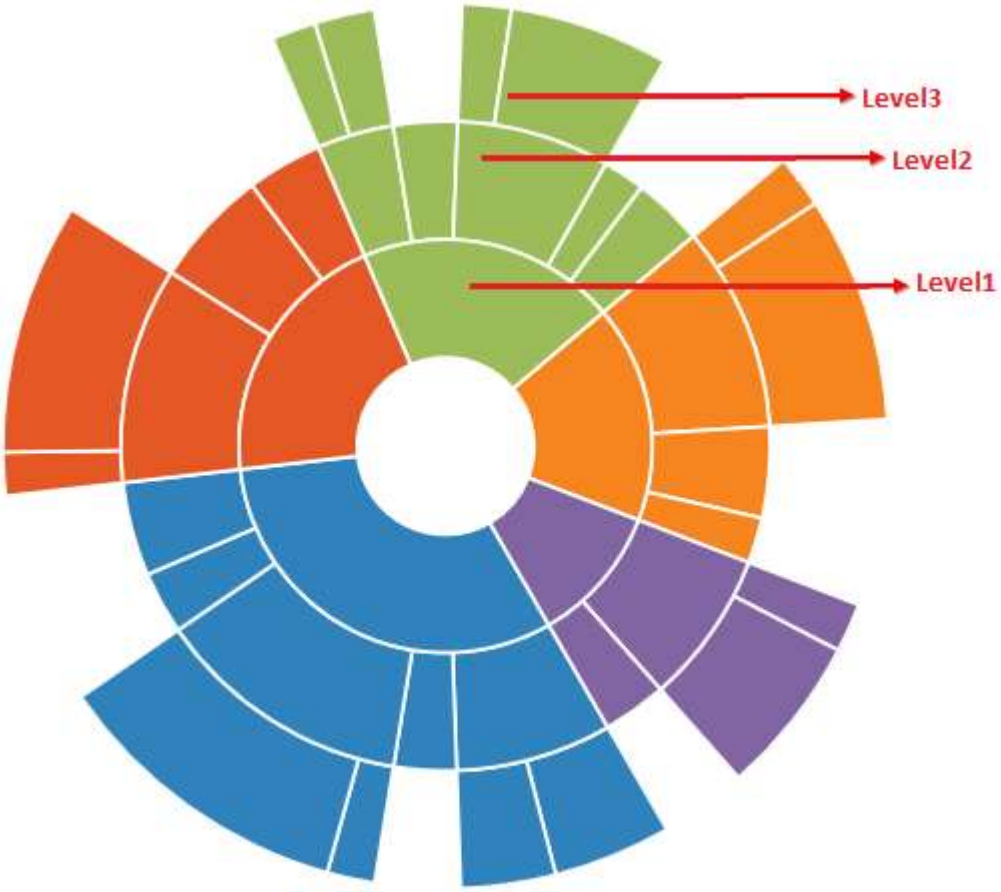
JS

```
@(Html.EJ().SunburstChart("chartContainer")
.Levels(
//.. to add the hierarchical levels
lv.GroupMemberPath("Level1").Add();
lv.GroupMemberPath("Level2").Add();
lv.GroupMemberPath("Level3").Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

The following screenshot illustrates the Sunburst Chart with different levels



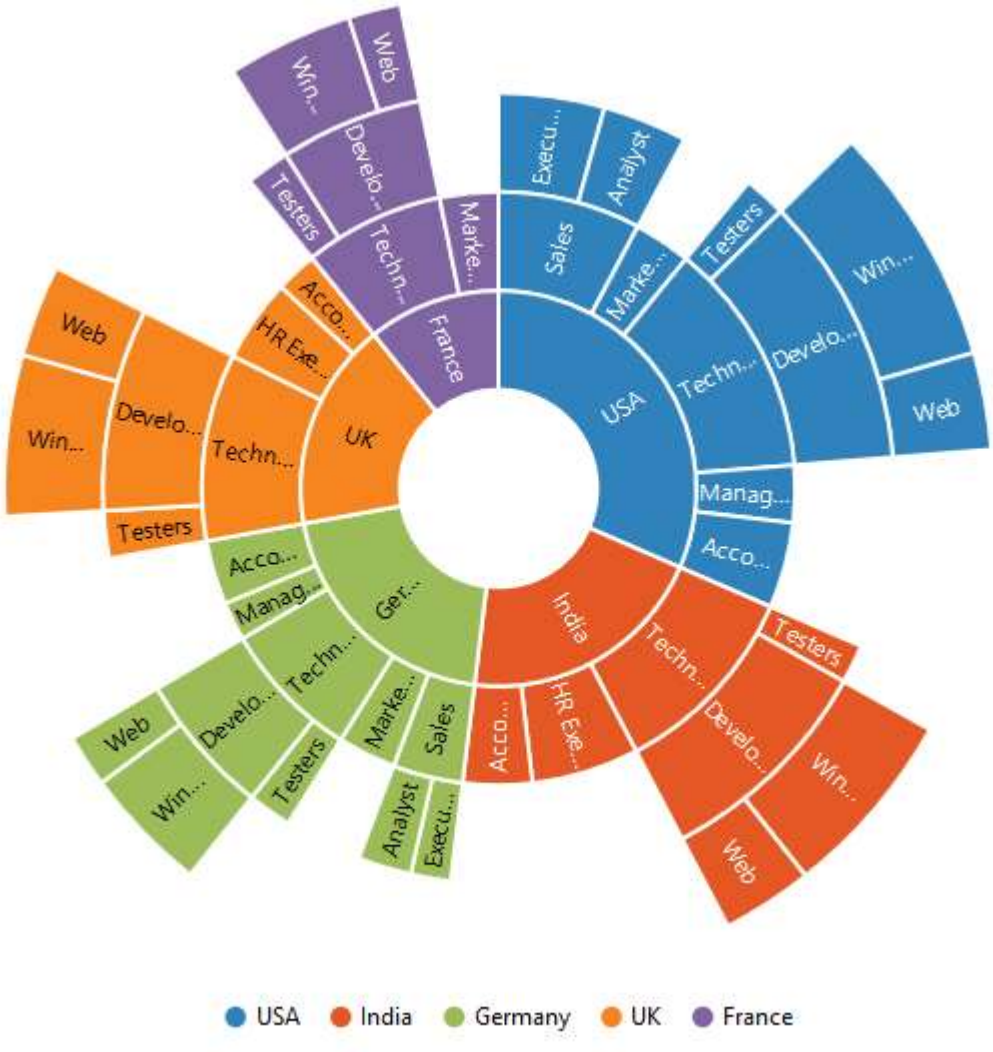
Legend

The legend is used to represent the first level of items in the Sunburst Chart.The **Legend** can be initialized using the below code snippet

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.Legend(lg => lg.Visible(true))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Legend Icon

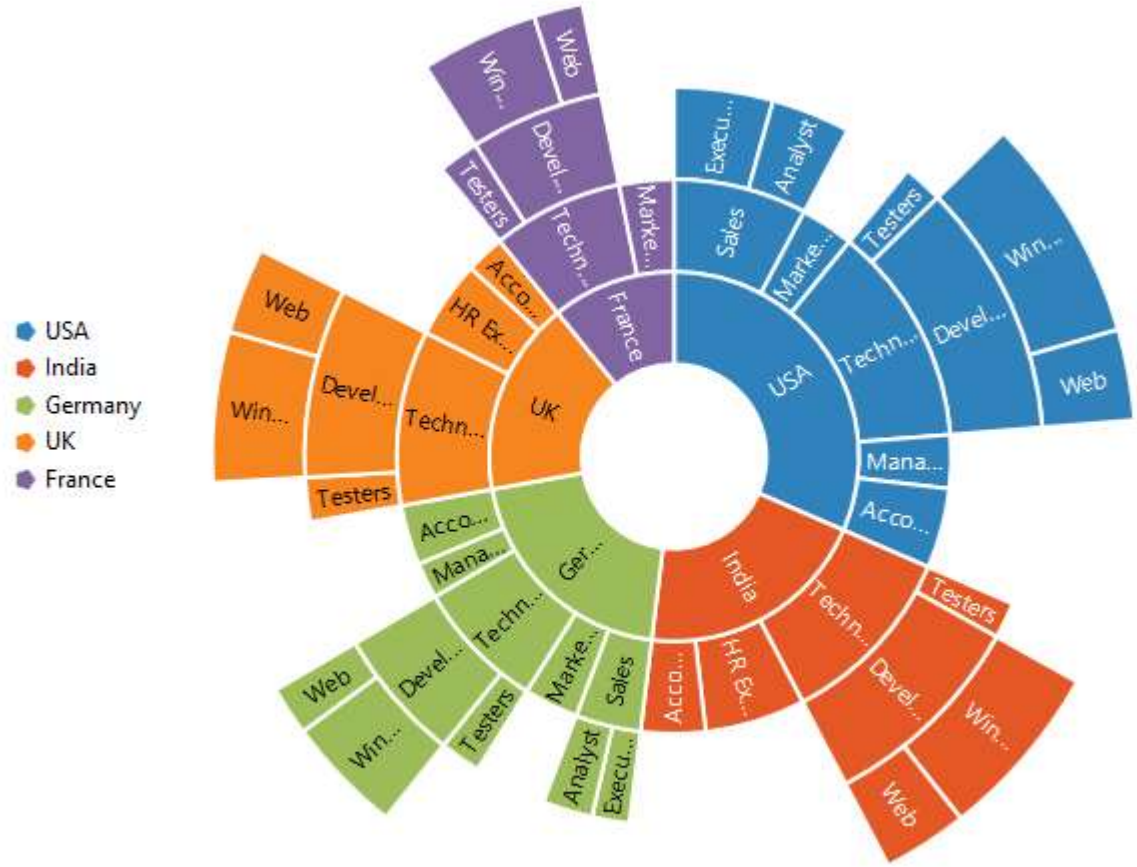
You can specify different shapes of legend icon by using the **Shape** property of the legend. By default, legend shape is **Circle**. The Sunburst chart has some predefined shapes such as:

- Circle
- Cross
- Diamond
- Pentagon
- Rectangle
- Triangle

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.Legend(lg => lg.Visible(true).Shape(SunburstLegendShape.Pentagon))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

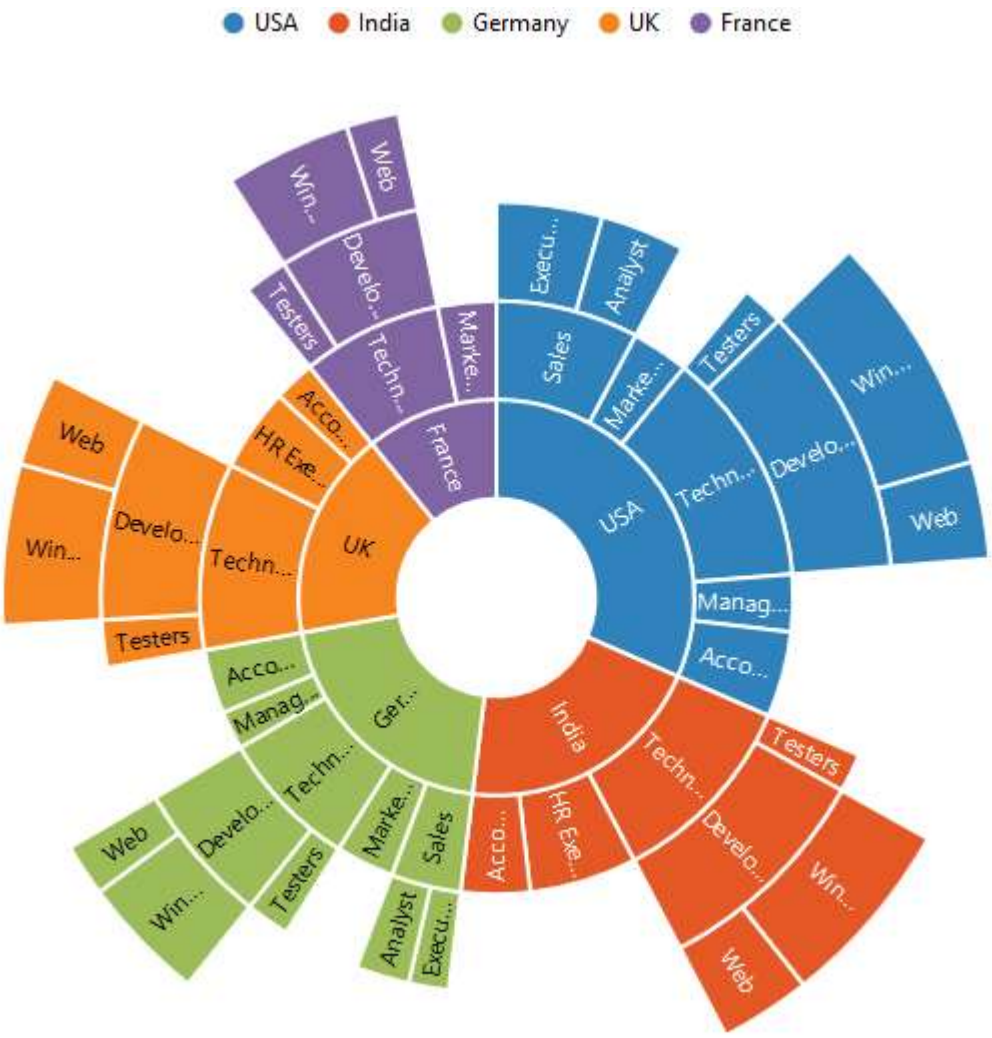


Positioning the Legend

By using the **Position** property, you can position the legend at left, right, top or bottom of the chart.

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.Legend(lg => lg.Visible(true).Position(SunburstLegendPosition.Top))
)
```



Customization

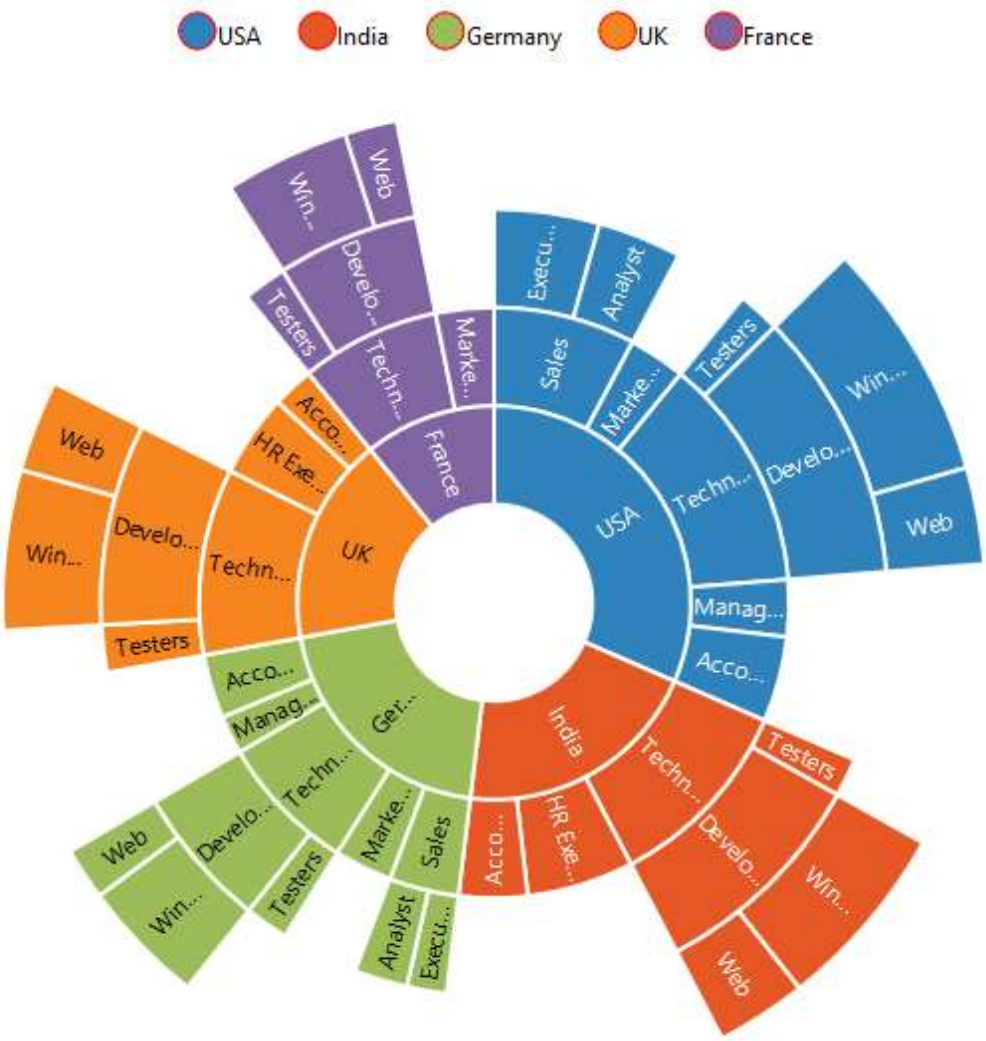
Legend Item Size and border

You can change the size of the legend items by using the **LegendItemStyle-Width** and **LegendItemStyle-Height** properties. To change the legend item border, use **Border** property of the legend .

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.Legend(lg =>
lg.Visible(true).Position(SunburstLegendPosition.Top).LegendItemStyle(lt=
>lt.Width(13).Height(13)).Border(br=>br.Color("#FF0000").Width(1)))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



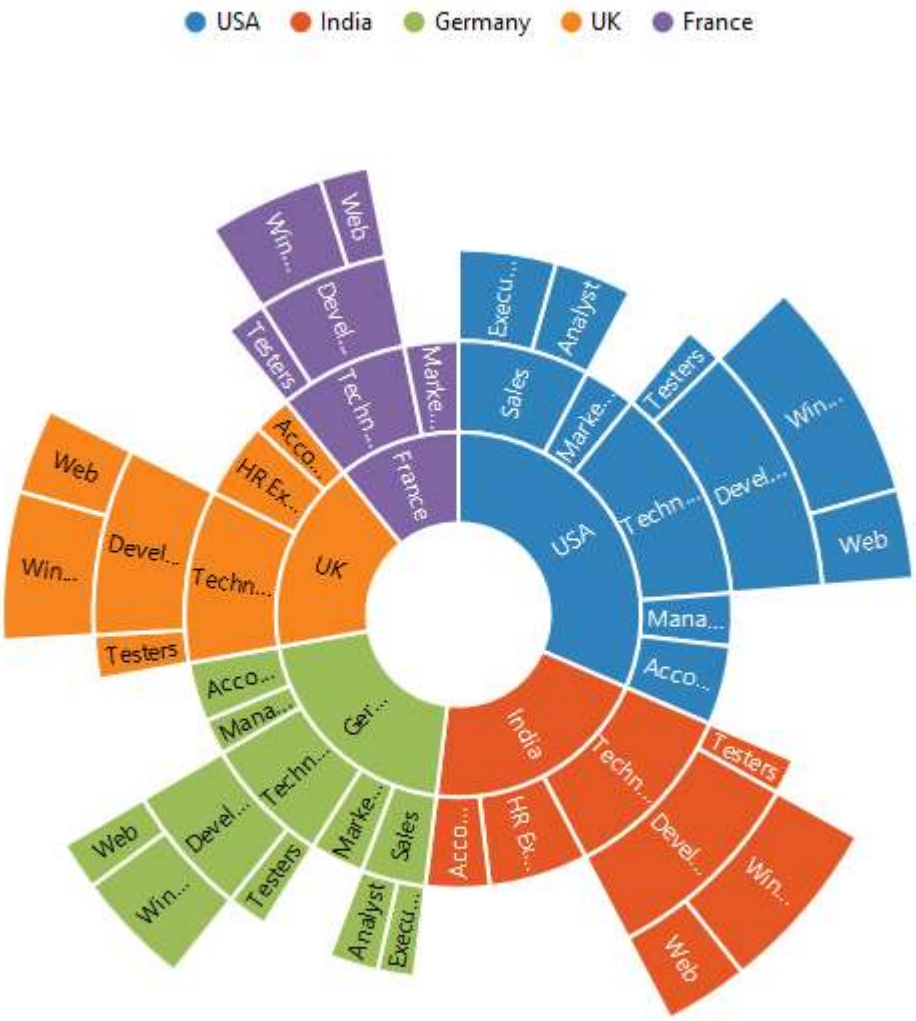
Legend Size

By default, legend takes 20% of the height horizontally when it was placed on the top or bottom position and 20% of the width vertically while placing on the left or right position of the chart. You can change this default legend size by using the **Size** property of the legend.

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.Legend(lg =>
lg.Visible(true).Position(SunburstLegendPosition.Top).Size(size=>size.Wid
th(200).Height(75)))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Legend Row and Columns

You can arrange the legend items horizontally and vertically by using the **RowCount** and **ColumnCount** properties of the legend.

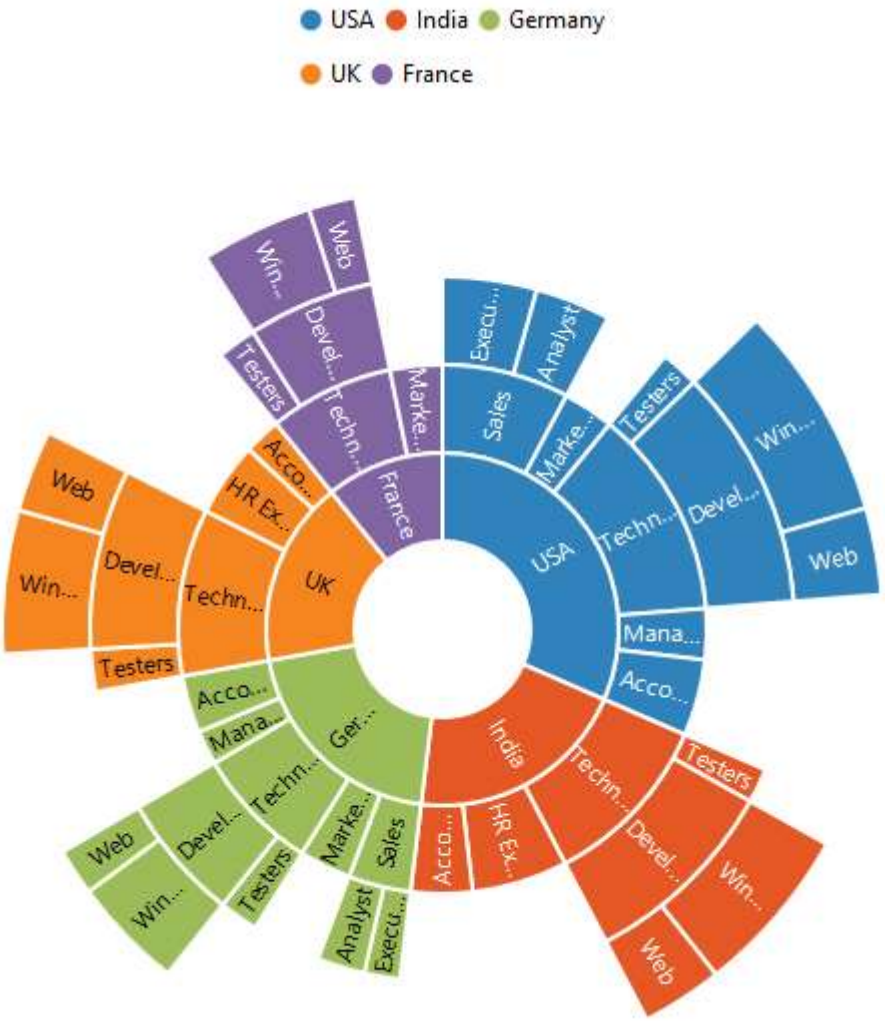
- When only the rowCount is specified, the legend items are arranged according to the rowCount and number of columns may vary based on the number of legend items.
- When only the columnCount is specified, the legend items are arranged according to the columnCount and number of rows may vary based on the number of legend items.
- When both the properties are specified, then the one which has higher value is given preference. For example, when the rowCount is 4 and columnCount is 3, legend items are arranged in 4 rows.
- When both the properties are specified and have the same value, the preference is given to the columnCount when it is positioned at the top/bottom position. The preference is given to the rowCount when it is positioned at the left/right position.

JS

```
@(Html.EJ().SunburstChart("chartContainer")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Legend(lg => lg.Visible(true).RowCount(2).ColumnCount(3))
)
```



LegendInteractivity

You can select a specific category while clicking on corresponding legend item through **ClickAction** property.

It has three types of action

ToggleSegmentSelection ToggleSegmentVisibility * None

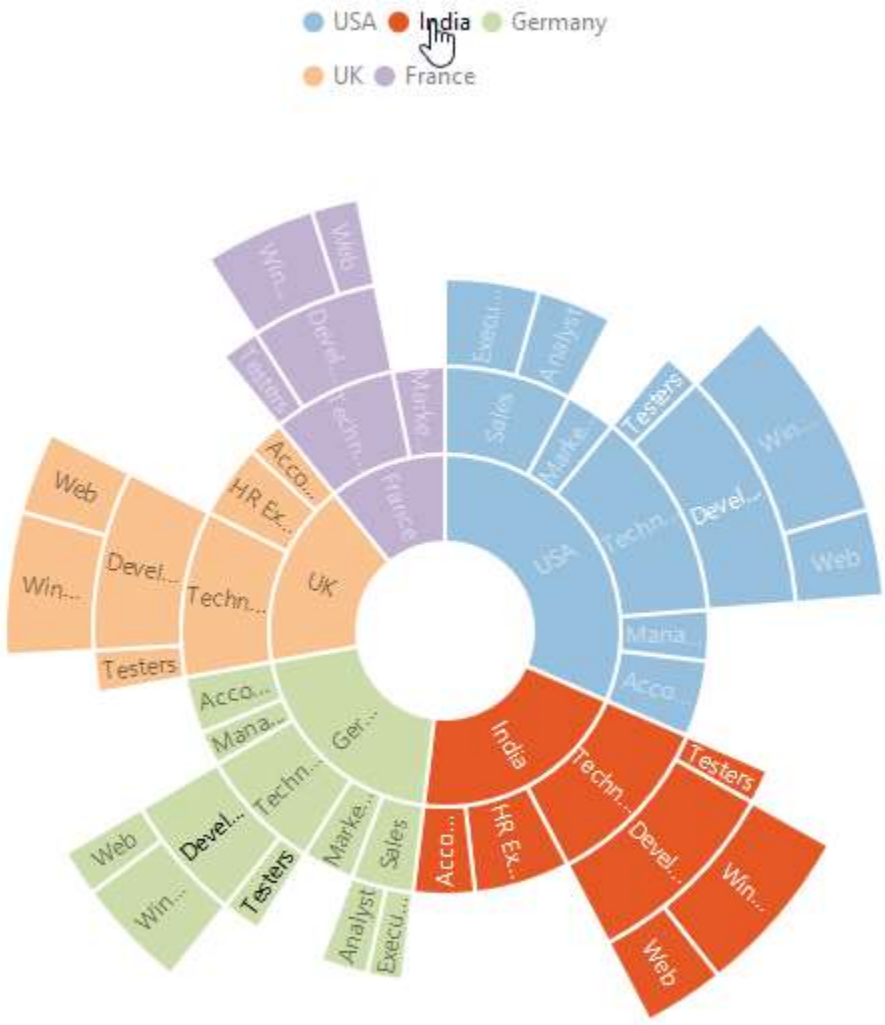
ToggleSegmentSelection

Used to highlight specific category while clicking on legend item

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.Legend(lg =>
lg.Visible(true).ClickAction(SunburstLegendClickAction.ToggleSegmentSelec
tion))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



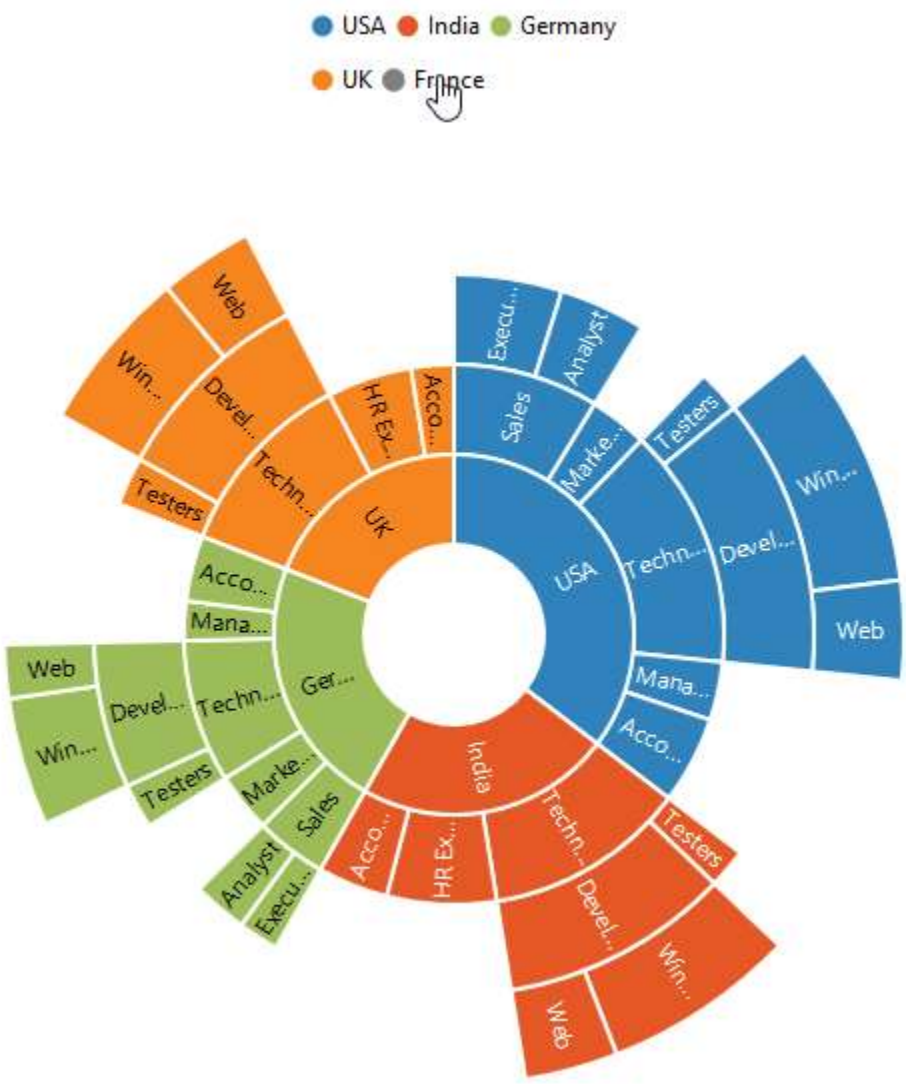
Toggle Segment Visibility

Used to disable the specific category while clicking on legend item.

JS

```
@(Html.EJ().SunburstChart("chartContainer")
.Legend(lg =>
lg.Visible(true).ClickAction(SunburstLegendClickAction.ToggleSegmentVisibility))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Data Labels

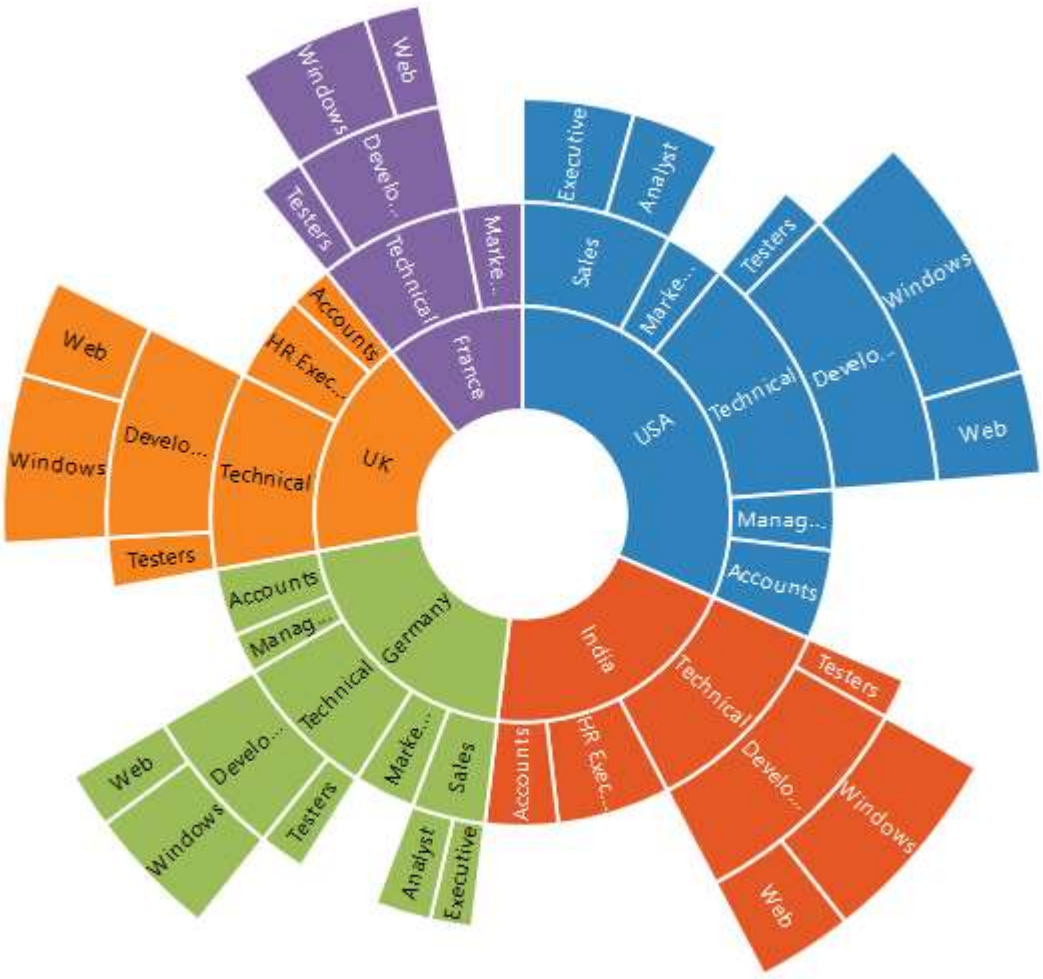
Sunburst data labels are used to display the data related to the segment. It helps to provide the information about the data points to the users.

You can enable or disable the data labels by setting the visible property of the **DataLabelSettings** to true as shown in the below code

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//...Palette colors
.DataLabelSettings(dt => dt.Visible(true))
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Label Overflow mode

When you represent huge data with data labels, they may intersect each other. You can avoid this using the *SunburstLabelOverflowMode* property.

The following properties are used to avoid the overlapping.

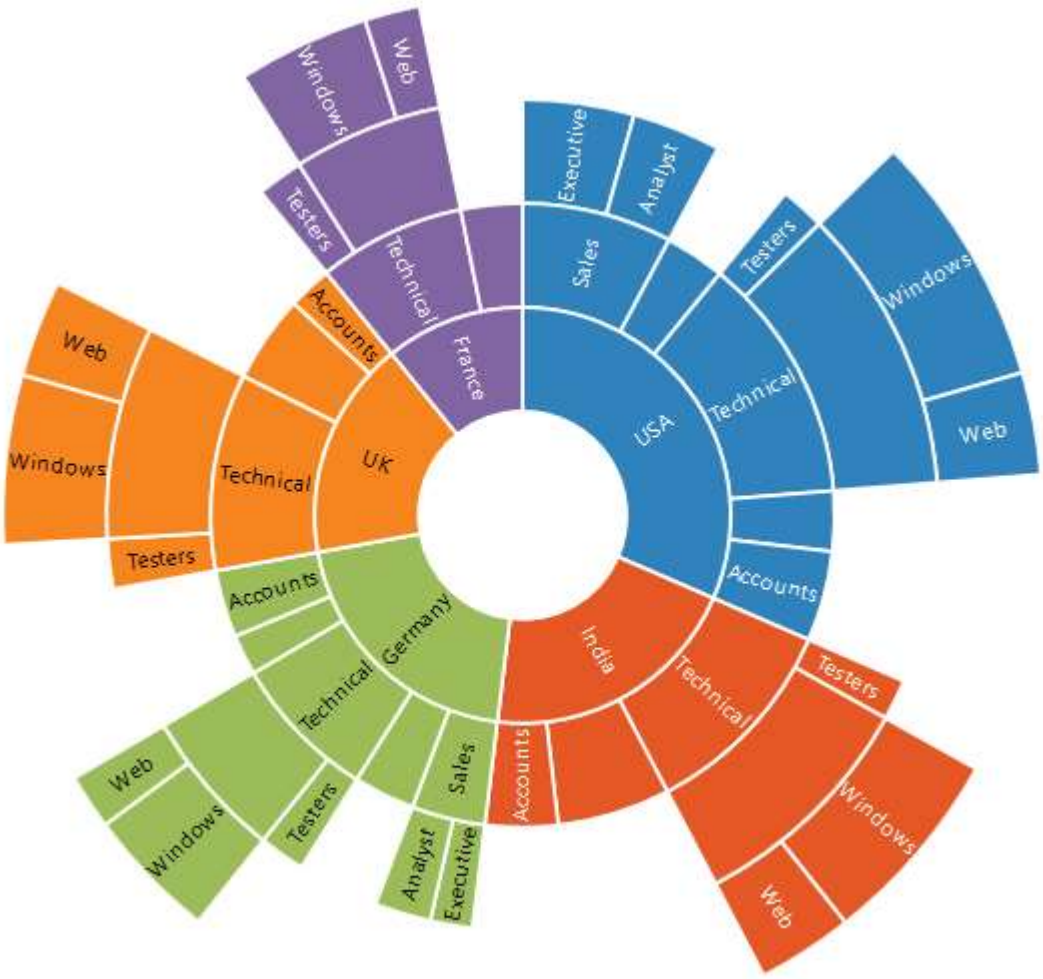
Trim – To trim the large data labels. Hide – To hide the overlapped data labels.

The following code shows how to set Hide and Trim mode.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//.
.DataLabelSettings(dt =>
dt.Visible(true).SunburstLabelOverflowMode(SunburstLabelOverflowMode.Hide
))
//...
)
```

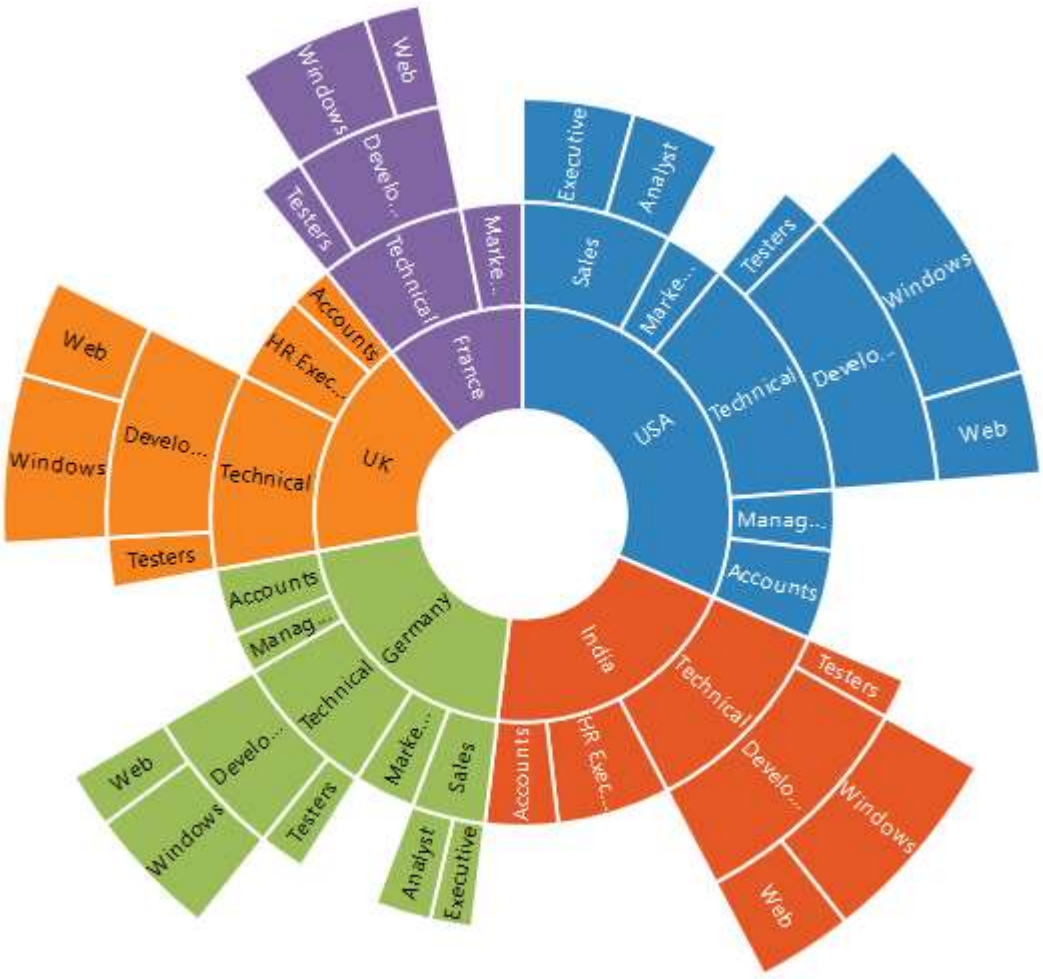
Copyright © 2001 - 2020 Syncfusion Inc.



ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//.
.DataLabelSettings(dt =>
dt.Visible(true).SunburstLabelOverflowMode(SunburstLabelOverflowMode.Trim
))
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Label Rotation Mode

You can rotate the data label by using *SunburstLabelRotationMode* property. By default, the labelRotationMode is set as **angle**.

The following code shows how to set labelRotationMode as normal and angle.

ASPX-CS

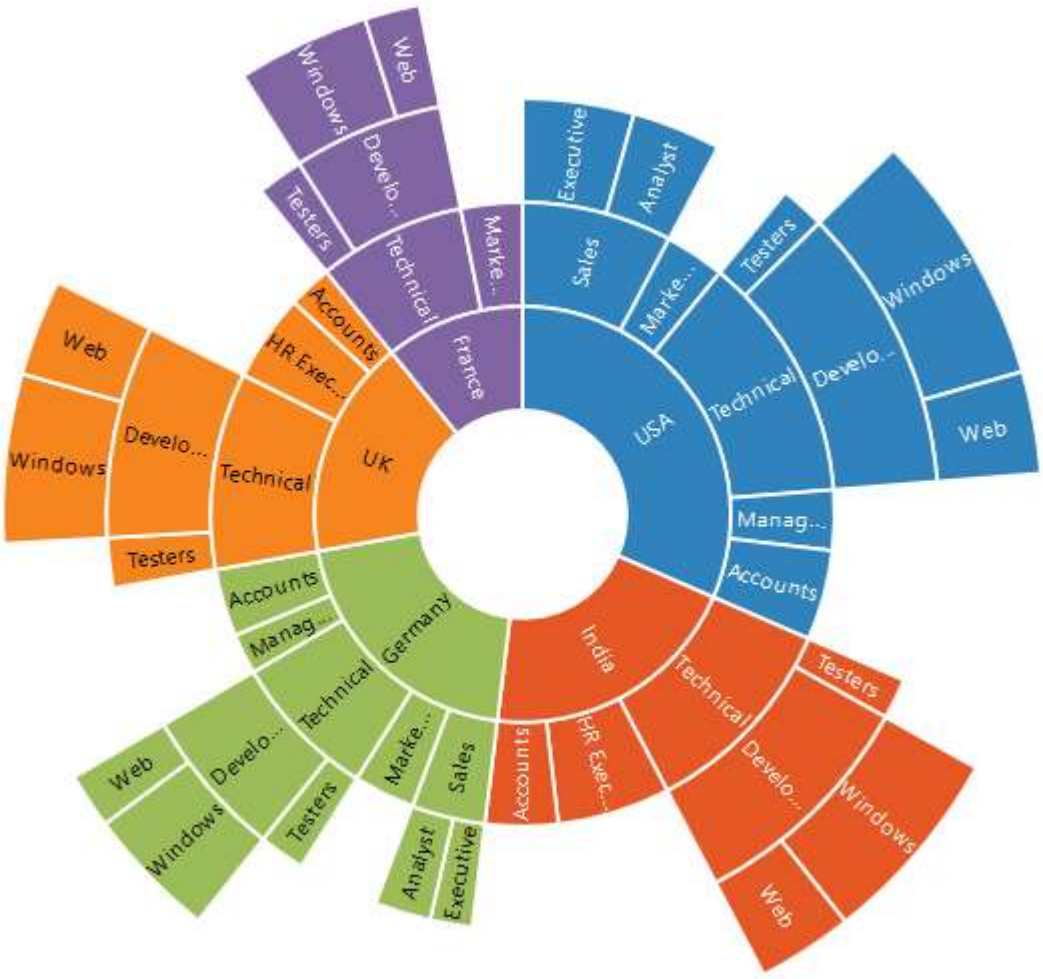
```
@(Html.EJ().SunburstChart("chartContainer")
//.
.DataLabelSettings(dt =>
dt.Visible(true).SunburstLabelRotationMode(SunburstLabelRotationMode.Normal)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//.
.DataLabelSettings(dt =>
dt.Visible(true).SunburstLabelRotationMode(SunburstLabelRotationMode.Angle)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Customizing the data labels

You can customize the appearance of the data point using the Font property.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//.
.DataLabelSettings(dt =>
dt.Visible(true).Font(font=>font.Color("Black").Font-
Weight("Bold").Size("15px")))
//...
)
```

Tooltip

ToolTip allows you to display any information over a sunburst segment. It appears when mouse hovered over or touch any chart segment. By default, it displays the corresponding segment category name and its value

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.Tooltip(tooltip => tooltip.Visible(true))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Tooltip Template

HTML elements can be displayed in the tooltip by using the *Template* property of the tooltip. The template property takes the value of the id attribute of the HTML element. You can use the **#point.x#** and **#point.y#** as place holders in the HTML element to display the x and y values of the corresponding point.

ASPX-CS

```
<div id="Tooltip" style="display: none;">
<div id="value" style="background-color:red;padding-top:3px;padding-
right:3px">
<div>
<label id="efpercentage" style="color:white">
  Category: #point.x#
<br />  Value:#point.y#
</label>
</div>
</div>
</div>
@(Html.EJ().SunburstChart("chartContainer")
.Tooltip(tooltip => tooltip.Visible(true).Template("Tooltip"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

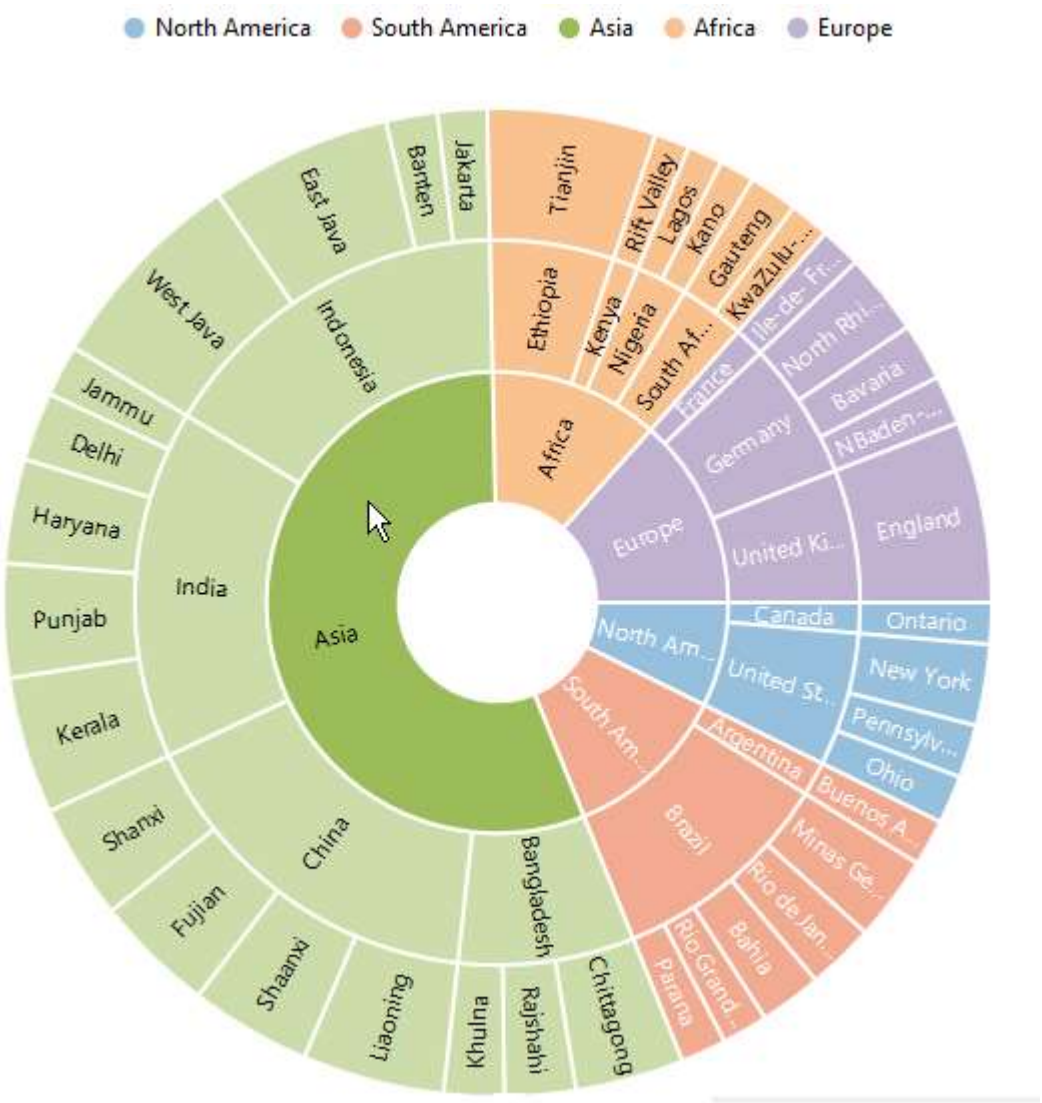
Highlight

SunburstChart provides highlighting support for the points on mouse hover. To enable the highlighting , set the *Enable* property to true in the **HighlightSettings**.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.HighlightSettings(highlight=>highlight.Enable(true))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Highlight Display mode

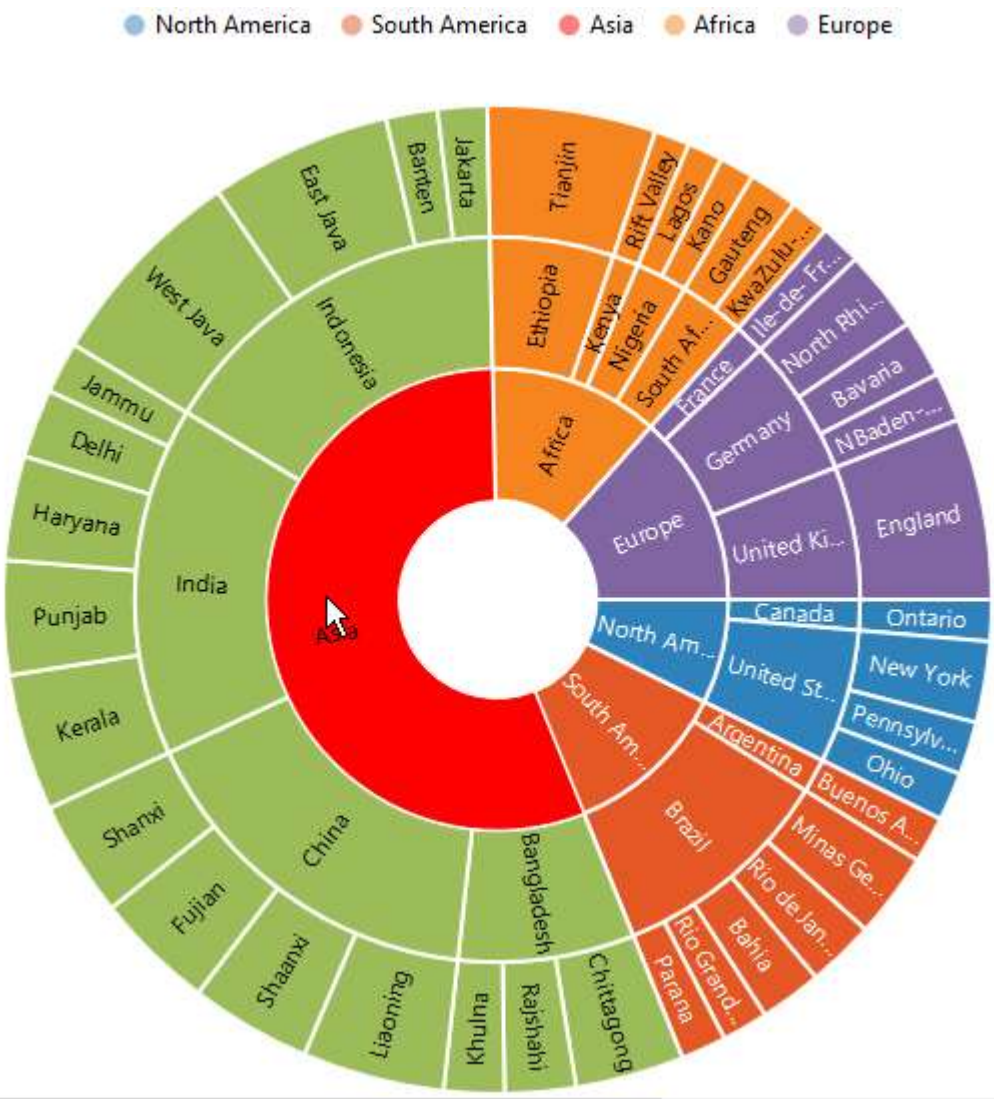
You can customize the highlighted segment appearance by using color or opacity. You can choose between color or opacity using the **Type** property in the highlight Settings.

HighlightByColor – To display the highlighted segment appearance using color. HighlightByOpacity – To display the highlighted segment appearance using opacity.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.HighlightSettings(highlight=>highlight.Enable(true).Type(SunburstHighlig
htType.Color).Color("Red"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Highlight Mode

Sunburst chart provides multiple option to represent the highlighted categories. You can highlight the segment categories by using the **Mode** property in highlightSettings

Child – To highlight the child of selected parent. All – To highlight the entire categories in group. *Parent – To highlight the parent of selected child.* Single - To highlight single item in the category.

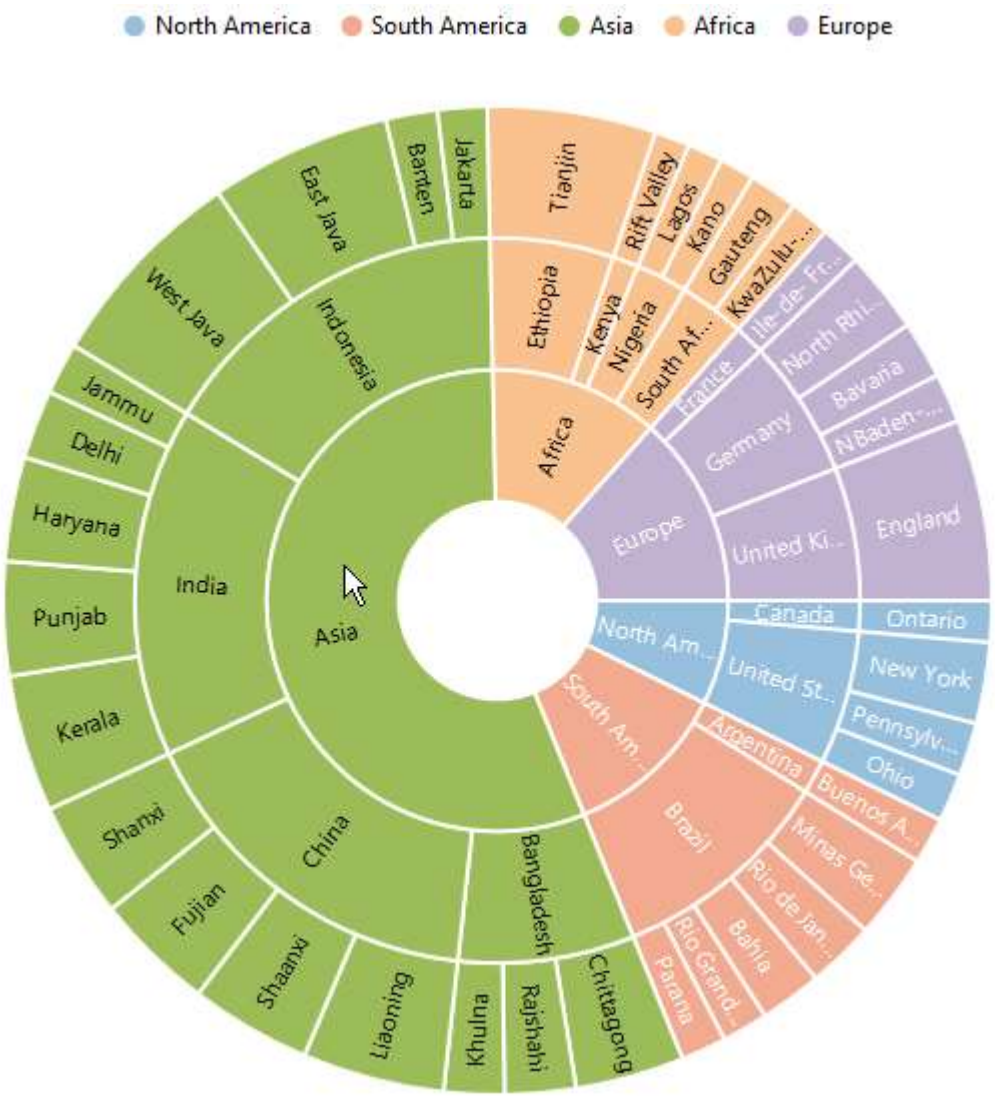
Child

The following code shows how to set the highlight type as child

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.HighlightSettings(highlight=>highlight.Enable(true).Mode(SunburstHighlig
htMode.Child))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Parent

The parent mode can be enabled by using the below code

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.HighlightSettings(highlight=>highlight.Enable(true).Mode(SunburstHighlig
htMode.Parent))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

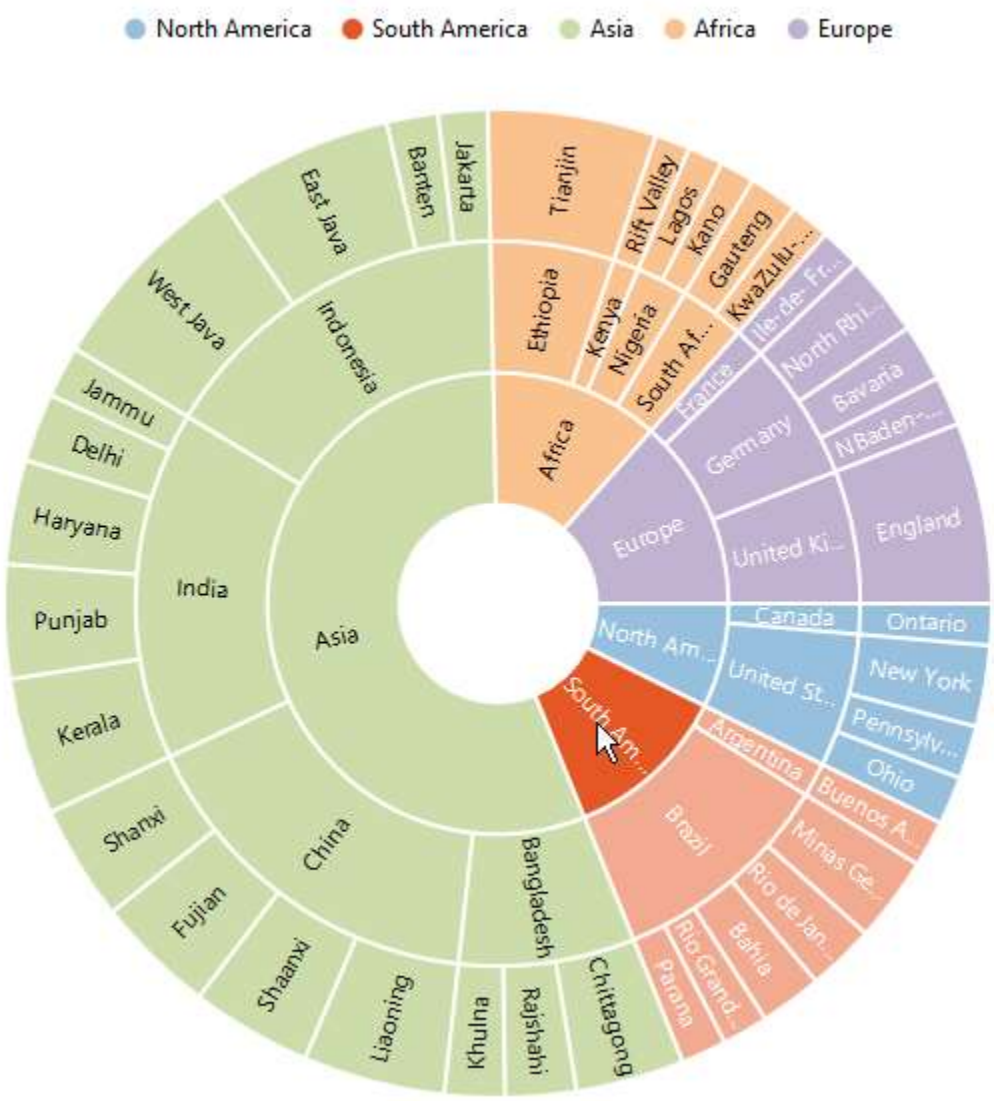
Point

To highlight the particular segment, the point mode of the highlight settings is used.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.HighlightSettings(highlight=>highlight.Enable(true).Mode(SunburstHighlig
htMode.Point))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

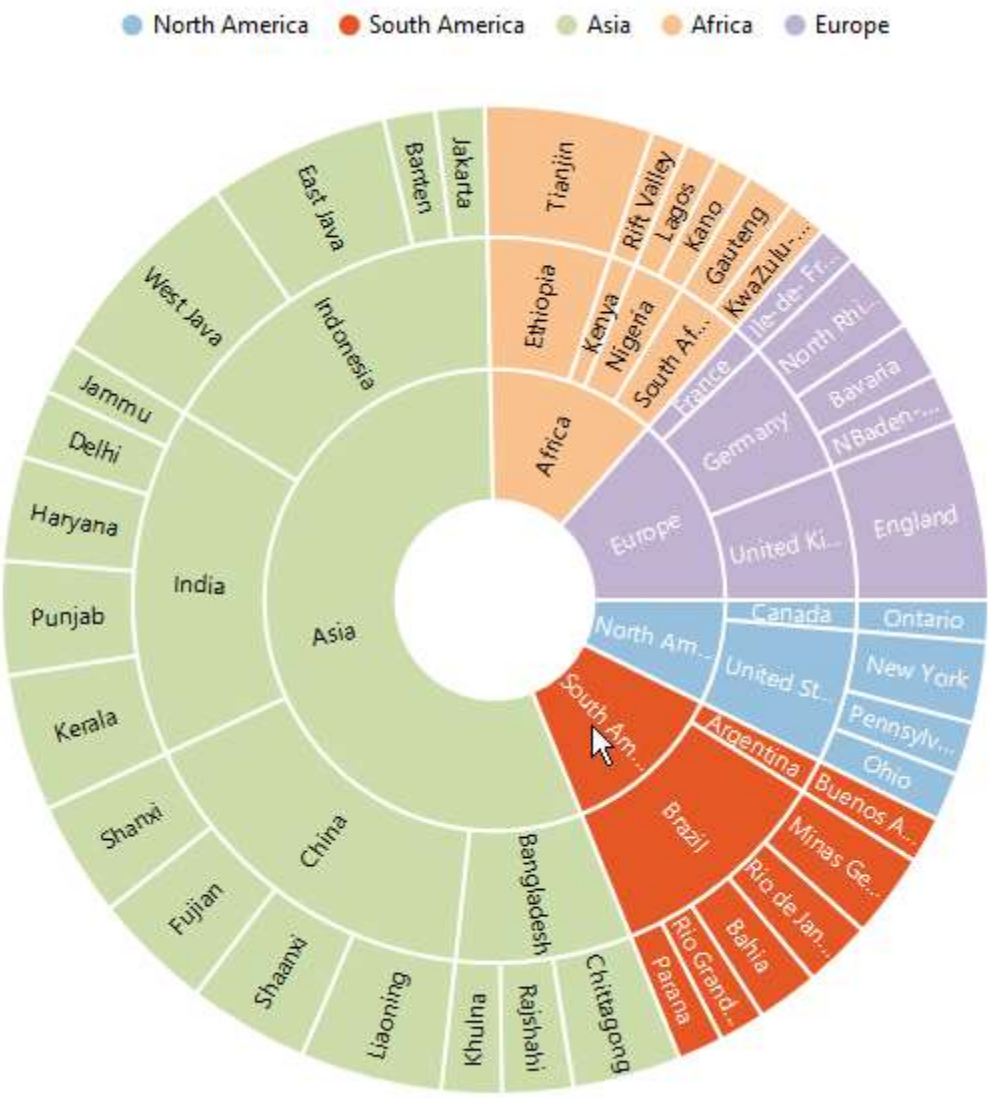


All

The following code snippet is used for the all mode of highlight settings

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.HighlightSettings(highlight=>highlight.Enable(true).Mode(SunburstHighlig
htMode.All))
)
```



Click here to view the online demo sample of Highlight in the Sunburst Chart.

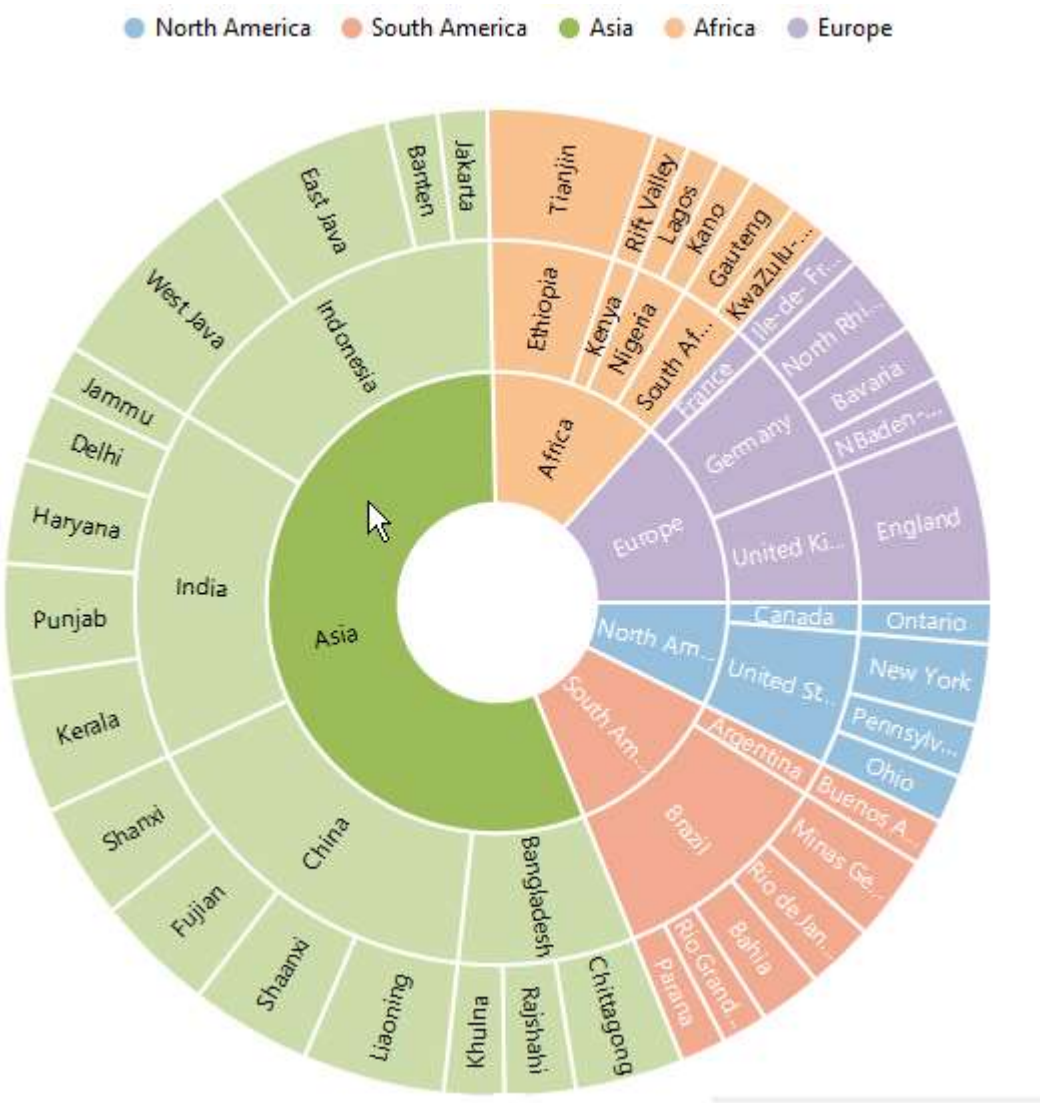
Selection

SunburstChart provides selection support for the points on mouse click. To enable the selection , set the *Enable* property to true in the **SelectionSettings**.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.SelectionSettings(selection=>selection.Enable(true))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Selection Display mode

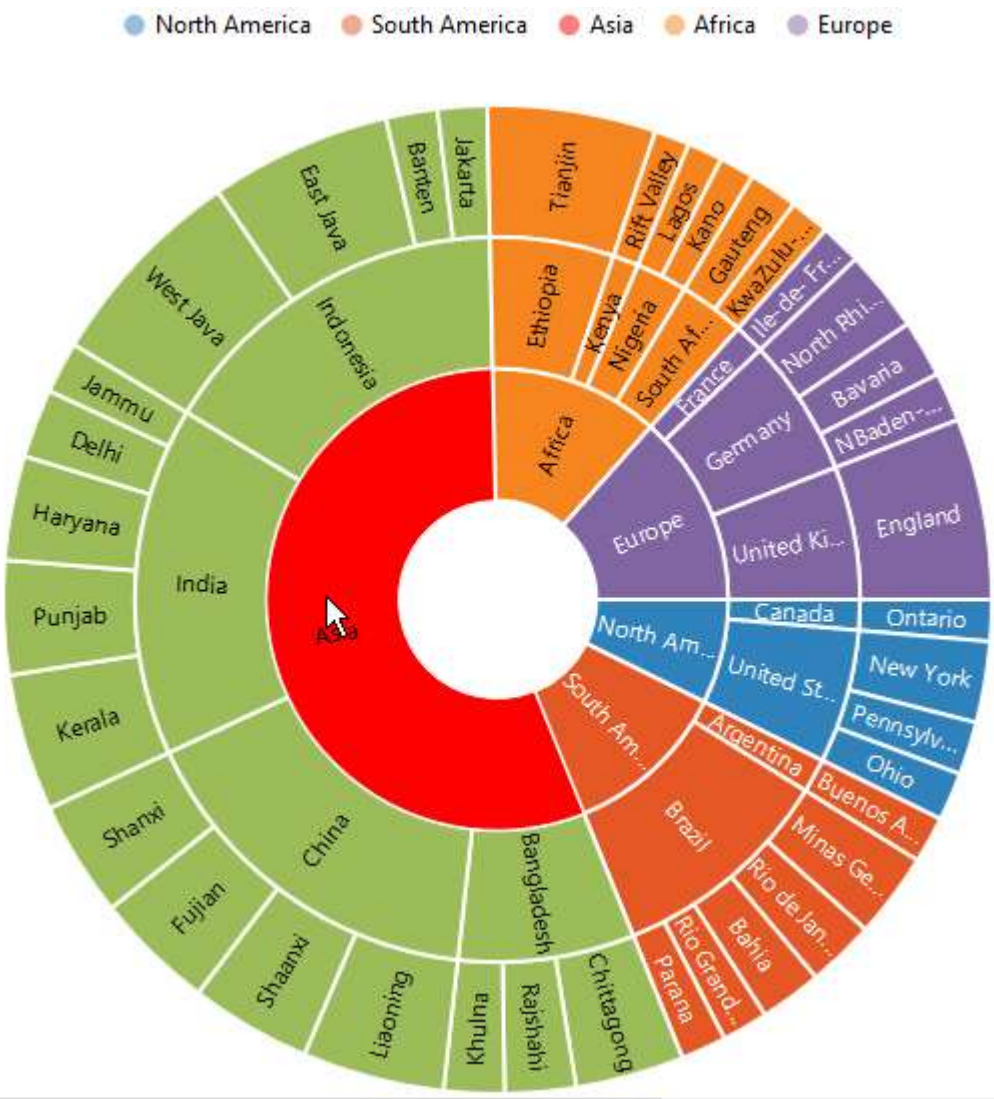
You can customize the selected segment appearance by using color or opacity. You can choose between color or opacity using the **Type** selection Settings.

selectionByColor – To display the selected segment appearance using color. selectionByOpacity – To display the selected segment appearance using opacity.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.SelectionSettings(selection=>selection.Enable(true).Type(SunburstSelecti
onType.Color).Color("Red"))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Selection Mode

Sunburst chart provides multiple option to represent the selected categories. You can select the segment categories by using the **Mode** property in selectionSettings

Child – To selection the child of selected parent. All – To selection the entire categories in group. *Parent – To selection the parent of selected child.* Single - To selection single item in the category.

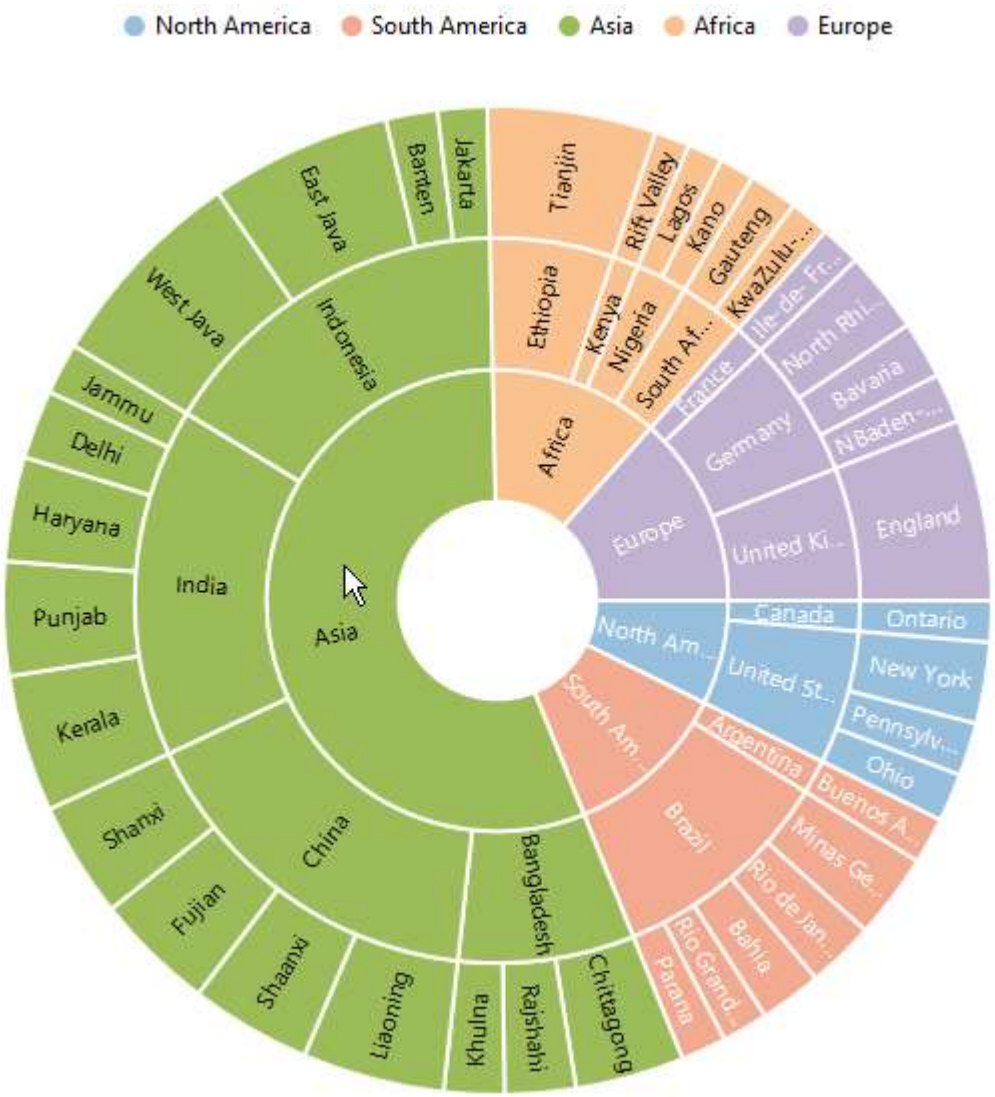
Child

The following code shows how to set the selection type as child

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.SelectionSettings(selection=>selection.Enable(true).Mode(SunburstSelecti
onMode.Child))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Parent

The parent mode can be enabled by using the below code

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.SelectionSettings(selection=>selection.Enable(true).Mode(SunburstSelecti
onMode.Parent))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

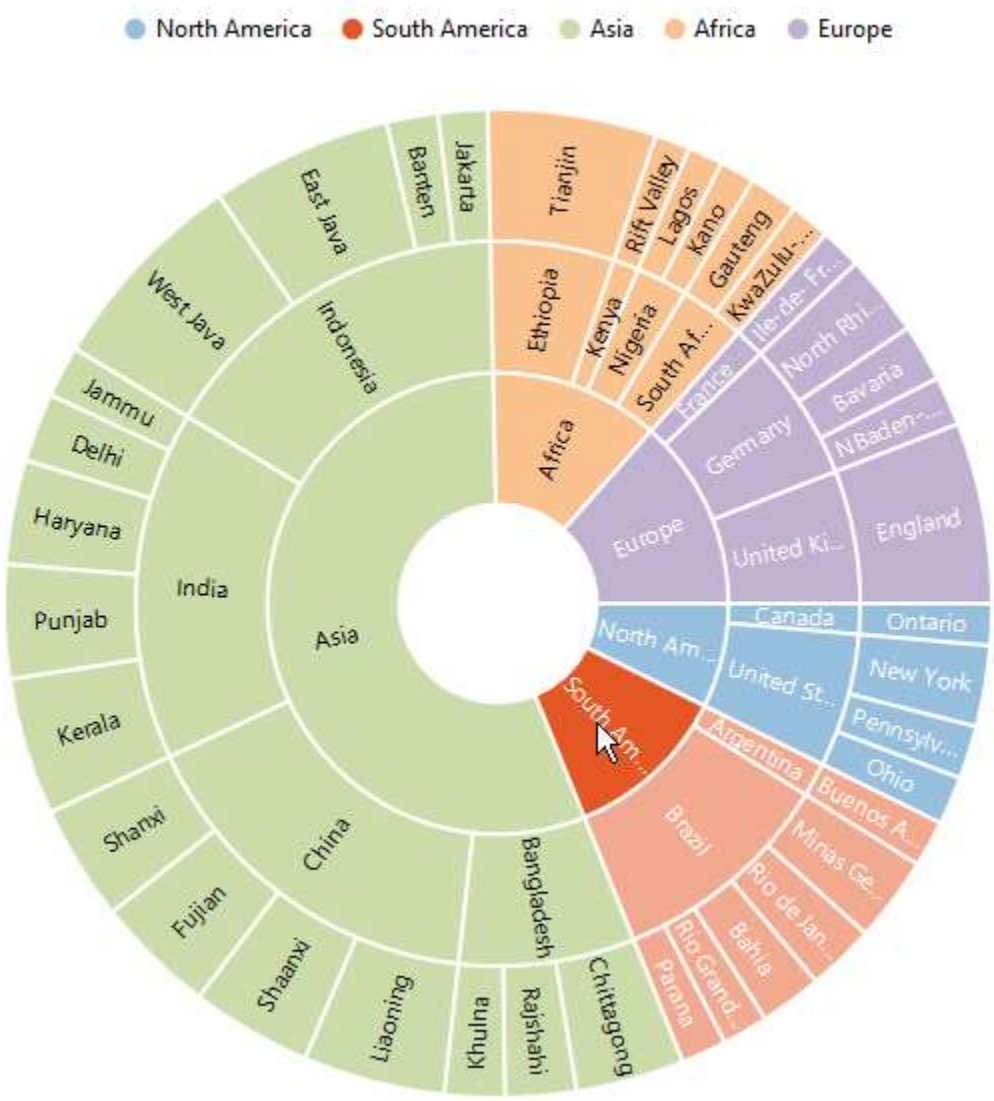
Point

To selection the particular segment, the point mode of the selection settings is used.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.SelectionSettings(selection=>selection.Enable(true).Mode(SunburstSelecti
onMode.Point))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



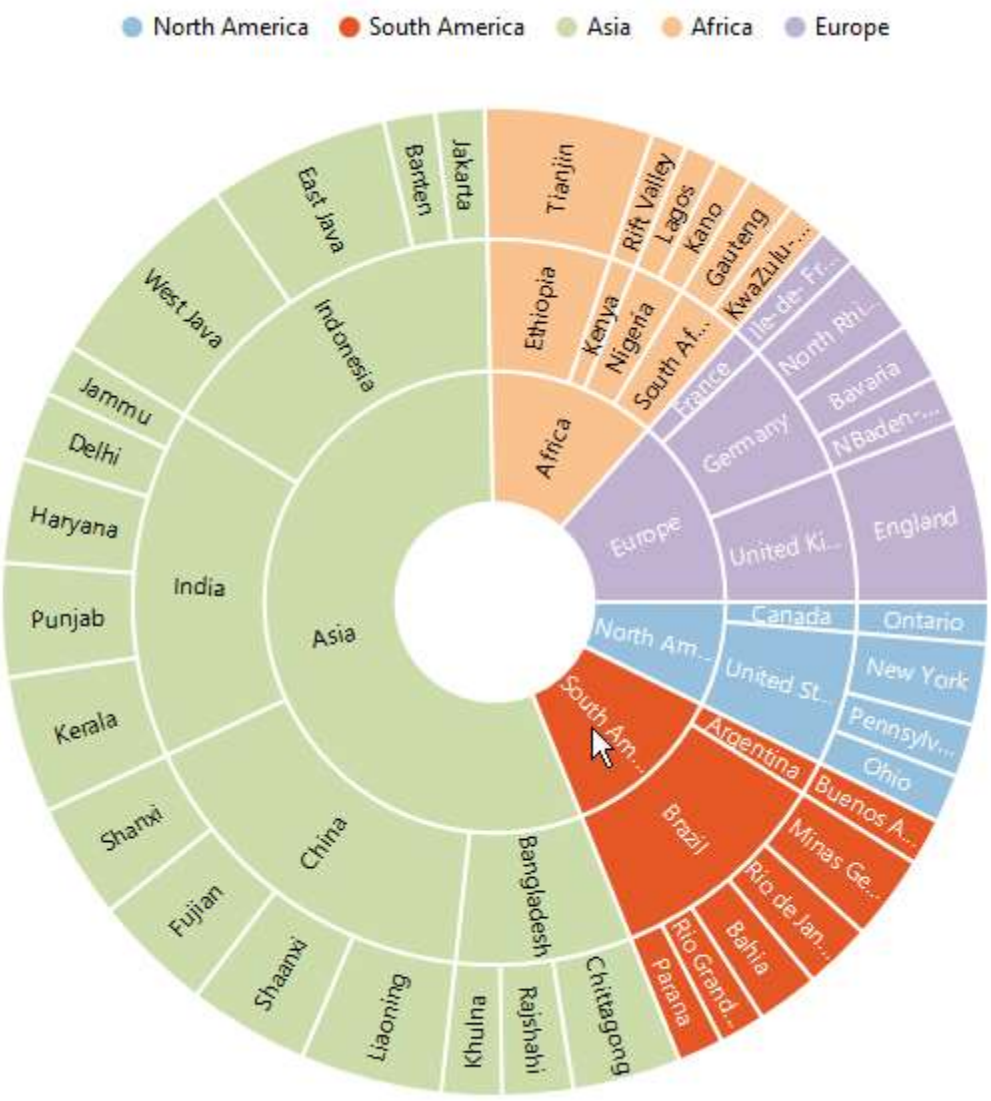
All

The following code snippet is used for the all mode of selection settings

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.SelectionSettings(selection=>selection.Enable(true).Mode(SunburstSelecti
onMode.All))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the online demo sample of Selection in the Sunburst Chart.

Zooming

Sunburst chart provides zooming (drill down) experience with animation for both mouse and touch enabled devices. It allows you to Virtualize large sets of data into minimum data view.The zooming is achieved by using the property of *zoomSettings*

The following code shows how to initialize the zooming.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.ZoomSettings(zoom => zoom.Enable(true))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Zooming toolbar

By default, zooming toolbar will be enabled while zooming the segment.It contains both back and reset option.

You can align the zooming toolbar position by using *ToolbarHorizontalAlignment* and *ToolbarVerticalAlignment* property.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
.ZoomSettings(zoom =>
zoom.Enable(true).ToolbarHorizontalAlignment(SunburstHorizontalAlignment.
Left))
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Click here to view the online demo sample of Zooming in the Sunburst Chart.

Animation

Sunburst chart allows you to animate the chart segments. You can enable animation using **EnableAnimation** property.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//...Enable Animation
.EnableAnimation(true)
//...
)
```

Animation Types

Sunburst chart provide options to animate the chart segments in different ways using **AnimationType** property.

FadeIn – It gradually changes opacity of the chart segment.

Copyright © 2001 - 2020 Syncfusion Inc.

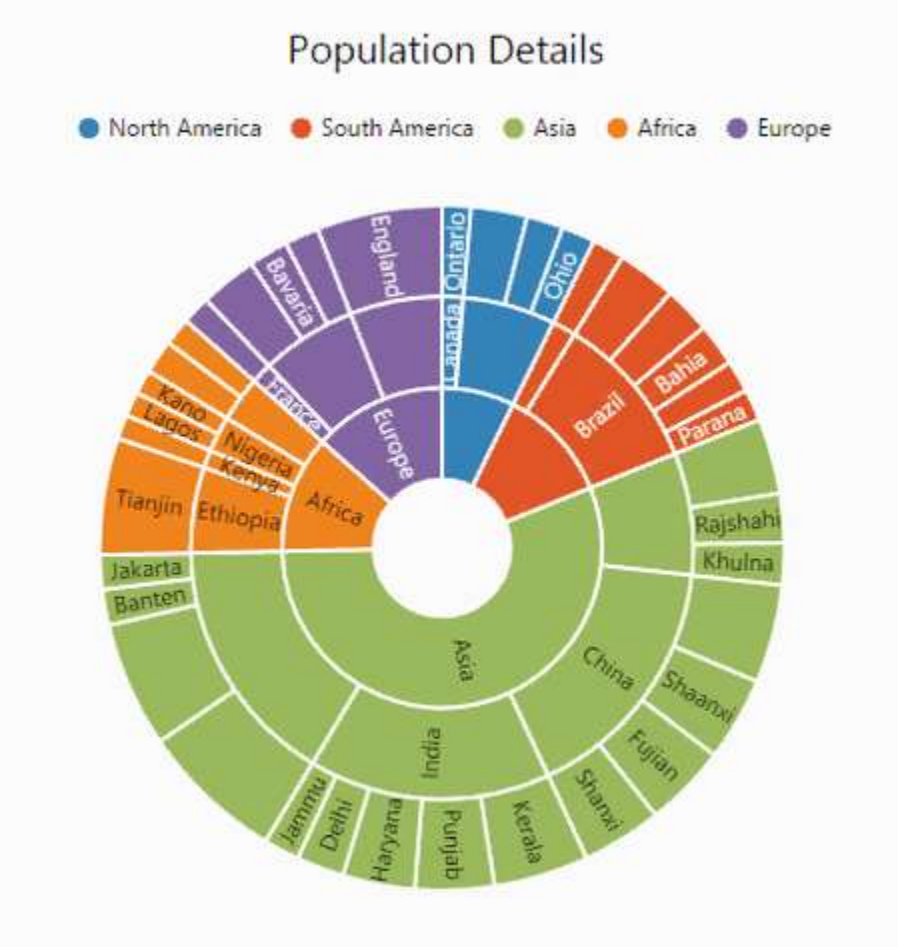
Rotation – During an animation, control rotate from 0 to 360 angle.

Fade In

The Fade In animation is enabled as follows

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//...Enable Animation
.EnableAnimation(true)
.SunburstAnimationType(SunburstAnimationType.FadeIn)
//...
)
```



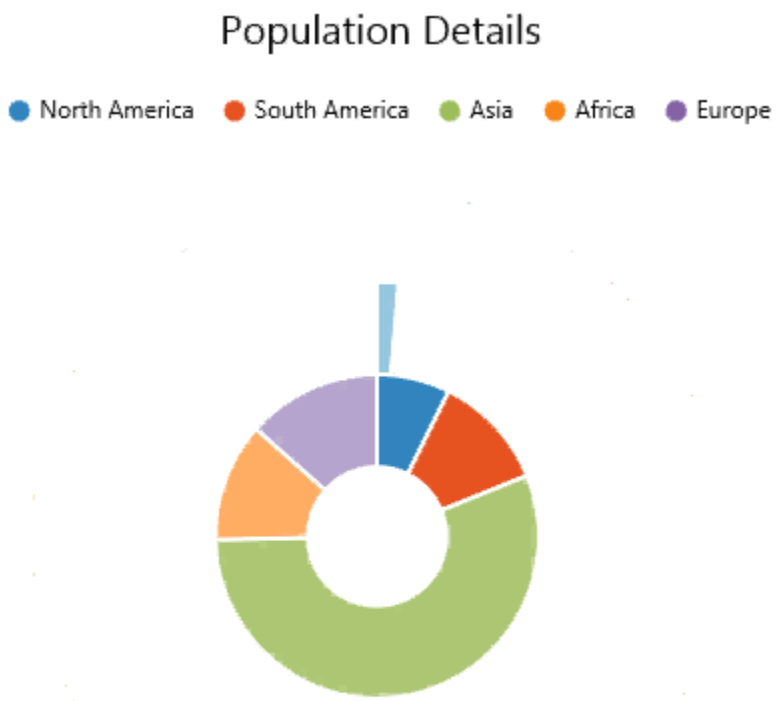
Rotation

The following example shows how to enable rotation animation in ejSunburstChart

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//...Enable Animation
.EnableAnimation(true)
.SunburstAnimationType(SunburstAnimationType.Rotation)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the online demo sample of Animation in the Sunburst Chart.

Appearance

The appearance of the Sunburst Chart can be customized as shown below

Palette

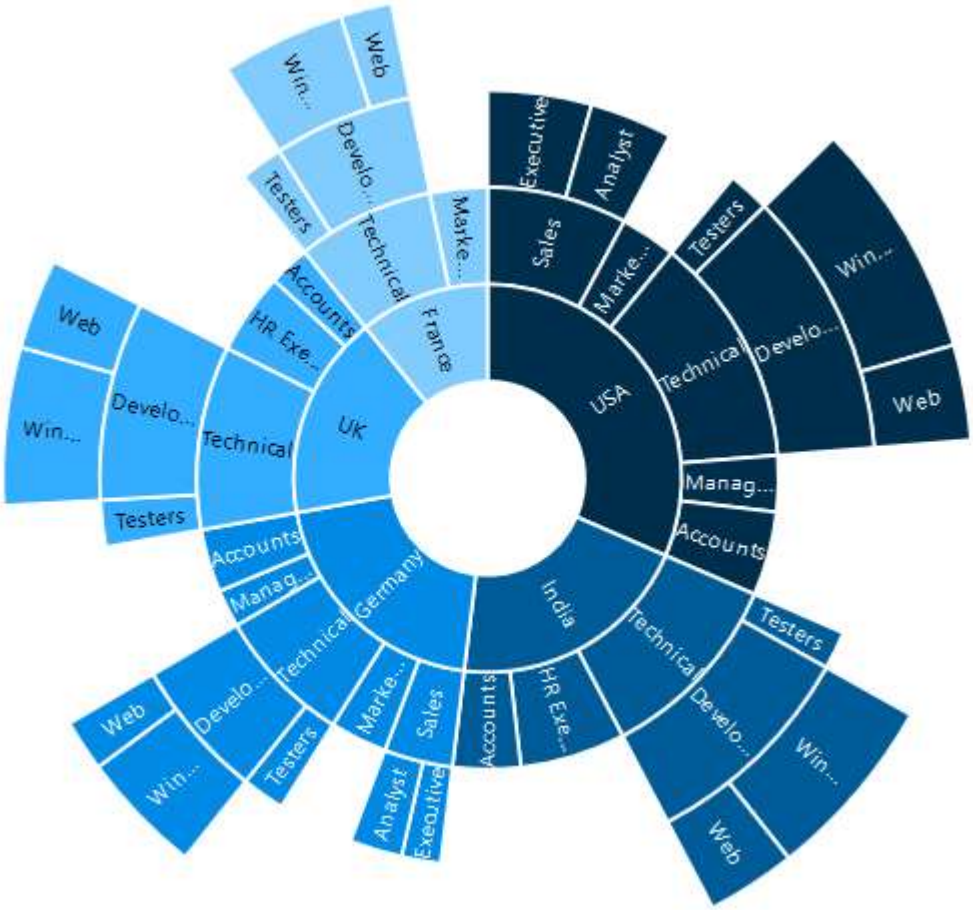
The Sunburst Chart displays different segments in different colors by default. You can customize the color of each segment by providing a custom color palette of your choice by using the **Palette** property.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//...Palette colors
.Palette(new List<string> { "#002e4d", "#005c99", "#008ae6", "#33adff",
"#80ccff" })
//...
)
```

The Sunburst Chart rendered with palette colors

Copyright © 2001 - 2020 Syncfusion Inc.



Built- in Themes

The Sunburst Chart supports different themes.

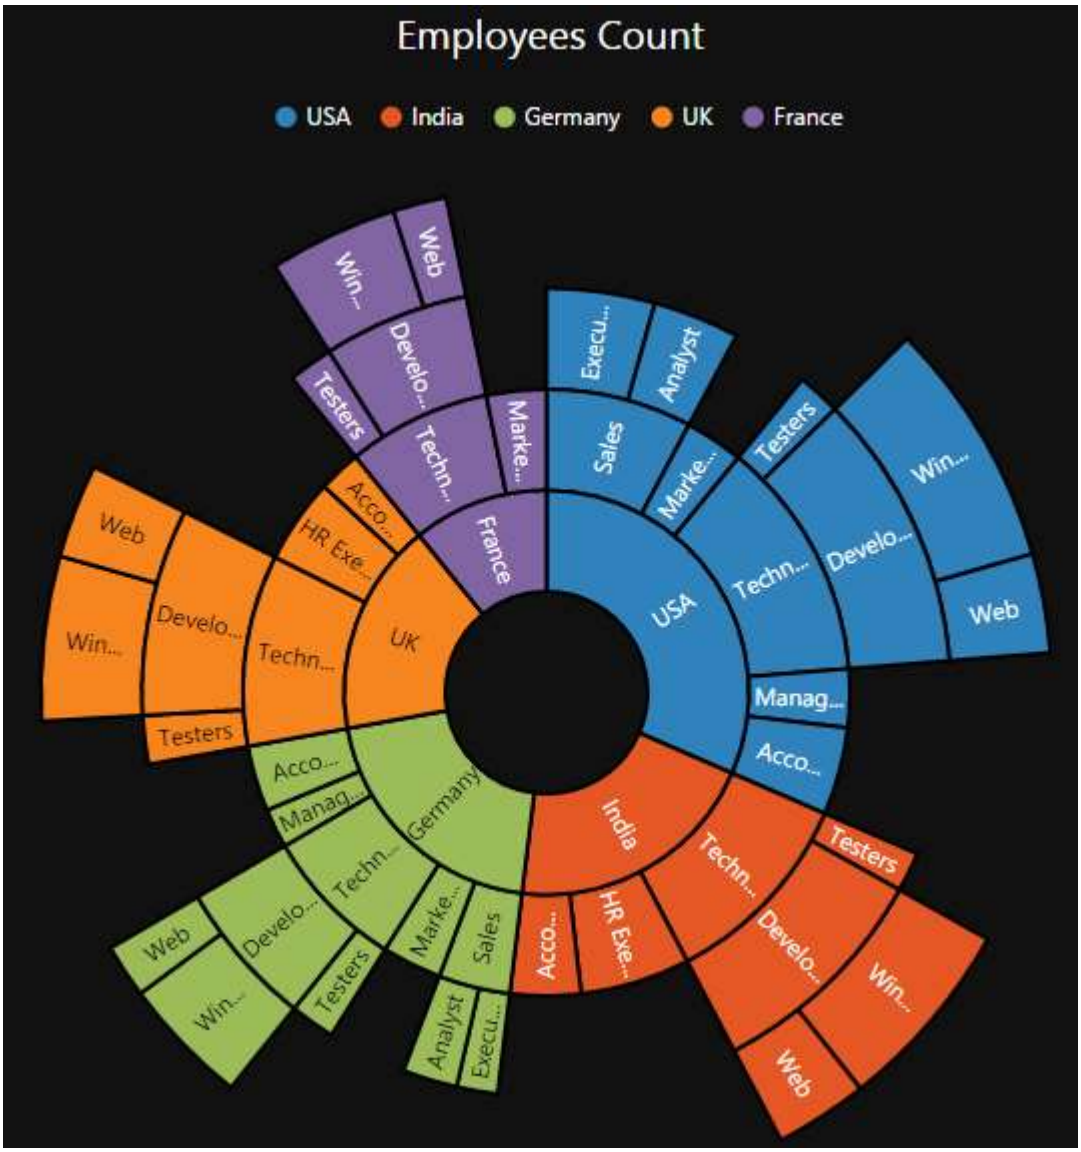
flatlight flatdark *gradientlight* gradientdark *azure* azuredark *lime* limedark *saffron* saffrondark *gradient-azure* gradient-azuredark *gradient-lime* gradient-limedark *gradient-saffron* gradient-saffrondark

You can set your desired theme by using the **Theme** property. **Flat light** is the default theme used in the Sunburst Chart.

ASPX-CS

```
@(Html.EJ().SunburstChart("chartContainer")
//...Palette colors
.Theme(Syncfusion.JavaScript.DataVisualization.SunburstTheme.FlatDark)
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Methods

redraw()

redraw the entire sunburst. You can call this method whenever you update, add or remove points from the data source or whenever you want to refresh the UI.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1"))
```

JS

```
var sun = $("#SunburstChart1").data("ejSunburstChart");
sun.redraw();
```

destroy ()

destroy the sunburst

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1"))
```

JS

```
var sun = $("#SunburstChart1").data("ejSunburstChart");
sun.destroy();
```

Events

Load

Fires before loading, you can use Load event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.Load("load")
)
```

JS

```
function load(){
// Do Something
}
```

PreRender

Fires before rendering sunburst, you can use PreRender event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.PreRender("prerender")
)
```

JS

```
function prerender(){
// Do Something
}
```

Loaded

Fires after rendering sunburst, you can use Loaded event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.Loaded("loaded")
)
```

JS

```
function loaded(){
// Do Something
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
```

DataLabelRendering

Fires before rendering the data label, you can use DataLabelRendering event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.DataLabelRendering("dataLabelRendering")
)
```

JS

```
function dataLabelRendering(){
// Do Something
}
```

SegmentRendering

Fires before rendering each segment, you can use SegmentRendering event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.SegmentRendering("segmentRendering")
)
```

JS

```
function segmentRendering(){
// Do Something
}
```

TitleRendering

Fires before rendering sunburst title, you can use TitleRendering event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.TitleRendering("titleRendering")
)
```

JS

```
function titleRendering(){
// Do Something
}
```

TooltipInitialize

Fires during initialization of tooltip, you can use TooltipInitialize event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.TooltipInitialize("tooltipInitialize")
)
```

JS

```
function tooltipInitialize(){
// Do Something
}
```

PointRegionClick

Fires after clicking the point in sunburst, you can use PointRegionClick event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.PointRegionClick("pointRegionClick")
)
```

JS

```
function pointRegionClick(){
// Do Something
}
```

PointRegionMouseMove

Fires while moving the mouse over sunburst points, you can use PointRegionMouseMove event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.PointRegionMouseMove("pointRegionMouseMove")
)
```

JS

```
function pointRegionMouseMove(){
// Do Something
}
```

DrillDownClick

Fires when clicking the point to perform drilldown, you can use DrillDownClick event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.DrillDownClick("drillDownClick")
)
```

JS

```
function drillDownClick(){
// Do Something
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

DrillDownBack

Fires when resetting drilldown points, you can use DrillDownBack event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.DrillDownBack("drillDownBack")
)
```

JS

```
function drillDownBack(){
// Do Something
}
```

DrillDownReset

Fires after resetting the sunburst points, you can use DrillDownReset event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.DrillDownReset("drillDownReset")
)
```

JS

```
function drillDownReset(){
// Do Something
}
```

LegendItemRendering

Fires before rendering the legend item, you can use LegendItemRendering event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.LegendItemRendering("legendItemRendering")
)
```

JS

```
function legendItemRendering(){
// Do Something
}
```

LegendItemClick

Fires when clicking the legend item, you can use LegendItemClick event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.LegendItemClick("legendItemClick")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

JS

```
function legendItemClick(){
// Do Something
}
```

Click

Fires when clicking the sunburst points, you can use Click event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.Click("click")
)
```

JS

```
function click(){
// Do Something
}
```

DoubleClick

Fires when double clicking the sunburst points, you can use DoubleClick event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.DoubleClick("doubleClick")
)
```

JS

```
function doubleClick(){
// Do Something
}
```

RightClick

Fires when right clicking the sunburst points, you can use RightClick event.

ASPX-CS

```
@(Html.EJ().SunburstChart("SunburstChart1")
.RightClick("rightClick")
)
```

JS

```
function rightClick(){
// Do Something
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Tab

Tab

The Tab control is an interface where list of items are expanded from a single item. Each Tab panel defines its header text or header template, as well as a content template. Tab items are dynamically added and removed. Tabs can be loaded with AJAX content that is useful for building dashboards where space is limited.

Key Features

- Collapsible header: All headers are collapsible.
- AJAX load: Load AJAX content in the Tab content panel.
- Close button: Provides a close button for each Tab item.
- Custom event for expanding header: Activate a Tab item on a single click, or bind custom events such as mouse over or mouse up to activate a Tab.
- Header orientation: Change the header position to the top or bottom of the control.
- Persist: Save the current model value to browser cookies to maintain the state.
- Height style: Adjust the content panel height.
- RTL: Tab headers and content can display right-to-left languages.
- Add Tab dynamically: New Tab items can be added and removed at run time.
- Theme: Essential ASP.NET MVC controls feature 12 built-in themes, six flat themes and six with gradient effects, and also support custom skin options to set user-defined themes.
- Keyboard navigation: You can interact with the control using the keyboard.

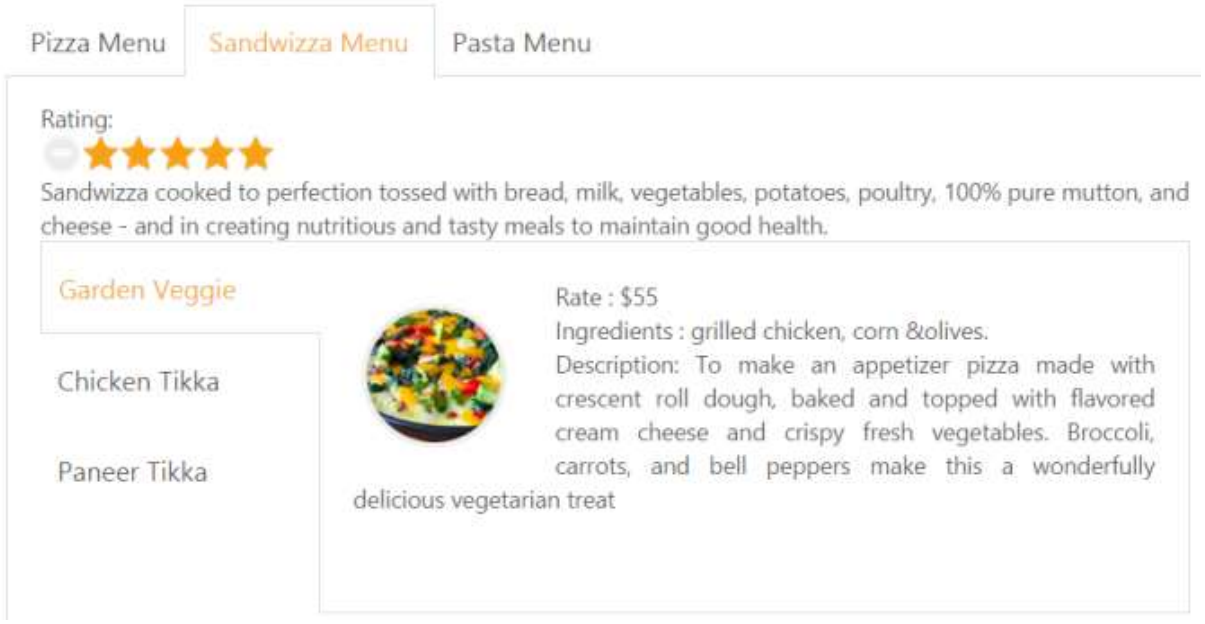
Getting Started

This section explains briefly about how to create a Tab Control in your application with ASP.NET MVC.

Create your first Tab Control in MVC

The ASP.NET MVCTab control is an interface that displays the content in multiple sections. A TabPanel consists of HeaderText as well as a ContentTemplate. Tab is useful for a dashboard that is having limited space. The following section guides you to customize the Tab for displaying Hotel menu items, its rate details and the ingredients on demand.

Copyright © 2001 - 2020 Syncfusion Inc.



Tab control with Hotel Menu items

Create Tab Control

The ASP.NET MVCTab widget basically builds a dynamic, interactive, menu-driven interface from your content. The content can be text, graphics or HTML. You can create the Tab headers using Text and Content template property

The following steps are used to create Tab control.

1. You can create an MVC Project and add necessary assembly and script with the help of the given MVC-Getting Started Documentation.
2. Add the mentioned code to the corresponding view page for Tab rendering.

ASPX-CS

```
@Html.EJ().Tab("Dish").Items(data =>
{
data.Add().ID("dish").Text("dish Menu").ContentTemplate(@<div></div>);
data.Add().ID("type").Text("dish Type").ContentTemplate(@<div></div>);
data.Add().ID("sandwich").Text("Sandwich
Type").ContentTemplate(@<div></div>);
})
```

The following output is displayed.

Tab control with Header

Copyright © 2001 - 2020 Syncfusion Inc.

Configure Content

In this application, a detailed description is provided to each item. You can specify the contents in the Tab section within the Content template.

ASPX-CS

```
@Html.EJ().Tab("DishType").Items(data =>
{
data.Add().ID("dish").Text("dish Menu").ContentTemplate(@<div> Rating:
@Html.EJ().Rating("RatingDish").Value(4).Precision(Precision.Exact)
<!--Food item description-->
<p>dish cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.</p>
</div>);
})
```

You can provide more customization to the Tab by using rating control, to describe an item's price.

Create the Rating

The ASP.NET MVC Rating control provides an intuitive rating experience that allows you to select the number of stars that represents the rating. The following code example explains you the creation of rating control. We can create the Rating control using HTML helper. We can render the rating control and its description inside the content template of first tab control.

For more information about rating, refer to the following link:

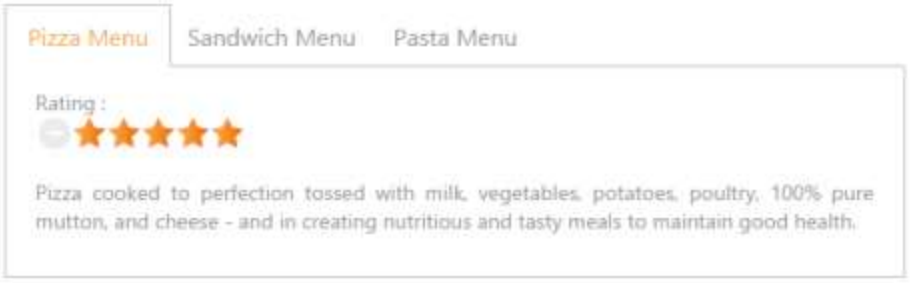
http://help.syncfusion.com/aspnetmvc

ASPX-CS

```
<!--Use the following codes with above Html contents-->
@Html.EJ().Tab("DishType").Items(data =>
{
data.Add().ID("dish").Text("dish Menu").ContentTemplate(@<div> Rating:
@Html.EJ().Rating("RatingDish").Value(4).Precision(Precision.Exact)
<!--Food item description-->
<p>dish cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.</p>
</div>);
data.Add().ID("type").Text("dish Type").ContentTemplate(@<div></div>);
data.Add().ID("sandwich").Text("Sandwich
Type").ContentTemplate(@<div></div>);
})
```

The following screenshot is the output for the given code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Sub Tab with Content

Each item has a variety of options, and these options are also specified in the limited space. So you can choose the Tab control that is used within the root Tab to specify more details.

The following code example represents sub Tab control rendering using helper function.

ASPX-CS

```
<!--Use the following codes with in the  above Html -->
@Html.EJ().Tab("DishType").Items(data =>
{
data.Add().ID("dish").Text("dish Menu").ContentTemplate(@<div> Rating:
@Html.EJ().Rating("RatingDish").Value(4).Precision(Precision.Exact)
<!--Food item description-->
<p>dish cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.</p>
@firstTab()
</div>);
data.Add().ID("type").Text("dish Type").ContentTemplate(@<div></div>);
data.Add().ID("sandwich").Text("Sandwich
Type").ContentTemplate(@<div></div>);
})
@helper firstTab()
{
@Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("Corn-Spinach").Text("Corn Spinach").ContentTemplate(@<div
class="e-content">
<img src=" http://js.syncfusion.com/demos/web/images/accordion/corn-and-
spinach-05.png" alt="corn-spinach">
<div class="ingredients">
Rate     : $70<br />
Ingredients : cheese, sweet corn &#38; green capsicums.
<br />
Description: Small dish bases are topped with spinach and paneer and
fresh cream, a nice layer of mozzarella cheese. This is baked until the
cheese is all hot and gooey.
</div>
</div>
);
data.Add().ID("ChickenDelite").Text("Chicken-
Delite").ContentTemplate(@<div class="e-content">
<img src="http://js.syncfusion.com/demos/web/images/accordion/chicken-
delite.png" alt="chicken-delite">
<div class="ingredients">
Rate     : $100<br />
```

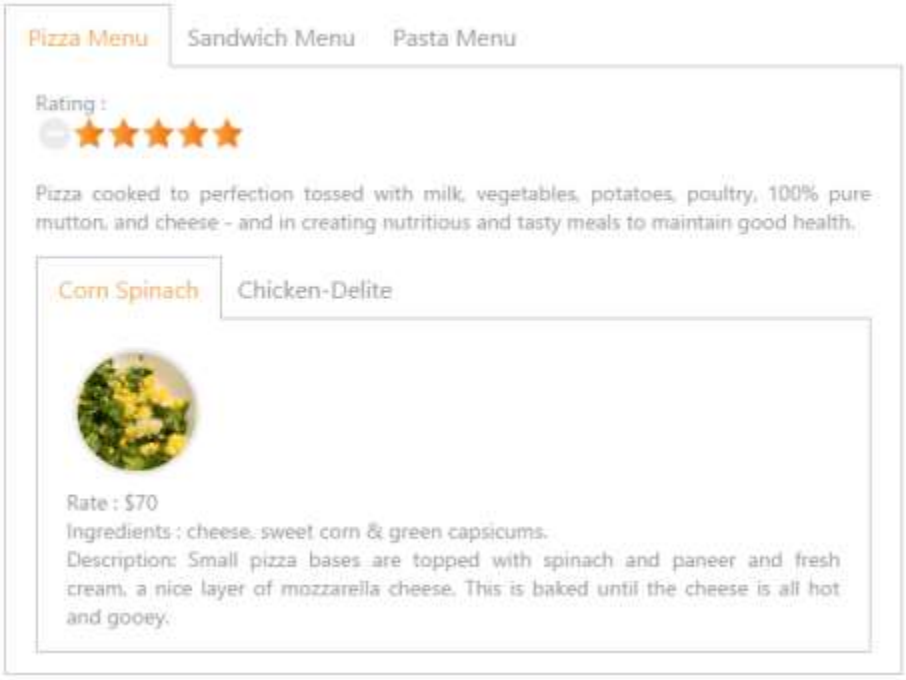
```
Ingredients : cheese, chicken chunks, onions &#38; pineapple chunks.
<br />
Description: This is a tasty, elegant chicken dish that is easy to
prepare.
</div>
</div>
);
})
});
}
```

The following code example is used to position the image and content.

CSS

```
<style type="text/css" class="cssStyles">
/*reuse the previous rating control style section code*/
.ingredients
{
height: 180px;
margin-top: 8px;
}
img
{
float: left;
margin: 10px 26px 5px 1px;
}
</style>
```

The following screenshot illustrates the first Tab with the sub Tab control.



Copyright © 2001 - 2020 Syncfusion Inc.

Orientation Change

Now, you can learn how to set the sub Tab orientation to vertical. By default, Tab control is rendered in horizontal orientation. You can change this orientation to vertical by using the HeaderPosition property. In the following code section, set the Tab header orientation as Left.

The following code section renders the sub Tab element in the vertical orientation.

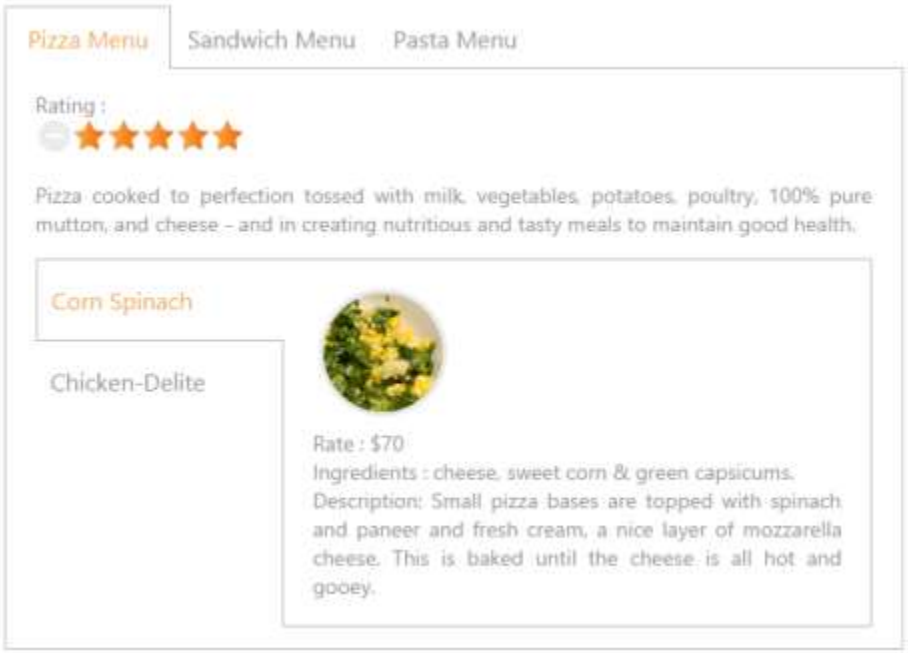
ASPX-CS

```
<!--Use the following codes with in the  above Html -->
@Html.EJ().Tab("DishType").Items(data =>
{
data.Add().ID("dish").Text("dish Menu").ContentTemplate(@<div>
Rating:
@Html.EJ().Rating("RatingDish").Value(4).Precision(Precision.Exact)
<!--Food item description-->
<p>dish cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.</p>
@firstTab()
</div>);
data.Add().ID("type").Text("dish Type").ContentTemplate(@<div></div>);
data.Add().ID("sandwich").Text("Sandwich
Type").ContentTemplate(@<div></div>);
})
@helper firstTab()
{
@Html.EJ().Tab("dish").HeaderPosition(HeaderPosition.Left).Height("221").
Items(data =>
{
data.Add().ID("Corn-Spinach").Text("Corn Spinach").ContentTemplate(@<div
class="e-content">
<img src=" http://js.syncfusion.com/demos/web/images/accordion/corn-and-
spinach-05.png" alt="corn-spinach">
<div class="ingredients">
Rate     : $70<br />
Ingredients : cheese, sweet corn &#38; green capsicums.
<br />
Description: Small dish bases are topped with spinach and paneer and
fresh cream, a nice layer of mozzarella cheese. This is baked until the
cheese is all hot and gooey.
</div>
</div>
);
data.Add().ID("ChickenDelite").Text("Chicken-
Delite").ContentTemplate(@<div class="e-content">
<img src="http://js.syncfusion.com/demos/web/images/accordion/chicken-
delite.png" alt="chicken-delite">
<div class="ingredients">
Rate     : $100<br />
Ingredients : cheese, chicken chunks, onions &#38; pineapple chunks.
<br />
Description: This is a tasty, elegant chicken dish that is easy to
prepare.
</div>
</div>
);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
});
```

The following screenshot is the output of above steps.



Configure Contents to remaining Tab items

The second and third Tab contents are declared in the same method as of the first Tab content declaration. These Tabs also consist of rating and sub Tab controls.

ASPX-CS

```
@{Html.EJ().Tab("DishType").Items(data =>
{
data.Add().ID("type").Text("dish Menu").ContentTemplate(@<div>
dish cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.
@firstTab()
</div>);
data.Add().ID("sandwichType").Text("Sandwizza
Menu").ContentTemplate(@<div>
Sandwizza cooked to perfection tossed with bread, milk, vegetables,
potatoes, poultry, 100% pure mutton, and cheese - and in creating
nutritious and tasty meals to maintain good health.
@secondTab()
</div>);
data.Add().ID("Pasta").Text("Pasta Menu").ContentTemplate(@<div>
</div>);
}).Render();
@helper secondTab(){
@Html.EJ().Tab("SandwichMenu").HeaderPosition(HeaderPosition.Left).Height
("221").Items(data =>
{
```

```
data.Add().ID("GardenVeggie").Text("Garden Veggie").ContentTemplate(@<div
class="e-content">
<img src="http://js.syncfusion.com/demos/web/images/accordion/garden-
veggie.png" alt="garden-veggie ">
<div class="ingredients">
Rate     : $55<br />
Ingredients : grilled chicken, corn &#38;olives.
<br />
Description: To make an appetizer dish made with crescent roll dough,
baked and topped with flavored cream cheese and crispy fresh vegetables.
Broccoli, carrots, and bell peppers make this a wonderfully delicious
vegetarian treat
</div>
</div>);
data.Add().ID("ChickenTikka").Text("Chicken Tikka
").ContentTemplate(@<div class="e-content">
<img src="http://js.syncfusion.com/demos/web/images/accordion/chicken-
tikka.png" alt="chicken-tikka">
<div class="ingredients">
Rate     : $100<br />
Ingredients : onions, grilled chicken, chicken salami &#38; tomatoes.
<br />
Description: Juicy chunks of boneless chicken roasted on open fire.This
takeaway favorite is freezer-friendly and quick to reheat, giving you the
chance to get ahead.
</div>
</div>);
data.Add().ID("PaneerTikka").Text("Paneer Tikka  ").ContentTemplate(@<div
class="e-content">
<img src="http://js.syncfusion.com/demos/web/images/accordion/paneer-

Behavior Settings

Close Button

By default, Tab contents are rendered without CloseButton. You can add the CloseButton by setting the 'ShowCloseButton' property to 'true'. When you move cursor over the Tab headers, the CloseButton is displayed.

The following code example is used to render the Tab widget with CloseButton.

1. Add the following code in your view page for simple Tab creation with CloseButton.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with close button.
<div style="width: 550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("dish").Text("dish Type")
.ContentTemplate(@<div>dish cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwich").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
}).ShowCloseButton(true).Render();}
</div>
```

2. The following screenshot illustrates the Tab with CloseButton.

Orientation

By default, Tab control renders in horizontal orientation. You can change the Orientation to vertical using the 'HeaderPosition' property. Using this property, you can customize the header by " Top"," Bottom", "Left", and "Right".

The following code example is used to render the sub Tab widget in the vertical orientation.

1. Add the following code in your view page for Tab orientation.

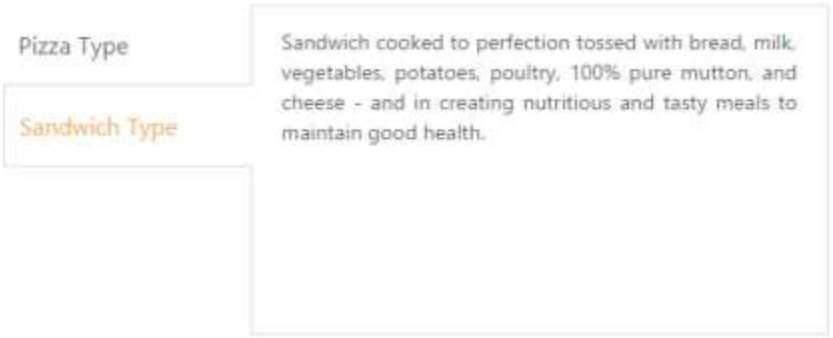
ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with customized orientation.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div style="width: 550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("dish").Text("dish Type")
.ContentTemplate(@<div>dish cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwich").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
}).HeaderPosition(HeaderPosition.Left).Height("220").Render();}
</div>
```

2. The following screenshot illustrates the sub Tab with vertical orientation.



State Maintenance

When the page gets refreshed or reloaded, the Tab state is changed (i.e.) the focus is moved to start Tab. You can maintain the state of the Tab by using 'EnablePersistence' property. When this property is set to 'true', it retains the state.

The following code example is used to render the Tab widget with state maintenance.

1. Add the following code in your view page for Tab state maintenance.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with state maintenance.
<div style="width: 550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("dish").Text("dish Type")
.ContentTemplate(@<div>dish cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwich").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</div>);
}).EnablePersistence(true).Render();}
</div>
```

2. The following screenshot illustrates the Tab with State maintenance.

State before page refresh

Appearance and Styling

Header Image Customization

To set the Tab header image for each Tab item you need to specify image in “ImageCssClass” property during the TabItem declaration.

The following code example is used to add the header image for the root Tab header element.

1. Add the following code in your view page to render Tab with header image.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with header image.
<div style="width: 500px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("pizza").Text("Pizza").ContentTemplate(@<div id="pizzatype"
style="background-color: #F5F5F5">
<p>Pizza cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.</p>
</div>);
data.Add().ID("sandwichType").Text("Sandwich").ContentTemplate(@<div
id="sandwichType" style="background-color: #F5F5F5">
<p>Sandwich cooked to perfection tossed with bread, milk, vegetables,
potatoes, poultry, 100% pure mutton, and cheese - and in creating
nutritious and tasty meals to maintain good health.</p>
</div>);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}).SelectedItemIndex(1).ClientSideEvents(e
=>e.Create("create")).Render();}
</div>
<script>
function create(args)
{
$("#dish ul li:first").find("a").prepend('<span class="dish
pizzaImg"></span>');
$("#dish ul li:last").find("a").prepend('<span class="dish
sandwichImg"></span>');
}
</script>
```

2. Add following CSS for header image customization.

CSS

```
<style type="text/css" class="cssStyles">
.dish {
display: inline-block;
}
.pizzaImg {
background:
url("http://js.syncfusion.com/demos/web/content/images/accordion/chicken-
delite.png") no-repeat;
height: 25px;
width: 25px;
margin:2px;
background-position: -18px;
}
.sandwichImg {
background:
url("http://js.syncfusion.com/demos/web/content/images/accordion/garden-
fresh.png") no-repeat;
padding:1px;
height: 25px;
width: 25px;
margin:2px;
background-position: -18px;
}
</style>
```

3. The following screenshot illustrates the Tab with the customized header image.

Copyright © 2001 - 2020 Syncfusion Inc.

Header Image Customization

Rounded corner

By enabling 'ShowRoundedCorner' property, you can customize the shape of the Tab widget from regular rectangular shape to rounded rectangle shape that is set to 'false' by default.

The following code example is used to render the Tab widget with rounded corner.

1. Add the following code in your view page to render Tab with rounder corner.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with rounded corner.
<div style="width: 550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("dish").Text("dish Type")
.ContentTemplate(@<div>dish cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwich").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
}).ShowRoundedCorner(true).Render();}
</div>
```

2. The following screenshot illustrates the Tab with Rounded corner.

Tab with rounded corner

Enable/Disable

You can enable or disable the Tab widget by 'Enabled' property. By default, the property set to 'true'.

The following code example is used to render the Tab widget with enable/disable.

1. Add the following code in your view page to render Tab with enable/disable.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with Enable/Disable format.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div style="width: 550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("dish").Text("dish Type")
.ContentTemplate(@<div>dish cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwich").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
}).Enabled(false).Render();}
</div>
```

2. The following screenshot illustrates the Tab with disabled format.

Tab with disabled format

Enabling Reload Icon

Without refresh/reload the whole page, you can reload a particular Tab using Reload icon. The Reload icon is appeared at right corner of the Tab by enabling the property 'ShowReloadIcon' to 'true'. When you move cursor over the Tab headers, the Reload icon is displayed. By default the property value is set to 'false'.

The following code example is used to render the Tab widget with Reload icon.

1. Add the following code in your view page to render Tab with Reload icon.

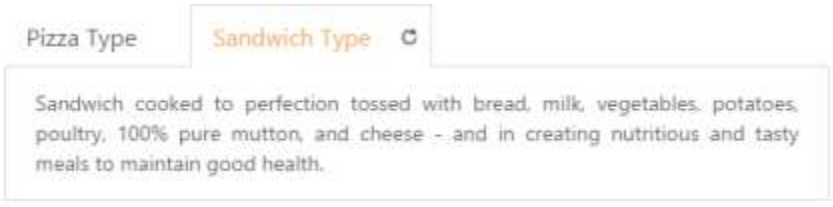
ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with reload icon.
<div style="width: 550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("dish").Text("dish Type")
.ContentTemplate(@<div>dish cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwich").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}).ShowReloadIcon(true).Render();}
</div>
```

2. The following screenshot illustrates the Tab with Reload icon.



Tab with reload icon

Collapsible Tabs

You can collapse the Tab content by enabling the 'Collapsible' property to 'true'. When the property is set to 'true' then click the active Tab header, the Tab contents are hidden. By default, the property value is set to 'false'.

The following code example is used to render the Tab widget with customized collapsible mode.

1. Add the following code in your view page to render Tab with customized collapsible mode.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with collapsible mode.
<div style="width: 550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("dish").Text("dish Type")
.ContentTemplate(@<div>dish cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwich").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
}).Collapsible(true).Render();}
</div>
```

2. The following screenshot illustrates the Tab with customized collapsible mode.

Tab with customized collapsible mode

Adjusting Tab Size

Height Adjust Mode and Height

The height of the Tab widget is customized by 'height' property. The Tab widget height depends on 'HeightAdjustMode' property. Using the HeightAdjustMode property, you can adjust height by "Content", "Auto", "Fill". By default the HeightAdjustMode is set as content.

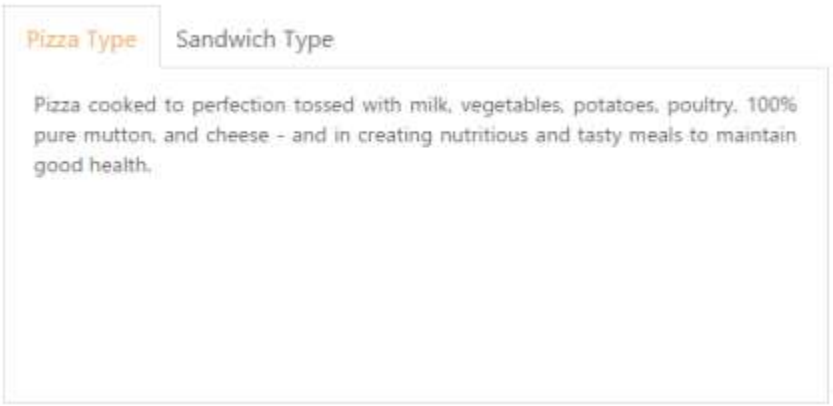
The following code example is used to render the Tab widget with customized height and height adjust mode.

1. Add the following code in your view page to render Tab with customized height and height adjust mode.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with customized height and height adjust mode.
<div style="width: 550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("dish").Text("dish Type")
.ContentTemplate(@<div>dish cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwichType").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
}).HeightAdjustMode(HeightAdjustMode.Fill).Height("300px").Render();}
</div>
```

2. The following screenshot illustrates the Tab with customized height and height adjust mode.



Tab with customized height and height adjust mode

Width

The width of the Tab widget is customized by using 'Width' property that accepts only the pixel values.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example is used to render the Tab widget with customized width.

1. Add the following code in your view page to render Tab with customized width.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with customized width.
<div>
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("dish").Text("dish Type")
.ContentTemplate(@<div>dish cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwichType").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
}).Width("450").Render();}
</div>
```

2. The following screenshot illustrates the Tab with customized width.

Tab with customized width

Theme

Tab control's style and appearance are controlled based on CSS classes. In order to apply styles to the Tab control, you can refer 2 files namely, ej.widgets.core.min.css and ej.theme.min.css. When the file ej.widgets.all.min.css is referred, then it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these two.

By default, there are 13 themes support available for Tab control namely

- default-theme
- bootstrap-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure

Copyright © 2001 - 2020 Syncfusion Inc.

- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

Custom styles

The style of the Tab widget is customized by 'CssClass' property.

The following code example is used to render the Tab widget with customized style.

1. Add the following code in your view page to render Tab with customized style.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with customized style.
<div>
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("dish").Text("dish Type")
.ContentTemplate(@<div>dish cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwichType").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
}).CssClass("custom").Render();}
</div>
```

2. Add the following styles

CSS

```
<style type="text/css">
.custom
{
width:650px;
}
</style>
```

3. The following screenshot illustrates the Tab with customized style.

Copyright © 2001 - 2020 Syncfusion Inc.

Tab with customized style

Integration with other widgets

You can provide more customization to the Tab with Rating control as content in it for describing the item rating value.

The Essential ASP.NET MVC Rating control provide you an intuitive rating experience that allows you to select the number of stars that represents the rating. For more information about the rating, you can refer the following link:

http://help.syncfusion.com/aspnetmvc/tab/integration-with-other-widgets

The following code example explains you the Rating control creation. The input element is used to create the rating control. Render the input element as rating control using the input element id.

1. Add the following code in your view page to render Tab with other widget (rating).

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with other widgets.
<div style="width:550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("pizza").Text("Pizza Type")
.ContentTemplate(@<div>Rating:@Html.EJ().Rating("PRating").Value(4)
Pizza cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.
</div>);
data.Add().ID("sandwich").Text("Sandwich Type")
.ContentTemplate(@<div>Rating:@Html.EJ().Rating("SRating").Value(4)
Sandwich cooked to perfection tossed with bread, milk, vegetables,
potatoes, poultry, 100% pure mutton, and cheese - and in creating
nutritious and tasty meals to maintain good health.
</div>);
}).Render();}
</div>
```

To render the rating controls in the first Tab element refer the styles mentioned in the following code example.

1. Add the following styles to render Tab.

CSS

```
<style type="text/css" class="cssStyles">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.dishRating
{
position: absolute;
margin: -31px 0px 0px 80px;
}
</style>
```

2. The following screenshot illustrates the Tab content with rating control.

Tab content section with Rating Control

AJAX Content Load (Load on Demand)

You can change the contents in sub Tab element periodically and you are provided with a support to change the contents without any problems. To achieve the content load, use the Load on Demand concept.

In Load On-Demand, the external HTML file with the necessary details is referred in URL section during Tab header declaration section. Also include “DataType”, “ContentType”, and “Async” in the script like the following example when rendering the control. When you click the Tab header, the AJAX automatically calls the content from the external files and displays in a Tab content section.

Sub Tab with AJAX Content

Each item has a variety of options and these options are also specified in the limited space. So you can choose the Tab control that is used within the root Tab to specify more details.

1. Add the following code in your view page to render sub Tab with AJAX content.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render sub Tab with AJAX content.
@{Html.EJ().Tab("DishType").Items(data =>
{
data.Add().ID("Pizza").Text("Pizza Menu").ContentTemplate(@<div>
Pizza cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.
@firstTab()
</div>);
data.Add().ID("sandwich").Text("Sandwizza Menu").ContentTemplate(@<div>
Sandwizza cooked to perfection tossed with bread, milk, vegetables,
potatoes, poultry, 100% pure mutton, and cheese - and in creating
nutritious and tasty meals to maintain good health.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@secondTab()
</div>);
data.Add().ID("Pasta").Text("Pasta Menu").ContentTemplate(@<div>
Pasta cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.
</div>);
}).Render();
@helper firstTab()
{
@Html.EJ().Tab("Pizza").Items(data =>
{
data.Add().ID("Corn-Spinach").Text("Corn
Spinach").Url("Content/cornSpinach.html");
data.Add().ID("ChickenDelite").Text("Chicken-
Delite").Url("Content/chickenDelite.html");
})
}
@helper secondTab()
{
@Html.EJ().Tab("sandwich").Items(data =>
{
data.Add().ID("GardenVeggie").Text("Corn
Spinach").Url("Content/gardenVeggie.html");
data.Add().ID("ChickenTikka").Text("Chicken-
Delite").Url("Content/chickenTikka.html");
data.Add().ID("PaneerTikka").Text("PaneerTikka").Url("Content/paneerTikka
.html");
})
}
}
```

2. The file ‘cornSpinach.html’ content is as follows.

ASPX-CS

```
<!DOCTYPE html>
<html xmlns="http://www.w3.org/1999/xhtml">
<body>
<div class="e-content">
<img src="http://js.syncfusion.com/demos/web/images/accordion/corn-and-
spinach-05.png" alt="corn-spinach">
<div class="ingredients">
Rate     : $70<br/> Ingredients : cheese, sweet corn &#38; green
capsicums.
<br />
Description: Small pizza bases are topped with spinach and paneer and
fresh cream, a nice layer of mozzarella cheese. This is baked until the
cheese is all hot and gooey.                    </div>
</div>
</body>
</html>
```

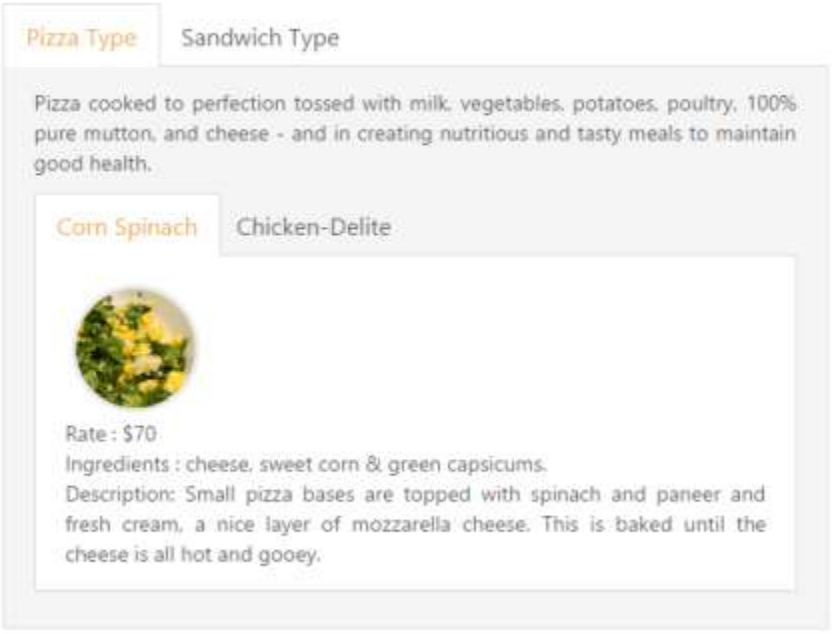
Copyright © 2001 - 2020 Syncfusion Inc.

3. The file ‘chickenDelite.html’ content is as follows.

ASPX-CS

```
<!DOCTYPE html>
<html xmlns="http://www.w3.org/1999/xhtml">
<body>
<div class="e-content">
<img src="http://js.syncfusion.com/demos/web/images/accordion/chicken-delite.png" alt="chicken-delite">
<div class="ingredients">
Rate     : $100<br /> Ingredients : cheese, chicken chunks, onions &#38; pineapple chunks.   <br />
Description: This is a tasty, elegant chicken dish that is easy to prepare.
</div>
</div>
</body>
</html>
```

The following screenshot illustrates the First Tab with the sub Tab control using Load on Demand.



Tab section with sub Tab control using Load on Demand.

RTL Support

Tab control provides support for load contents in right to left format. This is achieved by setting ‘EnableRTL’ property to “true”.

The following code example is used to render the Tab element in RTL format.

1. Add the following code in your view page to render Tab with RTL format.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab in Rtl format.
<div style="width:550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("pizza").Text("Pizza Type")
.ContentTemplate(@<div>
Pizza cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.
</div>);
data.Add().ID("sandwich").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
}).EnableRTL(true).Render();}
</div>
```

2. The following screenshot illustrates the Tab with RTL format.

Keyboard Navigation

Tab control provides supports keyboard interaction. Using this functionality you can interact with control using keyboard. This is achieved by enabling 'AllowKeyboardNavigation'to 'true'. By default this property value is set to 'true'.

Following table illustrates the accessible key and their usage

Keys	Behavior
Up	Selected previous item.
Right	Selected previous item.
Down	Selected next item.
Left	Selected next item.
Home	Selected first item.
End	Selected last item.

The following code example is used to render the Tab element in RTL format.

Copyright © 2001 - 2020 Syncfusion Inc.

1. Add the following code in your view page to render Tab with keyboard navigation.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render Tab with keyboard navigation.
<div style="width:550px">
@{Html.EJ().Tab("dishTab").Items(data =>
{
data.Add().ID("pizzaType").Text("Pizza Type")
.ContentTemplate(@<div>
Pizza cooked to perfection tossed with milk, vegetables, potatoes,
poultry, 100% pure mutton, and cheese - and in creating nutritious and
tasty meals to maintain good health.
</div>);
data.Add().ID("sandwichType").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.
</div>);
}).AllowKeyboardNavigation(true).Render();}</div>
// Add the following script to render Tab with keyboard navigation.
<script type="text/javascript">
$(function () {
//Control focus key
$(document).on("keydown", function (e) {
if (e.altKey && e.keyCode === 74) {
// j- key code.
$("#dishTab ul a").focus();
}
});
});
</script>
```

2. The following screenshot illustrates the Tab with keyboard navigation.

Scroll Support

Tab control provides you scrolling support on Tab items to display a larger number of tabs with scroll buttons to get rid of the extending page size. The enabled Scroll buttons can be used to traverse through the elements.

By default, Tab header is rendered without scroll button. You can add the scroll button by setting the "EnableTabScroll" property to "true". When you move the cursor over the Tab header the scroll button is displayed.

You can use the following code example to render the Tab widget with scroll button.

Copyright © 2001 - 2020 Syncfusion Inc.

1. Add the following code in your view page to create a simple Tab with scroll button.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render Tab with scroll button.*@
<div style="width: 550px">
@{Html.EJ().Tab("dish").Items(data =>
{
data.Add().ID("pizza").Text("Pizza Type")
.ContentTemplate(@<div>Pizza cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("pasta").Text("Pasta Type")
.ContentTemplate(@<div>Pasta cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("burger").Text("Burger Type")
.ContentTemplate(@<div>Burger cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("sandwich").Text("Sandwich Type")
.ContentTemplate(@<div>Sandwich cooked to perfection tossed with bread,
milk, vegetables, potatoes, poultry, 100% pure mutton, and cheese - and
in creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("spaghetti").Text("Spaghetti Type")
.ContentTemplate(@<div>Spaghetti cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
data.Add().ID("ramen").Text("Ramen Type")
.ContentTemplate(@<div>Ramen cooked to perfection tossed with milk,
vegetables, potatoes, poultry, 100% pure mutton, and cheese - and in
creating nutritious and tasty meals to maintain good health.</div>);
}).EnableTabScroll(true).Render();}
</div>
```

The following screenshot illustrates you the Tab control with scroll button.

Tab control with scroll support

Template Support

ASP.NET MVC

The Content template option provided in MVC is used to specify the HTML elements inside the Tab control. We can use this option to load any HTML elements and showcase it in the Tab panels as per our requirement.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code block showcases how to use content template option in the Tab control.

ASPX-CS

```
<div style="width:650px">
@{Html.EJ().Tab("pizza").Items(data =>
{
data.Add().ID("garden").Text("GARDEN FRESH (Veg)")
.ContentTemplate(@<div>
<img src="~/Content/accordion/garden-veggie.png" alt="garden-fresh" />
<div class="ingredients">
Rate     : $50
<br />
Ingredients : cheese, onions, green capsicums & tomatoes.
</div>
</div>);
data.Add().ID("corn").Text("CORN & SPINACH (Veg)")
.ContentTemplate(@<div>
<img src="~/Content/accordion/corn-and-spinach-05.png" alt="garden-fresh"
/>
<div class="ingredients">
Rate     : $70
<br />
Ingredients : cheese, sweet corn & green capsicums.
</div>
</div>);
data.Add().ID("chicken").Text("CHICKEN DELITE (Non-veg)")
.ContentTemplate(@<div>
<img src="~/Content/accordion/chicken-delite.png" alt="garden-fresh" />
<div class="ingredients">
Rate     : $100
<br />
Ingredients : cheese, chicken chunks, onions & pineapple chunks.
</div>
</div>);
}).Render();}
</div>
```

Output:

Tab control with template support

Render Tab from code behind

Tab can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of Tab using Tab properties from code behind.

RAZOR

```
@{
Html.EJ().Tab("Tab",
(Syncfusion.JavaScript.Models.TabProperties)ViewData["tab"]).Render();
}
```

C#

```
public ActionResult Index()
{
TabProperties tab = new TabProperties();
tab.Items.Add(new TabBaseItem() { ID = "javaScript", Text = "JavaScript",
ContentTemplate = new MvcTemplate<TabBaseItem> { RazorViewTemplate =
(data) => { return "JavaScript (JS) is an interpreted computer
programming language"; } } });
tab.Items.Add(new TabBaseItem() { ID = "cSharp", Text = "C Sharp",
ContentTemplate = new MvcTemplate<TabBaseItem> { RazorViewTemplate =
(data) => { return " C# is intended to be a simple, modern, general-
purpose, object-oriented programming language."; } } });
tab.Items.Add(new TabBaseItem() { ID = "vb", Text = "VB.Net",
ContentTemplate = new MvcTemplate<TabBaseItem> { RazorViewTemplate =
(data) => { return "  The command-line compiler, VBC.EXE, is installed as
part of the Freeware .NET Framework SDK."; } } });
ViewData["tab"] = tab;
return View();
}
```

How To

Add a tab item dynamically based on condition

To add tab item dynamically based on condition, we can use the conditional operators to check and add the items within the items property. Refer to the following code.

HTML

```
@{Html.EJ().Tab("defaultTabs").Items(data =>
{
data.Add().ID("reviews").Text("Reviews").ContentTemplate(@<div>@{
Html.RenderPartial("_ReviewList"); }</div>);
if (user == "admin") { // check the condition to load the item in tab
data.Add().ID("calendar").Text("Calendar").ContentTemplate(@<div> @{
Html.RenderPartial("_Calendar"); }</div>);
}
}).ShowRoundedCorner(true).Render();}
```

In the above code, based on the “user” the second tab will be displayed.

Sample

TagCloud

TagCloud

The ASP.NET MVC TagCloud control allows the user to display a list of links or tags with a structured cloud format where the importance of the tags can differentiate with varied font sizes, colors, and styles.

Key Features

- Data binding: Supports data binding with JSON data as well as remote data.
- Accessible: Supports adding or removing tags dynamically.
- Format: Supports tag structure in both cloud format and list format.
- Font-size: Supports limiting the font size with a minimum and maximum range.
- RTL: Supports changing the TagCloud direction for right-to-left alignment.
- Themes: JavaScript controls include 12 built-in themes (6 flat and 6 gradient effects) and also support a custom skin option to set user defined themes.

Getting Started

This section explains briefly about how to create a TagCloud in your ASP.NET MVC application.

Create your first TagCloud in MVC

ASP.NET MVC TagCloud provides support to display a weighted list, where the weight of each item is reflected by the size of the item's text. TagCloud is rendered as a link and as you click it, you can drill into the selected category. Refer the following guidelines to create TagCloud scenario. This allows you to display a weighted list.

In the above screenshot, you can see the weighted list and a click on any item drills into the respective category.

Create a TagCloud

Essential Studio ASP.NET MVC TagCloud widget has built-in features such as clicking on one of the sites in the TagCloud brings all relevant results only from the selected source. You can easily create the TagCloud widget element as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

1. You can create a MVC Project and add required assemblies, scripts and styles to it. Refer MVC-Getting Started.
2. Add the following code to the corresponding view page to render TagCloud.

ASPX-CS

```
@Html.EJ().TagCloud("tagEvents").Datasource((IEnumerable<MvcApplication.Models.WebsiteCollection>)ViewBag.datasource).TagCloudFields(tag => tag.Text("text").Url("url").Frequency("frequency")).Title("Tech Sites")
```

3. Add the following style to show the weighted list.

CSS

```
<style type="text/css">
#tagEvents
{
margin: 0 auto;
}
</style>
```

Set the Min and Max Font Size

Create the class for WebsiteCollection and define the necessary data members. Add the following code in WebsiteCollection.cs part.

C#

```
// Define local data source elements with  fields
public class WebsiteCollection
{
public string text { get; set; }
public string url { get; set; }
public int frequency { get; set; }
}
```

You can set the minimum and maximum font size in frequency property by adding the following code example in the Controller.

C#

```
//Refer the Model in the controller
using <Applicationname>.Models;
public ActionResult Index()
{
List<WebsiteCollection> sites = new List<WebsiteCollection>();
sites.Add(new WebsiteCollection { text = "Google", url =
"http://tech.firstpost.com/tag/google", frequency = 12 });
sites.Add(new WebsiteCollection { text = "Apple", url =
"http://tech.firstpost.com/tag/apple-iwork", frequency = 3 });
sites.Add(new WebsiteCollection { text = " Drone ", url =
"http://tech.firstpost.com/tag/drone", frequency = 8 });
sites.Add(new WebsiteCollection { text = "google Drone", url =
"http://tech.firstpost.com/tag/google-drones/", frequency = 2 });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
sites.Add(new WebsiteCollection { text = "apple iwork", url =
"http://tech.firstpost.com/tag/apple-iwork", frequency = 12 });
sites.Add(new WebsiteCollection { text = "tech-buzz", url =
"http://tech.firstpost.com/tag/tech-buzz", frequency = 5 });
sites.Add(new WebsiteCollection { text = "netizens", url =
"http://tech.firstpost.com/tag/netizens", frequency = 8 });
sites.Add(new WebsiteCollection { text = "selfile", url =
"http://tech.firstpost.com/tag/selfie", frequency = 20 });
sites.Add(new WebsiteCollection { text = "globalselfile", url =
"http://tech.firstpost.com/tag/nasa-globalselfie", frequency = 1 });
sites.Add(new WebsiteCollection { text = "extreme", url =
"http://www.extremetech.com/", frequency = 3 });
sites.Add(new WebsiteCollection { text = "at-t move", url =
"http://www.extremetech.com/extreme/182815-att-moves-to-acquire-directv-
to-defend-against-comcast-everyone-loses", frequency = 5 });
sites.Add(new WebsiteCollection { text = "Gearlog", url =
"http://www.gearlog.com/", frequency = 9 });
sites.Add(new WebsiteCollection { text = "Information Week", url =
"http://www.informationweek.com/", frequency = 0 });
sites.Add(new WebsiteCollection { text = "PCWorld", url =
"http://www.pcworld.com/", frequency = 11 });
sites.Add(new WebsiteCollection { text = "Tech Republic", url =
"http://techrepublic.com/", frequency = 3 });
sites.Add(new WebsiteCollection { text = "Valleywag", url =
"http://valleywag.gawker.com/", frequency = 6 });
sites.Add(new WebsiteCollection { text = "computing", url =
"http://www.extremetech.com/category/computing", frequency = 9 });
sites.Add(new WebsiteCollection { text = "WebProNews", url =
"http://www.webpronews.com/", frequency = 2 });
ViewBag.datasource = sites;
return View();
}
```

Set an event to perform operation

You can perform the event operations like MouseOver, MouseOut and Click by adding the following code example inside View page.

ASPX-CS

```
@Html.EJ().TagCloud("tagEvents").Datasource((IEnumerable<MvcApplication.M
odels.WebsiteCollection>)ViewBag.datasource).TagCloudFields(tag =>
```

```
tag.Text("text").Url("url").Frequency("frequency")).Title("Tech
sites").ClientSideEvents(event =>
event.Create("create").MouseOver("mouseover").MouseOut("mouseout").Click(
"click"))
<div id="tagCloudTarget">
<ul>
<li>mouseover</li>
<li>mouseout</li>
<li>click</li>
</ul>
</div>
@Html.EJ().DropDownList("selectControls_input").TargetID("tagCloudTarget"
).ShowCheckbox(true).CheckAll(true).ClientSideEvents(event =>
event.Change("event"))
<style type="text/css">
#tagEvents
{
margin: 0 auto;
}
</style>
<script>
function event(args)
{
tagObj = $("#tagEvents").data("ejTagCloud");
if (args.isChecked)
{
switch (args.selectedText)
{
case "mouseover": tagObj.option(args.selectedText, "mouseover"); break;
case "mouseout": tagObj.option(args.selectedText, "mouseout"); break;
case "click": tagObj.option(args.selectedText, "click"); break;
}
}
else tagObj.option(args.selectedText, null);
}
function create(args)
{
alert("Tagcloud has been created.");
}
function mouseover(args)
{
alert("Mouse pointer is hovered on " + args.value);
}
function mouseout(args)
{
alert("Mouse pointer is hovered away from " + args.value);
}
function click(args)
{
alert( args.value + " is clicked.");
}
</script>
```

When you move the mouse to latest technology (weighted) list, it is denoted in Alert box. You can execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Data-Binding

To render the TagCloud widget, it is necessary to bind the data to it in a proper way. The following sub-properties provides you a way to bind local or remote data to the TagCloud widget by binding the appropriate data fields to the corresponding options.

Fields

dataSource

The Datasource property receives Essential DataManager object and JSON object. Then assign the local JSON data or remote (URL binding) data to the TagCloud control.

Query

This property receive query to retrieve data from the table (query is same as SQL).This property is applicable only when a remote Datasource is used. Each data value is used to render an item for the TagCloud. The value set to this property is object type.

Text

It maps the corresponding text field name from the data table or JSON data that is assigned to the Datasource with the Text property of the TagCloud control. The Text value that is fetched from the table renders the value to be displayed in the TagCloud.

URL

URL field in the data table or JSON data assigned the Datasource is mapped to the URL property of the TagCloud control. The URL property defines the link to be navigated on clicking the corresponding text item.

Frequency

It maps to the Frequency field name from the data table or JSON data that is assigned to the Datasource. The frequency value that is fetched from the table should be a number to categorize the font size.

Local Binding

Local data binding allows you to map JSON data to TagCloud, that the corresponding Text, URL, and Frequency fields are assigned with a local JSON data.

Defining the Local data for TagCloud

The following steps explains you the local data binding to TagCloud widget,

C#

Copyright © 2001 - 2020 Syncfusion Inc.

```
// Add the following data list to be bind in the controller page and
define the corresponding data.
// Define local data source elements with  fields
public class WebsiteCollection
{
//TagCloud data source should have Text and Url as Mandatory
public string Text { get; set; }
public string Url { get; set; }
public int Frequency { get; set; }
}
//Refer the Model in the controller using <Applicationname>.Models;
List<WebsiteCollection> sites = new List<WebsiteCollection>();
public ActionResult Index()
{
sites.Add(new WebsiteCollection
{
Text = "Google", Url = "http://www.google.com", Frequency = 12 });
sites.Add(new WebsiteCollection { Text = "All Things Digital", Url =
"http://allthingsd.com/", Frequency = 3 });
sites.Add(new WebsiteCollection { Text = "Arts Technica", Url =
"http://arstechnica.com/", Frequency = 8 });
sites.Add(new WebsiteCollection { Text = "Business Week", Url =
"http://www.businessweek.com/", Frequency = 2 });
sites.Add(new WebsiteCollection { Text = "Yahoo", Url =
"http://in.yahoo.com/", Frequency = 12 });
sites.Add(new WebsiteCollection { Text = "Center Networks", Url =
"http://www.centernetworks.com/", Frequency = 5 });
sites.Add(new WebsiteCollection { Text = "Crave", Url =
"http://news.cnet.com/crave/", Frequency = 8 });
sites.Add(new WebsiteCollection { Text = "Crunch Gear", Url =
"http://techcrunch.com/gadgets/", Frequency = 20 });
sites.Add(new WebsiteCollection { Text = "Daily Tech", Url =
"http://www.dailytech.com/", Frequency = 1 });
sites.Add(new WebsiteCollection { Text = "Electronista", Url =
"http://www.electronista.com/", Frequency = 3 });
sites.Add(new WebsiteCollection { Text = "Engadget", Url =
"http://www.engadget.com/", Frequency = 5 });
sites.Add(new WebsiteCollection { Text = "Gearlog", Url =
"http://www.gearlog.com/", Frequency = 9 });
sites.Add(new WebsiteCollection { Text = "Information Week", Url =
"http://www.informationweek.com/", Frequency = 0 });
sites.Add(new WebsiteCollection { Text = "PCWorld", Url =
"http://www.pcworld.com/", Frequency = 11 });
sites.Add(new WebsiteCollection { Text = "Tech Republic", Url =
"http://techrepublic.com/", Frequency = 3 });
sites.Add(new WebsiteCollection { Text = "Valleywag", Url =
"http://valleywag.gawker.com/", Frequency = 6 });
sites.Add(new WebsiteCollection { Text = "Rediff", Url =
"http://in.rediff.com/", Frequency = 9 });
sites.Add(new WebsiteCollection { Text = "WebProNews", Url =
"http://www.webpronews.com/", Frequency = 2 });
ViewBag.datasource = sites;
return View();
}
```

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
// Map Local datasource to corresponding fields in TagCloud control.
@Html.EJ().TagCloud("tagcloud").Datasource((IEnumerable<WebsiteCollection
>)ViewBag.datasource)
.TagCloudFields(tag =>
tag.Text("Text").Url("Url").Frequency("Frequency"))
```

The following screenshot displays the TagCloud control with local data binding.

Remote Binding

TagCloud provides remote data binding support to populate TagCloud items and the values can be mapped to the TagCloud fields from a remote web service by using DataManager and Query.

DataManager is used to manage relational data in ASP.NET MVC. It supports CRUD (Create, Read, Update, and Destroy) in individual requests and batch. DataManager use two different classes, ej.DataManager for processing, and ej.Query for serving data. ej.DataManager communicates with data source and ej.Query generates data queries that are read by DataManager.

Configuring Remote data for TagCloud

The following script explains you the Remote data binding to TagCloud widget.

ASPX-CS

```
<%-- Configure datasource referring remote data binding section and
assign it to datasource property -- %>
@Html.EJ().TagCloud("tagcloud").Datasource(d =>
d.URL("http://mvc.syncfusion.com/Services/Northwnd.svc/").Offline(false))
.Query("ej.Query().from('Orders').take(10)").TagCloudFields(tag =>
tag.Text("CustomerID").Frequency("EmployeeID")).Title("Tagcloud Data")
```

The following screenshot displays a TagCloud control with remote data binding.

Copyright © 2001 - 2020 Syncfusion Inc.

Title Customization

ShowTitle

The TagCloud items are displayed with a Title element by default. ShowTitle is a Boolean type, which allow us to Hide or Show the Title. This property is set true by default.

How to disable title in TagCloud

The following step explains you on how to configure title for a TagCloud.

ASPX-CS

```
<%-- Configure datasource referring local data binding section and assign
it to datasource property -- %>
@Html.EJ().TagCloud("tagcloud").Datasource((IEnumerable<WebsiteCollection
>)ViewBag.datasource)
.TagCloudFields(tag => tag.Text("Text").Url("Url")
.Frequency("Frequency"))
.ShowTitle(false)
```

The following screenshot illustrates a TagCloud control when you set false to ShowTitle,

Title

TagCloud widget allows us to set a custom Title text by using the Title property. By default Title property is set to string value “Title”.

Defining title text for TagCloud

The following step explain to us on how to configure Title for a TagCloud.

ASPX-CS

```
@Html.EJ().TagCloud("tagcloud").Datasource((IEnumerable<WebsiteCollection
>)ViewBag.datasource)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.TagCloudFields(tag => tag.Text("Text").Url("Url")
.Frequency("Frequency"))
.Title("Tech sites")
```

The following screenshot illustrates the TagCloud control with customized title text.

TitleImage

TagCloud widget provides TitleImage to set an image for the title. You can set the desired image URL to TitleImage property.

Defining Title Image for TagCloud

The following step explains us to configure TitleImage for a TagCloud.

ASPX-CS

```
<%-- Configure datasource referring local data binding section and assign
it to datasource property -- %>
@Html.EJ().TagCloud("tagcloud").Datasource((IEnumerable<WebsiteCollection
>)ViewBag.datasource)
.TagCloudFields(tag => tag.Text("Text").Url("Url")
.Frequency("Frequency")).Title("Tech sites")
.TitleImage("http://js.syncfusion.com/demos/web/images/waitingpopup/js_lo
go.png")
```

1. Using CSS class you can resize the Title image content as follows.

CSS

```
<style type="text/css">
.e-title-img
{
height::35px;
width:35px;
}
</style>
```

The following screenshot illustrates the TagCloud control with customized title image.

Copyright © 2001 - 2020 Syncfusion Inc.

Appearance and Styling

Minimum and maximum Font size

The TagCloud content are set to different font sizes from minimum to maximum based on its frequency values. By default, MinFontSize is “10px” and MaxFontSize is “40px”, using these properties you can customize the minimum and maximum font sizes.

Customizing font sizes of TagCloud

The following steps explains you on how to configure font sizes for a TagCloud.

ASPX-CS

```
@Html.EJ().TagCloud("tagcloud").Datasource((IEnumerable<WebsiteCollection
>)ViewBag.datasource).TagCloudFields(tag =>
tag.Text("Text").Url("Url").Frequency("Frequency")).Title("Tech
sites").MinFontSize("20px").MaxFontSize("50px")
```

The following screenshot illustrates the TagCloud control with customized font sizes.

Copyright © 2001 - 2020 Syncfusion Inc.

Display Formats

You can set the TagCloud content display format using Format property. The Format has two variant. By default Format is set to Cloud, which displays content in TagCloud. Another one format is as List to display the content in linear format.

Defining Cloud and List format

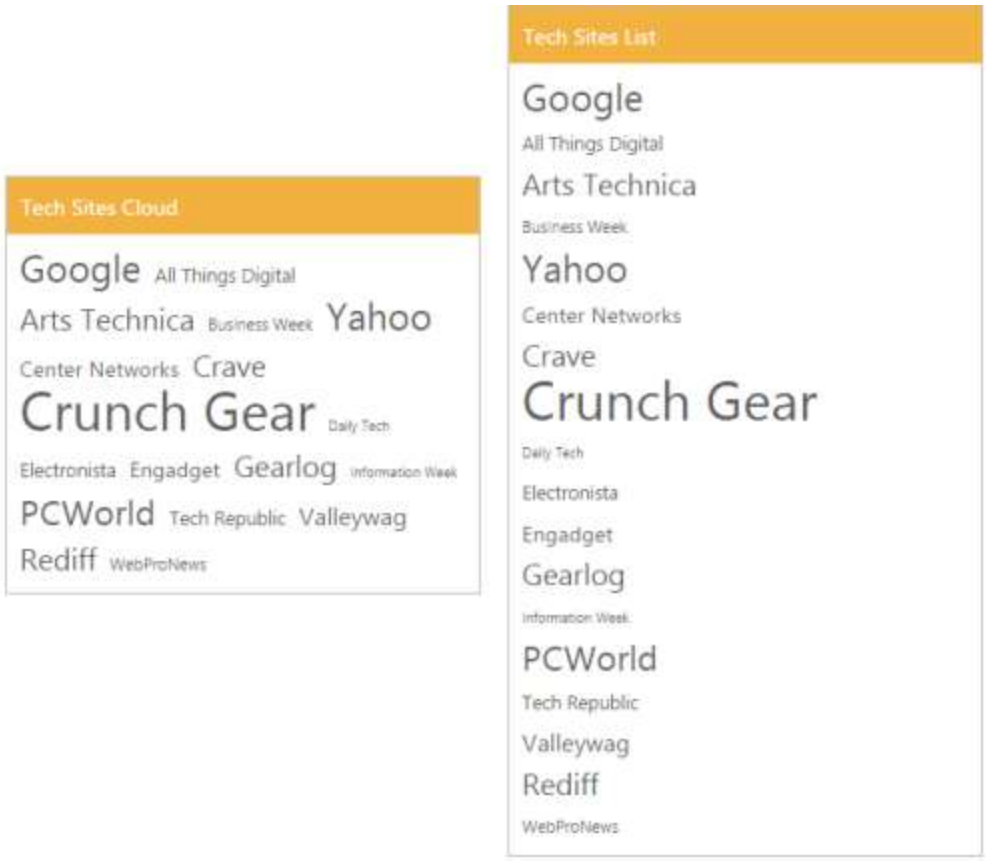
The following steps explains you to configure format for a TagCloud.

ASPX-CS

```
<%-- Configure datasource referring local data binding section and assign
it to datasource property -- %>
@Html.EJ().TagCloud("tagcloud").Datasource((IEnumerable<WebsiteCollection
>)ViewBag.datasource).TagCloudFields(tag =>
tag.Text("Text").Url("Url").Frequency("Frequency")).Title("Tech
sites").Format(Formats.Cloud)
@Html.EJ().TagCloud("tagCloud").Datasource((IEnumerable<WebsiteCollection
>)ViewBag.datasource).TagCloudFields(tag =>
tag.Text("Text").Url("Url").Frequency("Frequency")).Title("Tech
sites").Format(Formats.List)
```

The following screenshot illustrates the TagCloud control with customized formats.

Copyright © 2001 - 2020 Syncfusion Inc.



Theme

You can control the style and appearance of TagCloud based on CSS classes. To apply styles to the TagCloud control, you can refer two files, ej.widgets.core.min.css and ej.theme.min.css. When you refer ej.widgets.all.min.css file, it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these two.

By default, there are 12 themes support available for TagCloud control namely,

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

Copyright © 2001 - 2020 Syncfusion Inc.

CssClass

You can use the CssClass to customize the TagCloud appearance. Any of the CssClass properties can be used to modify look and feel of tag cloud based on the requirement. Define a CSS class as per requirement and assign the class name to CssClass property.

Configure TagCloud using CSS class

The following steps allows you to configure CssClass for TagCloud.

1. In the View page, add the below script to configure TagCloud widget.

ASPX-CS

```
<%-- Configure datasource referring local data binding section and assign
it to datasource property -- %>
@Html.EJ().TagCloud("tagcloud").Datasource((IEnumerable<WebsiteCollection
>)ViewBag.datasource)
.TagCloudFields(tag => tag.Text("Text").Url("Url")
.Frequency("Frequency")).Title("Tech sites")
.CssClass("CustomCss")
```

2. Define CSS class for customizing the TagCloud widget.

CSS

```
<style type="text/css" class="cssStyles">
/* Customize the TagCloud div element */
.CustomCss
{
background-color: #DDC;
width: 400px;
}
/* Customize the TagCloud header element */
.CustomCss .e-header.e-title
{
text-align: center;
font-weight: bold;
}
</style>
```

The following screenshot illustrates the TagCloud with customized CSS class,

RTL Support

The EnableRTL feature supports you to change the left-to-right alignment of the TagCloud widget to right-to-left (RTL). This displays the content from right-to-left in the widget. You can achieve this using EnableRTL property that is set false by default.

Enabling RTL Support

The following steps explains you the EnableRTL property in TagCloud.

ASPX-CS

```
<%-- Configure datasource referring local data binding section and assign
it to datasource property -- %>
@Html.EJ().TagCloud("tagcloud").Datasource((IEnumerable<WebsiteCollection
>)ViewBag.datasource)
.TagCloudFields(tag => tag.Text("Text").Url("Url")
.Frequency("Frequency"))
.Title("Tech sites")
.EnableRTL(true)
```

The following screenshot illustrates the TagCloud control with RTL support.

Render TagCloud from Server Side

TagCloud can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of TagCloud using TagCloud properties from code behind.

RAZOR

```
@{Html.EJ().TagCloud("tagEvents", Model).Render(); }
```

C#

```
public ActionResult Index()
{
List<WebsiteCollection> sites = new List<WebsiteCollection>();
sites.Add(new WebsiteCollection { text = "Google", url =
"http://tech.firstpost.com/tag/google", frequency = 12 });
sites.Add(new WebsiteCollection { text = "Apple", url =
"http://tech.firstpost.com/tag/apple-iwork", frequency = 3 });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
sites.Add(new WebsiteCollection { text = " Drone ", url =
"http://tech.firstpost.com/tag/drone", frequency = 8 });
sites.Add(new WebsiteCollection { text = "google Drone", url =
"http://tech.firstpost.com/tag/google-drones/", frequency = 2 });
sites.Add(new WebsiteCollection { text = "apple iwork", url =
"http://tech.firstpost.com/tag/apple-iwork", frequency = 12 });
sites.Add(new WebsiteCollection { text = "tech-buzz", url =
"http://tech.firstpost.com/tag/tech-buzz", frequency = 5 });
sites.Add(new WebsiteCollection { text = "netizens", url =
"http://tech.firstpost.com/tag/netizens", frequency = 8 });
sites.Add(new WebsiteCollection { text = "selfile", url =
"http://tech.firstpost.com/tag/selfie", frequency = 20 });
sites.Add(new WebsiteCollection { text = "globalselfile", url =
"http://tech.firstpost.com/tag/nasa-globalselfie", frequency = 1 });
sites.Add(new WebsiteCollection { text = "extreme", url =
"http://www.extremetech.com/", frequency = 3 });
sites.Add(new WebsiteCollection { text = "at-t move", url =
"http://www.extremetech.com/extreme/182815-att-moves-to-acquire-directv-
to-defend-against-comcast-everyone-loses", frequency = 5 });

}
```

Tile

Tile

The Essential Studio for ASP.NET MVC Web Tiles are simple, opaque rectangles or squares and they are arrayed on the start screen in a grid-like pattern. Tapping or selecting a Tile, launches the app or does some other action that is represented by the Tile. Tiles are arranged in a group separated by columns that looks like a start screen of a device and it can be either static or live.

Getting Started

This section explains briefly on how to create a Tile control in your application.

Copyright © 2001 - 2020 Syncfusion Inc.

Create your first Tile in MVC

The Essential Studio for ASP.NET MVC Web Tiles are simple, opaque rectangles or squares that are arrayed on the Start screen in a grid-like pattern and it can be either static or live. Tapping or selecting a Tile launches the app or other experience that is represented by the Tile.

Create Tile Widget

The following steps guide you to add group of Tiles for creating a home page that displays all the available applications.

1. You can create an MVC Project and add necessary assemblies, styles and scripts to it. Refer MVC-Getting Started.
2. To add a Tile control, call Tile helper. You can specify the tile name, size and image URL as follows.
3. Add the following code example to the corresponding view page.

ASPX-CS

```
@Html.EJ().Tile("tile1")
.TileSize(TileSize.Medium)
.ImageUrl("http://js.syncfusion.com/ug/web/content/tile/map.png")
.Text("Maps")
```

4. Run the application to render the following output.

In this scenario, a home page is designed using tile for easy navigation. Therefore, you require many different sizes of tiles aligned in a grid-like manner. To align the tiles automatically, define the necessary tile elements inside the wrapper element that contains a ‘column’ class. You can define all columns elements under the wrapper element with ‘group’ class to make ‘n’ number of tiles as a grouped tile.

Refer to the following code example.

ASPX-CS

```
<div id="tile" style="margin-top: 45px;">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div class="e-tile-group">
<div class="e-tile-column">
@Html.EJ().Tile("tile1").ImagePosition(TileImagePosition.Fill).TileSize(T
ileSize.Medium).ImageUrl("http://js.syncfusion.com/ug/
web/content/tile/people_1.png").Text("People")
<div class="e-tile-small-col-2">
@Html.EJ().Tile("tile2").ImagePosition(TileImagePosition.Center).TileSize
(TileSize.Small).ImageUrl("http://js.syncfusion.com/ug/web/content/tile/a
lerts.png")
@Html.EJ().Tile("tile3").ImagePosition(TileImagePosition.Center).TileSize
(TileSize.Small).ImageUrl("http://js.syncfusion.com/ug/web/content/tile/b
ing.png")
@Html.EJ().Tile("tile4").ImagePosition(TileImagePosition.Center).TileSize
(TileSize.Small).ImageUrl("http://js.syncfusion.com/ug/web/content/tile/c
amera.png")
@Html.EJ().Tile("tile5").ImagePosition(TileImagePosition.Center).TileSize
(TileSize.Small).ImageUrl("http://js.syncfusion.com/ug/
web/content/tile/messages.png")
</div>
@Html.EJ().Tile("tile6").ImagePosition(TileImagePosition.Center).TileSize
(TileSize.Medium).ImageUrl("http://js.syncfusion.com/ug/web/content/tile/
games.png").Text("Play")
@Html.EJ().Tile("tile7").TileSize(TileSize.Medium).ImageUrl("http://js.sy
ncfusion.com/ug/web/content/tile/map.png").Text("Maps")
</div>
<div class="e-tile-column">
@Html.EJ().Tile("tile9").ImagePosition(TileImagePosition.Fill).TileSize(T
ileSize.Medium).ImageUrl("http://js.syncfusion.com/ug/web/content/tile/pe
ople_2.png").Text("People")
@Html.EJ().Tile("tile10").ImagePosition(TileImagePosition.Center).TileSiz
e(TileSize.Medium).ImageUrl("http://js.syncfusion.com/ug/web/content/tile
/pictures.png").Text("Photo")
@Html.EJ().Tile("tile11").ImagePosition(TileImagePosition.Center).TileSiz
e(TileSize.Wide).ImageUrl("http://js.syncfusion.com/ug/web/content/tile/w
eather.png").Text("Weather")
</div>
</div>
</div>
```

Run the application to render the following output.

Tile dependencies

This section deals with the dependency files for Tile control. The file ej.web.all.min.js is a mass collection of Web Controls. When you are using this file, you can skip this section. Otherwise, refer to the following mentioned script files to render the Tile control.

Copyright © 2001 - 2020 Syncfusion Inc.

File	Description/Usage
ej.core.min.js	Must be referred always before using all the Web controls.
ej.data.min.js	Must be referred while using data binding feature in Web controls that is used to handle data manger operation.
ej.touch.min.js	Must be referred for touch events supports.
ej.tile.min.js	Must be referred to render Tile control and to handle Tile specific operations.

Image Configuration

ImagePosition property is used to adjust the position of Tile image at the Center on initialization. The possible values for the ImagePosition are as follows

1. Center
2. TopCenter
3. BottomCenter
4. RightCenter
5. LeftCenter
6. TopLeft
7. TopRight
8. BottomRight
9. BottomLeft
10. Fill

ImageUrl property is used to set the background image for Tile, where the image is given in the path specified by ImageUrl property.

Refer to the following code examples.

ASPX-CS

```
@Html.EJ().Tile("tile").Text("Weather").ImagePosition(TileImagePosition.C
enter).TileSize(TileSize.Wide).ImageUrl("http://js.syncfusion.com/UG/web/
Content/tile/Weather_2.png ")
```

You can give images for each tile through CSS classes by using ImageClass property. You can define your desired styles in the specified class.

Refer to the following code examples.

ASPX-CS

```
@Html.EJ().Tile("tile").Text("Pictures").ImagePosition(TileImagePosition.
Center).TileSize(TileSize.Medium).ImageClass("pictures")
<style>
.pictures
{
background:
url("http://js.syncfusion.com/UG/web/Content/tile/pictures.png ");
background-size:30px 30px;
}
</style>
```

Text Configuration

ShowText property is used to show or hide the Tile caption. By default, the ShowText property is to true on initialization.Text property is used to set the caption of a Tile as a Text on initialization. TextAlignment property is used to align the Tile text as Normal on initialization. The possible position values for TextAlignment are as follows:

1. Normal
2. Left
3. Right
4. Center

Refer to the following code examples.

ASPX-CS

```
@Html.EJ().Tile("tile").Text("Camera").TextAlignment(TextAlignment.Center
).ImagePosition(TileImagePosition.Center).TileSize(TileSize.Medium).Image
Url("http://js.syncfusion.com/UG/web/Content/tile/camera.png")
```

Template Support

ImageTemplateId property is used to customize the image of Tile with template feature by setting the id. CaptionTemplateId property is used to customize the text of Tile with template feature by setting the id.

Copyright © 2001 - 2020 Syncfusion Inc.

Refer to the following code examples.

Add the following code example for MVC samples

CSS

```
<style>
#appImage
{
background-image:
url("http://js.syncfusion.com/UG/mobile/content/google.png");
background-position: center center;
background-repeat: no-repeat;
background-size: 50% auto;
display: table-cell;
width: 45%;
}
.tileMargin
{
display: table-cell;
padding-top: 25px;
}
.e-tile-template
{
display: table;
height: 100%;
width: 100%;
}
</style>
```

ASPX-CS

```
@Html.EJ().Tile("tile").ImageTemplateId("imageTemplate").ImagePosition(Ti
leImagePosition.Fill).TileSize(TileSize.Wide).Caption(caption => {
caption.Enabled(true); caption.Text("Windows Store"); })
<div id="imageTemplate">
<div id="appImage">
</div>
<div class="tileMargin">
<span class="caption">Google Search</span><br />
<span class="description">The world's information</span><br />
<span class="sub">Free</span>
</div>
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Configure Badge

The Badge property handles badge specific functionalities like enable or disable the badge and setting badge value for Tile.

Enabled property enables or disables the badge for a Tile. The Tile renders with hidden badge when it is set to false.

The Value property is used to set the badge value to a Tile. By default, the Value is set to 1 on initialization. The Text property is used to set the text instead of number for Tile badge. The MaxValue property is used to set the maximum badge value to a Tile. When you set the badge value greater than MaxValue, it shows maximum value in badge with plus symbol. The MinValue property is used to set the minimum badge value to a Tile. When you set the badge value less than MinValue, it shows minimum value in badge.

Refer to the following code examples.

ASPX-CS

```
@Html.EJ().Tile("tile").ImageUrl("http://js.syncfusion.com/UG/Web/Content
/tile/messages.png").Badge(badge => {
badge.Enabled(true).MaxValue(80).MinValue(10).Value(88);
}).ImagePosition(TileImagePosition.Center).TileSize(TileSize.Medium)
```

LiveTile Configuration

Live Tiles are used to display the current or up to date information like scores, stocks, weather, etc. You can enable Live Tile using enabled property by setting it to true. Type property allows you to specify the type of animation while updating the information in Tile. There are three types of Tile animation supported: Flip, Slide and Carousel.

ImageUrl property sets background image for Live Tile. This property accepts array values so you can specify the image url's for all the Tiles that are used in single Live Tile.

You can specify time interval for each Tile update/animation using UpdateInterval property. Time interval is given in milliseconds. The default value is 2000.

Refer to the following code examples.

ASPX-CS

```
@Html.EJ().Tile("tile").LiveTile(live => {
live.Enabled(true).Type(LiveTileType.Flip).UpdateInterval(2500).ImageUrl(
new string[] {
"http://js.syncfusion.com/UG/Web/Content/tile/people_1.png","http://js.sy
ncfusion.com/UG/Web/Content/tile/people_2.png"});
}).ImagePosition(TileImagePosition.Fill).TileSize(TileSize.Medium)
```

Copyright © 2001 - 2020 Syncfusion Inc.

In ImageTemplateId property, you can give Live Tile images outside the Tile rendering. To achieve this, you are required to give image content inside the element where the path is specified by template id. You can update the ImageTemplateId dynamically through updateTemplateID public method.

Refer to the following code examples.

ASPX-CS

```
@Html.EJ().Tile("tile").LiveTile(live => {
live.Enabled(true).ImageTemplateId(new string[] { "temp1", "temp2" });
}).ImagePosition(TileImagePosition.Fill).TileSize(TileSize.Medium)
<div id="temp1" style="background-
image:url('http://js.syncfusion.com/ug/web/content/tile/people_1.png');
width:100%; height:100%;">
</div>
<div id="temp2" style="background-image:
url('http://js.syncfusion.com/ug/web/content/tile/people_2.png');
width:100%; height:100%;">
</div>
```

You can specify the array of images for Live Tile through CSS classes by using ImageClass property and you can define the desired styles in the specified class.

Refer to the following code examples.

ASPX-CS

```
@Html.EJ().Tile("tile").LiveTile(live => {
live.Enabled(true).ImageClass(new string[] { "people1", "people2" });
}).ImagePosition(TileImagePosition.Fill).TileSize(TileSize.Medium)
<style>
.people1
{
background-image:
url('http://js.syncfusion.com/UG/Web/Content/tile/people_1.png');
}
.people2
{
background-image:
url('http://js.syncfusion.com/UG/Web/Content/tile/people_2.png');
}
</style>
```

Customize size

You can customize the size of the Tile by using TileSize property. The following built-in tile sizes are supported.

1. Medium
2. Small
3. Large
4. Wide

The default TileSize value is set to Small.

Copyright © 2001 - 2020 Syncfusion Inc.

Refer to the following code examples.

ASPX-CS

```
@Html.EJ().Tile("tile").Text("Pictures").ImagePosition(TileImagePosition.
Center).TileSize(TileSize.Medium).ImageUrl("http://js.syncfusion.com/UG/W
eb/Content/tile/pictures.png ")
```

Add Group Tiles

To make a Tile as grouped tile, you can use the following mentioned pre-defined classes.

Class Name	Explanation
e-tile-group	To group the column elements
e-tile-column	To align the tile in column manner
e-tile-small-col-2	To align the small size tiles

To render group tile, refer to the following code example.

ASPX-CS

```
<div class="group">
<div class="column">
<!– Add tile control here -->
</div>
</div>
```

To render column grouped tile, you need to render the number of tiles inside a element with class ‘column’. Then that column group element is appended to a with class ‘group’.

To render small-col-2 grouped tile, you need to render the number of tiles inside a element with class ‘small-col-2’. Then that small-col-2 group element is appended to a with class ‘column’. Then you need to append those column inside the main group element.

Refer the following code examples.

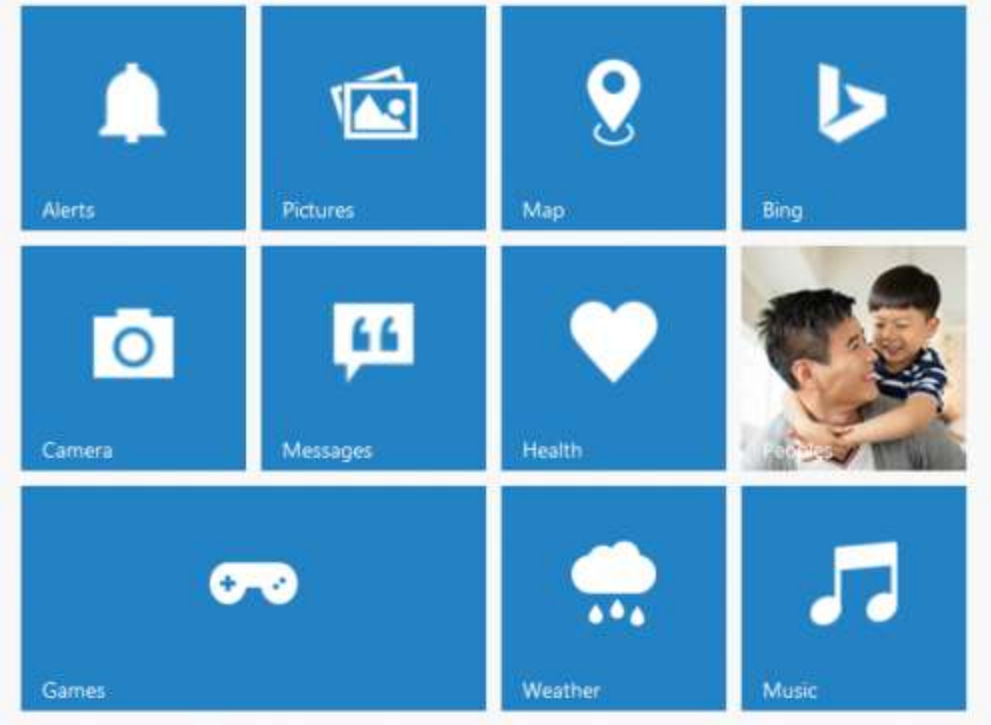
ASPX-CS

```
<div class="e-tile-group">
<div class="e-tile-column">
@Html.EJ().Tile("tile1").ImageUrl("http://js.syncfusion.com/UG/Web/Conten
t/tile/alerts.png").TileSize(TileSize.Medium).Caption(caption =>
caption.Enabled(true).Text("Alert"))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().Tile("tile2").ImageUrl("http://js.syncfusion.com/UG/Web/Conten
t/tile/pictures.png").TileSize(TileSize.Medium).Caption(caption =>
caption.Enabled(true).Text("pictures"))
@Html.EJ().Tile("tile3").ImageUrl("http://js.syncfusion.com/UG/Web/Conten
t/tile/camera.png").TileSize(TileSize.Medium).Caption(caption =>
caption.Enabled(true).Text("Camera"))
@Html.EJ().Tile("tile4").ImageUrl("http://js.syncfusion.com/UG/Web/Conten
t/tile/messages.png").TileSize(TileSize.Medium).Caption(caption =>
caption.Enabled(true).Text("Messages"))
@Html.EJ().Tile("tile5").ImageUrl("http://js.syncfusion.com/UG/Web/Conten
t/tile/games.png").TileSize(TileSize.Wide).Caption(caption =>
caption.Enabled(true).Text("Games"))
</div>
<div class="e-tile-column">
@Html.EJ().Tile("tile6").ImageUrl("http://js.syncfusion.com/UG/Web/Conten
t/tile/map.png").TileSize(TileSize.Medium).Caption(caption =>
caption.Enabled(true).Text("Map"))
@Html.EJ().Tile("tile7").ImageUrl("http://js.syncfusion.com/UG/Web/Conten
t/tile/bing.png").TileSize(TileSize.Medium).Caption(caption =>
caption.Enabled(true).Text("Bing"))
@Html.EJ().Tile("tile8").ImageUrl("http://js.syncfusion.com/UG/Web/Conten
t/tile/favs.png").TileSize(TileSize.Medium).Caption(caption =>
caption.Enabled(true).Text("Health"))
@Html.EJ().Tile("tile9").ImageUrl("http://js.syncfusion.com/UG/Web/Conten
t/tile/people_2.png").TileSize(TileSize.Medium).ImagePosition(TileImagePo
sition.Fill).Caption(caption => caption.Enabled(true).Text("Peoples"))
@Html.EJ().Tile("tile10").ImageUrl("http://js.syncfusion.com/UG/Web/Conte
nt/tile/weather.png").TileSize(TileSize.Medium).Caption(caption =>
caption.Enabled(true).Text("Weather"))
@Html.EJ().Tile("tile11").ImageUrl("http://js.syncfusion.com/UG/Web/Conte
nt/tile/music.png").TileSize(TileSize.Medium).Caption(caption =>
caption.Enabled(true).Text("Music"))
</div>
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.



Styles and Appearance

Styles and appearance of Tile works based on CSS class. You need two style sheets to apply styles to the Tile control: ej.widget.core.min.css and ej.theme.min.css.

Customize styles

To change the color or design of the Tile control appearance, you can override default styles of the Tile control by using its class names. The following are the specific class names to modify styles and appearance in the Tile.

File	Description/Usage
e-tile	It is the root class of the Tile.
e-child-tile	It class is applied to the child of the Tile.
e-enabled-text	It class is applied to the text of Tile when text element is active
e-tile-text	It class is applied to the text of Tile
e-tile-image	It class is applied to image of Tile
e-tile-template	It class is applied to tile image when tile has image template id property.
e-live-tile-text	It class is applied to text elements of individual live tile in the Tile control.
e-template-caption	This class is applied to tile caption when tile has caption template id property.

Copyright © 2001 - 2020 Syncfusion Inc.

How to

Render TileView from Code behind

TileView can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side

The following code illustrates the initialization of TileView properties in the controller.

C#

```
//Namespace to get the JavaScript (TileView) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class TileController: Controller
{
public ActionResult TileFeatures()
{
//Initializing the TileView model
TileProperties tileObj = new TileProperties();
//Initializing the other properties
tileObj.TileSize = Syncfusion.JavaScript.TileSize.Medium;
tileObj.ImageUrl =
"http://js.syncfusion.com/ug/web/content/tile/alerts.png";
tileObj.Text = "Alerts";
//Passing TileView properties using the ViewData
ViewData["TileModel"] = tileObj;
return View();
}
}
}
```

Binding the TileView properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().Tile("Tile1",
(Syncfusion.JavaScript.Models.TileProperties)ViewData["TileModel"]).Rende
r();
}
```

TimePicker

TimePicker

The Essential ASP.NET MVC TimePicker control allows users to select a time value. The available times can be restricted to a range by setting minimum and maximum time values. The TimePicker sets the time as a mask to prevent users from entering invalid values.

Key Features

- Time format: Supports all valid time formats.
- Localization: Supports localization with different cultures.
- Picker and editor: Allows users to pick or edit the time.

Copyright © 2001 - 2020 Syncfusion Inc.

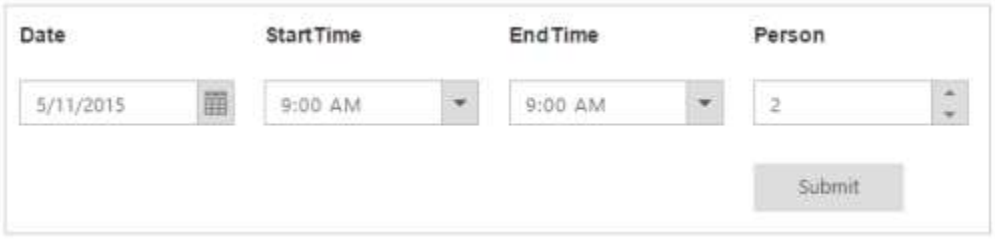
- Persist: Supports state maintenance when refreshing the page.
- RTL: Supports right-to-left alignment in the TimePicker control.
- Themes: The TimePicker control features 12 built-in themes (six flat and six with gradient effects) and also supports custom skin options for user-defined themes.

Getting Started

This section explains briefly about how to create a TimePicker in your application with ASP.NET MVC.

Create your first TimePicker in MVC

Essential MVCTimePicker provides support to display the time in your web page and allows you to pick a time from the list. In this section you can learn how to customize TimePickers in a real-time application. The following example shows you how to use the TimePicker control to book a hotel dining table booking application, within a limited time, in any day.



The above screenshot illustrates the functionality of a TimePicker, with a time range from morning to evening. You can select the time to book a table ranging from 9.00 AM to 10.00 PM in the current day. This avoids selecting a time prior to that day.

Create a TimePicker

Essential MVC TimePicker widget has built-in features such as keyboard navigation, other time navigation with animations, and flexible APIs. You can easily create the TimePicker widget using simple TimePicker element as follows.

1. You can create an MVC Project and add necessary assemblies and scripts to it. Refer MVC-Getting Started Documentation.
2. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget*@
<table>
<tr>
<td class="table-cell">Date</td>
<td class="table-cell">Time</td>
<td class="table-cell">Person</td>
</tr>
<tr>
<td class="table-cell">
<span class="inner-display">
@Html.EJ().DatePicker("startDate")
</span>
</td>
<td class="table-cell">
<span class="inner-display">
```

```
@Html.EJ().TimePicker("timeStart")
</span>
</td>
<td class="table-cell">
<span class="inner-display">
@Html.EJ().NumericTextbox("NumericTextbox").Value("0")
</span>
</td>
</tr>
<tr>
<td></td>
<td></td>
<td class="table-cell">
<span class="inner-display">
@Html.EJ().Button("Submit").Width("100px").Size(ButtonSize.Small).Text("S
ubmit").ClientSideEvents(s => s.Click("button"))
</span>
</td>
</tr>
</table>
```

3. Add the following styles to show the TimePicker control in horizontal order in the Content folder.

CSS

```
<style type="text/css" class="cssStyles">
.table-cell
{
width: 70px;
height: 10px;
font-weight: bold;
padding: 10px;
}
.inner-display
{
display: inline-block;
}
</style>
```

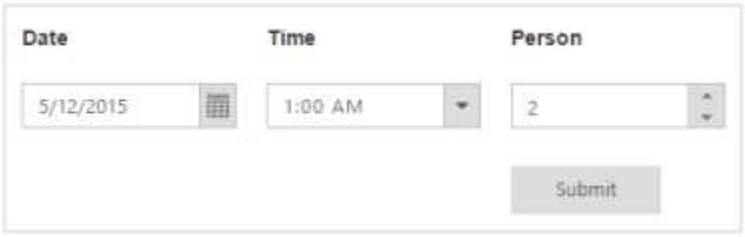
4. Add the following code to the Layout page for DatePicker and TimePicker initialization.

JS

```
<script type="text/javascript">
function button()
{
alert("You have Successfully booked");
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

5. The following screenshot displays the output for the above code.



6. Click the submit button in the application to render the following output.

Set Min and Max Date

In a real-time scenario, the booking is open only for a limited time. You can select a date and time from the given range using the properties MinDate, MinTime and MaxDate, MaxTime that enables only the dates and times ranging between the MinDate, MinTime and MaxDate, MaxTime in the DatePicker and TimePicker.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget*@
<table>
<tr>
<td class="table-cell">Date</td>
<td class="table-cell">StartTime</td>
<td class="table-cell">EndTime</td>
<td class="table-cell">Person</td>
</tr>
<tr>
<td class="table-cell">
<span class="inner-display">
@Html.EJ().DatePicker("startDate").Value("5/11/2015").MinDate("5/11/2015"
).MaxDate("6/11/2015")
</span>
```

```
</td>
<td class="table-cell">
<span class="inner-display">
@Html.EJ().TimePicker("timeStart").MinTime("9:00 AM").MaxTime("10:00
PM").Interval(60).ClientSideEvents(e => e.Select("selectedStartTime"))
</span>
</td>
<td class="table-cell">
<span class="inner-display">
@Html.EJ().TimePicker("timeEnd").MinTime("9:00 AM").MaxTime("10:00
PM").Interval(60)
</span>
</td>
<td class="table-cell">
<span class="inner-display">
@Html.EJ().NumericTextbox("NumericTextbox").Value("0")
</span>
</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td class="table-cell">
<span class="inner-display">
@Html.EJ().Button("Submit").Width("100px").Size(ButtonSize.Small).Text("S
ubmit").ClientSideEvents(s => s.Click("button"))
</span>
</td>
</tr>
</table>
```

2. Add the following styles to show the TimePicker control in horizontal order in the Content folder.

CSS

```
<style type="text/css" class="cssStyles">
.table-cell
{
width: 70px;
height: 10px;
font-weight: bold;
padding: 10px;
}
.inner-display
{
display: inline-block;
}
</style>
```

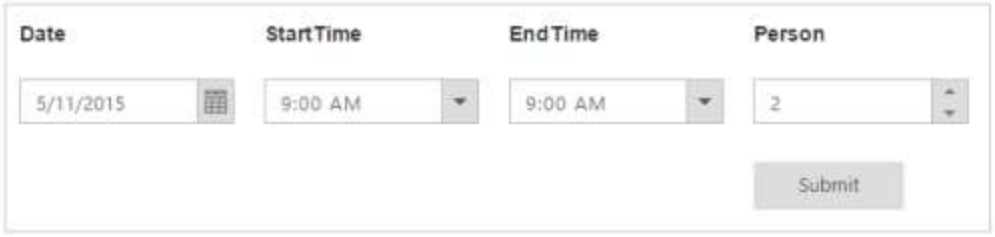
3. Add the following code to the Layout page for DatePicker and TimePicker initialization.

Copyright © 2001 - 2020 Syncfusion Inc.

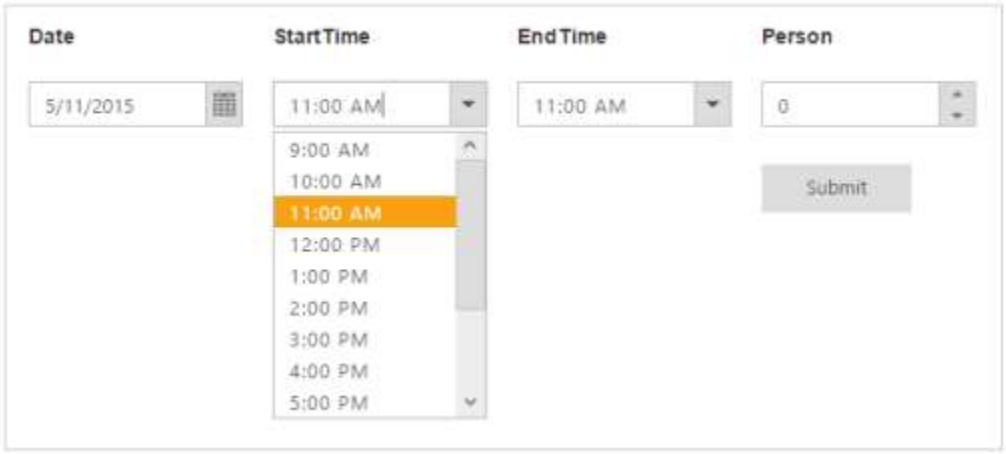
JS

```
<script type="text/javascript">
function selectedStartTime(sender) {
var selDate = sender.value; // mentions the selected time.
minTimepicker = $("#timeEnd").data("ejTimePicker");// creating TimePicker
object
minTimepicker.setModel({ "minTime": selDate });// setting minTime
property through setModel of TimePicker object.
}
function button()
{
alert("You have Successfully booked");
}
</script>
```

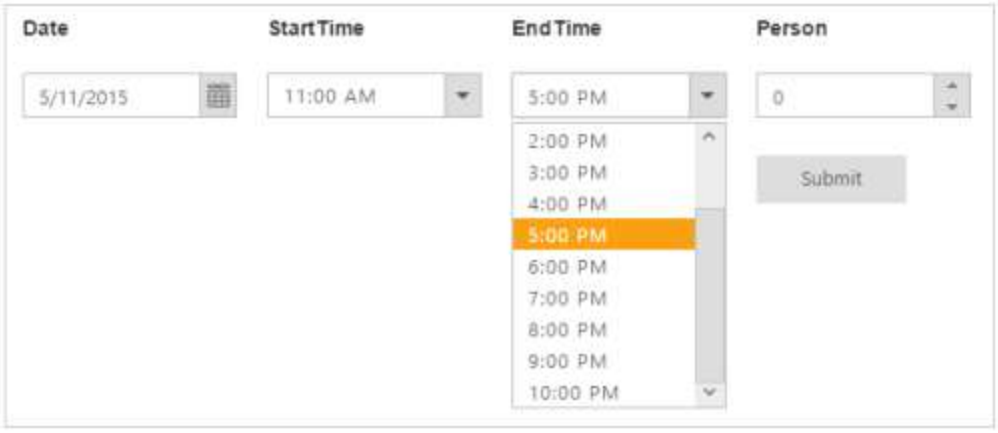
4. The following screenshot displays the output for the above code.



You can select the Start time in the first TimePicker and select the End time within the given range. The second TimePicker start value is based on the first TimePicker's selected value. This is illustrated in the following screenshots.



Copyright © 2001 - 2020 Syncfusion Inc.



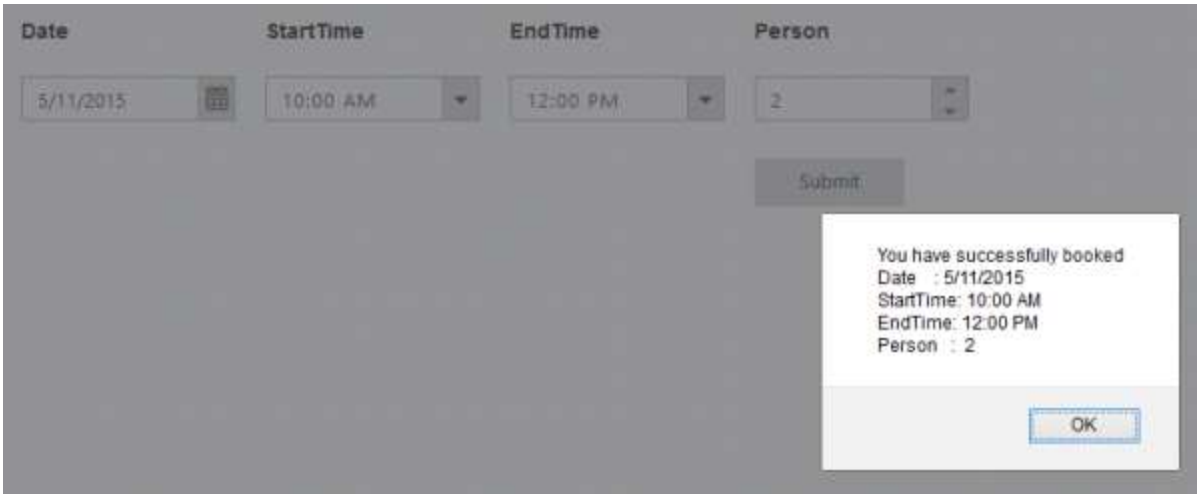
Display Reserved Time

An acknowledgment message appears when you click the Submit button.

You can specify the alert message in the script as follows.

JS

```
<script type="text/javascript">
function button()
{
var a = $('#startDate').val();
var b = $('#timeStart').val();
var d = $('#timeEnd').val();
var c = $('#NumericTextbox').val();
alert("You have successfully booked\nDate    : " + a + "\nStartTime: " +
b + "\nEndTime: " + d + " \nPerson   :  " + c);
}
</script>
```



TimePicker Customization

The TimePicker provides support to display a TimePicker in your web page and allows you to pick a time from it.

Copyright © 2001 - 2020 Syncfusion Inc.

Creating TimePicker Widget

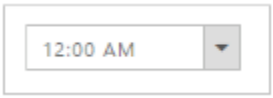
The following steps explains you to create a TimePicker widget.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget*@
@Html.EJ().TimePicker("time")
```

2. The following screenshot illustrates you a default TimePicker.



TimePicker Control

Localization

You can globalize the TimePicker, so that users of different cultures can make use of it and post their content. For your convenience, you can format the TimePicker control to your culture. When your blog is in your culture, the viewers of your culture can understand about your company and its products. You can achieve localization using the “Locale” property.

More than 350 culture specific files are available to localize the time. To know more about EJ globalize support, please refer the below link

http://help.syncfusion.com/js/localization

Note: Seven culture-specific script files are available in the below specified location. For all other culture files, please download from the GitHub location.

(installed location)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n
For example, If you have installed the Essential Studio package within C:\Program Files (x86), then navigate to the below location, C:\Program Files (x86)\Syncfusion\Essential Studio\{{ site.releaseversion }}\JavaScript\assets\scripts\i18n

The following code example is used to set TimePicker in Spanish language.

Enabling Localization Support

The following steps explains you on how to enable Locale property for TimePicker.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget with Spanish culture*@
@Html.EJ().TimePicker("time").Locale("es-ES")
```

Copyright © 2001 - 2020 Syncfusion Inc.

Execute the above code to render the following output.

TimePicker with es-ES Localization

Behavior Settings

Set value of the TimePicker widget

You can use Value property to set default time for the TimePicker.

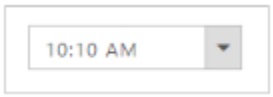
The following steps explains you on how to set the default value of the TimePicker.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget with given time value*@
@Html.EJ().TimePicker("time").Value("10:10 AM")
```

Execute the above code to render the following output.



TimePicker default value

Enable/Disable TimePicker widget

TimePicker widget provides you an option to enable /disable the widget. You can disable the TimePicker by setting the “Enabled” property value as false.

The following steps explain you to enable/disable property in TimePicker widget.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render disabled TimePicker widget*@
@Html.EJ().TimePicker("time").Enabled(false)
```

Disabled TimePicker widget

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.

Restrict editing

TimePicker widget provides ReadOnly property to disable editing in the control. Therefore you can only read the value set to TimePicker and cannot modify it. The Value property allows you to set the default value for TimePicker widget when it is created.

Configure TimePicker textbox to restrict editing

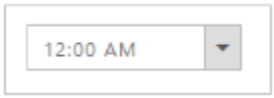
The following steps allows you to disable editing value in TimePicker.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget*@
@Html.EJ().TimePicker("time").ReadOnly(true)
```

The following screenshot illustrates a TimePicker textbox configured to restrict editing.



,

TimePicker with PopUp button and enable ReadOnly property

Rounded Corner

You can customize the shape of the TimePicker widget from regular rectangular shape to rounded rectangle shape using ShowRoundedCorner property that is set to false by default.

Configure Rounded corner to TimePicker Text box

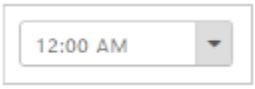
The following steps explain you to change the edges of the textbox to rounded corner.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget with rounded corner*@
@Html.EJ().TimePicker("time").ShowRoundedCorner(true)
```

The following screenshot illustrates a TimePicker when ShowRoundedCorner is set to “true”.



Rounded corner of TimePicker Textbox

Scaling

TimePicker widget provides you options to change its height, width and also to change popup height and width.

Change TimePicker widget Height and Width

You can use Height and Width property to customize TimePicker width and height.

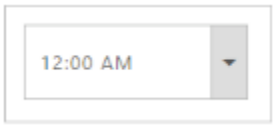
Copyright © 2001 - 2020 Syncfusion Inc.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget with specified height and width*@
@Html.EJ().TimePicker("time").Height("50px").Width("150px")
```

Execute the above code to render the following output.



Changing Width and Height of the TimePicker.

Changing TimePicker PopupHeight and PopupWidth

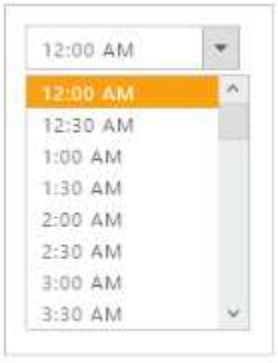
You can use PopupHeight and PopupWidth property to customize TimePicker width and height.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget with specified popup height and width*@
@Html.EJ().TimePicker("time").PopupHeight("170px").PopupWidth("150px")
```

Execute the above code to render the following output.



Changing popup height and width

State persistence

TimePicker widget provide options to maintain the selected value after you refresh the page by using EnablePersistence property.

Steps to use State persistence of the TimePicker

The following steps explains you to use EnablePersistence property.

1. Add the following code to the corresponding view page to render the TimePicker.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget*@
@Html.EJ().TimePicker("time").Value("10:10 AM").EnablePersistence(true)
```

Strict mode of the TimePicker

TimePicker widget provides you an option to set default value when there is no default value between MinTime and MaxTime by using EnableStrictMode property.

Steps to use EnableStrictMode property

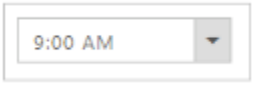
The following steps explains you to use EnableStrictMode property.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget with specifies min and max time*@
@Html.EJ().TimePicker("time").Value("09:00 AM").MinTime("10:00
AM").MaxTime("09:00 PM").EnableStrictMode(true)
```

Execute the above code to render the following output.



Using EnableStrictMode property

Interval

TimePicker widget provides you an option to change the interval of the hour, minute and seconds.

Steps to change the Time interval of the TimePicker control

The following steps explains you to change the Time Interval of the TimePicker.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget*@
@Html.EJ().TimePicker("time").TimeFormat("hh:mm:ss
tt").HourInterval(2).MinutesInterval(60).SecondsInterval(20)
```

Range

TimePicker widget provide options to set the Range (MinTime & MaxTime) for the time.

Steps to change MinTime & MaxTime of the TimePicker

The following steps explains you to change the Range of the TimePicker.

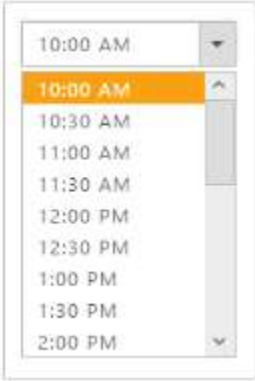
1. Add the following code to the corresponding view page to render the TimePicker.

Copyright © 2001 - 2020 Syncfusion Inc.

HTML

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget with Min and Max time*@
@Html.EJ().TimePicker("time").MinTime("10:00 AM").MaxTime("10:00 PM")
```

Execute the above code to render the following output.



Range for TimePicker widget

Time Format

TimePicker widget provides you an option to change the TimeFormat property.

Steps to change Time Format of TimePicker widget

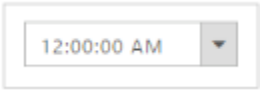
The following steps explains you to change the time format for the TimePicker.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget with time format*@
@Html.EJ().TimePicker("time").TimeFormat("hh:mm:ss tt")
```

Execute the above code to render the following output.



TimePicker with TimeFormat.

RTL

This feature supports to change the left-to-right alignment of the TimePicker widget to right-to-left when set the EnableRTL as true. By default EnableRTL value is set as “false”. The custom template TimePicker also supports RTL.

Enabling Right-To-Left Support

The following steps explains you in enabling the right-to-left property for the TimePicker.

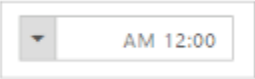
1. Add the following code to the corresponding view page to render the TimePicker.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget with right to left appearance*@
@Html.EJ().TimePicker("time").EnableRTL(true)
```

The following screenshot illustrates a TimePicker control when EnableRTL is set to “true”



TimePicker template with RTL support

Keyboard Interaction

You can use Keyboard shortcut keys as an alternative to the mouse on using TimePicker widget. TimePicker widget allows you to perform all kinds of actions using keyboard shortcuts. For enabling the keyboard navigation, we need to set the access key to TimePicker control by using HtmlAttributes property. The HtmlAttributes receives the IDictionary object. The IDictionary represents a generic collection of key/value pairs.

The various keyboard shortcuts available within the TimePicker widget are discussed in the following table.

List of keyboard shortcuts

Shortcut Key	Description
Access keyÂ + j	Focuses into Timepicker widget
Alt + Down	Opens/Hides the popup
Right/Left	Moves to adjacent part
Up	Increments the value
Down	Decrements the value

When popup is open

List of keyboard shortcuts

Shortcut Key	Description
Up	Selects the previous time
Down	Selects the next time.
Home/End	Moves to the first / last item
Esc	Closes the popup

Copyright © 2001 - 2020 Syncfusion Inc.

Configure Keyboard Interaction

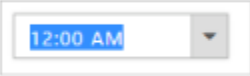
The following steps explains you on how to enable keyboard interaction for the TimePicker widget with access key as “j”. We can set the any other key as access key in TimePicker control.

1. Add the following code to the corresponding view page to render the TimePicker.

ASPX-CS

```
@*Add the following code example to the corresponding CSHTML page to
render TimePicker widget*@
@{IDictionary<string, object> parameters = new Dictionary<string,
object>();
parameters.Add("accesskey", "j");
}
@Html.EJ().TimePicker("time").HtmlAttributes(parameters)
```

2. Run the code sample, press Access key + J to focus in the TimePicker widget that enables it and you can navigate using arrow keys and Esc key to close the popup.



TimePicker focused with keyboard shortcut

How to?

Render TimePicker from Code behind

TimePicker can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of TimePicker properties in the controller.

C#

```
//Namespace to get the JavaScript (TimePicker) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class TimePickerController : Controller
{
// GET: TimePicker
public ActionResult TimePickerFeatures()
{
//Initializing the TimePicker model
TimePickerProperties TimeObj = new TimePickerProperties();
//Initializing the datasource and other properties
TimeObj.Width = "300px";
TimeObj.Interval= 60;
TimeObj.Value = "10:10 AM";
//Passing TimePicker properties using the ViewData
ViewData["TimeModel"] = TimeObj;
return View();
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
```

Binding the TimePicker properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().TimePicker("searchCustomer",(Syncfusion.JavaScript.Models.TimeP
ickerProperties)ViewData["TimeModel"]).Render();
}
```

ToggleButton

ToggleButton

The Toggle Button allows you to perform the toggle option by using checked and unchecked state. This ToggleButton can be helpful to you to check their states. Toggle Button is used as normal click able button, submitting form data, resetting the form data to its initial value. According to the usage of button, you can render the Toggle Button in three types by using the type property.

Key Features

- Trendy Look : Rich Appearance with Theme Support
- RTL : Supports for Right to Left alignment
- Text and Image : Supports both text and image as Toggle Button content in both On/Off state
- Built-in Icon :Supports the built-in icon libraries
- Easy Customization: The customization of button control to any form is made simple

Getting Started

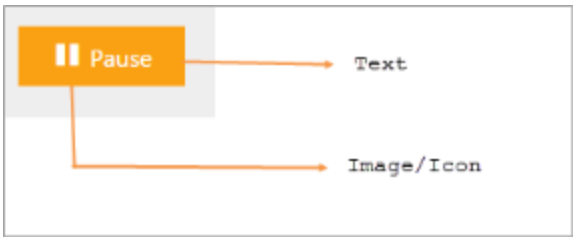
This section explains briefly about how to create a ToggleButton in your ASP.NET MVC application.

Create your first Toggle Button in MVC

The Toggle Button control displays both text and images. The text displayed on the Toggle Button is contained in the Text property. The Toggle Button control display images using the SpriteCssClass and ImagePosition properties. The Toggle Buttons has theme support also.

The following screenshot illustrates a Toggle Button control.

Toggle Button in OFF state_



Toggle Button in ON state

Create a Toggle Button

Essential Studio ASP.NET MVC Toggle Button control has a built-in feature to customize the size, text and images of button.

1. Create an MVC Project and add required assemblies, scripts, and styles to it. Refer MVC-Getting Started Documentation.
2. Add the following code example to the corresponding view page to render the Toggle Button.

ASPX-CS

```
@Html.EJ().ToggleButton("button").Size(ButtonSize.Mini).ShowRoundedCorner
(true).DefaultText("Play")
```

3. Output of the above steps.

Easy Customization

Toggle Button is used in all applications. ToggleButton size, content and content location is varied according to each application. The following section contains some customizable option for Toggle Button that can perform easily.

Toggle State

Toggle button has two states like off / on state in a switch. By default you can set any state at initial and then you can move from one state to another state by clicking on the Toggle Button. These two states are Default and Active.ToggleState property is used to set the state of Toggle Button as default state or active state. Default value of ToggleState is false.

The following steps explains you the details about rendering the Toggle Button with different ToggleState.

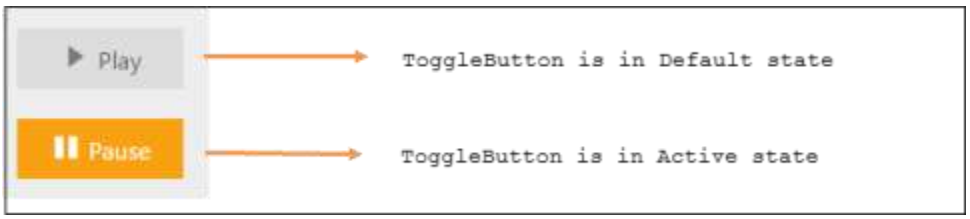
ASPX-CS

```
//Add the code in CSHTML page to configure the widget and initialize the
control
@*set the state for toggle button*@
@Html.EJ().ToggleButton("toggleButton_default").Size(ButtonSize.Small).Co
ntentType(ContentType.TextAndImage).DefaultText("Play").ActiveText("Pause
").DefaultPrefixIcon("e-icon e-mediaplay").ActivePrefixIcon("e-icon e-
mediapause").ToggleState(false)
<br/>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().ToggleButton("toggleButton_active").Size(ButtonSize.Small).Con
tentType(ContentType.TextAndImage).DefaultText("Play").ActiveText("Pause"
).DefaultPrefixIcon("e-icon e-mediaplay").ActivePrefixIcon("e-icon e-
mediapause").ToggleState(true)
```

Execute the above code to render the following output.



Toggle button with two different toggle states

ToggleState with icons

Prefix and Suffix Icons

You can add icons in prefix and suffix position of Toggle Button. Location of Icon is customized easily using the following mentioned option. This is applicable for the content type's ImageOnly, TextAndImage, ImageTextImage and ImageBoth.

Toggle Button control also supports the Built-in icon libraries. The ej.widgets.core.min.css contains the definition for important icons that are used in toggle buttons. You can use these Built-in icons by mentioning the icon class name as value in DefaultPrefixIcon, DefaultSuffixIcon, ActivePrefixIcon,and ActiveSuffixIcon property. You can use any font icons that is defined in ej.widgets.core.min.css it avoids the complexity in specifying icon using sprite image and CSS.

For example the following mentioned Built-in CSS class are used to show the font icons that are used by media player.

- e-mediaback
- e-mediaforward
- e-medianext
- e-mediaprev
- e-mediaeject
- e-mediaclose
- e-mediapause
- e-mediaplay

Prefix Icon

It inserts the icon at the starting position of Toggle Button. After this prefix icon, you can use text or suffix icon.

Suffix Icon

It inserts the icon at the ending position of Toggle Button. Before this suffix icon, you can use text or prefix icon.

You can also set icon in different location (prefix, suffix) and in different state (default, active) by using the option provided. The following properties are defined for merging the option to add text, icon with different position and in toggle states.

Copyright © 2001 - 2020 Syncfusion Inc.

Property Table

ActiveText	Specifies the text of toggle button in active state
ActivePrefixIcon	Specifies the prefix icon of toggle button in active state
ActiveSuffixIcon	Specifies the suffix icon of toggle button in active state
DefaultText	Specifies the text of toggle button in default state.
DefaultPrefixIcon	Specifies the prefix icon of toggle button in default state
DefaultSuffixIcon	Specifies the suffix icon of toggle button in default state

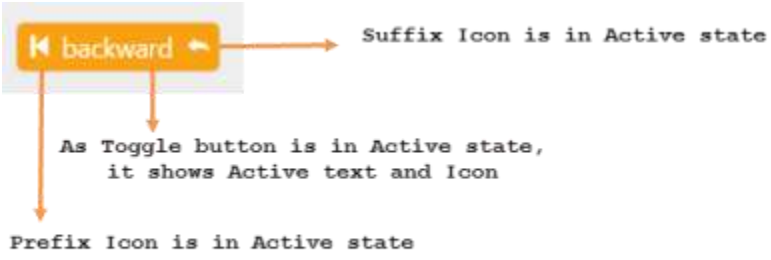
The following script explains you the details about rendering the Toggle Button with above mentioned customization properties.

ASPX-CS

```
//Add the code in CSHTML page to configure the widget and initialize the
control
@*set the prefix, suffix built-in icons in default and active state*@
@Html.EJ().ToggleButton("toggleButton_iconsAndStates").ContentType(Conten
tType.ImageTextImage).ShowRoundedCorner(true).DefaultText("forward").Acti
veText("backward").DefaultPrefixIcon("e-icon e-
mediaforward").ActivePrefixIcon("e-icon e-
mediaback").DefaultSuffixIcon("e-icon e-redo").ActiveSuffixIcon("e-icon
e-undo")
```

Execute the above code to render the following output.

Before clicking the toggle button



After clicking the toggle button

Copyright © 2001 - 2020 Syncfusion Inc.

Toggle button size

You can render the Toggle Button in different sizes by using Size property. You can use some predefined size option for rendering a Toggle Button in easiest way. Each size option has different height and width. It mainly avoids the complexity in rendering Toggle Button with complex CSS class. You can mention the size of the Toggle Button using the following five predefined size options.

Predefined Toggle Button size

Normal	Creates toggle button with content size.
Mini	Creates toggle button with Built-in mini size height, width specified.
Small	Creates toggle button with Built-in small size height, width specified.
Medium	Creates toggle button with Built-in medium size height, width specified.
Large	Creates toggle button with Built-in large size height, width specified.

You can also set your own width and height for toggle button using Height and Width property.

The following steps explains you the details about rendering the Toggle Button with above mentioned size options.

1. In the View page, add the following button elements to configure Toggle Button widget.

ASPX-CS

```
//Add the code in CSHTML page to configure the widget and initialize the
control
<div class="control">
@*Set the different size types for toggle button control as follows. *@
<table>
<tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_normal").Size(ButtonSize.Normal).Sh
owRoundedCorner(true).ContentType(ContentType.ImageOnly).DefaultPrefixIco
n("e-icon e-mediaplay").ActivePrefixIcon("e-icon e-mediaforward")
</td> </tr><tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_mini").Size(ButtonSize.Mini).ShowRo
undedCorner(true).DefaultText("Play").ActiveText("Next")
</td></tr><tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_small").Size(ButtonSize.Small).Show
RoundedCorner(true).DefaultText("Play").ActiveText("Next")
</td></tr><tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_medium").Size(ButtonSize.Medium).Sh
owRoundedCorner(true).DefaultText("Play").ActiveText("Next")
</td></tr><tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_large").Size(ButtonSize.Large).Show
RoundedCorner(true).ContentType(ContentType.TextAndImage).DefaultText("Pl
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
ay").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-mediaforward")
</td></tr><tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_customSize").ShowRoundedCorner(true
).ContentType(ContentType.TextAndImage).DefaultText("Play").ActiveText("N
ext").DefaultPrefixIcon("e-icon e-mediaplay").ActivePrefixIcon("e-icon e-
mediaforward").Height("50").Width("150")
</td>
</tr>
</table>
</div>
```

Execute the above code to render the following output.

Toggle button in different sizes

Content type

The content of the Toggle Button is mainly text and images. Instead of using complex CSS classes to render Toggle Button with different content types, you can use some predefined content type options as listed in the following table. Using this ContentType property you can easily add different types of content for Toggle Button. The Toggle Button supports the following content types.

List of Content types

TextOnly	Supports only for text content only.
ImageOnly	Supports only for image content only
ImageBoth	Supports image for both ends of the toggle button.
TextAndImage	Supports image with the text content.
ImageTextImage	Supports image with both ends and middle in text.

The following steps explains you the details about rendering the Toggle Button with above mentioned content type options.

1. In the View page, add the following button elements to configure Toggle Button widget.

Copyright © 2001 - 2020 Syncfusion Inc.

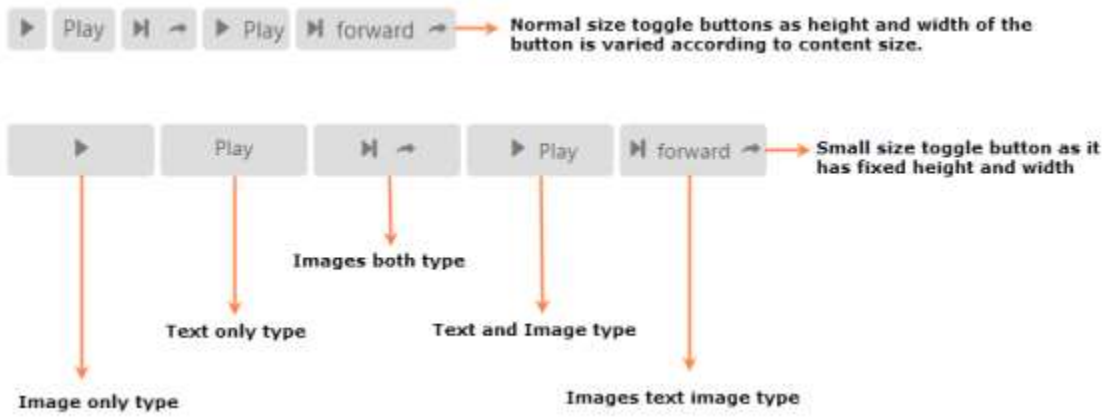
ASPX-CS

```
//Add the code in CSHTML page to configure the widget and initialize the
control
<div class="normal">
@*set different content types for toggle button*@
<table>
<tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_imageOnly").ShowRoundedCorner(true)
.ContentType(ContentType.ImageOnly).DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-mediaforward")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_textOnly").ShowRoundedCorner(true).
DefaultText("Play").ActiveText("Next")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_imageBoth").ShowRoundedCorner(true)
.ContentType(ContentType.ImageBoth).DefaultPrefixIcon("e-icon e-
mediaforward").ActivePrefixIcon("e-icon e-
mediaback").DefaultSuffixIcon("e-icon e-undo").ActiveSuffixIcon("e-icon
e-redo")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_textAndImage").ShowRoundedCorner(tr
ue).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).Default
Text("Play").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-mediaforward")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_imageTextImage").ShowRoundedCorner(
true).ContentType(ContentType.ImageTextImage).DefaultText("forward").Acti
veText("backward").DefaultPrefixIcon("e-icon e-
mediaforward").ActivePrefixIcon("e-icon e-
mediaback").DefaultSuffixIcon("e-icon e-undo").ActiveSuffixIcon("e-icon
e-redo")
</td>
</tr>
</table>
</div>
<div class="small">
<table>
<tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_small_imageOnly").Size(ButtonSize.S
mall).ShowRoundedCorner(true).ContentType(ContentType.ImageOnly).DefaultP
refixIcon("e-icon e-mediaplay").ActivePrefixIcon("e-icon e-mediaforward")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_small_textOnly").Size(ButtonSize.Sm
all).ShowRoundedCorner(true).DefaultText("Play").ActiveText("Next")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_small_imageBoth").Size(ButtonSize.S
mall).ShowRoundedCorner(true).ContentType(ContentType.ImageBoth).DefaultP
refixIcon("e-icon e-mediaforward").ActivePrefixIcon("e-icon e-
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
mediaback").DefaultSuffixIcon("e-icon e-undo").ActiveSuffixIcon("e-icon
e-redo")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_small_textAndImage").Size(ButtonSiz
e.Small).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).De
faultText("Play").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-mediaforward")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_small_imageTextImage").Size(ButtonS
ize.Small).ShowRoundedCorner(true).ContentType(ContentType.ImageTextImage
).DefaultText("forward").ActiveText("backward").DefaultPrefixIcon("e-icon
e-mediaforward").ActivePrefixIcon("e-icon e-
mediaback").DefaultSuffixIcon("e-icon e-undo").ActiveSuffixIcon("e-icon
e-redo")
</td>
</tr>
</table>
</div>
```

Execute the above code to render the following output.



Toggle button with different content type

ImagePosition

To provide the best look and feel for Toggle Button, position of images in toggle button is important. You can easily customize the position of images inside toggle button using ImagePosition property without using any complex CSS. ImagePosition property is applicable only with the TextAndImage content type property. This property represent the position of images with respect to text.

Property Table

ImageLeft	Support for aligning text in right and image in left.
ImageRight	Support for aligning text in left and image in right.
ImageTop	Support for aligning text in bottom and image in top.
ImageBottom	Support for aligning text in top and image in bottom.

Copyright © 2001 - 2020 Syncfusion Inc.

The following steps explains you the details about rendering the Toggle Button with above mentioned image Position options.

1. In the View page, add the following button elements to configure Toggle Button widget.

ASPX-CS

```
@*Add the code in CSHTML page to configure the widget and initialize the
control*@
@*set images of toggle button in different location*@
<div class="one">
@*align the images in left side*@
<table>
<tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_normal_imageLeft").Size(ButtonSize.
Normal).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).Def
aultText("Play").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-
mediaforward").ImagePosition(ImagePosition.ImageLeft)
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_mini_imageLeft").Size(ButtonSize.Mi
ni).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).Default
Text("Play").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-
mediaforward").ImagePosition(ImagePosition.ImageLeft)
</td>
<td class="btnsht">

</td>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</tr>
</table>
</div>
```

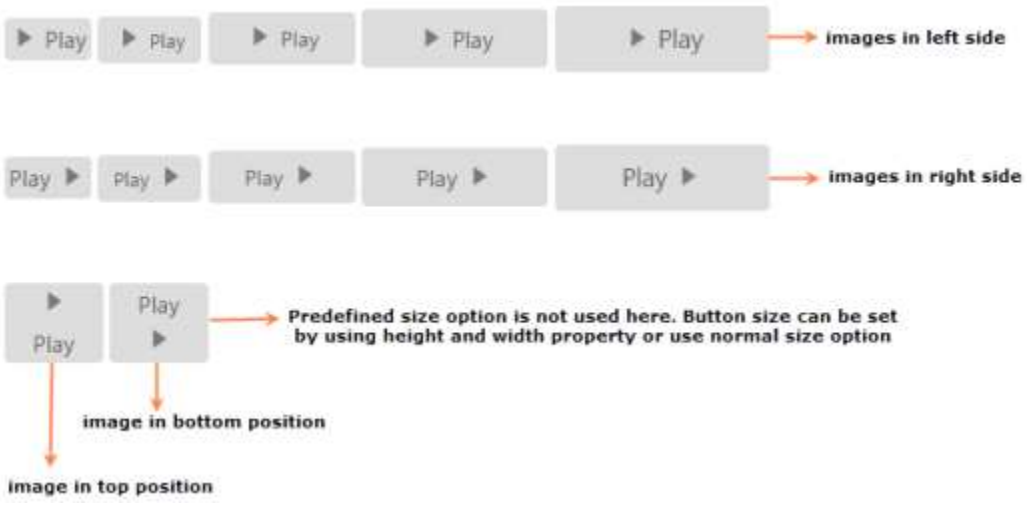
Execute the above code to render the following output.



Toggle button with different type of image position

Theme support

You can control the style and appearance of Toggle Button based on CSS classes. To apply styles to the Toggle Button control, you can refer two files, ej.widgets.core.min.css and ej.theme.min.css. When you refer ej.widgets.all.min.css file, then it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these two.

By default, there are 12 themes support available for Toggle Button control namely,

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

Custom CSS

You can use the CSS to customize the Toggle Button control appearance. Define a CSS class as per requirement and assign the class name to CssClass property.

The following steps explains you the details about rendering the Toggle Button with custom CSS.

Copyright © 2001 - 2020 Syncfusion Inc.

1. In the View page, add the following button elements to configure Toggle Button widget.

ASPX-CS

```
@*Add the code in CSHTML page to configure the widget and initialize the
control*@
@*set different custom CSS class for toggle button*@
<div class="one">
@*apply custom CSS class for toggle buttons*@
<table>
<tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_customCSS1").Size(ButtonSize.Small)
.ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).DefaultTex
t("Play").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-
mediaforward").CssClass("customCss1")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_customCSS2").Size(ButtonSize.Small)
.ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).DefaultTex
t("Play").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-
mediaforward").CssClass("customCss2")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_customCSS3").Size(ButtonSize.Small)
.ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).DefaultTex
t("Play").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-
mediaforward").CssClass("customCss3")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_customCSS4").Size(ButtonSize.Small)
.ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).DefaultTex
t("Play").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-
mediaforward").CssClass("customCss4")
</td>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_customCSS5").Size(ButtonSize.Small)
.ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).DefaultTex
t("Play").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-
mediaforward").CssClass("customCss5")
</td>
</tr>
</table>
</div>
```

2. Configure the CSS styles to apply on buttons.

CSS

```
<style type="text/css" class="cssStyles">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
/* Customize the button background */
.e-togglebutton.customCss1
{
background-color: #121111;
}
.e-togglebutton.customCss2
{
background-color: #94bbd5;
}
.e-togglebutton.customCss3
{
background-color: #f3533c;
}
.e-togglebutton.customCss4
{
background-color: #d1eeed;
}
.e-togglebutton.customCss5
{
background-color: #deb66e;
}
/* Customize the button image & text color */
.e-togglebutton.customCss1.e-btn.e-select .e-icon, .e-
togglebutton.customCss1.e-btn.e-select .e-btntxt
{
color: #94bbd5;
}
.e-togglebutton.customCss2.e-btn.e-select .e-icon, .e-
togglebutton.customCss2.e-btn.e-select .e-btntxt
{
color: #121111;
}
.e-togglebutton.customCss3.e-btn.e-select .e-icon, .e-
togglebutton.customCss3.e-btn.e-select .e-btntxt
{
color: #cef6f7;
}
.e-togglebutton.customCss5.e-btn.e-select .e-icon, .e-
togglebutton.customCss5.e-btn.e-select .e-btntxt
{
color: #534f4f;
}
</style>
```

Execute the above code to render the following output.

Toggle button with Custom CSS

Button types

Toggle Button is used as normal click able button, submitting form data, resetting the form data to its initial value. According to the usage of button, you can render the Toggle Button in the following three types by using the Type property.

Copyright © 2001 - 2020 Syncfusion Inc.

Toggle Button Types

Button	The button is a click able button
Submit	The button is a submit button (submits form-data)
Reset	The button is a reset button (resets the form-data to its initial values)

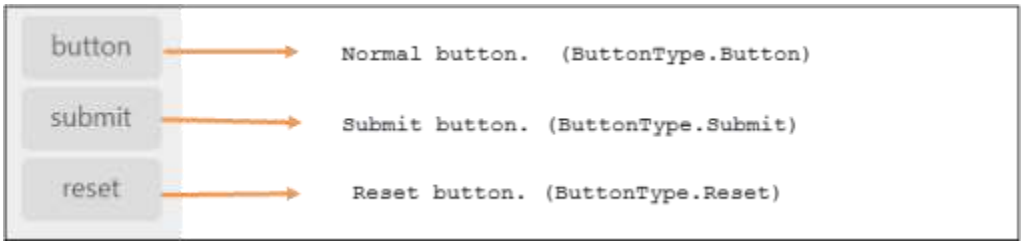
The following steps explains you the details about rendering the Toggle Button with above mentioned types.

1. In the View page, add the following button elements to configure Toggle Button widget.

ASPX-CS

```
@*Add the code in CSHTML page to configure the widget and initialize the
control*@
<div class="one">
@*set toggle button type using type property*@
<table>
<tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_button").Size(ButtonSize.Mini).Show
RoundedCorner(true).ContentType(ContentType.TextOnly).DefaultText("button
").ActiveText("Next").Type(ButtonType.Button)
</td>
</tr>
<tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_submit").Size(ButtonSize.Mini).Show
RoundedCorner(true).ContentType(ContentType.TextOnly).DefaultText("submit
").ActiveText("Next").Type(ButtonType.Submit)
</td>
</tr>
<tr>
<td class="btnsht">
@Html.EJ().ToggleButton("toggleButton_reset").Size(ButtonSize.Mini).ShowR
oundedCorner(true).ContentType(ContentType.TextOnly).DefaultText("reset")
.ActiveText("Next").Type(ButtonType.Reset)
</td>
</tr>
</table>
</div>
```

Execute the above code to render the following output.



Copyright © 2001 - 2020 Syncfusion Inc.

Types of Toggle button

RTL support

In some cases, it is necessary to use right to left alignment. You can render RTL support by using EnableRTL property. In RTL mode, when there is more than one content (image/text, image/image) in button, then the content is aligned in right to left format. For example, when text is in left and image is in right position, after applying right to left alignment these positions are interchanged.

The following steps explains you the details about rendering the Toggle Button with Right to left alignment support.

1. In the View page, add the following button elements to configure Toggle Button widget.

ASPX-CS

```
//Add the code in CSHTML page to configure the widget and initialize the
control
<div class="one">
@*enable right to left alignment*@
@Html.EJ().ToggleButton("toggleButton_rtl").Size(ButtonSize.Small).ShowRo
undedCorner(true).ContentType(ContentType.TextAndImage).DefaultText("Play
").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-medianext").EnableRTL(true)
</div>
```

In above mentioned code example PrefixIcon property is used and the icon that is to be on left side, (before text) is rendered on right side as EnableRTL property is used with PrefixIcon. Consequently, the alignment is changed in right to left order.

Output of above steps

Toggle button with RTL support

Miscellaneous

ShowRoundedCorner

It sets the corner of Toggle Button in rounded shape. The Toggle Button, by default doesn't have rounded corner. To set rounded corner, you can enable ShowRoundedCorner property.

The following steps explains you the details about rendering the Toggle Button with Rounded corner support.

1. In the View page, add the following button elements to configure Toggle Button widget.

ASPX-CS

```
@*Add the code in CSHTML page to configure the widget and initialize the
control*@
<div class="one">
@*set rounded corner for toggle button*@
@Html.EJ().ToggleButton("toggleButton_roundedCorner").Size(ButtonSize.Sma
ll).ShowRoundedCorner(true).ContentType(ContentType.TextAndImage).Default
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Text("Play").ActiveText("Next").DefaultPrefixIcon("e-icon e-
mediaplay").ActivePrefixIcon("e-icon e-medianext")
</div>
```

Execute the above code to render the following output.

Toggle button with Rounder corner

PreventToggle

This property is used to prevent the state change of Toggle Button when it is clicked. When you set PreventToggle property as true, then the state of the Toggle Button is not changed even though it is clicked. Default value of PreventToggle is false.

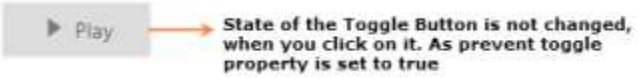
The following steps explains you the details about rendering the Toggle Button with PreventToggle property enabled.

1. In the View page, add the following button elements to configure Toggle Button widget.

ASPX-CS

```
@*Add the code in CSHTML page to configure the widget and initialize the
control*@
<div class="one">
@* set prevent toggle property for preventing states*@
@Html.EJ().ToggleButton("toggleButton_preventToggle").Size(ButtonSize.Sma
ll).ContentType(ContentType.TextAndImage).DefaultText("Play").ActiveText(
"Next").DefaultPrefixIcon("e-icon e-mediaplay").ActivePrefixIcon("e-icon
e-medianext").PreventToggle(true)
</div>
```

Execute the above code to render the following output.



Toggle button with prevent Toggle

How to?

Render ToggleButton from Code behind

ToggleButton can be rendered from the code behind by initializing the required properties in controller and passing those properties via **ViewData** or **Model** to the client side.

The following code illustrates the initialization of ToggleButton properties in the controller.

C#

```
//Namespace to get the JavaScript (ToggleButton) component properties
using Syncfusion.JavaScript.Models;
namespace MvcApplication.Controllers
{
public class ToggleButtonController : Controller
```

```
{
// GET: ToggleButton
public ActionResult ToggleButtonFeatures()
{
//Initializing the ToggleButton model
ToggleButtonProperties BtnObj = new ToggleButtonProperties();
//Initializing the datasource and other properties
BtnObj.ActiveText = "pause";
BtnObj.DefaultText = "Play";
BtnObj.ShowRoundedCorner = true;
BtnObj.Size = ButtonSize.Large;
//Passing ToggleButton properties using the ViewData
ViewData["BtnModel"] = BtnObj;
return View();
}
}
}
```

Binding the ToggleButton properties passed via **ViewData** from the controller in the client side as below.

ASPX-CS

```
@{
Html.EJ().ToggleButton("searchCustomer",(Syncfusion.JavaScript.Models.Tog
gleButtonProperties)ViewData["BtnModel"]).Render();
}
```

Toolbar

Toolbar

The Toolbar control for ASP.NET MVC supports displaying a list of tools within a web page. This control is capable of customizing toolbar items with any functionality by using enriched client-side methods. This control is composed of collection of unordered lists containing text and images contained into a div.

Key Features

- Modern look: Rich appearance with theme support.
- RTL: Supports right-to-left alignment.
- Text and Image: Supports both text and images as toolbar content.
- Easy Customization: The customization of toolbar control to any form is made simple.
- Data binding: Supports for data binding with local data and remote data.
- Template: Supports for Customizing toolbar with user needed tools.
- Keyboard navigation: Support for navigation through keyboard.

Getting Started

This section explains briefly about how to create a Toolbar in your ASP.NET MVC application.

Create your first Toolbar in MVC

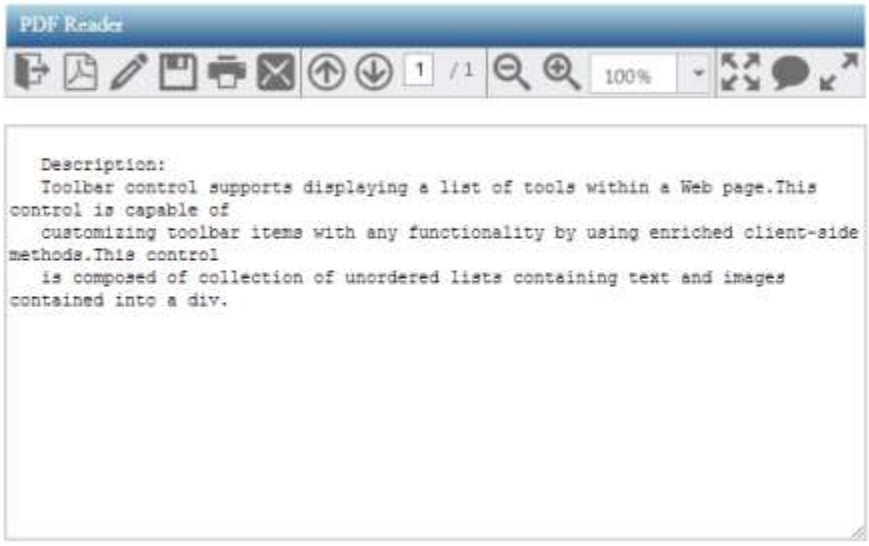
Create Toolbar for PDF Reader

Toolbar control displays a list of tools in a web page. It is used to customize Toolbar items of any functionality, by using enriched client-side methods. This control consists of a collection of unordered

Copyright © 2001 - 2020 Syncfusion Inc.

lists, containing text and images into a . From the following section, you can learn how to customize Toolbar control for a PDF Reader scenario. The following screen shot shows the appearance of Toolbar in PDF Reader simulator application.

Here, the Toolbar consists of a Toolbar with title and text area as PDF Reader.



Create a Toolbar

Using the following steps, you can create a Toolbar control. The basic rendering of ASP.NET MVC Toolbar is achieved with default functionality.

1. You can create an MVC Project and add necessary assembly and script with the help of the given MVC-Getting Started Documentation.

2. Add the mentioned code to the corresponding view page for Toolbar rendering.

ASPX-CS

```
@Html.EJ().Toolbar("ToolbarItem")
```

The following output is displayed.

Toolbar without Toolbar items

Initialize Toolbar Items

Toolbar consists of a list of items. From the following guidelines, you can learn how to initialize the Toolbar items with <UL> <LI> template.

Initialize the Toolbar items with <UL> <LI> template as follows.

ASPX-CS

```
<div id="ToolbarItem">
<!--list of toolbar items-->
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<ul>
<li id="OtherFormat" title="Convert PDF files to Word or Excel Online…">
<div class="PdfDocument e-icon convertToOthers "></div>
</li>
<li id="PDFOnline" title="Convert files to PDF Online">
<div class="PdfDocument e-icon convertToPdf "></div>
</li>
<li id="Signature" title="Sign, add text or send a document for
signature">
<div class=" PdfDocument e-icon signature "></div>
</li>
<li id="Save" title="Save file ( Ctrl+S )">
<div class=" PdfDocument e-icon save "></div>
</li>
<li id="Print" title="Print file ( Ctrl+P ) ">
<div class=" PdfDocument e-icon print "></div>
</li>
<li id="Message" title="Message">
<div class=" PdfDocument e-icon msg "></div>
</li>
</ul>
</div>
@Html.EJ().Toolbar("ToolbarItem").Width("auto").EnableSeparator(true).Hei
ght("33px")
```

Apply the given styles in the code table to show the Toolbar items as follows. You can refer images from any location.

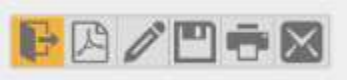
CSS

```
<style type="text/css" class="cssStyles">
.e-tooltxt .e-icon
{
background-image: url('http://js.syncfusion.com/UG/Web/Content/pdf-
icon.png');
background-repeat: no-repeat;
display: block;
height: 30px;
width: 30px;
}
.convertToOthers
{
background-position: -349px 0px;
}
.convertToPdf
{
background-position: -527px 0px;
}
.signature
{
background-position: 2px 0px;
}
.save
{
background-position: -87px 0px;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.print
{
background-position: -43px 0px;
}
.msg
{
background-position: -483px 0px;
}
</style>
```

Execute the code to render a Toolbar with a list of Toolbar items.



Toolbar with list of toolbar items

Render remaining Toolbar Items

To achieve the requirements, you need to render all the Toolbar items. You can separate or group the Toolbar items. The separation or grouping of Toolbar items is achieved when you give Toolbar items as a list of <UL> <LI> values inside the toolbar or span element. From the following sections, you can learn how to initialize the remaining Toolbar items with <UL> <LI> template and how to group the toolbar items.

Initialize the Toolbar items with <UL> <LI> template as follows.

ASPX-CS

```
<div id="ToolbarItem">
<!--Initialize toolbar items from above code snippet -->
<!-- Separator will be added at the end of each ul inside the toolbar
element-->
<!-- list of Remaining toolbar items with item separator -->
<ul>
<li id="Previous" title="Show previous page ( Left Arrow )">
<div class=" PdfDocument e-icon previous "></div>
</li>
<li id="Next" title="Show next page ( Right Arrow )">
<div class="PdfDocument e-icon next "></div>
</li>
<li id="page">
<div class="PdfDocument">
<input type="text" value="1" />
</div>
</li>
<li id="count">
<span>/ 1</span></li>
</ul>
<ul>
<li id="ZoomOut" title="Zoom Out">
<div class=" PdfDocument e-icon zoomOut "></div>
</li>
<li id="ZoomIn" title="Zoom In">
<div class=" PdfDocument e-icon zoomIn "></div>
</li>
<li id="ZoomValue">
```

```
<div id="car">
<ul>
<li>10%</li>
<li>25%</li>
<li>50%</li>
<li>100%</li>
<li>400%</li>
<li>800%</li>
<li>1600%</li>
<li>3200%</li>
<li>6400%</li>
</ul>
</div>
@Html.EJ().DropDownList("car").Width("90").Value("100%").TargetID("car")
</li>
</ul>
<ul>
<li id="FitFull" title="Fit one full page to window">
<div class=" PdfDocument e-icon fitOne "></div>
</li>
<li id="StickyNote" title="Add stick note ( Ctrl+6 ) ">
<div class=" PdfDocument e-icon sticky "></div>
</li>
<li id="ReadMode" title="View File in Read Mode">
<div class=" PdfDocument e-icon readMode "></div>
</li>
</ul>
</div>
```

Add the following styles in the code table to display the Toolbar items as follows.

CSS

```
/*Additional style for Remaining toolbar items*/
<style>
.zoomIn
{
background-position: -175px 0px;
}
.readMode
{
background-position: -307px -1px;
}
.zoomOut
{
background-position: -219px 0px;
}
.fitOne
{
background-position: -264px 0px;
}
.sticky
{
background-position: -131px -1px;
}
#ZoomValue.e-tooltxt .e-icon
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
background-image: none;
}
#page .PdfDocument input
{
text-align: center;
width: 20px;
height: 21px;
}
#count span
{
width: 30px;
height: 30px;
position: relative;
top: 2px;
text-align: center;
vertical-align: middle;
background-image: none;
}
.PdfDocument.e-icon.previous
{
background-position: -395px 0px;
}
.PdfDocument.e-icon.next
{
background-position: -439px 0px;
}
</style>
```

Set Zoom value is one of the items in the Toolbar. You need to render the DropDownList control for select zoom value. DropDownList control is rendered with <UL> <LI> elements. The ASP.NET MVCDropdown control with a list of zoom values is used to render Set Zoom value in the above sample code. Refer to the provided link for Dropdown creation.

Dropdown – GettingStarted

Execute the code to render Toolbar items with separator.

Add Actions to Toolbar Items

Now that the Toolbar is rendered, you need to render the header and content area to create a PDF Reader. In the following section, you can learn how to render the header (Toolbar), content section (PDF viewer area) and how to set the action to Toolbar items.

Note: PDF reading or rendering is not shown here. Simulation of the PDF Reader app to demonstrate the usage of Toolbar control is provided. PDF rendering area is ignored._

Initialize the content area and header as specified in the code table.

ASPX-CS

```
<!—"control" class used for aligns the pdf reader in center of a page. --
>
```

Copyright © 2001 - 2020 Syncfusion Inc.

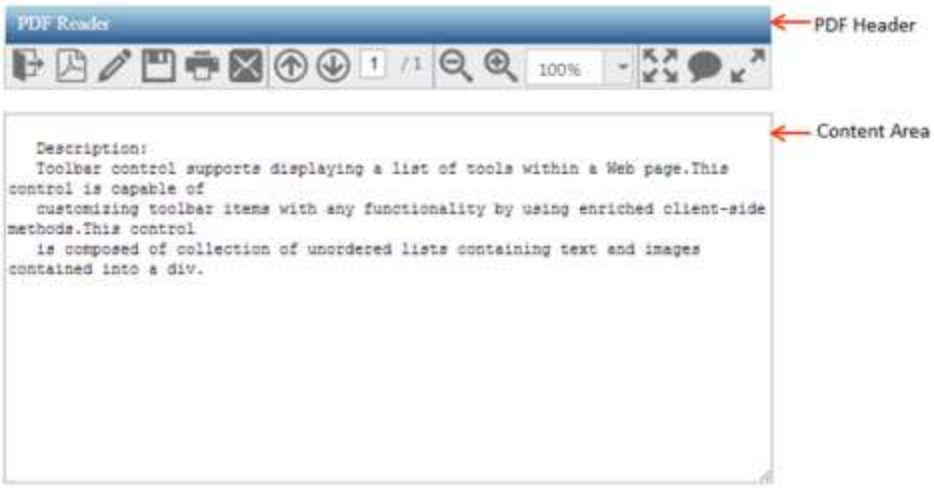
```
<div class="control">
<div class="label"></div>
<div id="ToolbarItem">
<!--Add toolbar items from above code snippet -->
</div>
<!-- Here Initialize the Toolbar items as like above code sample -->
<div id="contentSection">
<textarea id="content" rows="10" cols="30">
Description:
Toolbar control supports displaying a list of tools within a Web page.
This control is capable of
customizing toolbar items with any functionality by using enriched
client-side methods.This control
Is composed of collection of unordered lists containing text and images
contained into a div.
</textarea>
</div>
</div>
```

You can apply the following styles with the above styles to design the PDF header and content area.

CSS

```
<style type="text/css" class="cssStyles">
#content
{
float: left;
height: 300px;
width: 633px;
position: absolute;
}
.control
{
position: relative;
}
.label
{
background-image: url('http://js.syncfusion.com/UG/Web/Content/pdf-
header.png');
background-repeat: no-repeat;
width: 638px;
height: 32px;
}
</style>
```

Copyright © 2001 - 2020 Syncfusion Inc.



PDF Reader Appearance

So far, you have added the required toolbar items and configured its appearance. When you click on

Toolbar items, the operation is performed through client-slide click event. The following code example explains how to perform operations, when you click on the Toolbar items.

ASPX-CS

```
<div id="ToolbarItem">
<!--Add toolbar items from above code snippet -->
</div>
<!-- Here Initialize the Toolbar items as shown in above code sample and add Client side Event as follows -->
@Html.EJ().Toolbar("ToolbarItem").ClientSideEvents(e =>
e.Click("onItemClick")).Width("auto").EnableSeparator(true)
<script type="text/javascript">
function onItemClick(args)
{
//Finds Out the Item that was Clicked in Toolbar
//args.currentTarget returns the clicked Toolbar element
var option = args.currentTarget.id; /* Find Out the Id of Clicked item.
*/
switch (option)
{
case "OtherFormat":
//writes a code for Convert pdf files to Other format.
case "PdfOnline":
//writes a code for Convert files to Pdf online.
case "Signature":
//writes a code for Send a document for signature.
case "Save":
//writes a code for Save content.
case "Print":
//writes a code for Print content.
case "Message":
//writes a code for Send a Message.
case "Previous":
//writes a code for Show previous page.
case "Next":
//writes a code for Show Next page.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
case "ZoomOut":
//writes a code for Zoom out the page.
case "ZoomIn":
//writes a code for Zoom In the page.
case "FitFull":
//writes a code for Fit one full page to window.
case "StickyNote":
//writes a code for Add Sticky Note.
case "ReadMode":
//writes a code for view file in read mode.
}
}
</script>
```

Data Binding

Toolbar provides you a flexible approach for binding data from various data sources. There are various properties in Toolbar for Data Binding.

Data fields and configuration

The following sub-properties provides a way to bind either the local/remote data to the Toolbar control.

Property Table of MVC Toolbar control

Property	Value type	Description
Datasource	object	It specifies the data source of the Toolbar. The data source contains the list of data for generating the Toolbar items.
Fields	object	It specifies the mapping fields for the data items of the Toolbar.
Id	string	It specifies the id of the element
Text	string	It specifies the text content of the element.
ImageUrl	string	This property defines the imageURL for the image location. While setting images, the folder name in which the images are stored should be set to imageUrl property.
ImageAttributes	string	This property defines style for the image. While setting an image, styles can be applied such as height, width by using this property.
SpriteCssClass	string	This property sets the Sprite CSS for the image element in Toolbar.
HtmlAttributes	object	This property sets the HTML attribute for the Toolbar item. It can be any HTML attribute such as id, class, style.
TooltipText	string	This property sets the text value for Toolbar item while mouse over in Toolbar.
Query	object	It specifies the query to retrieve the data from online server.
Group	string	It groups the given Toolbar items.

Copyright © 2001 - 2020 Syncfusion Inc.

Local data

To bind the Local Data to the Toolbar control, map the user-defined JSON data names with its appropriate data source field. You can bind data to Toolbar by mapping fields such as Id, SpriteCssClass, ImageUrl, group and TooltipText.

The following steps explain how you can bind local data to Toolbar Control.

In the View page, add Toolbar helper to configure Toolbar.

C#

```
// Add the following data list to be bind in the controller page and
define the corresponding data.
// Define local data source elements with  fields
public class ToolbarLocalBinding
{
public string IconId { get; set; }
public string SpriteCss { get; set; }
public string Tooltip { get; set; }
}
//Refer the Model in the controller
using <Applicationname>.Models;
public ActionResult Index()
{
List<ToolbarLocalBinding> tools = new List<ToolbarLocalBinding>();
tools.Add(new ToolbarLocalBinding { IconId = "1", SpriteCss =
"LeftAlign_tool", Tooltip = "left" });
tools.Add(new ToolbarLocalBinding { IconId = "2", SpriteCss =
"CenterAlign_tool", Tooltip = "center" });
tools.Add(new ToolbarLocalBinding { IconId = "3", SpriteCss =
"RightAlign_tool", Tooltip = "right" });
tools.Add(new ToolbarLocalBinding { IconId = "4", SpriteCss =
"Justify_tool", Tooltip = "justify" });
tools.Add(new ToolbarLocalBinding { IconId = "5", SpriteCss =
"Bold_tool", Tooltip = "bold" });
tools.Add(new ToolbarLocalBinding { IconId = "6", SpriteCss =
"Italic_tool", Tooltip = "italic" });
tools.Add(new ToolbarLocalBinding { IconId = "7", SpriteCss =
"StrikeThrough_tool", Tooltip = "strike" });
tools.Add(new ToolbarLocalBinding { IconId = "8", SpriteCss =
"Underline_tool", Tooltip = "underline" });
ViewBag.datasource = tools;
return View();
}
```

ASPX-CS

```
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<MVCSam
ples.Models.ToolbarLocalBinding>)
ViewBag.datasource).ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip"))
.Orientation(Orientation.Horizontal)
</div>
```

CSS

Copyright © 2001 - 2020 Syncfusion Inc.

```
<style type="text/css" class="cssStyles">
.darktheme .cols-sample-area .e-tooltxt .ToolbarItems
{
background-image: url('../images/toolbar/ui-icons-metro.png');
}
.cols-sample-area .e-tooltxt .ToolbarItems
{
display: block;
background-image: url('../images/toolbar/ui-icons-dark.png');
height: 22px;
width: 22px;
}
.e-tooltxt:hover .ToolbarItems, .darktheme .cols-sample-area .e-
tooltxt:hover .ToolbarItems
{
background-image: url('../images/toolbar/ui-icons-light.png');
}
.ToolbarItems.LeftAlign_tool
{
background-position: -26px -39px;
}
.ToolbarItems.CenterAlign_tool
{
background-position: -55px -39px;
}
.ToolbarItems.RightAlign_tool
{
background-position: -89px -39px;
}
.ToolbarItems.Justify_tool
{
background-position: -123px -39px;
}
.ToolbarItems.Bold_tool
{
background-position: -159px -39px;
}
.ToolbarItems.Italic_tool
{
background-position: -196px -39px;
}
.ToolbarItems.StrikeThrough_tool
{
background-position: -55px -70px;
}
.ToolbarItems.Underline_tool
{
background-position: -23px -68px;
}
.html
{
background-color: yellowgreen;
}
</style>
```

Copyright © 2001 - 2020 Syncfusion Inc.

ToolBar control bounded to Local Data

Remote data

You can bind Toolbar to Remote Data using DataManager and the query in fields is used to retrieve the data. DataManager supports the following types of data-binding: JSON, Web Services and OData. It uses two different classes; ej.DataManager for processing, and ej.Query for serving data. ej.DataManager communicates with data source and ej.Query generates data queries that are read by the DataManager. In the following link, how to create DataManager is explained in full detail.

http://help.syncfusion.com/aspnetmvc/toolbar/data-binding

The following steps explain how you can bind remote data to Toolbar control.

1. In the View page, add Toolbar helper to configure Toolbar.

ASPX-CS

```
@Html.EJ().Toolbar("toolbar").Datasource(dataSource =>
dataSource.URL("http://mvc.syncfusion.com/Services/Northwnd.svc/")).Query
("ej.Query().from('Orders').take(6)").ToolbarFields(f =>
f.Text("CustomerID")).Orientation(Orientation.Horizontal).Width("340")
```

ToolBar control bounded to Remote Data

Behavior settings

The following are some miscellaneous properties that enables you to change the behavior of Toolbar control.

Enabling Toolbar

Enabled property is Boolean type, which allow us to enable or disable the Toolbar control. By default Enabled value is true. You can specify the property Enabled in the script as follows.

ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<Toolba
rLocalBinding>)ViewBag.datasource)
.ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip")).Enable
d(false)
</div>
```

The following screenshot illustrates a Toolbar with Disable mode.

ToolBar control in Enabled (false)

Hiding Toolbar

The Hide property is Boolean type, which allow us to show or hide the Toolbar. Default value of Hide is false. You can specify the property Hide in the script as follows.

ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<Toolba
rLocalBinding>)ViewBag.datasource)
.ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip")).Hide(t
rue)
</div>
```

Disable Or Enable Separate Toolbar Item

We can enable or disable a separate toolbar item by using the following methods.

Disable Item

The **Toolbar** method **disableItem** and **disableItemByID** can be used to disable separate toolbar item. In the below code we have disabled the third toolbar item by using these two methods

HTML

```
@Html.EJ().Toolbar("editingToolbar").Items(s =>
{
s.Add().SpriteCssClass("e-icon e-cut_01").TooltipText("Cut");
s.Add().SpriteCssClass("e-icon e-copy_02").TooltipText("Copy");
s.Add().SpriteCssClass("e-icon e-paste_01").TooltipText("Paste");
}).Items(s1 =>
{
s1.Add().SpriteCssClass("e-icon e-bold_01").TooltipText("Bold");
s1.Add().SpriteCssClass("e-icon e-
underline_01").TooltipText("Underline");
s1.Add().SpriteCssClass("e-icon e-
strikethrough_01").TooltipText("StrikeThrough");
}).Items(s2 =>
{
s2.Add().SpriteCssClass("e-icon e-align-left_01").TooltipText("Left");
s2.Add().SpriteCssClass("e-icon e-align-
center_01").TooltipText("Center");
s2.Add().SpriteCssClass("e-icon e-align-right_01").TooltipText("Right");
s2.Add().SpriteCssClass("e-icon e-align-
justify_01").TooltipText("Justify");
}).ClientSideEvents(e=>e.Create("create"))
```

JAVASCRIPT

```
function create() {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
var obj = $("#editingToolbar").data("ejToolbar");
obj.disableItem($(".e-toolbar li")[2]);
}
```

OR

JAVASCRIPT

```
function create() {
var obj = $("#editingToolbar").data("ejToolbar");
obj.disableItemByID("paste");
}
```

Enable Item

The **Toolbar** method **enableItem** and **enableItemByID** can be used to enable separate toolbar item. In the below code we have disabled the first five items initially and enabled the third toolbar item by using these two methods

HTML

```
@Html.EJ().Toolbar("editingToolbar").DisabledItemIndices(new List<int>
{0,1,2,3,4}).Items(s =>
{
s.Add().SpriteCssClass("e-icon e-cut_01").TooltipText("Cut");
s.Add().SpriteCssClass("e-icon e-copy_02").TooltipText("Copy");
s.Add().SpriteCssClass("e-icon e-paste_01").TooltipText("Paste");
}).Items(s1 =>
{
s1.Add().SpriteCssClass("e-icon e-bold_01").TooltipText("Bold");
s1.Add().SpriteCssClass("e-icon e-
underline_01").TooltipText("Underline");
s1.Add().SpriteCssClass("e-icon e-
strikethrough_01").TooltipText("StrikeThrough");
}).Items(s2 =>
{
s2.Add().SpriteCssClass("e-icon e-align-left_01").TooltipText("Left");
s2.Add().SpriteCssClass("e-icon e-align-
center_01").TooltipText("Center");
s2.Add().SpriteCssClass("e-icon e-align-right_01").TooltipText("Right");
s2.Add().SpriteCssClass("e-icon e-align-
justify_01").TooltipText("Justify");
}).ClientSideEvents(e=>e.Create("create"))
```

JAVASCRIPT

```
function create() {
var obj = $("#editingToolbar").data("ejToolbar");
obj.enableItem($(".e-toolbar li")[2]);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
```

OR

JAVASCRIPT

```
function create() {
var obj = $("#editingToolbar").data("ejToolbar");
obj.enableItemByID("paste");
}
```

Orientation

The Toolbar control supports both vertical and horizontal orientations, allowing it to fit into any scenario. The Orientation property of Toolbar defines the orientation in which the control is rendered. Set the value to this property as enum or string type. It accepts the following values.

- Syncfusion.JavaScript.Orientation.Horizontal
- Syncfusion.JavaScript.Orientation.Vertical

The following section explains you on how to set orientation for the toolbar.

Horizontal

By default the Orientation property sets the Toolbar in horizontal orientation. You can refer the following steps to set horizontal orientation for Toolbar control. Default value of Orientation is Horizontal.

1. In View, create UL-LI list of toolbar items and invoke the toolbar helper.
2. Add the following code in your CSHTML page.

ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<Toolba
rLocalBinding>)ViewBag.datasource).ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip")).Orient
ation(Syncfusion.JavaScript.Orientation.Horizontal)
</div>
```

3. Build and run the application.

The following screenshot illustrates a Toolbar with horizontal orientation.

Copyright © 2001 - 2020 Syncfusion Inc.

Toolbar with Horizontal Orientation

Vertical

This property sets the Toolbar in vertical orientation. You can refer the following steps to set Vertical Orientation for Toolbar control.

1. Create UL-LI list of toolbar items and invoke the toolbar helper.
2. Add the following script in your HTML page.

ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<Toolba
rLocalBinding>)ViewBag.datasource).ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip")).Orient
ation(Syncfusion.JavaScript.Orientation.Vertical)
</div>
```

3. Build and run the application.

The following screenshot illustrates a Toolbar with vertical orientation.

Toolbar with Vertical Orientation

Appearance and Styling

Adjusting Toolbar size

Height

The Height property is used to set height of the Toolbar. Set the value to this property as number or string type.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Height("300").Datasource((IEnu
merable<ToolbarLocalBinding>)ViewBag
.datasource).ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip"))
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Width

The Width property is used to set width of the Toolbar. Set the value to this property as number or string type.

ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<Toolba
rLocalBinding>)ViewBag.datasource)
.ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip"))
</div>
```

Enabling Rounded Corner

The ShowRoundedCorner property is Boolean type, which allows us to enable rounded corner for Toolbar control. Default value of this property is false. You can specify the property ShowRoundedCorner in the script as below,

ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<Toolba
rLocalBinding>)ViewBag.datasource)
.ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip")).ShowRo
undedCorner(true)
</div>
```

ToolBar control with rounded corner

Enabling Separator

The EnableSeparator property is Boolean type, which allow us to set separator between Toolbar items in Toolbar control. It separates one or more list items. When you want to separate two set of items, then define them in two separate ‘UL’ elements. Default value of EnableSeparator is false.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<Toolba
rLocalBinding>)ViewBag.datasource).ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip")).Enable
Separator(true)
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

ToolBar control with item separator

Themes

You can control the style and appearance of the Toolbar based on CSS classes. In order to apply styles to the Toolbar control, you can refer two files - ej.widgets.core.min.css and ej.theme.min.css. When you refer ej.widgets.all.min.css file, it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these two.

By default, there are 12 themes support available for Toolbar control namely

- default-theme
- flat-azure-dark
- fat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark

CssClass

The CssClass property is used to set root class for Toolbar control theme. Set the value to this property as string type.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<Toolba
rLocalBinding>)ViewBag.datasource)
.ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip")).CssCla
ss("gradient-lime")
</div>
```

CSS

```
<style>
.gradient-lime
{
background-color: yellowgreen;
}
</style>
```

Copyright © 2001 - 2020 Syncfusion Inc.

ToolBar control with CssClass

Template Support

Template allows you to insert custom or ASP.NET MVC controls inside the toolbar items. Also you can design simple drop down buttons listing the items and radio button inside the Toolbar.

Set the list for DropDown control inside a list element and define this element as a Toolbar item. You can use all simple controls as a ToolBar item. For example to add RadioButton and DropDownList to Toolbar, use the following code example.

ASPX-CS

```
/ / Add this code in your CSHTML page and refer local data section for
data source
@Html.EJ().Toolbar("toolbar").Items(s =>
{
s.Add().ContentTemplate(@<div>
@Html.EJ().RadioButton("radio1").Checked(false)
</div>);
s.Add().ContentTemplate(@<div>
@Html.EJ().DropDownList("select").Height("23").Width("100").TargetID("car
s").SelectedItemIndex(0)
<div id="cars">
<ul>
<li>Audi A4</li>
<li>Audi A5</li>
<li>Audi A6</li>
<li>Audi A7</li>
</ul>
</div>
</div>);
})
```

The following screenshot displays a Toolbar with embedded controls.

Toolbar with Template

RTL

EnableRTL property is Boolean type, which allow us to change the left-to-right alignment of the Toolbar to right-to-left (RTL) that sets the Toolbar to do its actions from right to left. Default value of EnableRTL is false. You can specify the EnableRTL property in the script as below,

ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<Toolba
rLocalBinding>)
ViewBag.datasource).ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip")).Enable
RTL(true)
</div>
```

Toolbar from RTL

Keyboard Navigation

The entire Toolbar commands can be accessed through the keyboard by specifying the Keyboard Shortcut listed in the following table.

List of keyboard shortcuts

Keyboard Shortcut	Function
Alt + j	Focuses the control
UP	Navigates up and left.
Down	Navigates down and right.
Left	Navigates up and left.
Right	Navigates down and right.
Home	Navigates to the starting item.
End	Navigates to the ending item.
Enter	Selects the focused item

The following code example illustrates shortcuts associated with the Toolbar items.

ASPX-CS

```
// Add this code in your CSHTML page and refer local data section for
data source
<div class="cols-sample-area">
@Html.EJ().Toolbar("toolbar").Width("250").Datasource((IEnumerable<Toolba
rLocalBinding>)
ViewBag.datasource).ToolbarFields(f =>
f.ID("IconId").SpriteCssClass("SpriteCss").TooltipText("Tooltip"))
</div>
```

ToolBar control with Keyboard shortcuts

Responsive Layout

Responsive Layout is aimed at crafting sites to provide an optimal viewing experience—easy reading and navigation with a minimum of resizing, panning, and scrolling—across a wide range of devices (from mobile phones to desktop computer monitors). You can achieve Responsive Layout by using default functionality of Toolbar with IsResponsive as true and also you need to give Toolbar Width as in percentage value and add ej.responsive.css file in this sample. CDN link for the responsive CSS file is as follows.

http://cdn.syncfusion.com/13.1.0.21/js/web/responsive-css/ej.responsive.css

Add the above css link in the code sample.

1. Add the following code example in your HTML page.

ASPX-CS

```
<div class="control">
@Html.EJ().Toolbar("Toolbar").Width("65%").Height("33px").IsResponsive(tr
ue).Items(s =>
{
s.Add().Id("OtherFormat").SpriteCssClass("PdfDocument e-icon
convertToOthers ").TooltipText("Convert PDF files to Word or Excel
Online…");
s.Add().Id("PDFOnline").SpriteCssClass("PdfDocument e-icon convertToPdf
").TooltipText("Convert files to PDF Online");
s.Add().Id("Signature").SpriteCssClass("PdfDocument e-icon signature
").TooltipText("Sign, add text or send a document for signature");
s.Add().Id("Save").SpriteCssClass("PdfDocument e-icon save
").TooltipText("Save file ( Ctrl+S )");
s.Add().Id("Print").SpriteCssClass("PdfDocument e-icon print
").TooltipText("Print file ( Ctrl+P )");
s.Add().Id("Message").SpriteCssClass("PdfDocument e-icon msg
").TooltipText("Message");
}).Items(s1 =>
{
s1.Add().Id("Previous").SpriteCssClass("PdfDocument e-icon previous
").TooltipText("Show previous page ( Left Arrow )");
s1.Add().Id("Next").SpriteCssClass("PdfDocument e-icon next
").TooltipText("Show next page ( Right Arrow )");
s1.Add().Id("page").SpriteCssClass("PdfDocument
").ContentTemplate(@<input type="text" value="1" />);
s1.Add().Id("count").ContentTemplate(@<span>/1</span>);
}).Items(s2 =>
{
s2.Add().Id("ZoomOut").SpriteCssClass("PdfDocument e-icon zoomOut
").TooltipText("Zoom Out");
s2.Add().Id("ZoomIn").SpriteCssClass("PdfDocument e-icon zoomIn
").TooltipText("Zoom In");
s2.Add().Id("ZoomValue").SpriteCssClass("PdfDocument
").ContentTemplate(@<div>
@dropdown()
</div>);
}).Items(s3 =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
s3.Add().Id("FitFull").SpriteCssClass("PdfDocument e-icon fitOne
").TooltipText("Fit one full page to window");
s3.Add().Id("StickyNote").SpriteCssClass("PdfDocument e-icon sticky
").TooltipText("Add stick note ( Ctrl+6 ) ");
s3.Add().Id("ReadMode").SpriteCssClass("PdfDocument e-icon readMode
").TooltipText("View File in Read Mode");
})
@helper dropdown()
{
<div id="percent">
<ul>
<li>10%</li>
<li>25%</li>
<li>50%</li>
<li>100%</li>
<li>400%</li>
<li>800%</li>
<li>1600%</li>
<li>3200%</li>
<li>6400%</li>
</ul>
</div>
@Html.EJ().DropDownList("selectPercent").Width("90").Value("100%").Target
ID("percent")
}
</div>
```

CSS

```
<style type="text/css" class="cssStyles">
.e-tooltxt .PdfDocument.e-icon
{
background-image: url('http://js.syncfusion.com/UG/Web/Content/pdf-
icon.png');
background-repeat: no-repeat;
display: block;
height: 30px;
width: 30px;
}
.e-tooltxt .PdfDocument.e-icon:hover
{
background-image: url('http://js.syncfusion.com/UG/Web/Content/pdf-icon-
white.png');
}
.PdfDocument.e-icon.convertToOthers
{
background-position: -349px 0px;
}
.PdfDocument.e-icon.convertToPdf
{
background-position: -527px 0px;
}
.PdfDocument.e-icon.signature
{
background-position: 2px 0px;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.PdfDocument.e-icon.save
{
background-position: -87px 0px;
}
.PdfDocument.e-icon.msg
{
background-position: -483px 0px;
}
.PdfDocument.e-icon.previous
{
background-position: -395px 0px;
}
.PdfDocument.e-icon.next
{
background-position: -439px 0px;
}
.PdfDocument.e-icon.zoomIn
{
background-position: -175px 0px;
}
.PdfDocument.e-icon.zoomOut
{
background-position: -219px 0px;
}
.PdfDocument.e-icon.fitOne
{
background-position: -264px 0px;
}
.PdfDocument.e-icon.sticky
{
background-position: -131px -1px;
}
.PdfDocument.e-icon.readMode
{
background-position: -308px 0px;
}
.PdfDocument.e-icon.print
{
background-position: -43px 0px;
}
#ZoomValue .PdfDocument
{
width: 90px;
}
#page .PdfDocument input
{
text-align: center;
width: 20px;
height: 21px;
}
#count span
{
width: 30px;
height: 30px;
position: relative;
top: 2px;
text-align: center;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
vertical-align: middle;
}
</style>
```

Execute the above code to render the following output.

responsiveType:Inline

We can set the responsiveType property to inline to display the overflown toolbar items as inline toolbar.

ASPX-CS

```
@Html.EJ().Toolbar("Toolbar").Width("65%").Height("33px").IsResponsive(tr
ue).ResponsiveType(ResponsiveType.Inline).Items(s =>
{
s.Add().Id("OtherFormat").SpriteCssClass("PdfDocument e-icon
convertToOthers ").TooltipText("Convert PDF files to Word or Excel
Online…");
s.Add().Id("PDFOnline").SpriteCssClass("PdfDocument e-icon convertToPdf
").TooltipText("Convert files to PDF Online");
s.Add().Id("Signature").SpriteCssClass("PdfDocument e-icon signature
").TooltipText("Sign, add text or send a document for signature");
s.Add().Id("Save").SpriteCssClass("PdfDocument e-icon save
").TooltipText("Save file ( Ctrl+S )");
s.Add().Id("Print").SpriteCssClass("PdfDocument e-icon print
").TooltipText("Print file ( Ctrl+P )");
s.Add().Id("Message").SpriteCssClass("PdfDocument e-icon msg
").TooltipText("Message");
}).Items(s1 =>
{
s1.Add().Id("Previous").SpriteCssClass("PdfDocument e-icon previous
").TooltipText("Show previous page ( Left Arrow )");
s1.Add().Id("Next").SpriteCssClass("PdfDocument e-icon next
").TooltipText("Show next page ( Right Arrow )");
s1.Add().Id("page").SpriteCssClass("PdfDocument
").ContentTemplate(@<input type="text" value="1" />);
s1.Add().Id("count").ContentTemplate(@<span>/1</span>);
}).Items(s2 =>
{
s2.Add().Id("ZoomOut").SpriteCssClass("PdfDocument e-icon zoomOut
").TooltipText("Zoom Out");
s2.Add().Id("ZoomIn").SpriteCssClass("PdfDocument e-icon zoomIn
").TooltipText("Zoom In");
s2.Add().Id("ZoomValue").SpriteCssClass("PdfDocument
").ContentTemplate(@<div>
@dropdown()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</div>);
}).Items(s3 =>
{
s3.Add().Id("FitFull").SpriteCssClass("PdfDocument e-icon fitOne
").TooltipText("Fit one full page to window");
s3.Add().Id("StickyNote").SpriteCssClass("PdfDocument e-icon sticky
").TooltipText("Add stick note ( Ctrl+6 ) ");
s3.Add().Id("ReadMode").SpriteCssClass("PdfDocument e-icon readMode
").TooltipText("View File in Read Mode");
})
@helper dropdown()
{
<div id="percent">
<ul>
<li>10%</li>
<li>25%</li>
<li>50%</li>
<li>100%</li>
<li>400%</li>
<li>800%</li>
<li>1600%</li>
<li>3200%</li>
<li>6400%</li>
</ul>
</div>
@Html.EJ().DropDownList("selectPercent").Width("90").Value("100%").Target
ID("percent")
}
```

The following output will be displayed while executing the above code:

responsiveType:Popup

We can set the responsiveType property to popup to display the overflown toolbar items as popup. This the default value of enum responsiveType.

ASPX-CS

```
@Html.EJ().Toolbar("Toolbar").Width("65%").Height("33px").IsResponsive(tr
ue).ResponsiveType(ResponsiveType.Popup).Items(s =>
{
s.Add().Id("OtherFormat").SpriteCssClass("PdfDocument e-icon
convertToOthers ").TooltipText("Convert PDF files to Word or Excel
Online…");
s.Add().Id("PDFOnline").SpriteCssClass("PdfDocument e-icon convertToPdf
").TooltipText("Convert files to PDF Online");
s.Add().Id("Signature").SpriteCssClass("PdfDocument e-icon signature
").TooltipText("Sign, add text or send a document for signature");
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
s.Add().Id("Save").SpriteCssClass("PdfDocument e-icon save
").TooltipText("Save file ( Ctrl+S )");
s.Add().Id("Print").SpriteCssClass("PdfDocument e-icon print
").TooltipText("Print file ( Ctrl+P )");
s.Add().Id("Message").SpriteCssClass("PdfDocument e-icon msg
").TooltipText("Message");
}).Items(s1 =>
{
s1.Add().Id("Previous").SpriteCssClass("PdfDocument e-icon previous
").TooltipText("Show previous page ( Left Arrow )");
s1.Add().Id("Next").SpriteCssClass("PdfDocument e-icon next
").TooltipText("Show next page ( Right Arrow )");
s1.Add().Id("page").SpriteCssClass("PdfDocument
").ContentTemplate(@<input type="text" value="1" />);
s1.Add().Id("count").ContentTemplate(@<span>/1</span>);
}).Items(s2 =>
{
s2.Add().Id("ZoomOut").SpriteCssClass("PdfDocument e-icon zoomOut
").TooltipText("Zoom Out");
s2.Add().Id("ZoomIn").SpriteCssClass("PdfDocument e-icon zoomIn
").TooltipText("Zoom In");
s2.Add().Id("ZoomValue").SpriteCssClass("PdfDocument
").ContentTemplate(@<div>
@dropdown()
</div>);
}).Items(s3 =>
{
s3.Add().Id("FitFull").SpriteCssClass("PdfDocument e-icon fitOne
").TooltipText("Fit one full page to window");
s3.Add().Id("StickyNote").SpriteCssClass("PdfDocument e-icon sticky
").TooltipText("Add stick note ( Ctrl+6 ) ");
s3.Add().Id("ReadMode").SpriteCssClass("PdfDocument e-icon readMode
").TooltipText("View File in Read Mode");
})
@helper dropdown()
{
<div id="percent">
<ul>
<li>10%</li>
<li>25%</li>
<li>50%</li>
<li>100%</li>
<li>400%</li>
<li>800%</li>
<li>1600%</li>
<li>3200%</li>
<li>6400%</li>
</ul>
</div>
@Html.EJ().DropDownList("selectPercent").Width("90").Value("100%").Target
ID("percent")
}
```

The following output will be displayed while executing the above code:

Copyright © 2001 - 2020 Syncfusion Inc.

How To

Render Toolbar from code behind

Toolbar can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of Toolbar using Toolbar properties from code behind.

RAZOR

```
@{
Html.EJ().Toolbar("toolbar",
(Syncfusion.JavaScript.Models.ToolbarProperties)ViewData["toolbar"]).Rend
er();
}
```

C#

```
public ActionResult Index()
{
List<ToolbarBaseItem> obj = new List<ToolbarBaseItem>();
obj.Add(new ToolbarBaseItem() { SpriteCssClass= "e-icon e-cut"
,TooltipText="cut"});
obj.Add(new ToolbarBaseItem() { SpriteCssClass = "e-icon e-copy",
TooltipText = "copy" });
obj.Add(new ToolbarBaseItem() { SpriteCssClass = "e-icon e-paste",
TooltipText = "paste" });
ToolbarProperties toolbar = new ToolbarProperties();
toolbar.Items = obj;
ViewData["toolbar"] = toolbar;
return View();
}
```

Tooltip

Overview

The Tooltip control displays a pop-up hint when users hover, click, or focus on an element. The Tooltip will be positioned based on browser window, mouse, target element, or x and y coordinates. The Tooltip's layout can be customized to create a distinct visualized element.

Key Features

Responsive – Flexible positioning of Tooltip and can even reposition themselves when the viewport is resized. **Template** - The Tooltip's layout can be customized to create a distinct visualized element. *Animation – Custom animation effects can be used for showing/hiding the Tooltip* **RTL support** -

Provides a full-fledged right-to-left mode which aligns content in the Tooltip control from right to left. * **Accessibility** - Supports keyboard and ARIA accessibility.

Getting started

Create a Tooltip

Using the following steps, you can create a Tooltip control. The basic rendering of ASP.NET MVC Tooltip is achieved with default functionality.

1. You can create an MVC Project and add necessary assembly and script with the help of the given MVC-Getting Started Documentation.

2. Add the mentioned code to the corresponding view page for Tooltip rendering.

ASPX-CS

```
<div class="frame">
<div class="img" id="sample1">
<a target="_blank" href="image/taj.png">
<img
src="http://mvc.syncfusion.com/demos/web/content/images/tooltip/template-
05.png" alt="Delphi">
</a>
<div class="desc">Delphi Succinctly</div>
</div>
</div>
@Html.EJ().Tooltip("sample1").Content("Learn the fundamentals of Delphi
to build a variety of solutions for many devices and platforms.")
```

Apply the following style sheet

CSS

```
<style>
div.img {
border: 1px solid #ccc;
width: 159px;
height: 213px;
left: 35%;
position: relative;
top: 20%;
}
div.img img {
width: 159px;
height: 179px;
}
div.desc {
padding: 8px;
text-align: center;
}
</style>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Setting Dimensions

Tooltip dimensions can be set using width and height API.

ASPX-CS

```
<div class="control">
TypeScript lets you write <a id="tooltip1"><u> JavaScript</u> </a>the way
you really want to.
</div>
@Html.EJ().Tooltip("tooltip1").Content("JavaScript is the programming
language of HTML and the Web.").Width("100px").Height("100px")
```

Tooltip Appearance

You can configure the appearance of the Tooltip with the title, close button and call out as your application requires.

ASPX-CS

```
<div class="img" id="sample">
<a target="_blank" href="image/taj.png">
<img
src="http://mvc.syncfusion.com/demos/web/content/images/tooltip/template-
05.png" alt="Delphi">
</a>
<div class="desc">Delphi Succinctly</div>
</div>
@Html.EJ().Tooltip("sample").Content("Learn the fundamentals of Delphi to
build a variety of solutions for many devices and
platforms.").Width("180px").Title("Delphi
Succinctly").CloseMode(CloseMode.Sticky).IsBalloon(false)
```

Apply the following styles to show the Tooltip.

CSS

```
<style>
div.img {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
border: 1px solid #ccc;
float: left;
box-sizing: border-box;
height: 200px;
width: 146px;
}
div.img img{
width: 100%;
height: 166px;
}
div.desc {
padding: 6px;
text-align: center;
}
</style>
```

Customization

Template Support

By default you can add any text or image to the Tooltip. To customize the tooltip layout or to create your own visualized elements you can use this template support.

ASPX-CS

```
<div class="ctrl" id="centerImage">
<img class="ctrImg"
src="http://mvc.syncfusion.com/demos/web/content/images/tooltip/template-
04.png" />
<div class="new">Roslyn Succinctly</div>
</div>
@Html.EJ().Tooltip("centerImage").Content("<div class='main'> <div
class='poster'> <img
src='http://mvc.syncfusion.com/demos/web/content/images/tooltip/template-
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
2.png' width='150px' height='120px'> </div> <div class='def'> <h4> Roslyn
Succinctly </h4><div class='description'>Microsoft has only recently
embraced the world of open source software, offering <a
href='#'>More...</a> </div>").Width("350px")
```

CSS

```
<style>
h4 {
margin-top: 0px;
margin-bottom: 2px;
}
.e-tooltip-wrap .e-tipContainer .e-tipcontent {
padding: 5px 0px;
}
.poster {
float: left;
padding: 4px 0px;
}
.new {
text-align: center;
}
.def {
float: right;
}
.ctrl {
border: 1px solid #ebebe0;
width: 150px;
padding: 5px;
height: 180px;
margin-top: 239px;
margin-left: 250px;
}
.ctrImg {
width: 150px;
height: 160px;
}
.category {
margin-left: 10px;
}
.description {
width: 200px;
height: 60px;
line-height: 22px;
margin-top: 10px;
}
</style>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Tooltip's title customization

Tooltip title can be customized with the image or any HTML element.

ASPX-CS

```
<div class="ctrl" id="centerImage">
<img class="ctrImg"
src="http://mvc.syncfusion.com/demos/web/content/images/tooltip/template-04.png" />
<div class="new">Roslyn Succinctly</div>
</div>
@Html.EJ().Tooltip("centerImage").Content("<div>Microsoft has only recently embraced the world of open source software, offering <a href='#'>More...</a> </div>").Title("<div><img class='titleImg' src='http://mvc.syncfusion.com/demos/web/content/images/tooltip/template-2.png' /> <div class='description'> Roslyn Succinctly </div> </div> ")
```

CSS

```
<style>
.titleImg {
width: 20px;
height: 20px;
float: left;
margin-right: 10px;
}
#centerImage{
margin-left : 300px;
margin-top : 250px;
position : absolute;
border: 1px solid grey;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
.description {
height: 20px;
}
</style>
```

Animation Effects

Determines the type of effect that takes place when showing/hiding the tooltip.

We can specify the effect and the duration for the animation.

Effects	Description
Slide	Sliding animation effect takes place with a duration of 200ms.
Fade	Fading animation effect takes place with a duration of 800ms.
None (Default)	No effect takes place

Let's create a Tooltip that slides down when shown using the animation property:

ASPX-CS

```
<div class="control">
TypeScript lets you write <a id="tooltip1"><u> JavaScript</u> </a>the way
you really want to.
</div>
@Html.EJ().Tooltip("tooltip1").Content("JavaScript is the programming
language of HTML and the Web.").Animation(animationEffect =>
animationEffect.Effect(Effect.Slide).Speed(1000))
```

Custom Animation

Custom animation effect for both Tooltip show/hide can also be done by show and hide method.

Copyright © 2001 - 2020 Syncfusion Inc.

Show or Hide method may receive an optional 'callback' parameter, which represents a function you'd like to call which will animate the tooltip.

ASPX-CS

```
<div class="control">
TypeScript lets you write <a id="tooltip2"><u> JavaScript</u> </a>the way
you really want to.
</div>
@Html.EJ().Button("open").Size(ButtonSize.Large).ShowRoundedCorner(true).
Text("Open").ClientSideEvents(events => events.Click("onClick"))
@Html.EJ().Tooltip("tooltip2").Content("JavaScript is the programming
language of HTML and the Web.")
<script>
var tip;
function onClick(args){
tip = $("#tooltip2").data("ejTooltip");
tip.show(null,"myFunc");
}
function myFunc(args) {
tip = $("#tooltip2").data("ejTooltip");
$(tip.tooltip).slideDown(200, "easeOutElastic");
}
</script>
```

Note: Show or Hide method can also receive an optional parameter “effect name”, (e.g any easing effect name) which specifies the type of effect taken place when showing/hiding of the tooltip, please refer to the following link for online demo - link.

Modernize the tooltip’s content

It's easy to update a tooltip’s content – whether it’s open or closed.

ASPX-CS

```
<div class="control">
TypeScript lets you write <a id="tooltip3"><u> JavaScript</u> </a>the way
you really want to.
@Html.EJ().Button("open").Size(ButtonSize.Large).ShowRoundedCorner(true).
Text("Update Content").ClientSideEvents(events =>
events.Click("onClick"))
</div>
@Html.EJ().Tooltip("tooltip3").Content("JavaScript is the programming
language of HTML and the Web.")
<script type="text/javascript">
function onClick(args){
tip = $("#tooltip3").data("ejTooltip");
tip.setModel({ content: "JavaScript" });
tip.show();
}
</script>
```

Closing Mode

By default, the Tooltip will be hidden when mouse leaves the target element. Different types of close mode as follows

Copyright © 2001 - 2020 Syncfusion Inc.

Types	Description
Auto	Tooltip will be hidden after a particular period of time.
Sticky	Tooltip rendered with the button, it will close the tooltip.
None (Default)	Tooltip will be hidden when mouse leaves the target element.

Auto

The tooltip will be visible only for the period of time specified in the autoCloseTimeout.

Let see an example, this Tooltip will only hide after hovering the target for 2000ms

ASPX-CS

```
<div class="control">
TypeScript lets you write <a id="tooltip4"><u> JavaScript</u> </a>the way
you really want to.
</div>
@Html.EJ().Tooltip("tooltip4").Content("JavaScript is the programming
language of HTML and the
Web.").CloseMode(CloseMode.Auto).AutoCloseTimeout(2000)
```

Note: Time specified in the autoCloseTimeout will be in milliseconds and the default value is 4000ms

Sticky

A close button will be shown with the Tooltip. The button element (i.e. close button) located by default at the top right of the Tooltip or title bar (if title is enabled). The tooltip gets closed when the button is clicked.

ASPX-CS

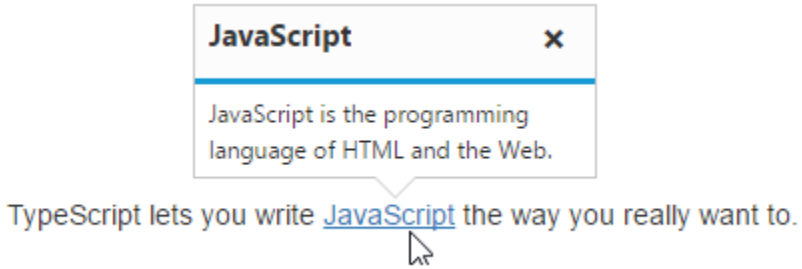
```
<div class="control">
TypeScript lets you write <a id="tooltip5"><u> JavaScript</u> </a>the way
you really want to.
</div>
@Html.EJ().Tooltip("tooltip5").Content("JavaScript is the programming
language of HTML and the
Web.").CloseMode(CloseMode.Sticky).Width("200px")
```

You can also have Tooltip with a title, in which case the button will lye within it:

ASPX-CS

```
<div class="control">
TypeScript lets you write <a id="tooltip6"><u> JavaScript</u> </a>the way
you really want to.
```

```
</div>
@Html.EJ().Tooltip("tooltip6").Content("JavaScript is the programming
language of HTML and the
Web.").CloseMode(CloseMode.Sticky).Width("200px").Title("JavaScript")
```



Position

The position object defines various attributes of the Tooltip position, including the element it is positioned in relation to, and how the position is adjusted within the defined container.

Lets position the Tooltips (stems) left center corner at the right center of the target element.

ASPX-CS

```
<div class="img" id="sample">
<a target="_blank" href="image/taj.png">
<img
src="http://mvc.syncfusion.com/demos/web/content/images/tooltip/template-
05.png" alt="Delphi">
</a>
<div class="desc">Delphi Succinctly</div>
</div>
@Html.EJ().Tooltip("sample").Content("Learn the fundamentals of Delphi to
build a variety of solutions for many devices and
platforms.").Position(position => position.Target(target =>
target.Horizontal("right").Vertical("center")).Stem(stem =>
stem.Horizontal("left").Vertical("center")))
```

Apply the following styles to show the Tooltip.

CSS

```
<style>
div.img {
border: 1px solid #ccc;
float: left;
box-sizing: border-box;
height: 200px;
width: 146px;
}
div.img img{
width: 100%;
height: 166px;
}
div.desc {
padding: 6px;
text-align: center;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
</style>
```

Note: By default, the Tooltips "center bottom" corner is placed at the center top of the target element.

Containment

Determines the HTML element in which the Tooltip is appended to e.g. its containing element and The tooltip will be restricted to move only within the specified container element.

Let's append our Tooltip to a custom 'frame' container:

ASPX-CS

```
<div class="frame">
<div class="control">
TypeScript lets you write <a id="tooltip1"><u> JavaScript</u> </a>the way
you really want to.
</div>
</div>
@Html.EJ().Tooltip("tooltip1").Content("JavaScript is the programming
language of HTML and the Web.").Containment(".frame")
```

Note: By default all Tooltips are appended to the document.body element.

Associates

The Tooltip will be positioned in relation to target element. Can also be set to 'mouse' or the window, or an absolute x/y position on the page.

Let's position the Tooltip in relation to the 'a' element inside the div element:

ASPX-CS

```
<div class="frame">
<div class="control">
TypeScript lets you write <a id="tooltip2"><u> JavaScript</u> </a>the way
you really want to.
</div>
</div>
@Html.EJ().Tooltip("tooltip2").Content("JavaScript is the programming
language of HTML and the Web.")
```

Copyright © 2001 - 2020 Syncfusion Inc.

We can also position the Tooltip in relation to the mouse.

ASPX-CS

```
<div class="frame">
<div class="control">
TypeScript lets you write <a id="tooltip3"><u> JavaScript</u> </a>the way
you really want to.
</div>
</div>
@Html.EJ().Tooltip("tooltip3").Content("JavaScript is the programming
language of HTML and the Web.").Associate(Associate.Mousefollow)
```

Position the tooltip at the current mouse position, once enter to the target element as follows

ASPX-CS

```
<div class="frame">
<div class="control">
TypeScript lets you write <a id="tooltip4"><u> JavaScript</u> </a>the way
you really want to.
</div>
</div>
@Html.EJ().Tooltip("tooltip4").Content("JavaScript is the programming
language of HTML and the Web.").Associate(Associate.Mouseenter)
```

It also possible to place the tooltip relation to the window as follows

ASPX-CS

```
<div class="frame">
<div class="control">
TypeScript lets you write <a id="tooltip5"><u> JavaScript</u> </a>the way
you really want to.
</div>
</div>
@Html.EJ().Tooltip("tooltip5").Content("JavaScript is the programming
language of HTML and the Web.").Position(position =>
position.Target(target =>
target.Horizontal("right").Vertical("bottom"))).Associate(Associate.Windo
w)
```

And last but not least, absolute positioning via X,Y co-ordinates e.g. a Tooltip at 10px from left and top of the page:

ASPX-CS

```
<div class="frame">
<div class="control">
TypeScript lets you write <a id="tooltip6"><u> JavaScript</u> </a>the way
you really want to.
</div>
</div>
@Html.EJ().Tooltip("tooltip6").Content("JavaScript is the programming
language of HTML and the Web.").Position(position =>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
position.Target(target =>
target.Horizontal(10).Vertical(10))).Associate(Associate.Axis)
```

Collision

When the positioned element overflows the window in some direction, move it to an alternative position.

The following values determines the kind of positioning that takes place.

Value	Description
Flip	Flips the element to the opposite side of the target if the collision detected.
Fit	Shift the element away from the edge of the window.
FlipFit(Default)	Ensure as much of the element is visible as possible to showcase.
None	Does not apply any collision detection.

ASPX-CS

```
<div class="frame">
<div class="control">
TypeScript lets you write <a id="tooltip7"><u> JavaScript</u> </a>the way
you really want to.
</div>
</div>
@Html.EJ().Tooltip("tooltip7").Content("JavaScript is the programming
language of HTML and the Web.").Collision(Collision.Fit)
```

How To

Use AJAX to generate the Tooltip's content

Use jQuery's built-in AJAX functionality to retrieve remote content and set the content to the Tooltip as follows.

Define three employee's JSON Array as given below(an array of 3 employees records)

JS

```
[
{
"EmployeeID": 1,
"LastName": "Davolio",
"Title": "Sales Representative",
"TitleOfCourtesy": "Dr.",
"Address": "507 - 20th Ave. E.Apt. 2A",
"City": "Seattle",
"Region": "WA",
"PostalCode": "98122",
},
{
"EmployeeID": 2,
"LastName": "Buchanan",
"Title": "Sales Representative",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
"TitleOfCourtesy": "Dr.",
"Address": "908 W. Capital Way",
"City": "Tacoma",
"Region": "WA",
"PostalCode": "98401",
},
{
"EmployeeID": 3,
"LastName": "Leverling",
"Title": "Sales Representative",
"TitleOfCourtesy": "Dr.",
"Address": "722 Moss Bay Blvd.",
"City": "Kirkland",
"Region": "WA",
"PostalCode": "98033",
}
]
```

Render the employees table and create the tooltip. Once the tooltip created, the data will be fetched using AJAX method as follows.

ASPX-CS

```
<div class="frame">
<table id="details">
<tr>
<th>EmployeeID</th>
<th>Name</th>
<th>Designation</th>
</tr>
<tr>
<td>SF6089</td>
<td><a href="#" class="e-info" title="Davolio">Davolio</a></td>
<td>Software Engineer</td>
</tr>
<tr>
<td>SF6073</td>
<td> <a href="#" class="e-info" title="Leverling">Leverling </a> </td>
<td>Tester</td>
</tr>
<tr>
<td>SF6073</td>
<td> <a href="#" class="e-info" title="Suyama"> Suyama </a> </td>
<td>Content Writer</td>
</tr>
<tr>
<td>SF7896</td>
<td> <a href="#" class="e-info" title="Buchanan"> Buchanan </a> </td>
<td>Graphics Designer</td>
</tr>
</table>
</div>
@Html.EJ().Tooltip("details").Target(".e-info").ClientSideEvents(events
=>
events.BeforeOpen("onOpen")).Width("350px").Height("128px").Position(pos
=> pos.Target(target =>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
target.Horizontal("right").Vertical("bottom")).Stem(stem =>
stem.Horizontal("left").Vertical("top"))).Content(" ")
<script type="text/javascript">
var content;
var target = $("#details").data("ejTooltip");
function onOpen(args) {
proxy = args;
$.ajax({
dataType: "json",
url: "tooltipData.js",
success: function (result) {
var employee = [
{ photo:
"http://mvc.syncfusion.com/demos/web/content/images/Employees/2.png" },
{ photo:
"http://mvc.syncfusion.com/demos/web/content/images/Employees/4.png" },
{ photo:
"http://mvc.syncfusion.com/demos/web/content/images/Employees/8.png" },
{ photo:
"http://mvc.syncfusion.com/demos/web/content/images/Employees/3.png" },
{ photo:
"http://mvc.syncfusion.com/demos/web/content/images/Employees/1.png" },
{ photo:
"http://mvc.syncfusion.com/demos/web/content/images/Employees/6.png" },
];
for (i = 0; i < result.length ; i++) {
if (result[i].LastName == $(proxy.event.target).attr("data-content"))
content = '<div class="main"> <img src=' + employee[i].photo + '
class="logo"/><div class="des"><table> <tr> <th> ' +
result[i].TitleOfCourtesy + ' ' + result[i].LastName + '</th> </tr> <tr>
<td> Title </td> <td>  : ' + result[i].Title + '</td> </tr>
<tr><td> Address</td><td>  : ' + result[i].Address + '</td>
</tr><tr> <td> City </td> <td>  : ' + result[i].City + '</td>
</tr> <tr> <td> PostalCode </td> <td>  : ' +
result[i].PostalCode + '</td> </tr> </table></div></div>';
}
target.setModel({ content: content });
}
});
target.show(args.event.target);
args.cancel = true;
}
</script>
```

Defines the style for the tooltip layout and table as follows.

CSS

```
<style>
.frame {
width: 100%;
box-sizing: border-box;
}
.frame table {
border-collapse: collapse;
width: 100%;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
.frame th, .frame td {
text-align: left;
padding: 8px;
}
.logo {
float: left;
width: 100px;
height: 114px;
}
.frame tr:nth-child(even) {
background-color: #f2f2f2;
}
.frame th {
background-color: #4CAF50;
color: white;
}
.des {
width: 230px;
float: right;
line-height: 24px;
}
</style>
```

Integration with the Slider control

Tooltip can also be integrated with various other jQuery plugin. Tooltip shows the slider value above the handle.

Render the slider control and finds its handle to render the Tooltip as follows

ASPX-CS

```
<div class="frame">
<div id="loanheading">
Details of Loan
</div>
<span class="ColumnLeft">
<span class="loan">Loan Amount</span>
</span>
<span class="ColumnRight">
```

```
<span class="value">1000</span><span id="loantext">$ </span>
</span>
@(Html.EJ().Slider("loanSlider").Height("16px").Value("100").MinValue(10)
.MaxValue(1000).IncrementStep(10)
.ClientSideEvents(evt =>
evt.Change("onSlide").Slide("onSlide").Stop("onStop")))
</div>
@Html.EJ().Tooltip("loanSlider").Target(".e-
handle").ShowRoundedCorner(true).IsBalloon(true)
<script>
$(function () {
var loanObj = $('#loanSlider').data("ejSlider");
var loadTip = $('#loanSlider').data("ejTooltip");
loadTip.setModel({content : "$ " + loanObj.getValue().toString() });
});
</script>
```

Once the handler in the slider, start its sliding the below function will be triggered

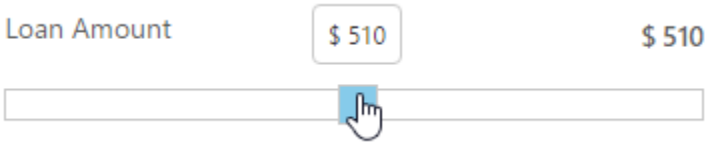
ASPX-CS

```
function onSlide(args) {
this.wrapper.prev().children('span.value').html(args.value);
var  value = args.value.toString();
if(args.id == "loanSlider")
value =  "$ " +value;
var tipWidth = (value < 10) ? "13px" : (10 <= value >= 100) ? "25px" :
"auto";
var tipObj = $('#loanSlider').data("ejTooltip");
tipObj.setModel({content : value, width : tipWidth});
tipObj.show($("div" + target).find(".e-handle"));
}
```

Once the sliding is stopped, the Tooltip will be shown for the particular period of time then it will be closed.

ASPX-CS

```
function onStop(args){
setTimeout( function(){
var tipObj = $('#loanSlider').data("ejTooltip");
tipObj.hide();
}, 1000);
}
```



Tip(arrow) customization

Styling the Tip's background and border colors is done using "cssClass" API of Tooltip. Change the size of the tip using the property name called "Tip" and CSS as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
<div class="frame">
<div class="img" id="custom">
<img
src="http://mvc.syncfusion.com/demos/web/content/images/tooltip/template-
04.png" alt="Roslyn Succinctly" >
<div class="desc">Roslyn Succinctly</div>
</div>
</div>
@Html.EJ().Tooltip("custom").Content("Learn to use the Python language to
create programs of all kinds to creating practical
applications.").Width("200px").Position(pos => pos.Target(target =>
target.Horizontal("right").Vertical("bottom")).Stem(stem =>
stem.Horizontal("left").Vertical("top"))).Tip(tip => tip.Size(size =>
size.Height(12).Width(25)))
<script type="text/javascript">
$(function () {
target = $("#custom").data("ejTooltip");
});
</script>
```

Defines the style for the tip as follow as

CSS

```
<style>
div.img {
border: 1px solid #ccc;
width: 159px;
height: 213px;
left: 35%;
position: relative;
top: 20%;
}
div.img img{
width: 159px;
height: 179px;
}
div.desc {
padding: 8px;
text-align: center;
}
</style>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Initialize Tooltip for the target element

Tooltips are also useful for input elements, to show hint in the context of each field.

Rather than using multiple Tooltips, a single Tooltip can be used to show the information of each and every field of the form/table element. This can be achieved using “target” API. Target property Specifies a selector for elements, within the container, for which the Tooltip will be displayed.

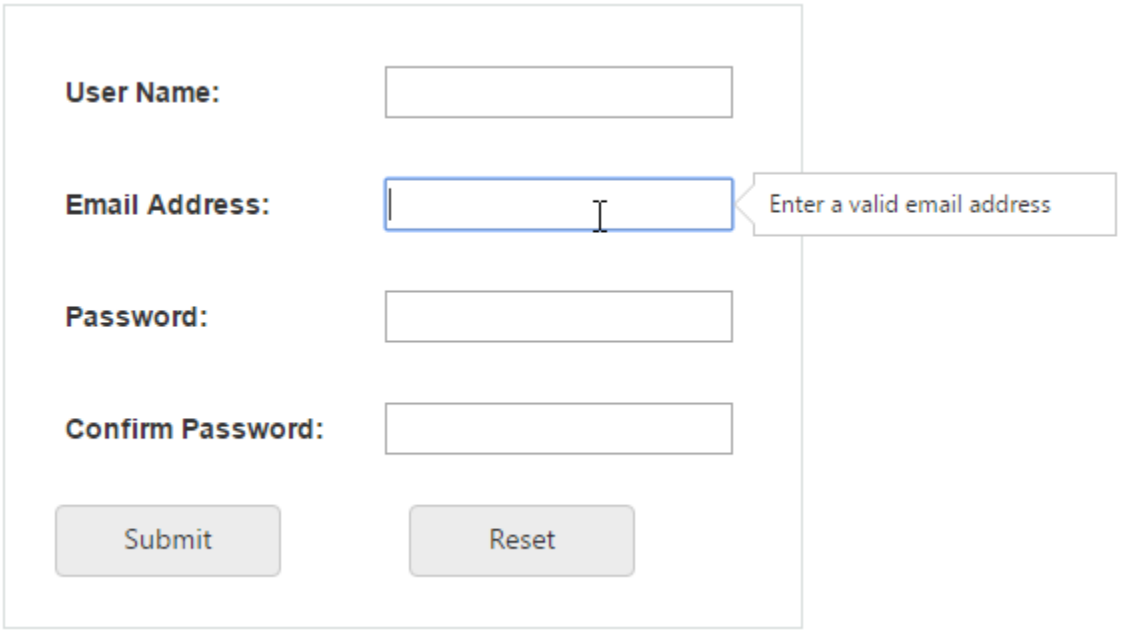
The example below demonstrates how to create a Tooltip for multiple targets element.

ASPX-CS

```
<form id="details" role="form">
<fieldset>
<table>
<tr>
<td class="info"> User Name:</td>
<td> <input type="text" class="e-info" name="firstname" title="Please
enter your name"> </td>
</tr>
<tr>
<td class="info"> Email Address:</td>
<td> <input type="text" class="e-info" name="email" title="Enter a valid
email address"></td>
</tr>
<tr>
<td class="info"> Password:</td>
<td> <input type="password" class="e-info" name="password" title="Be at
least 8 characters length"></td>
</tr>
<tr>
<td class="info"> Confirm Password:</td>
<td> <input type="password" class="e-info" name="Cpwd" title="Re-enter
your password"></td>
</tr>
</table>
@Html.EJ().Button("sample").Type(ButtonType.Submit).Text("Submit").ShowRo
undedCorner(true).Size(ButtonSize.Medium)
@Html.EJ().Button("clear").Type(ButtonType.Reset).Text("Reset").ShowRound
edCorner(true).Size(ButtonSize.Medium)
</fieldset>
</form>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().Tooltip("details").Target(".e-
info").Height("30px").Width("180px").Position(pos => pos.Target(target =>
target.Horizontal("right").Vertical("center")).Stem(stem =>
stem.Horizontal("left").Vertical("center"))).ClientSideEvents(events =>
events.Create("onCreate").BeforeOpen("onOpen"))
```



Apply the following styles to the form element.

CSS

```
<style>
th, td {
padding: 15px;
text-align: left;
}
#form {
position: absolute;
left: 200px;
}
fieldset {
border: 1px solid #D9DEDD;
padding: 15px;
width: 400px;
}
.info {
font-weight: bold;
}
#sample {
margin-right: 50px;
}
.e-button {
margin: 10px;
}
</style>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Interact with the Tooltip

Give users, the possibility to interact with the tooltip. If the tooltip is interactive and activated by a hover event, set the amount of time (milliseconds)allowed for a user to hover off of the tooltip activator on to the tooltip itself – keeping the tooltip from closing using “autoCloseTimeout” property.

Using this property, Links can be provided in Tooltip content where user can navigate to some other page. This is handy for situations where you need to grab the user attention.

ASPX-CS

```
<div class="control">
TypeScript lets you write <a id="test"><u> JavaScript</u> </a>the way you
really want to.
</div>
@Html.EJ().Tooltip("test").Content("JavaScript is the programming
language of HTML and the
Web.").CloseMode(CloseMode.Auto).AutoCloseTimeout(2000)
```

Render Tooltip from code behind

Tooltip can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of Tooltip using Tooltip properties from code behind.

RAZOR

```
<div class="control">
Alongside HTML and CSS, JavaScript is one of the three essential
technologies of <a id="link1"><u> World Wide Web </u>
</a>content production; the majority of websites employ it and it is
supported by all modern Web browsers without plug-ins.
</div>
@{
Html.EJ().Tooltip("link1",
(Syncfusion.JavaScript.Models.TooltipProperties)ViewData["tooltip"]).Rend
er();
}
```

C#

```
public ActionResult Index()
{
TooltipProperties obj = new TooltipProperties();
obj.Content = "The World Wide Web (WWW) is an information space where
documents and other web resources are identified by URLs, interlinked by
hypertext links, and can be accessed via the Internet.";
ViewData["tooltip"] = obj;
return View();
}
```

TreeMap

TreeMap

Essential TreeMap for **JavaScript** is ideal for visualizing large amounts of data. **TreeMap** holds a set of nested nodes to display hierarchical data. Each nested node may contain sub-nodes containing area proportional to a specified data value bounded. Color and annotation can be used to provide extra information about the leaf nodes. **EssentialTreeMap** is a perfect solution for developers looking to add advanced, feature rich **Treemap** to their applications.

Key Features

- **Levels** - TreeMap levels are used to define levels of various flat data and hierarchical data collection.
- **Layout** - Layouts such as Squarified, SliceAndDiceAuto, SliceAndDiceHorizontal and SliceAndDiceVertical determines the visual representation of nodes belonging to all the treemap levels in TreeMap.
- **Visualization for Colors** - Easy customization options is provided to customize the colors of the leaf nodes of TreeMap.

Use Case Scenarios

TreeMap is used to represent large or complex data sets in various applications, such as:

- Stock market analysis where the weight of each stock in the index is represented by the size of the rectangle and its range of loss or gain is represented by the color of the rectangle.
- Visualizing Internet usage in certain categories, such as retail, social networks, and search.
- Categorizing the news aggregated by Google News where the colors represent different sections, such as business or politics, and the size of the boxes represent how many similar stories also appear in Google News.
- Indicating weather report analysis around the world. The opacity of each rectangle can differ based on its humidity.

Getting Started

This section explains briefly about how to create a **TreeMap** in your application with ASP.NET MVC .

Configure a TreeMap

You can configure an **MVC TreeMap** in simple steps. This manual provides instructions on how to configure TreeMap with grouping of populated datum based on population growth in population in each continent. It also provides a walk-through on some of the customization feature available in TreeMap control.

Copyright © 2001 - 2020 Syncfusion Inc.

Create a simple MVC Application

You can create a new ASP.NET MVC project Razor application by adding the necessary dll's and scripts.

Add Data

You can populate the TreeMap data inside the controller. For example, you can populate data of few countries from the following location.

~/Controller/TreeMapController.cs

C#

```
public class TreeMapPopulationData
{
public string Continent { get; set; }
public string Region { get; set; }
public int Growth { get; set; }
public long Population { get; set; }
public static List<TreeMapPopulationData> GetData()
{
List<TreeMapPopulationData> population = new
List<TreeMapPopulationData>();
population.Add(new TreeMapPopulationData() { Continent = "Asia", Region =
"Southern Asia", Growth = 1.32, Population = 1749046000});
population.Add(new TreeMapPopulationData() { Continent = "Asia", Region =
"Eastern Asia", Growth = 0.57, Population = 1620807000});
population.Add(new TreeMapPopulationData() { Continent = "Asia", Region =
"South-Eastern Asia", Growth = 1.20, Population = 618793000});
population.Add(new TreeMapPopulationData() { Continent = "Asia", Region =
"Western Asia", Growth = 1.98, Population = 245707000});
population.Add(new TreeMapPopulationData() { Continent = "Asia", Region =
"Central Asia", Growth = 1.43, Population = 64370000});
population.Add(new TreeMapPopulationData() { Continent = "Europe", Region
= "Europe", Growth = 0.10, Population = 742452000});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
population.Add(new TreeMapPopulationData() { Continent = "America",
Region = "South America", Growth = 1.06, Population = 406740000});
population.Add(new TreeMapPopulationData() { Continent = "America",
Region = "Northern America", Growth = 0.85, Population = 355361000});
population.Add(new TreeMapPopulationData() { Continent = "America",
Region = "Central America", Growth = 1.40, Population = 167387000});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Region
= "Eastern Africa", Growth = 2.89, Population = 373202000});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Region
= "Western Africa", Growth = 2.78, Population = 331255000});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Region
= "Northern Africa", Growth = 1.70, Population = 210002000});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Region
= "Middle Africa", Growth = 2.79, Population = 135750000});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Region
= "Southern Africa", Growth = 0.91, Population = 60425000});
return population;
}
}
```

Note: Population data is referred from List of continents by population

Initialize TreeMap

1. Create a tag with a specific id and set the height and width to determine the TreeMap size to be rendered in “TreeMap.cshtml” file

ASPX-CS

```
<div style="width:700px; height:400px;">
</div>
```

2. Add the following code in “TreeMap.cshtml” file to create the TreeMap control in a View page.

ASPX-CS

```
<div style="width:700px; height:400px;">
@(Html.EJ().TreeMap("treemap")
.Render())
</div>
```

3. Add the TreeMap() action in “TreeMapController.cs” as illustrated in the following code sample.

C#

```
public ActionResult TreeMap()
{
ViewData["datasource"] = TreeMapPopulationData.GetData();
return View();
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Data Source

The DataSource property accepts the collection values as input. For example, you can provide the list of objects as input.

Weight Value Path

You can calculate the size of the object using WeightValuePath of TreeMap.

1. Populate the TreeMap by using the above properties.

ASPX-CS

```
@{
var datasource = ViewData["datasource"];
}
<html xmlns="http://www.w3.org/1999/xhtml">
<head> // ...
</head>
<body>
<div style="height:400px;width:700px;">
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.WeightValuePath("Population")
.Render())
</div>
// ...
</body>
</html>
```

2. Final TreeMap.cshtml file is illustrated in the following code sample.

ASPX-CS

```
@{
var datasource = ViewData["datasource"];
}
<html xmlns="http://www.w3.org/1999/xhtml">
<head>
<script src="http://code.jquery.com/jquery-1.10.1.min.js"></script>
<script src="http://cdn.syncfusion.com/13.1.0.21/js/
ej.widgets.all.min.js"></script>
<script src="http://cdn.jsdelivr.net/jsrender/1.0pre35/jsrender.min.js"
type="text/javascript"></script>
<script
src="http://cdn.syncfusion.com/13.1.0.21/js/web/ej.unobtrusive.min.js"
type="text/javascript"></script>
<script src="http://cdn.syncfusion.com/13.1.0.21/js/web/flat-
azure/ej.web.all.min.css" type="text/javascript"></script><body>
<div style="height:400px;width:700px;">
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.WeightValuePath("Population")
.Render())
</div>
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</body>
</html>
```

The following image displays a TreeMap with default properties using the above code.

GroupTreeMap Items using Levels

You can group TreeMap Items using Levels in TreeMap.

Group Path

You can use GroupPath property for every flat level of the TreeMap control. It is a path to a field on the source object that serves as the “Group” for the level specified. You can group the data based on the GroupPath in the TreeMap control. When the GroupPath is not specified, then the items are not grouped and the data is displayed in the order specified in the DataSource.

Group Gap

You can use GroupGap property to separate the items from every flat level and to differentiate the levels mentioned in the TreeMap control.

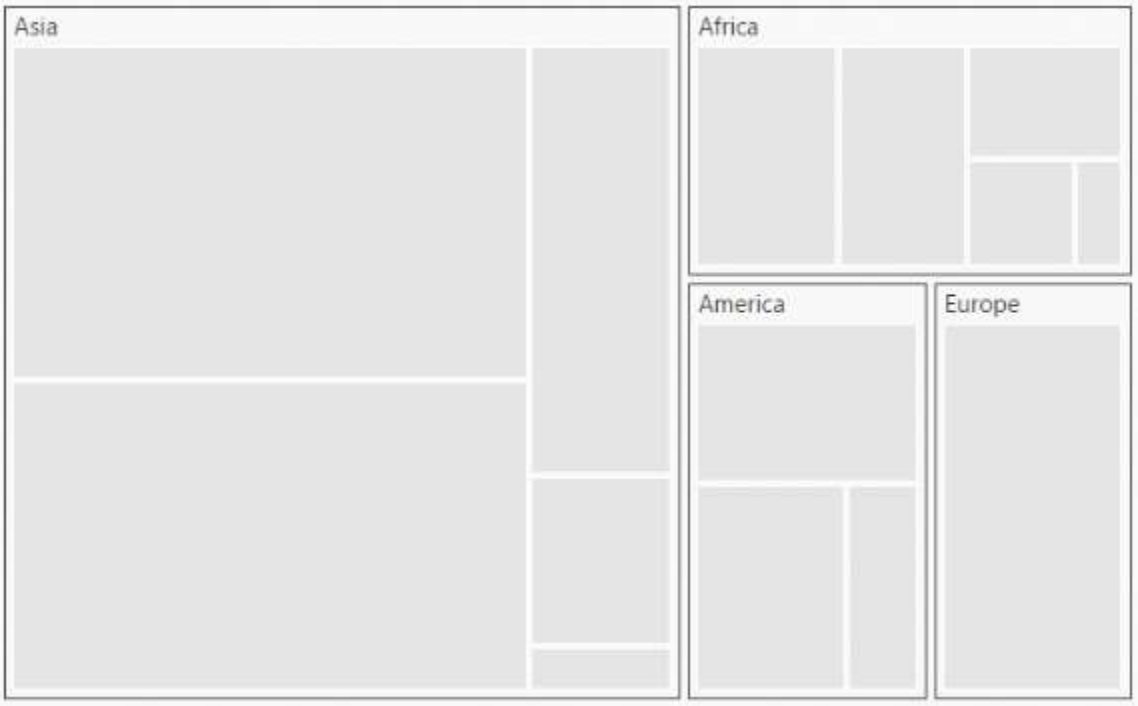
The following code sample explains how to group TreeMap Items using ‘Levels’

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.WeightValuePath("Population")
.Levels(lv =>
{
lv.GroupPath("Continent")
.GroupGap(5).Add();
})
.Render())
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot displays grouping of TreeMapItems using Levels.



Customize TreeMap Appearance by Range

You can differentiate the nodes based on its value and color ranges using RangeColorMapping . You can also define the color value range using From and To properties.

Color Value Path

The ColorValuePath of TreeMap is a path to a field on the source object. You can determine the color for the object using ColorValuePath of TreeMap.

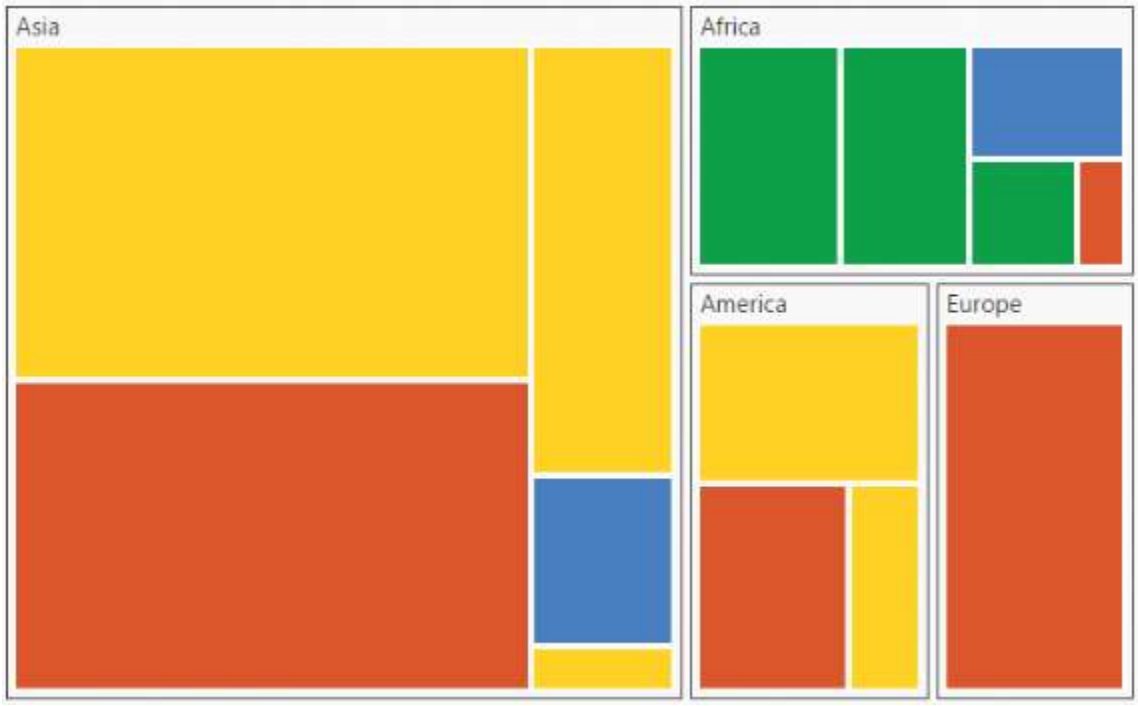
The following code sample explains how to customize TreeMap Appearance by Range.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.WeightValuePath("Population")
.Levels(lv =>
{
lv.GroupPath("Continent")
.GroupGap(5).Add();
})
.ColorValuePath("Growth")
.TreeMapRangeColorMappings(cm =>
{
cm.To(1).From(0).Color("#DC562D").Add();
cm.To(1.5).From(1).Color("#FED124").Add();
cm.To(2).From(1.5).Color("#487FC1").Add();
cm.To(3).From(2).Color("#0E9F49").Add();
})
.Render())
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot displays customized TreeMap Appearance by Range



Enable Tooltip

You can enable the tooltip by setting ShowTooltip property to 'true'. By default, it takes the property of the bound object that is referred in the WeightValuePath and displays its content when the corresponding node is hovered. You can customize the template for tooltip using TooltipTemplate property.

Leaf Item Settings

You can customize the Leaf level TreeMap items using LeafItemSettings. The Label and tooltip values take the property of bound object that is referred in the LabelPath when defined.

The following code sample displays how the tooltip is enabled.

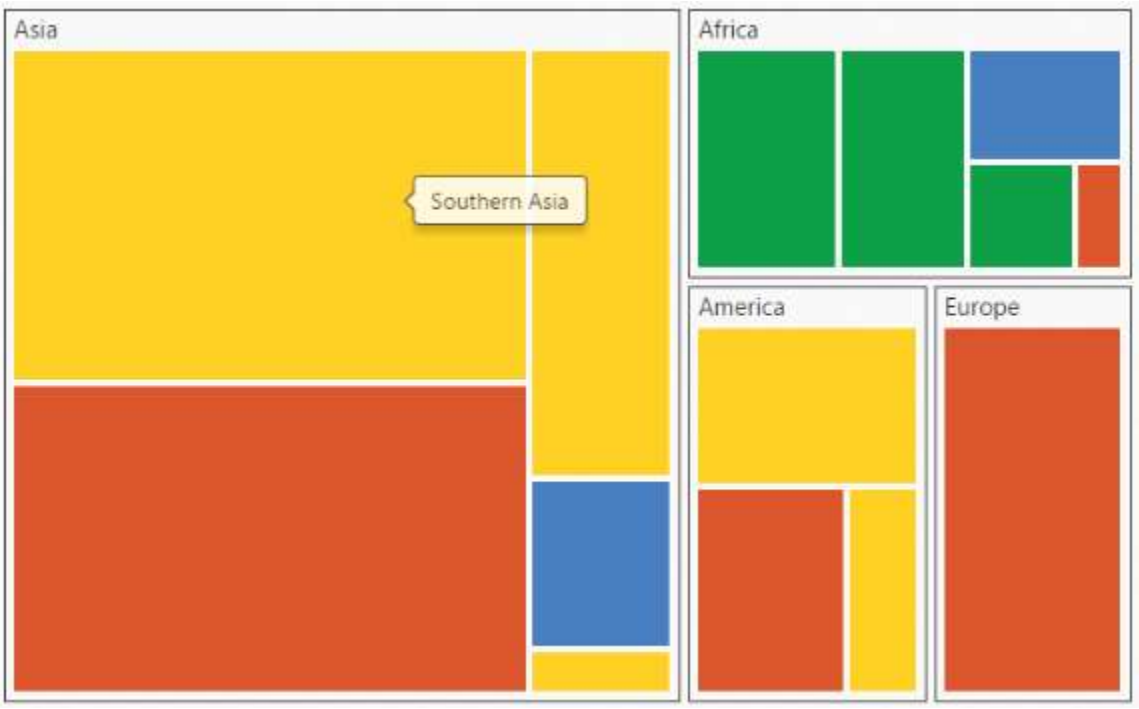
ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.WeightValuePath("Population")
.Levels(lv =>
{
lv.GroupPath("Continent")
.GroupGap(5).Add();
})
.ColorValuePath("Growth")
.TreeMapRangeColorMappings(cm =>
{
cm.To(1).From(0).Color("#DC562D").Add();
cm.To(1.5).From(1).Color("#FED124").Add();
cm.To(2).From(1.5).Color("#487FC1").Add();
cm.To(3).From(2).Color("#0E9F49").Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
.ShowTooltip(true)
.LeafItemsSettings(leaf =>
{
leaf.LabelPath("Region");
})
.Render())
```

The following screenshot displays the TreeMap when the Tooltip is enabled.



Legend

You can set the color value of leaf nodes using TreeMap LegendSettings . This legend is appropriate only for the TreeMap whose leaf nodes are colored using RangeColorMapping.

You can set ShowLegend property value to '*true*' to make a Legend visible.

Label for Legend

You can customize the labels of the legend item using LegendLabel property of RangeColorMapping.

The following code sample displays how to add labels for legend in a TreeMap.

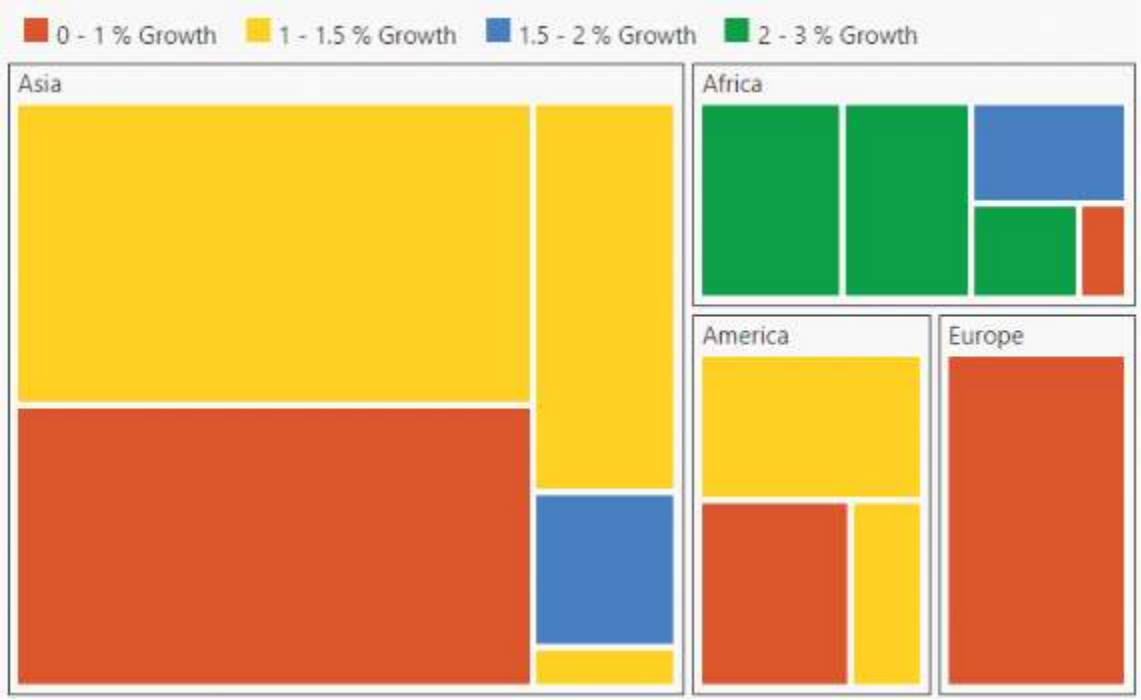
ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.WeightValuePath("Population")
.Levels(lv =>
{
lv.GroupPath("Continent")
.GroupGap(5).Add();
})
.ColorValuePath("Growth")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.TreeMapRangeColorMappings(cm =>
{
cm.To(1).From(0).Color("#DC562D").LegendLabel("0 - 1 % Growth").Add();
cm.To(1.5).From(1).Color("#FED124").LegendLabel("1 - 1.5 %
Growth").Add();
cm.To(2).From(1.5).Color("#487FC1").LegendLabel("1.5 - 2 %
Growth").Add();
cm.To(3).From(2).Color("#0E9F49").LegendLabel("2 - 3 % Growth").Add();
})
.ShowTooltip(true)
.LeafItemsSettings(leaf =>
{
leaf.LabelPath("Region");
})
.ShowLegend(true)
.Render())
```

The following screenshot displays the TreeMap when Labels are enabled.



DataBinding

TreeMap control supports Data Binding and it can be achieved using DataSource property.

The DataSource property accepts the collection values as input. For example, you can provide the list of objects as input. The following code illustrates you on how to bind a flat collection as datasource for **TreeMap**.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.WeightValuePath("Population")
.ColorValuePath("Population")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Render())
```

C#

```
public class TreeMapPopulationData
{
public string Continent { get; set; }
public string Region { get; set; }
public double Growth { get; set; }
public long Population { get; set; }
public static List<TreeMapPopulationData> GetData()
{
List<TreeMapPopulationData> population = new
List<TreeMapPopulationData>();
population.Add(new TreeMapPopulationData() { Continent = "Asia", Region =
"Southern Asia", Growth = 1.32, Population = 1749046000});
population.Add(new TreeMapPopulationData() { Continent = "Asia", Region =
"Eastern Asia", Growth = 0.57, Population = 1620807000});
population.Add(new TreeMapPopulationData() { Continent = "Asia", Region =
"South-Eastern Asia", Growth = 1.20, Population = 618793000});
population.Add(new TreeMapPopulationData() { Continent = "Asia", Region =
"Western Asia", Growth = 1.98, Population = 245707000});
population.Add(new TreeMapPopulationData() { Continent = "Asia", Region =
"Central Asia", Growth = 1.43, Population = 64370000});
population.Add(new TreeMapPopulationData() { Continent = "Europe", Region
= "Europe", Growth = 0.10, Population = 742452000});
population.Add(new TreeMapPopulationData() { Continent = "America",
Region = "South America", Growth = 1.06, Population = 406740000});
population.Add(new TreeMapPopulationData() { Continent = "America",
Region = "Northern America", Growth = 0.85, Population = 355361000});
population.Add(new TreeMapPopulationData() { Continent = "America",
Region = "Central America", Growth = 1.40, Population = 167387000});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Region
= "Eastern Africa", Growth = 2.89, Population = 373202000});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Region
= "Western Africa", Growth = 2.78, Population = 331255000});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Region
= "Northern Africa", Growth = 1.70, Population = 210002000});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Region
= "Middle Africa", Growth = 2.79, Population = 135750000});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Region
= "Southern Africa", Growth = 0.91, Population = 60425000});
return population;
}
}
```

TreeMapLevels

The Levels of TreeMap can be categorized into two types as,

- FlatLevel
- Hierarchical Level

Following customization options are available to customize the treemap level as per your requirements.

Copyright © 2001 - 2020 Syncfusion Inc.

- To specify the background color for the group, you can use GroupBackground property.
- To specify the border color for the group, you can use GroupBorderColor property.
- To maintain the border thickness for the group, you can use GroupBorderThickness property.
- You can specify the gaps between groups using GroupGap property.
- You can specify the padding using GroupPadding property.
- For specifying the header height, you can use HeaderHeight property.
- You can customize the header template using HeaderTemplate property.
- To specify the label position, you can use LabelPosition property.
- To specify the label template for treemap, you can use LabelTemplate property.
- You can specify the label visibility using LabelVisibilityMode property.
- You can control the label visibility using ShowLabels property.
- For controlling text overflow, you can use TextOverflow property.

Flat Level

Group Path

You can use GroupPath property for every flat level of the **TreeMap** control. It is a path to a field on the source object that serves as the **"Group"** for the level specified. You can group the data based on the GroupPath in the **TreeMap** control. When the GroupPath is not specified, then the items are not grouped and the data is displayed in the order specified in the DataSource.

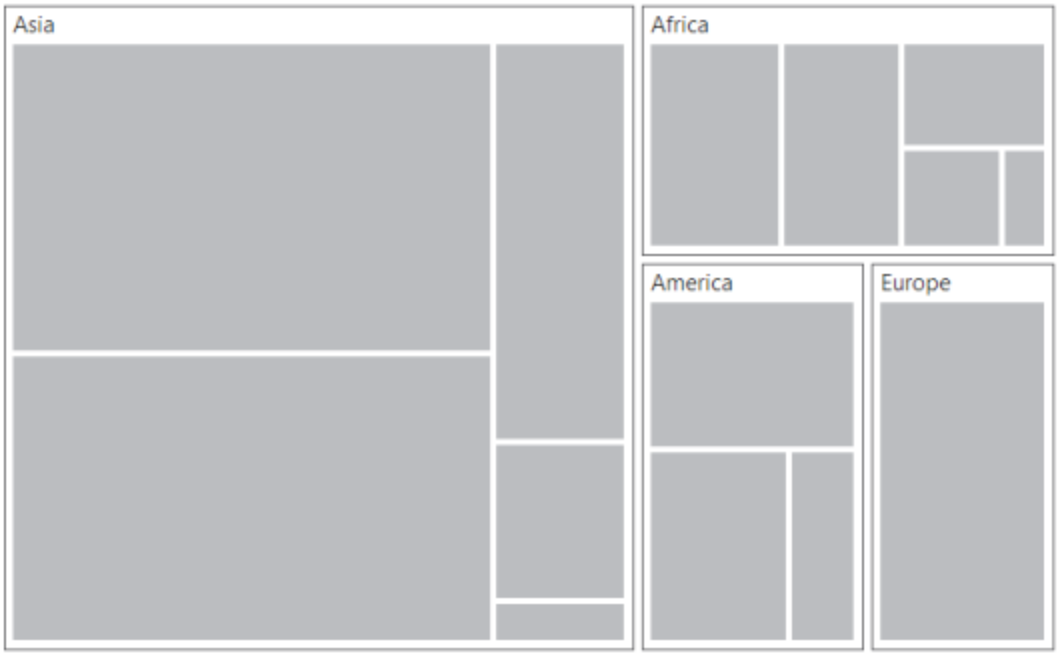
Group Gap

You can use GroupGap property to separate the items from every flat level and to differentiate the levels mentioned in the **TreeMap** control.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.ColorValuePath("Growth")
.WeightValuePath("Population")
.Levels(lv =>
{
lv.GroupPath("Continent")
.GroupGap(5).Add();
})
.Render())
```

Copyright © 2001 - 2020 Syncfusion Inc.



Hierarchical Level

TreeMap Hierarchical level is used to define levels for hierarchical data collection that contains tree-structured data.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.WeightValuePath("Population")
.Render())
```

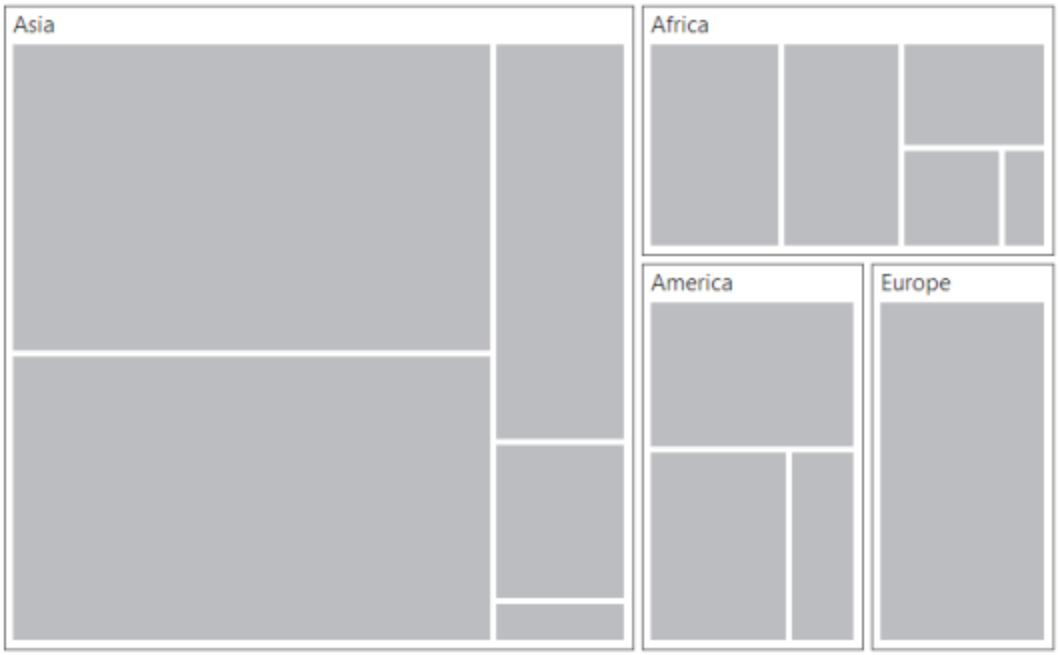
C#

```
public class ContinentData
{
public string Region { get; set; }
public double Growth { get; set; }
public long Population { get; set; }
public static List<ContinentData> GetAsiaData()
{
List<ContinentData> Asia = new List<ContinentData>();
Asia.Add(new ContinentData() { Region = "Southern Asia", Growth = 1.32,
Population = 1749046000 });
Asia.Add(new ContinentData() { Region = "Eastern Asia", Growth = 0.57,
Population = 1620807000 });
Asia.Add(new ContinentData() { Region = "South-Eastern Asia", Growth =
1.20, Population = 618793000 });
Asia.Add(new ContinentData() { Region = "Western Asia", Growth = 1.98,
Population = 245707000 });
Asia.Add(new ContinentData() { Region = "Central Asia", Growth = 1.43,
Population = 64370000 });
return Asia;
}
public static List<ContinentData> GetEuropeData()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
List<ContinentData> Europe = new List<ContinentData>();
Europe.Add(new ContinentData() { Region = "Europe", Growth = 0.10,
Population = 742452000 });
return Europe;
}
public static List<ContinentData> GetAmericaData()
{
List<ContinentData> America = new List<ContinentData>();
America.Add(new ContinentData() {  Region = "South America", Growth =
1.06, Population = 406740000 });
America.Add(new ContinentData() {  Region = "Northern America", Growth =
0.85, Population = 355361000 });
America.Add(new ContinentData() {  Region = "Central America", Growth =
1.40, Population = 167387000 });
return America;
}
public static List<ContinentData> GetAfricaData()
{
List<ContinentData> Africa = new List<ContinentData>();
Africa.Add(new ContinentData() { Region = "Eastern Africa", Growth =
2.89, Population = 373202000 });
Africa.Add(new ContinentData() { Region = "Western Africa", Growth =
2.78, Population = 331255000 });
Africa.Add(new ContinentData() { Region = "Northern Africa", Growth =
1.70, Population = 210002000 });
Africa.Add(new ContinentData() { Region = "Middle Africa", Growth = 2.79,
Population = 135750000 });
Africa.Add(new ContinentData() { Region = "Southern Africa", Growth =
0.91, Population = 60425000 });
return Africa;
}
}
public class TreeMapPopulationData
{
public string Continent { get; set; }
public List<ContinentData> Data { get; set; }
public static List<TreeMapPopulationData> GetData()
{
List<TreeMapPopulationData> population = new
List<TreeMapPopulationData>();
population.Add(new TreeMapPopulationData() { Continent = "Asia", Data =
ContinentData.GetAsiaData()});
population.Add(new TreeMapPopulationData() { Continent = "Europe", Data =
ContinentData.GetEuropeData()});
population.Add(new TreeMapPopulationData() { Continent = "America", Data
= ContinentData.GetAmericaData()});
population.Add(new TreeMapPopulationData() { Continent = "Africa", Data =
ContinentData.GetAfricaData() });
return population;
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.



Layout

You can decide on the visual representation of nodes belonging to all the treemap levels using the ItemsLayoutMode property of the TreeMap.

There are four different **TreeMap Layouts** such as

- Squarified Layout
- SliceAndDiceAuto Layout
- SliceAndDiceHorizontal Layout
- SliceAndDiceVertical Layout

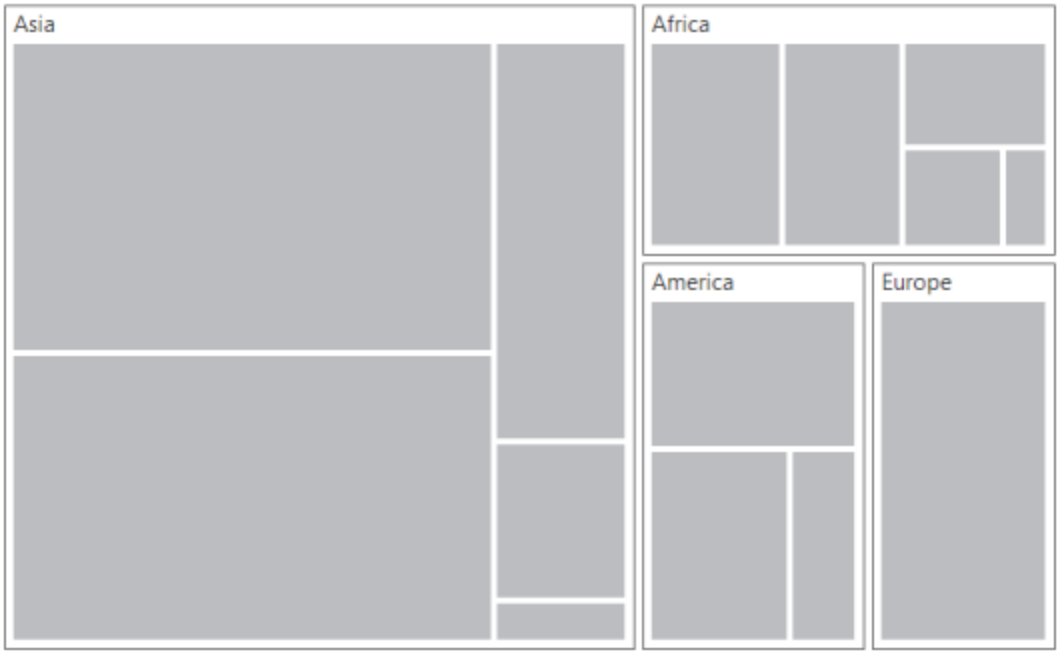
Squarified Layout

Squarified layout creates rectangles with best aspect ratio.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.ColorValuePath("Growth")
.WeightValuePath("Population")
.Levels(lv =>
{
lv.GroupPath("Continent")
.GroupGap(5).Add();
})
.ItemsLayoutMode("Squarified")
.Render())
```

Copyright © 2001 - 2020 Syncfusion Inc.

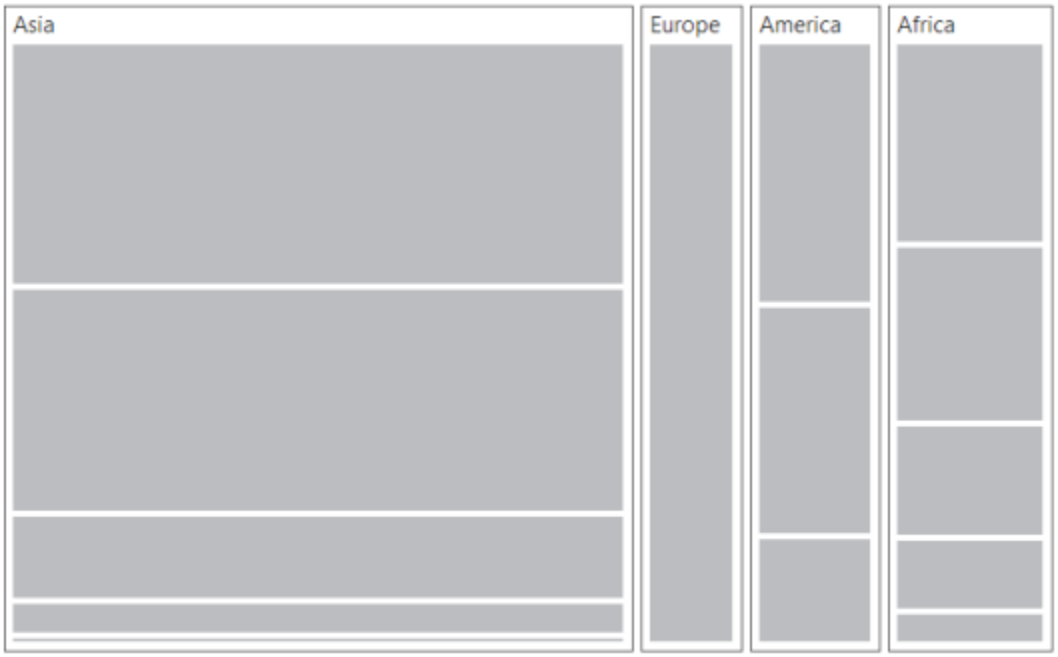


SliceAndDiceAuto Layout

SliceAndDiceAuto layout creates rectangles with high aspect ratio and displays them sorted both horizontally and vertically.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.ItemsLayoutMode("SliceAndDiceAuto ")
.Render())
```



Copyright © 2001 - 2020 Syncfusion Inc.

SliceAndDiceHorizontal Layout

SliceAndDiceHorizontal layout creates rectangles with high aspect ratio and displays them sorted horizontally.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.ItemsLayoutMode("SliceAndDiceHorizontal ")
.Render())
```

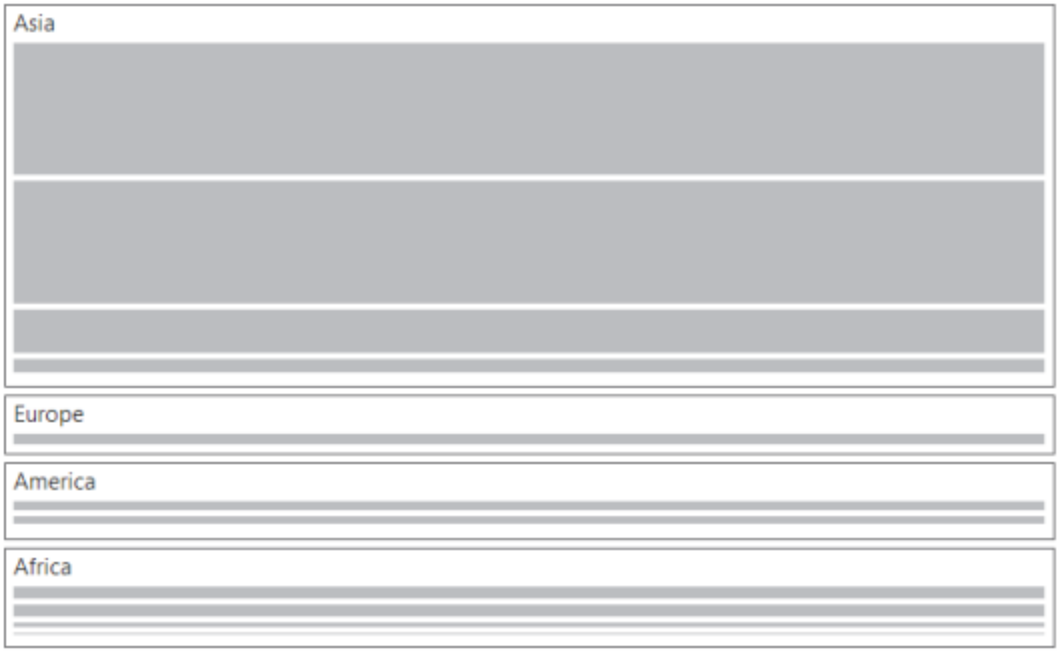
SliceAndDiceVertical Layout

SliceAndDiceVertical layout creates rectangles with high aspect ratio and displays them sorted vertical.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.ItemsLayoutMode("SliceAndDiceVertical ")
.Render())
```

Copyright © 2001 - 2020 Syncfusion Inc.



Customization

TreeMap control supports color customization to determine the exact combination of colors for tree nodes displayed in TreeMap and tooltip support to display additional information of treemap data.

Color

You can customize the color of leaf nodes in **Treemap** either using ColorMapping support of the **Treemap** or mapping a field in the datasource.

Binding color from the datasource

You can set color for each leaf items from data source by using `ColorPath` property.

Note: While setting color, do not set any other color mapping for treemap because color mapping has higher priority than `ColorPath` property. And also, if `ColorPath` is set, the legend will be generated for each leaf item in treemap.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.ColorPath("fill")
.Render())
```

Copyright © 2001 - 2020 Syncfusion Inc.

ColorMapping is categorized into three different types such as,

- UniColorMapping
- RangeBrushColorMapping
- DesaturationColorMapping

UniColorMapping

You can color, all the leaf nodes with the same color by setting the Color value of the UniColorMapping property of the TreeMap.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.TreeMapUniColorMapping(cm =>
{
cm.Color("crimson");
})
.Render())
```

Range Color Mapping

You can group the leaf nodes based on the range of the data's color values. You can set a unique color for every ranges. To achieve this, specify the To and From values as range bound and Color or GradientColors values to fill the leaf nodes of the particular range, through the RangeColorMapping property of the **TreeMap**.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.TreeMapRangeColorMappings(cm =>
{
cm.To(1).From(0).Color("#77D8D8").Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
cm.To(2).From(0).Color("#AED960").Add();
cm.To(3).From(0).Color("#FFAF51").Add();
cm.To(4).From(0).Color("#F3D240").Add();
})
.Render())
```

Desaturation Color Mapping

You can differentiate all the leaf nodes using the DesaturationColorMapping property of the TreeMap. Differentiation is achieved, even though same color is applied for all the leaf nodes by varying the opacity of the leaf nodes based on the color value specified in the color value range using RangeMinimum and RangeMaximum value of the data collection. You can also bound the opacity range by setting From and To property of the DesaturationColorMapping.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.TreeMapDesaturationColorMapping(cm =>
{
cm.To(0.2).From(1).Color("DeepSkyBlue")
.RangeMinimum(0).RangeMaximum(4);
})
.Render())
```

Copyright © 2001 - 2020 Syncfusion Inc.

Tooltip

You can enable the tooltip support for the TreeMap by setting the ShowTooltip property to true. By default, it takes the property of the bound object that is referred to in the GroupPath and displays its content when the corresponding node is tapped. The TooltipTemplate is a HTML element that is used to expose the custom template for the tooltip.

Leaf Item Setting

You can customize the **Leaf level TreeMap** items using LeafItemsSetting. In LeftItemSetting following customization options are available.

- You can specify the border color using BorderBrush property.
- For customizing border thickness, you can use BorderThickness property.
- To customize the gap between the leaf items, you can use Gap property.
- You can specify the label template for the leaf item using ItemTemplate property.
- The Label and tooltip values take the property of bound object that is referred in the LabelPath when defined.
- You can specify the position of the leaf labels using LabelPosition property.
- You can control the mode of label visibility of the labels using LabelVisibilityMode property.
- To show or hide the visibility of the leaf item labels you can use ShowLabels property.
- For specifying over flow action of left item labels you can use TextOverflow property.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.ColorValuePath("Growth")
.WeightValuePath("Population")
.Levels(lv =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
lv.GroupPath("Continent")
.GroupGap(5)
.Add();
})
.TreeMapRangeColorMappings(cm =>
{
cm.To(1).From(0).Color("#77D8D8").Add();
cm.To(2).From(0).Color("#AED960").Add();
cm.To(3).From(0).Color("#FFAF51").Add();
cm.To(4).From(0).Color("#F3D240").Add();
})
.LeafItemsSetting(li =>
{
li.LabelPath("Region")
.ShowLabels(true)
})
.ShowTooltip(true)
.TooltipTemplate("template")
.Render())
</div>
<script  id="template" type="application/jsrender">
<div  style="margin-left:17px;margin-top:-45px;">
<div style="height:auto;width:auto;background:black;border-
radius:3px;opacity:0.6">
<div style="margin-top:-20px;margin-left:9px;padding-top:3px;margin-
right:9px;">
<label style="margin-top:-20px;font-weight:normal;font-
size:12px;color:white;font-family:Segoe UI;">{{:Region}}</label>
</div>
<div style="height:10px;"></div>
<div style="margin-top:-10px;margin-left:9px;margin-right:9px;padding-
bottom:3px;">
<label style="margin-top:-10px;font-weight:normal;font-
size:14px;color:white;font-family:segoe ui
light;">{{:Population}}</label>
</div>
</div>
</div>
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Border Brush

You can able to customize the border color of the treemap using the property BorderBrush.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
//To set borderBrush API value during initialization
.BorderBrush('white')
)
```

Border Thickness

For customizing the border thickness of the treemap, you can use the BorderThickness property.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
//To set borderThickness API value during initialization
.BorderThickness(1)
)
```

Dock Position

You can position the legend at top, bottom, left and right side of the treemap as per your requirement. For changing the position as per your requirement, you can use DockPosition property.

<ts name="ej.datavisualization.TreeMap.DockPosition"/>

Specifies the dockPosition for legend

Name	Description
top	specifies the top position

Copyright © 2001 - 2020 Syncfusion Inc.

Name	Description
bottom	specifies the bottom position
right	specifies the bottom position
left	specifies the left position

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
//To set dockPosition API value during initialization
.TreeMapLegend(legend=>legend.DockPosition(TreeMapDockPosition.Top))
)
```

Clicking and Dragging

You can select the single treemap element on click and drag. To click and drag treemap items, you have to enable the DraggingOnSelection property.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
//To set draggingOnSelection API value during initialization
.DraggingOnSelection(false)
)
```

For selecting the group element of treemap while clicking and dragging, you can use DraggingGroupOnSelection property.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
//To set draggingGroupOnSelectionAPI value during initialization
.DraggingGroupOnSelection(false)
)
```

Fill with Gradient

You can customize that whether gradient color have to be applied for treemap or not. This can be customized using the property EnableGradient.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
//To set enableGradient API value during initialization
.EnableGradient(true)
)
```

Responsive Treemap

You can customize whether treemap have to be responsive or not while resizing the container. For making treemap responsive you can use EnableResize or IsResponsive property.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().TreeMap("treemap")
//To set enableResize API value during initialization
.EnableResize(false)
```

GroupColorMapping

You can customize the color of the each group using GroupColorMapping property. To use group color mapping, kindly specify GroupID and RangeColorMapping inside the GroupColorMapping.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
//To set groupColorMapping API value during initialization
.TreeMapGroupColorMapping( )
```

GroupSelectionMode

You can specifies the selection mode of the treemap using GroupSelectionMode property. You can set either group selection mode value as Default or Multiple.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
// Set the selection mode during initialization.
.GroupSelectionMode(GroupSelectionMode.Default)
```

Header

You can specify the header for the parent item using the property Header. This is applicable only for hierarchical data source.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
//To set header API value during initialization
.Header("Country")
```

Specifying HierarchicalDatasource

You can specify whether data source bound for the treemap is hierarchical or not using the property IsHierarchicalDatasource.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
//To set isHierarchicalDatasource API value during initialization
.IsHierarchicalDatasource(true)
```

Treemap Items

You can specify the treemap items which you want to display in the treemap using the property TreeMapItems.

TreeMap Elements

TreeMap contains various elements such as,

Copyright © 2001 - 2020 Syncfusion Inc.

- Legend
- Headers
- Labels

Legend

You can set the color value of **leaf nodes** using TreeMapLegend. This legend is appropriate only for the TreeMap whose leaf nodes are colored using RangeColorMapping.

You can set ShowLegend property value to “true” to enable or disable legend visibility.

TreeMap Legend

You can customize the treemap legend using following properties

- For customizing the alignment of legend, you can use Alignment property.
- You can set the legend column count using ColumnCount property.
- To set the dock position of the legend text, you can use DockPosition.
- You can specify the size of the legend by setting Height and Width of the TreeMapLegend.
- You can decide the size of the legend icons by setting IconWidth and IconHeight properties of the TreeMapLegend property avail in TreeMap.
- You can customize the left and right label text for the legend using LeftLabel and RightLabel properties.
- To set the legend mode as default or interactive, you can use Mode property.
- Using the property Template, you can specify template for legend settings.
- To set the legend title, you can use the Title property of the LegendSettings.

Label for Legend

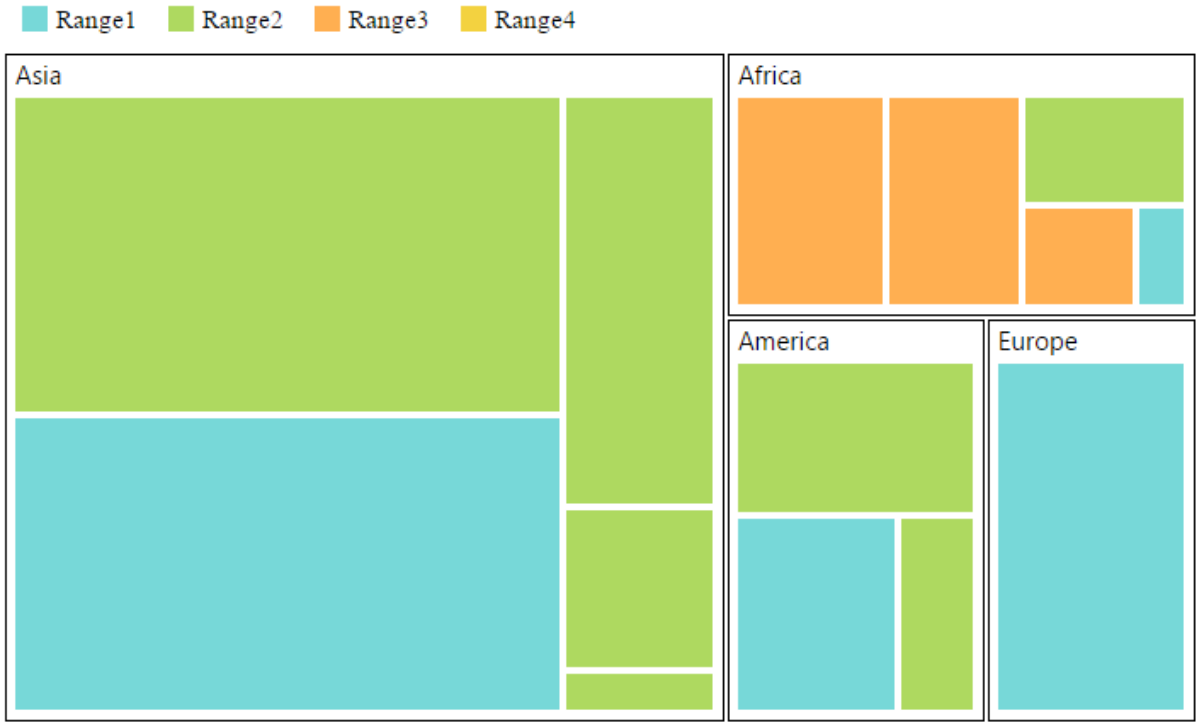
You can customize the labels of the legend item using LegendLabel property of RangeColorMapping.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.ColorValuePath("Growth")
.WeightValuePath("Population")
.ShowLegend(true)
.Levels(lv =>
{
lv.GroupPath("Continent")
.GroupGap(5)
.Add();
})
.TreeMapRangeColorMappings(cm =>
{
cm.To(1).From(0).Color("#77D8D8").LegendLabel("Range1").Add();
cm.To(2).From(0).Color("#AED960").LegendLabel("Range2").Add();
cm.To(3).From(0).Color("#FFAF51").LegendLabel("Range3").Add();
cm.To(4).From(0).Color("#F3D240").LegendLabel("Range4").Add();
})
.TreeMapLegend(legend =>
{
legend. IconWidth(20)
. IconHeight(20);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
.Render())
```



Interactive Legend

The legends can be made interactive with an arrow mark indicating the exact range color in the legend when the mouse hovers over the corresponding treemap items. You can enable this option by setting Mode property in Legend settings value as “interactive” and default value of Mode property is “default” to enable the normal legend.

Title for Interactive Legend

You can provide the title for interactive legend by using Title property in LegendSettings.

Label for Interactive Legend

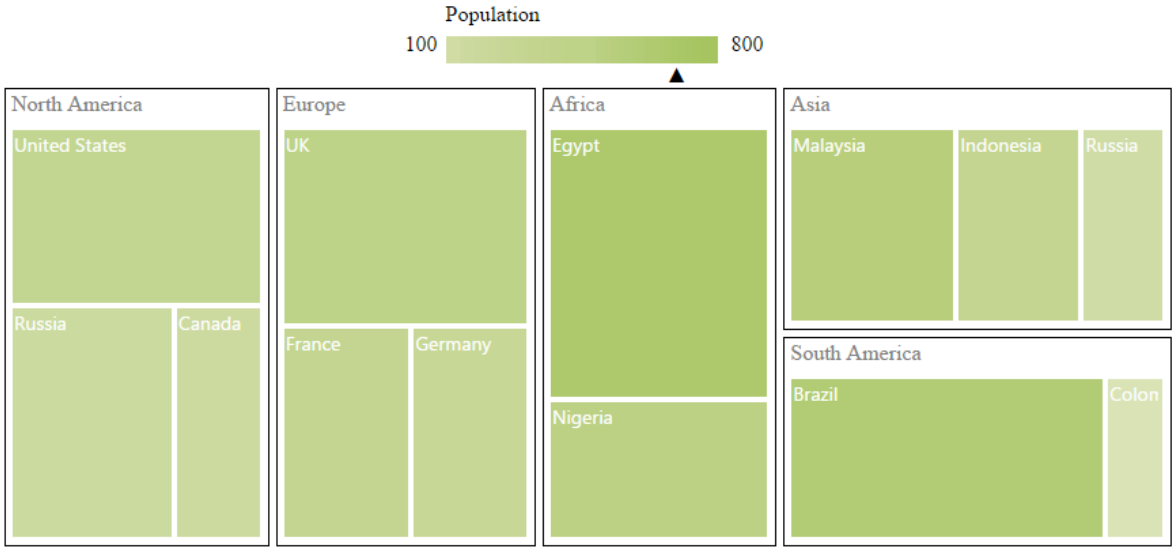
You can provide the left and right labels to interactive legend by using LeftLabel and RightLabel properties in LegendSettings.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
// ...
.ShowLegend(true)
.TreeMapLegend(legend =>
{
legend.DockPosition(TreeMapDockPosition.Top)
.Height(20)
.Width(150)
.Mode(LegendMode.Interactive)
.Title("population")
.LeftLabel("20000000")
.RightLabel("300000000");
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
)
```



Header

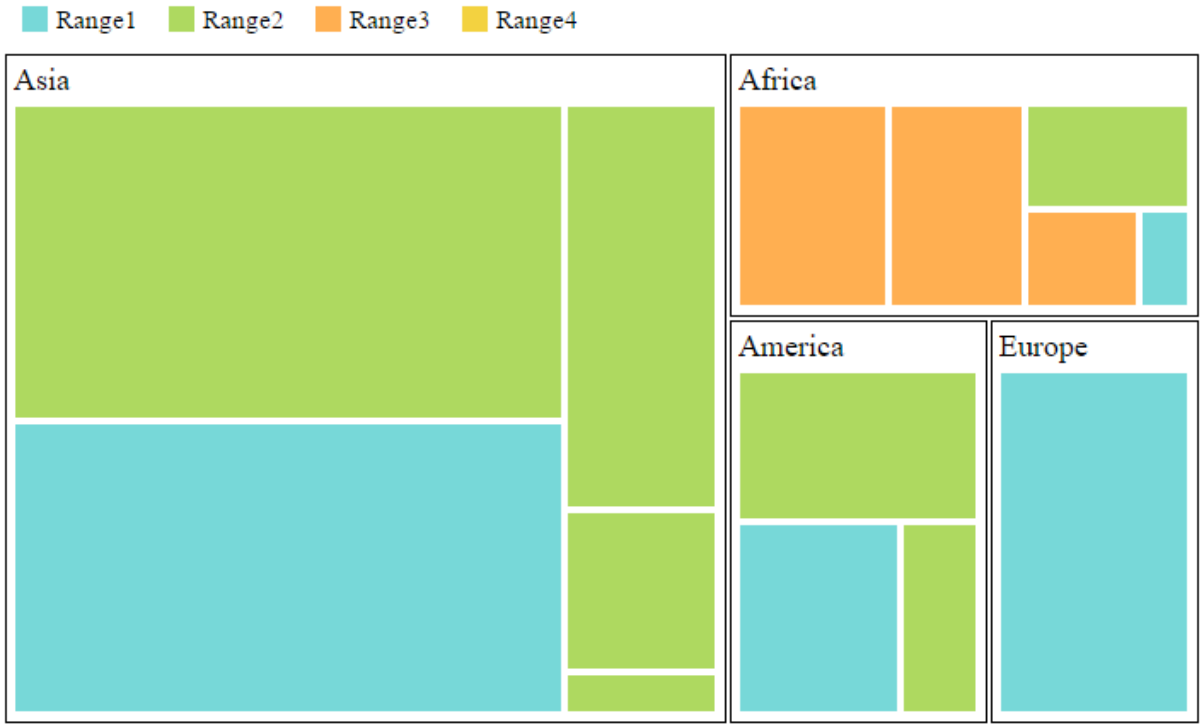
You can set headers for each level by setting the ShowHeader property of the each TreeMap levels. The HeaderHeight property helps to set the height of the header and Group path value determines the header value. You can customize the default header appearance by setting the HeaderTemplate of the TreeMap levels.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.ColorValuePath("Growth")
.WeightValuePath("Population")
.ShowLegend(true)
.TreeMapLegend(legend =>
{
legend.IconWidth(17)
.IconHeight(17);
})
.TreeMapRangeColorMappings(cm =>
{
cm.To(1).From(0).Color("#77D8D8").LegendLabel("Range1").Add();
cm.To(2).From(0).Color("#AED960").LegendLabel("Range2").Add();
cm.To(3).From(0).Color("#FFAF51").LegendLabel("Range3").Add();
cm.To(4).From(0).Color("#F3D240").LegendLabel("Range4").Add();
})
.Levels(lv =>
{
lv.GroupPath("Continent")
.GroupGap(5)
.HeaderHeight(30)
.HeaderTemplate("template").Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Render())
<script  id="template" type="application/jsrender">
<div style="background-color: white; margin:5px">
<label style="color:black;font-size:medium;" >{{:header}}</label><br />
</div>
</script>
```



Customizing the header

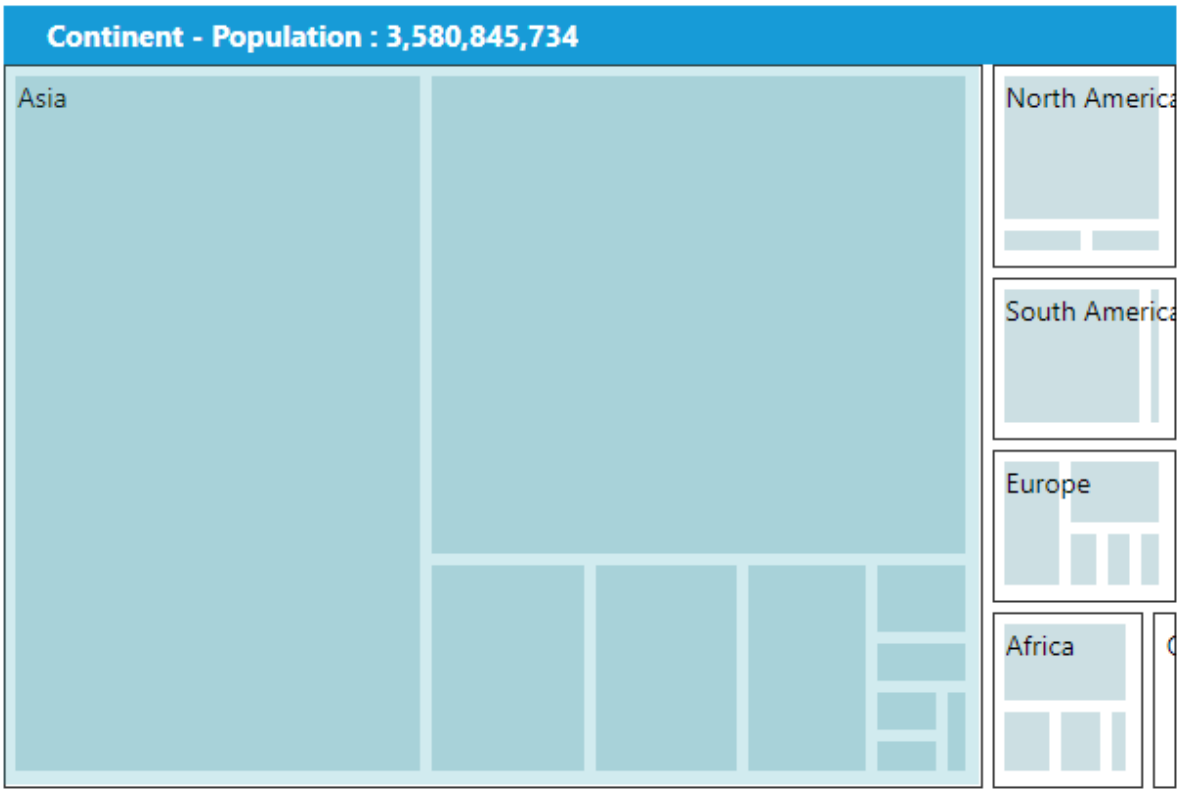
The text in the header can be customized by triggering the event HeaderTemplateRendering of the **TreeMap**. This event is triggered before rendering the header template.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.Levels(lv =>
{
lv.GroupPath("Continent")
.HeaderHeight(25)
.HeaderTemplate('Template')
.ShowHeader(false)
.GroupGap(5)
.LabelPosition(DockPosition.TopLeft)
.ShowLabels(true).Add();
})
.HeaderTemplateRendering("loadTemplate")
)
<script  id="Template" type="application/jsrender">
<div style="background-color: white; margin:5px">
<label style="color:black;font-size:large;" >{{:header}}</label><br />
</div>
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<script type="text/javascript">
function loadTemplate(sender) {
//...
}
</script>
```



Label

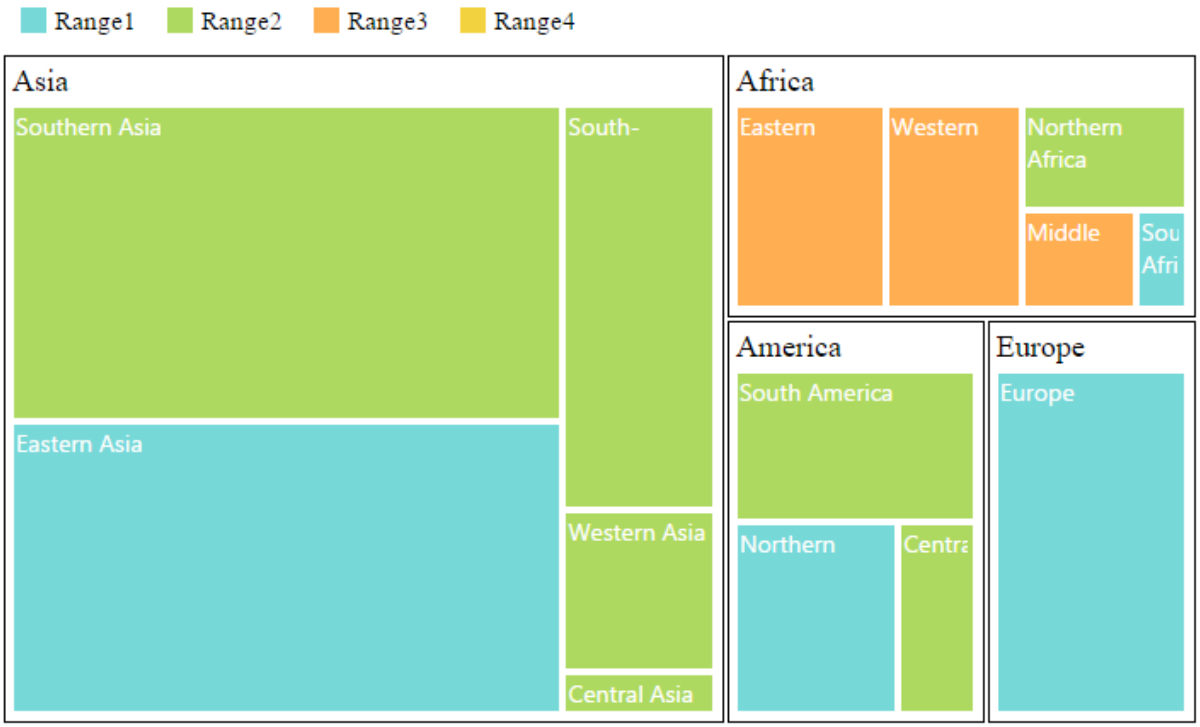
You can also set labels for the leaf nodes by setting the ShowLabels property as true. GroupPath value is displayed as a label for leaf nodes. You can customize the default label appearance by setting the LabelTemplate of the TreeMap levels.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.ColorValuePath("Growth")
.WeightValuePath("Population")
.ShowLegend(true)
.TreeMapLegend(legend =>
{
legend. IconWidth(17)
. IconHeight(17);
})
.Levels(lv =>
{
lv.GroupPath("Continent")
.GroupGap(5)
.HeaderHeight(30)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.HeaderTemplate("headerTemplate").Add();
})
.TreeMapRangeColorMappings(cm =>
{
cm.To(1).From(0).Color("#77D8D8").LegendLabel("Range1").Add();
cm.To(2).From(0).Color("#AED960").LegendLabel("Range2").Add();
cm.To(3).From(0).Color("#FFAF51").LegendLabel("Range3").Add();
cm.To(4).From(0).Color("#F3D240").LegendLabel("Range4").Add();
})
.LeafItemsSetting(li =>
{
li.LabelPath("Region")
.ShowLabels(true)
.LabelTemplate("labelTemplate");
})
.Render())
<script  id="headerTemplate" type="application/jsrender">
<div style="background-color: white; margin:5px">
<label style="color:black;font-size:medium;" >{{:header}}</label><br />
</div>
</script>
<script  id="labelTemplate" type="application/jsrender">
<div style="background-color: transparent;">
<label style="color:white;font-size:small;margin:5px;"
>{{:label}}</label><br/>
</div>
</script>
```



Customizing the Overflow labels

You can handle the label overflow, by specifying any one of the following values to the property TextOverflowas

None - It displays the default label text.

Hide - You can hide the label, when it exceeds the header width.

Wrap - You can wrap the label text by letter.

WrapByWord - You can wrap the label text by word.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.Levels(level =>
{
level.GroupPath("Continent")
.HeaderHeight(25)
.HeaderTemplate('Template')
.ShowHeader(false)
.GroupGap(5)
.LabelPosition(DockPosition.TopLeft)
.ShowLabels(true).Add();
})
.HeaderTemplateRendering("loadTemplate")
.LeafItemsSetting(leaf =>
{
leaf.ShowLabels(true)
.TextOverflow(TextOverflow.Wrap);
})
)
<script  id="headertemplate" type="application/jsrender">
<div style="background-color: white; margin:5px">
<label style="color:black;font-size:medium;" >{{:header}}</label><br />
</div>
</script>
```

Palette Color Mapping

Treemap is having support for PaletteColorMapping. You can set the color for palette color mapping using the property Color in palette color mapping.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.TreeMapPaletteColorMapping(
//..
)
```

Drill Down Support

Treemap enables drill down to expose the hierarchy achieved by clicking on a node and this results in enabling the Treemap to move to the next level or sub level and can return back to the normal Treemap view by clicking on the node header. Only a single level of the Treemap is visible at once.

Copyright © 2001 - 2020 Syncfusion Inc.

Enabling Drill Down

Treemap elements can be drilled down by setting the EnableDrillDown property to true. You can view the hierarchy of the Treemap by clicking on the treemap items and can move to the previous level by clicking on the drill down header. The header color can be customized by changing the values in the property DrillDownHeaderColor and the selection color can be done by changing the DrillDownSelectionColor property.

Drill down Properties

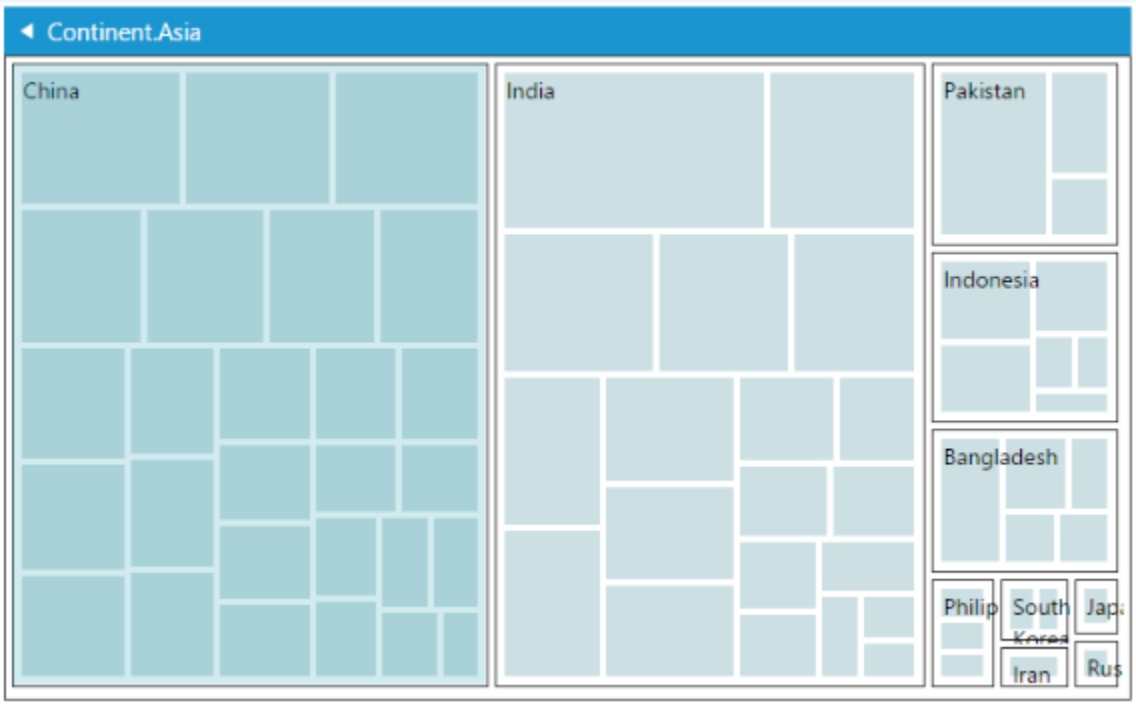
Property	Type	Description
enableDrillDown	bool	Gets or sets a value that indicates whether the drill down feature is enabled or not
drillDownHeaderColor	string	Gets or sets a color for header during drill down
drillDownSelectionColor	string	Gets or sets a color for highlighting tree map item during drill down.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DataSource(datasource)
.EnableDrillDown(true)
.DrillDownHeaderColor("#199DAF")
.DrillDownSelectionColor("#199DAF")
.WeightValuePath("Population")
.Levels(lv =>
{
lv.GroupPath("Continent")
.HeaderHeight(25)
.GroupGap(5)
.ShowLabels(true).Add();
lv.GroupPath("Country")
.HeaderHeight(25)
.GroupGap(0)
.ShowLabels(true).Add();
lv.GroupPath("Name")
.HeaderHeight(25)
.GroupGap(0)
.ShowLabels(true).Add();
})
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Before Drill Down



After Drill Down

Methods and Events

Method

Refresh()

refresh() method is used to reload the treemap with updated values.

Copyright © 2001 - 2020 Syncfusion Inc.

Returns: void

ASPX-CS

```
@(Html.EJ().TreeMap("treemap"))
<script type="text/javascript">
$("#treemap").ejTreeMap();
var treemapObj = $("#treemap").data("ejTreeMap");
treemapObj.refresh();
</script>
```

Events

TreeMapItemSelected

TreeMapItemSelected event will trigger when treemap item is selected.

Name	Type	Description
{% highlight html %}originalEvent{% endhighlight %}	object	Returns selected treeMapItem object.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.TreeMapItemSelected("itemSelected")
)
function itemSelected(sender) {
// do something
}
```

DrillStarted

DrillStarted event will fire, when the drilldown action is started in the treemap control.

Name	Type	Description
{% highlight html %}originalEvent{% endhighlight %}	object	Returns selected drilled treeMap object.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DrillStarted("onDrillStarted")
)
function onDrillStarted(sender) {
// do something
}
```

DrillDownItemSelected

If the treemap drilldown item is selected, then DrillDownItemSelected event will fire.

Name	Type	Description
{% highlight html %}originalEvent{% endhighlight %}	object	Returns selected drilldown treeMap object.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DrillDownItemSelected("drillDownItemSelected")
)
function drillDownItemSelected(sender) {
// do something
}
```

HeaderTemplateRendering

HeaderTemplateRendering event will fire before rendering the treemap drilldown header template.

Name	Type	Description
{% highlight html %}originalEvent{% endhighlight %}	object	Returns drilldown header.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.HeaderTemplateRendering("loadTemplate")
)
function loadTemplate(sender) {
// do something
}
```

Refreshed

Refreshed event will trigger after refreshing the treemap control with updated values.

Name	Type	Description
{% highlight html %}originalEvent{% endhighlight %}	object	Refresh and load the treemap.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.Refreshed("onRefreshed")
)
function onRefreshed(sender) {
// do something
}
```

TreeMapGroupSelected

TreeMapGroupSelected event will fired when the group selection is performed on treemap items.

Name	Type	Description
{% highlight html %}originalEvent{% endhighlight %}	object	Returns the selected group of treeMapItems as object.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.TreeMapGroupSelected("groupSelected")
)
function groupSelected(sender) {
// do something
}
```

ItemRendering

ItemRendering event will trigger while rendering each item in treemap.

Name	Type	Description
{% highlight html %}originalEvent{% endhighlight %}	object	Returns each leaf items in treemap

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.ItemRendering("itemRendering")
)
function itemRendering(sender) {
// do something
}
```

LegendItemRendering

LegendItemRendering event will trigger while rendering each legend item in treemap.

Name	Type	Description
{% highlight html %}originalEvent{% endhighlight %}	object	Returns each legend item in treemap

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.LegendItemRendering("legendItemRendering")
)
function legendItemRendering(sender) {
// do something
}
```

Click

Click event will trigger while clicking an item in the treemap.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.Click("click")
)
function click(){
// Do Something
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

DoubleClick

DoubleClick event will trigger while double clicking an item in the treemap

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.DoubleClick("doubleClick")
)
function doubleClick(){
// Do Something
}
```

RightClick

RightClick event will trigger while right clicking an item in the treemap.

ASPX-CS

```
@(Html.EJ().TreeMap("treemap")
.RightClick("rightClick")
)
function rightClick(){
// Do Something
}
```

AngularJS Support

AngularJS is a JavaScript framework added to a **HTML** page with a <script> tag. It extends HTML attributes with directives and binds data to HTML with expressions. AngularJS directives allow you to specify custom and reusable HTML tags that moderate the behavior of certain elements. **Angular binding** uses directives to plug its action into the page. Directives, all prefaced with ng-, are placed in HTML attributes. To know more about Angular binding refer to: http://help.syncfusion.com/aspnetmvc/treemap/angularjs-support

Apply the plugin and property assigning the **Treemap** element through the directive that starts with the letter “e-“. The following code illustrates how to bind data to the Treemap component through Angular support.

ASPX-CS

```
<script>
var population_data = [
{ Continent: "Asia", Country: "Indonesia", Growth: 3, Population:
237641326 },
{ Continent: "Asia", Country: "Russia", Growth: 2, Population: 152518015
},
{ Continent: "Asia", Country: "Malaysia", Growth: 1, Population: 29672000
},
{ Continent: "North America", Country: "United States", Growth: 4,
Population: 315645000 },
{ Continent: "North America", Country: "Mexico", Growth: 2, Population:
112336538 },
{ Continent: "North America", Country: "Canada", Growth: 1, Population:
39056064 },
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{ Continent: "South America", Country: "Colombia", Growth: 1, Population:
47000000 },
{ Continent: "South America", Country: "Brazil", Growth: 3, Population:
193946886 },
{ Continent: "Africa", Country: "Nigeria", Growth: 2, Population:
170901000 },
{ Continent: "Africa", Country: "Egypt", Growth: 1, Population: 83661000
},
{ Continent: "Europe", Country: "Germany", Growth: 1, Population:
81993000 },
{ Continent: "Europe", Country: "France", Growth: 1, Population: 65605000
},
{ Continent: "Europe", Country: "UK", Growth: 1, Population: 63181775 },
];
</script>
//References to be added for AngularJS support.
<script src="@Url.Content("~/Scripts/angular.min.js")"></script>
<script
src="@Url.Content("~/Scripts/ej/ej.widget.angular.min.js")"></script>
//Initializes controller

{
public ActionResult AngularTreeMap()
{
return View();
}
}
```

TreeGrid

TreeGrid

The TreeGrid is an efficient control designed for representing the hierarchical data in a tabular format, combining the visual representation of Grid and TreeView controls; it represents the data from datasource such as array of JSON objects, ej.DataManager or self-referential datasource.

Key Features

- **Editing** - Offers cell and row editing modes for updating the records.
- **Sorting** - Supports *n* levels of sorting.
- **Filtering** - Supports filtering records with filterbar,menu and excel filtering modes.
- **Virtualization** - Supports rendering large number of hierarchical data at once.
- **Column Template** - To display custom columns along with customized expand-collapse icon.
- **Row drag and drop** - Allows you to drag any row and drop it at any desired position.
- **Paging** - Paginated view of records.

Copyright © 2001 - 2020 Syncfusion Inc.

- **Summary rows** - To summarize the rows at each hierarchical levels.
- **Details template** - To display the detailed view of a record.
- **Frozen columns** - To freeze the columns from scrolling.
- **Exporting** - Exporting the TreeGrid contents to PDF and Excel files.
- **Column Menu** - Supports sorting, column visibility and filtering for the columns.
- **User Interaction** - Supports cell tooltip, expand collapse at ease, single and multiple row selection, columns resizing, contextual menu.
- **Column Template** - To render custom columns along with customized expand-collapse icon.
- **Command Column** - Allows you to perform custom action or default CRUD actions using TreeGrid column.
- **Row Template** - To customize the TreeGrid rows.
- **Column Reordering** - Provides support to re-arrange the column order.
- **Resize columns** - Provides option for resizing the columns.

Getting Started

Create your first TreeGrid in MVC

This section explains briefly about the control structure and how to create a TreeGrid.

1. First, create a new MVC Razor project, please refer MVC-Getting Started documentation to create new project and add necessary DLL's and script files.
2. Create a data source in Controllers/HomeController.cs file, We can bind datasource to TreeGrid using Datasource property.
3. Add the following code example in the Index.cshtml file to create a TreeGrid control in the View page.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ChildMapping("Children")
.Columns(co =>
{
co.Field("TaskId").HeaderText("Task
Id").EditType(TreeGridEditingType.Numeric).Add();
co.Field("TaskName").HeaderText("Task
Name").EditType(TreeGridEditingType.String).Add();
co.Field("StartDate").HeaderText("Start
Date").EditType(TreeGridEditingType.Datepicker).Add();
co.Field("Duration").HeaderText("Duration").EditType(TreeGridEditingType.
Numeric).Add();
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

C#

```
public class TreeGridController : Controller
{
public ActionResult Index()
{
ViewBag.datasource = this.GetData();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
return View();
}
private List<BusinessObject> GetData()
{
List<BusinessObject> dataCollection = new List<BusinessObject>();
BusinessObject Record1 = new BusinessObject()
{
TaskId = 1,
TaskName = "Planning",
StartDate = "02/03/2017",
Duration = 5,
Children = new List<BusinessObject>(),
};
BusinessObject Child1 = new BusinessObject()
{
TaskId = 2,
TaskName = "Plan timeline",
StartDate = "02/03/2017",
Duration = 5
};
BusinessObject Child2 = new BusinessObject()
{
TaskId = 3,
TaskName = "Plan budget",
StartDate = "02/03/2017",
Duration = 5
};
BusinessObject Child3 = new BusinessObject()
{
TaskId = 4,
TaskName = "Allocate resources",
StartDate = "02/03/2017",
Duration = 5
};
BusinessObject Child4 = new BusinessObject()
{
TaskId = 5,
TaskName = "Planning complete",
StartDate = "02/07/2017",
Duration = 0
};
Record1.Children.Add(Child1);
Record1.Children.Add(Child2);
Record1.Children.Add(Child3);
Record1.Children.Add(Child4);
BusinessObject Record2 = new BusinessObject()
{
TaskId = 6,
TaskName = "Design",
StartDate = "02/10/2017",
Duration = 3,
Children = new List<BusinessObject>(),
};
BusinessObject Child5 = new BusinessObject()
{
TaskId = 7,
TaskName = "Software Specification",
```

10	Design complete	2/14/2017	0

Simple TreeGrid

Enable Toolbar

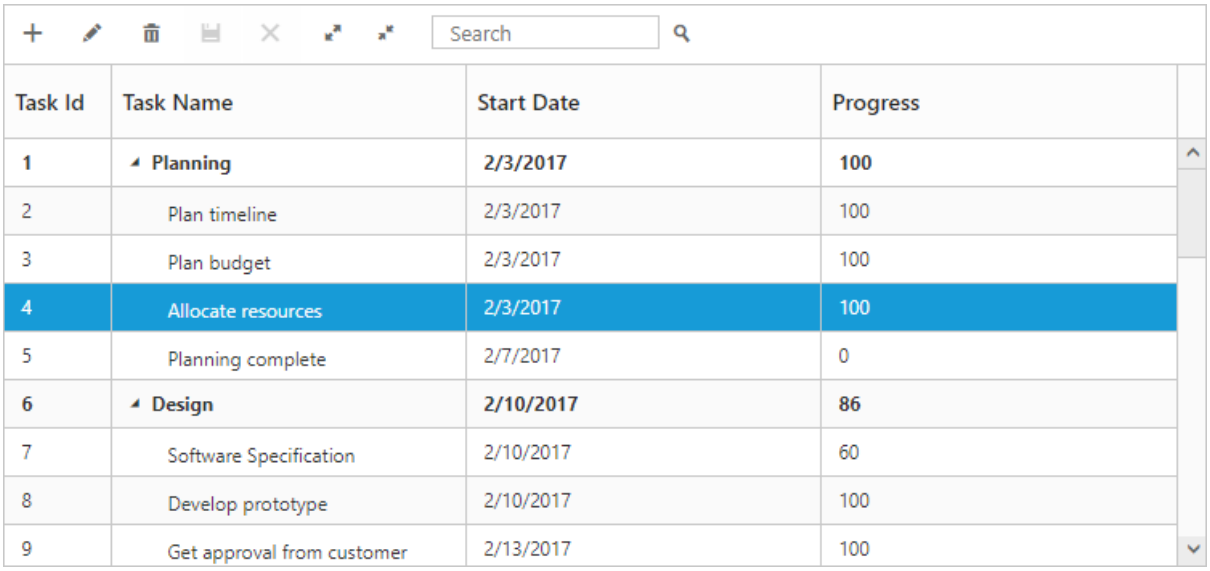
TreeGrid control contains the toolbar options to Add, Edit, Delete, Cancel, Update, Search, ExpandAll and CollapseAll operations, you can enable the toolbar by using ToolbarSettings property.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<TreeGridToolBarItems>()
{
TreeGridToolBarItems.Add,
TreeGridToolBarItems.Edit,
TreeGridToolBarItems.Delete,
TreeGridToolBarItems.Update,
TreeGridToolBarItems.Cancel,
TreeGridToolBarItems.ExpandAll,
TreeGridToolBarItems.CollapseAll,
TreeGridToolBarItems.Search
});
})
)
@(Html.EJ().ScriptManager())
```

The following screen shot displays a Toolbar in TreeGrid.

Copyright © 2001 - 2020 Syncfusion Inc.



Toolbar in TreeGrid

Note: Add, Edit, Delete options are enabled by `AllowEditing`, `AllowAdding`, `AllowDeleting` in the `EditSettings`.

Click here to refer more details for TreeGrid ToolbarSettings.

Enable Sorting

The TreeGrid control contains sorting functionality to arrange the data in **ascending** or **descending** order based on a particular column.

Multicolumn Sorting

You can enable the multicolumn sorting in TreeGrid by setting `AllowMultiSorting` as `true` .You can sort multiple columns in TreeGrid by selecting the desired column header when holding the **CTRL** key.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowSorting(true)
.AllowMultiSorting(true)
)
@(Html.EJ().ScriptManager())
```

Click here to refer more details for TreeGrid Sorting.

Enable Editing

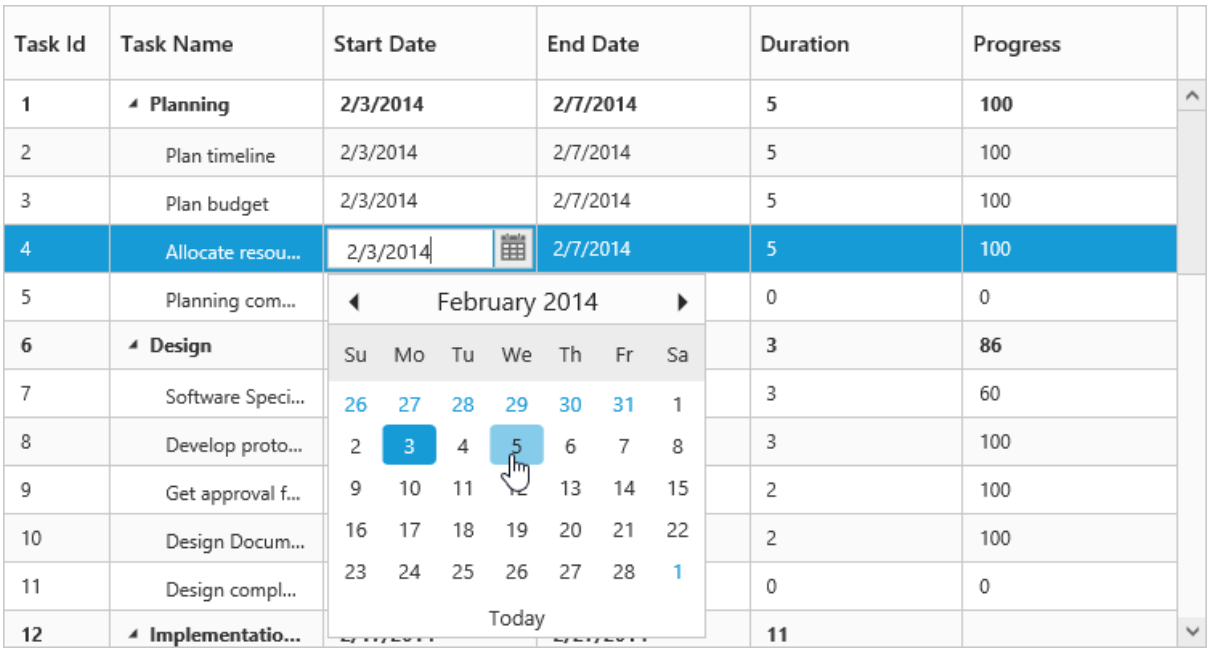
You can enable editing in TreeGrid by using `EditSettings` property and it is illustrated in the following code example.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit =>
{
edit.AllowEditing(true);
edit.AllowAdding(true);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
edit.AllowDeleting(true);
edit.EditMode(TreeGridEditMode.CellEditing);
})
)
@(Html.EJ().ScriptManager())
```



Click here to refer more details for TreeGrid Editing.

Enable Context Menu

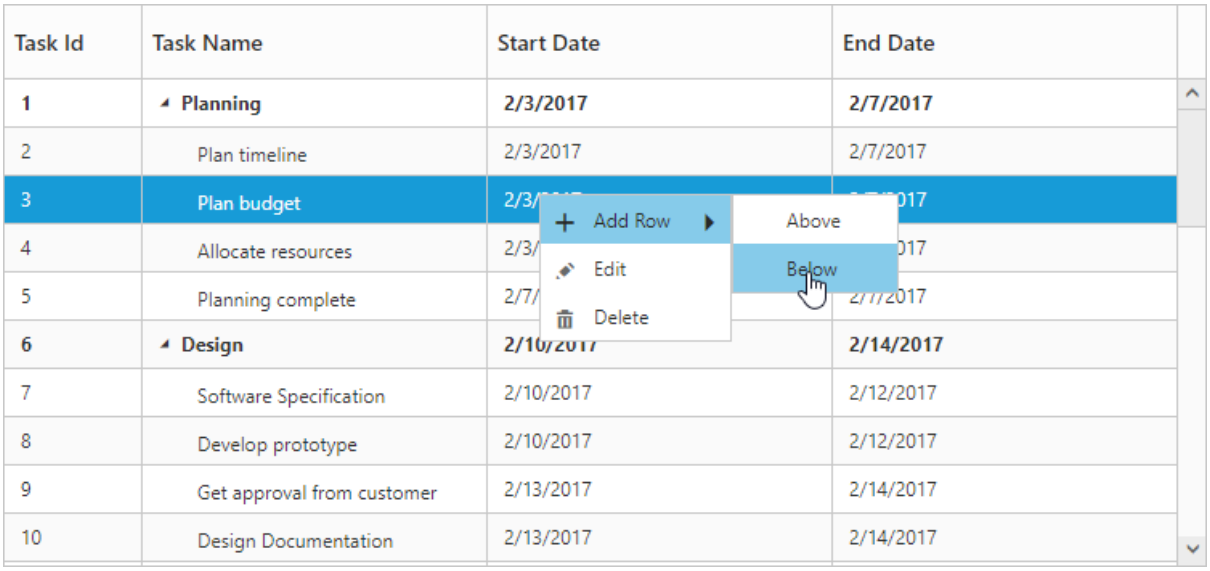
The **Context menu** in TreeGrid control is used to manipulate (add, edit and delete) the TreeGrid rows.

In TreeGrid, context menu can be enabled by ContextMenuSettings property. The ContextMenuSettings property contains two inner properties ShowContextMenu and ContextMenuItems.

ASPX-CS

```
@(Html.EJ().TreeGrid("treegrid1")
.ContextMenuSettings(context =>
{
context.ShowContextMenu(true);
context.ContextMenuItems(new List<TreeGridContextMenuItems>(){
TreeGridContextMenuItems.Add,
TreeGridContextMenuItems.Edit,
TreeGridContextMenuItems.Delete
});
})
)
@(Html.EJ().ScriptManager())
```

The following screenshot displays the context menu in TreeGrid control.



TreeGrid with context menu

Click here to refer more details for TreeGrid context menu.

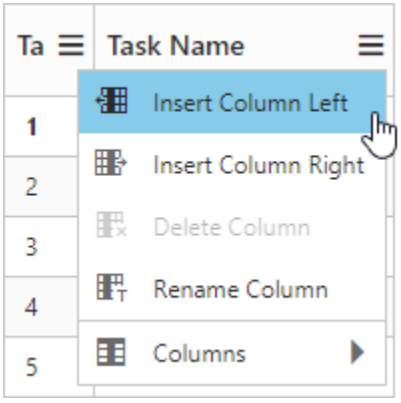
Enable Column Menu

You can enable the column menu in TreeGrid, by setting the ShowColumnChooser as true.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowColumnChooser(true)
.AllowSorting(true)
.AllowMultiSorting(true)
)
@(Html.EJ().ScriptManager())
```

The following screenshot displays the column chooser in TreeGrid control.



TreeGrid with column chooser

Define dimension of TreeGrid

By default TreeGrid control was rendered with 100% width and 450px height, we can define the dimension of TreeGrid control by using SizeSettings property. TreeGrid control width and height can be

Copyright © 2001 - 2020 Syncfusion Inc.

defined by either Height and Width properties or by defining inline style in TreeGrid container element. The below code example shows how to define width and height for TreeGrid control.

ASPX-CS

```
<!--<div id="TreeGridContainer" style="width:700px;height:350px"></div>--
>
<div id="TreeGridContainer"></div>
<script>
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.SizeSettings(size=>size.Height("350px").Width("700px"))
)
@(Html.EJ().ScriptManager())
</script>
```

Note: 1.TreeGrid control will automatically update the width and height value based on container element on window resize action, this can be enabled by setting IsResponsive property as true for this Height and Width value will be defined in percentage.

2.We can also render TreeGrid with auto height by setting SizeSettings.Height as auto.

Data Binding

Data Binding is the process that establishes a connection between the application and different kinds of datasources such as business objects.

Local Data Binding

In Local Data Binding, datasource for rendering the TreeGrid control is retrieved from the same application locally.

Two types of Data Binding are possible with TreeGrid control,

- Hierarchical Datasource Binding
- Self-Referential Data Binding (Flat Data)

Hierarchical Datasource Binding

The ChildMapping property is used to map the child records in hierarchical datasource.

The following code example shows you how to bind the hierarchical local data into the TreeGrid control.

C#

```
public class TreeGridController : Controller
{
public ActionResult Index()
{
ViewBag.datasource = this.GetData();
return View();
}
private List<BusinessObject> GetData()
{
List<BusinessObject> dataCollection = new List<BusinessObject>();
BusinessObject Record1 = new BusinessObject()
{
TaskId = 1,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
TaskName = "Planning",
StartDate = "02/03/2017",
Duration = 5,
Children = new List<BusinessObject>(),
};
BusinessObject Child1 = new BusinessObject()
{
TaskId = 2,
TaskName = "Plan timeline",
StartDate = "02/03/2017",
Duration = 5
};
BusinessObject Child2 = new BusinessObject()
{
TaskId = 3,
TaskName = "Plan budget",
StartDate = "02/03/2017",
Duration = 5
};
BusinessObject Child3 = new BusinessObject()
{
TaskId = 4,
TaskName = "Allocate resources",
StartDate = "02/03/2017",
Duration = 5
};
BusinessObject Child4 = new BusinessObject()
{
TaskId = 5,
TaskName = "Planning complete",
StartDate = "02/07/2017",
Duration = 0
};
Record1.Children.Add(Child1);
Record1.Children.Add(Child2);
Record1.Children.Add(Child3);
Record1.Children.Add(Child4);
BusinessObject Record2 = new BusinessObject()
{
TaskId = 6,
TaskName = "Design",
StartDate = "02/10/2017",
Duration = 3,
Children = new List<BusinessObject>(),
};
BusinessObject Child5 = new BusinessObject()
{
TaskId = 7,
TaskName = "Software Specification",
StartDate = "02/10/2017",
Duration = 3
};
BusinessObject Child6 = new BusinessObject()
{
TaskId = 8,
TaskName = "Develop prototype",
StartDate = "02/10/2017",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Duration = 3
};
BusinessObject Child7 = new BusinessObject()
{
TaskId = 9,
TaskName = "Get approval from customer",
StartDate = "02/13/2017",
Duration = 2
};
BusinessObject Child8 = new BusinessObject()
{
TaskId = 10,
TaskName = "Design complete",
StartDate = "02/14/2017",
Duration = 0
};
Record2.Children.Add(Child5);
Record2.Children.Add(Child6);
Record2.Children.Add(Child7);
Record2.Children.Add(Child8);
dataCollection.Add(Record1);
dataCollection.Add(Record2);
return dataCollection;
}
public class BusinessObject
{
public int TaskId { get; set; }
public string TaskName { get; set; }
public string StartDate { get; set; }
public int Duration { get; set; }
public List<BusinessObject> Children { get; set; }
}
}
```

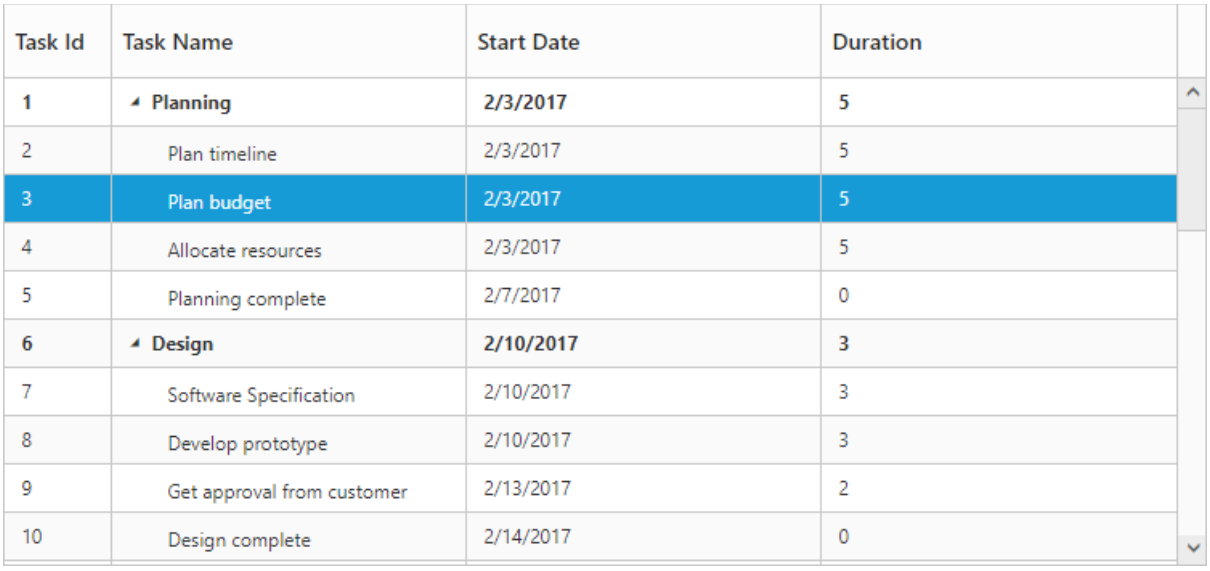
ASPX-CS

```
@using Syncfusion.JavaScript
@using Syncfusion.MVC.EJ
@using Syncfusion.JavaScript.Models
<!DOCTYPE html>
<html>
<head>
@*Add script reference and style reference here*@
</head>
<body>
@(Html.EJ().TreeGrid("TreeGridContainer")
.ChildMapping("Children")
.Columns(co =>
{
co.Field("TaskId").HeaderText("Task
Id").EditType(TreeGridEditingType.Numeric).Add();
co.Field("TaskName").HeaderText("Task
Name").EditType(TreeGridEditingType.String).Add();
co.Field("StartDate").HeaderText("Start
Date").EditType(TreeGridEditingType.Datepicker).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
co.Field("Duration").HeaderText("Duration").EditType(TreeGridEditingType.
Numeric).Add();
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
</body>
</html>
```

The output of the above steps is as follows:



Task Id	Task Name	Start Date	Duration
1	Planning	2/3/2017	5
2	Plan timeline	2/3/2017	5
3	Plan budget	2/3/2017	5
4	Allocate resources	2/3/2017	5
5	Planning complete	2/7/2017	0
6	Design	2/10/2017	3
7	Software Specification	2/10/2017	3
8	Develop prototype	2/10/2017	3
9	Get approval from customer	2/13/2017	2
10	Design complete	2/14/2017	0

Click here to view the online demo sample for hierarchical databinding.

Self-Referential Data Binding (Flat Data)

TreeGrid is rendered from Self-Referential data structures by providing two fields, **ID** field and **Parent ID** field.

- **ID Field**: This field contains unique values used to identify nodes. Its name is assigned to the IdMapping property.
- **Parent ID Field**: This field contains values that indicate parent nodes. Its name is assigned to the ParentIdMapping property.

C#

```
public class TreeGridController : Controller
{
public ActionResult Index()
{
ViewBag.datasource = this.GetSelfDataSource();
return View();
}
private List<BusinessObject> GetSelfDataSource()
{
List<BusinessObject> BusinessObjectCollection = new
List<BusinessObject>();
BusinessObjectCollection.Add(new BusinessObject()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
TaskId = 1,
TaskName = "Parent Task 1",
StartDate = "10/23/2017",
Duration = 10,
ParentId = null
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 2,
TaskName = "Child task 1",
StartDate = "10/23/2017",
Duration = 4,
ParentId = 1
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 3,
TaskName = "Child Task 2",
StartDate = "10/24/2017",
Duration = 5,
ParentId = 1
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 4,
TaskName = "Child task 3",
StartDate = "10/25/2017",
Duration = 6,
ParentId = 1
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 5,
TaskName = "Parent Task 2",
StartDate = "10/23/2017",
Duration = 10,
ParentId = null
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 6,
TaskName = "Child task 1",
StartDate = "10/23/2017",
Duration = 4,
ParentId = 5
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 7,
TaskName = "Child Task 2",
StartDate = "10/24/2017",
Duration = 5,
ParentId = 5
});
BusinessObjectCollection.Add(new BusinessObject()
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
TaskId = 8,
TaskName = "Child task 3",
StartDate = "10/25/2017",
Duration = 6,
ParentId = 5
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 9,
TaskName = "Child task 4",
StartDate = "10/25/2017",
Duration = 6,
ParentId = 5
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 10,
TaskName = "Parent Task 3",
StartDate = "10/23/2017",
Duration = 10,
ParentId = null
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 11,
TaskName = "Child task 1",
StartDate = "10/23/2017",
Duration = 4,
ParentId = 10
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 12,
TaskName = "Child Task 2",
StartDate = "10/24/2017",
Duration = 5,
ParentId = 10
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 13,
TaskName = "Child task 3",
StartDate = "10/25/2017",
Duration = 6,
ParentId = 10
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 14,
TaskName = "Child task 4",
StartDate = "10/25/2017",
Duration = 6,
ParentId = 10
});
BusinessObjectCollection.Add(new BusinessObject()
{
TaskId = 15,
```

Copyright © 2001 - 2020 Syncfusion Inc.

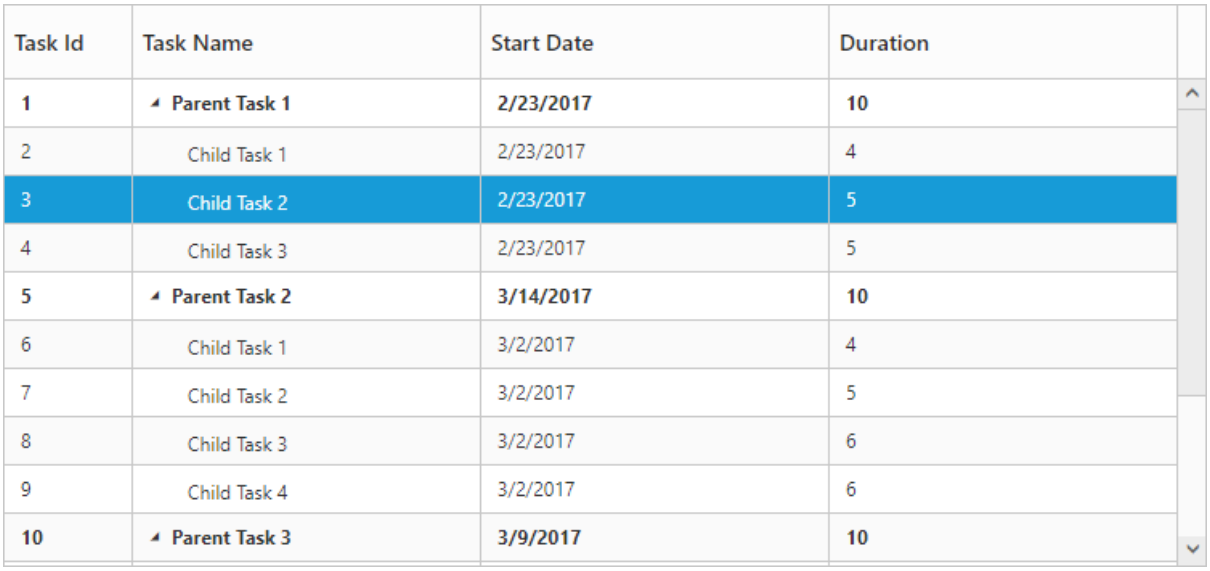
```
TaskName = "Child task 5",
StartDate = "10/25/2017",
Duration = 6,
ParentId = 10
});
return BusinessObjectCollection;
}
public class BusinessObject
{
public int TaskId { get; set; }
public string TaskName { get; set; }
public string StartDate { get; set; }
public int Duration { get; set; }
public int? ParentId { get; set; }
}
}
```

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.IdMapping("TaskId")
.ParentIdMapping("ParentId")
.Columns(co =>
{
co.Field("TaskId").HeaderText("Task
Id").EditType(TreeGridEditingType.Numeric).Add();
co.Field("TaskName").HeaderText("Task
Name").EditType(TreeGridEditingType.String).Add();
co.Field("StartDate").HeaderText("Start
Date").EditType(TreeGridEditingType.Datepicker).Add();
co.Field("Duration").HeaderText("Duration").EditType(TreeGridEditingType.
Numeric).Add();
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the output of the above steps,

Copyright © 2001 - 2020 Syncfusion Inc.



Task Id	Task Name	Start Date	Duration
1	Parent Task 1	2/23/2017	10
2	Child Task 1	2/23/2017	4
3	Child Task 2	2/23/2017	5
4	Child Task 3	2/23/2017	5
5	Parent Task 2	3/14/2017	10
6	Child Task 1	3/2/2017	4
7	Child Task 2	3/2/2017	5
8	Child Task 3	3/2/2017	6
9	Child Task 4	3/2/2017	6
10	Parent Task 3	3/9/2017	10

Click here to view the online demo sample for self-referential databinding.

Remote data binding

Load on demand

TreeGrid provides Load on Demand support for rendering remote data. Load on demand is considered in TreeGrid for the following actions,

- Expanding root nodes.
- Navigating pages, with paging enabled in TreeGrid.

When load on demand is enabled all the root nodes are rendered in collapsed state at initial load.

When load on demand support is enabled in TreeGrid with paging, the current or active page's root node alone will be rendered in collapsed state. On expanding the root node the child nodes will be loaded from the remote server.

When the root node is expanded its child nodes are rendered and are cached locally, such that on consecutive expand/collapse actions on root node, the child nodes are loaded from the cache instead from the remote server.

Similarly if the user navigates to a new page, the root nodes of that specific page will be rendered with request to the remote server.

Note: 1. Load on demand support in TreeGrid can be enabled only for remote data.

2. For better initial load time performance, we need to define the HasChildMapping property.

Load on demand support in TreeGrid can be enabled by using the property EnableLoadOnDemand.

The following code explains how to use Load on Demand in TreeGrid Control,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.IdMapping("TaskID")
.ParentIdMapping("ParentID")
.HasChildMapping("isParent")
```

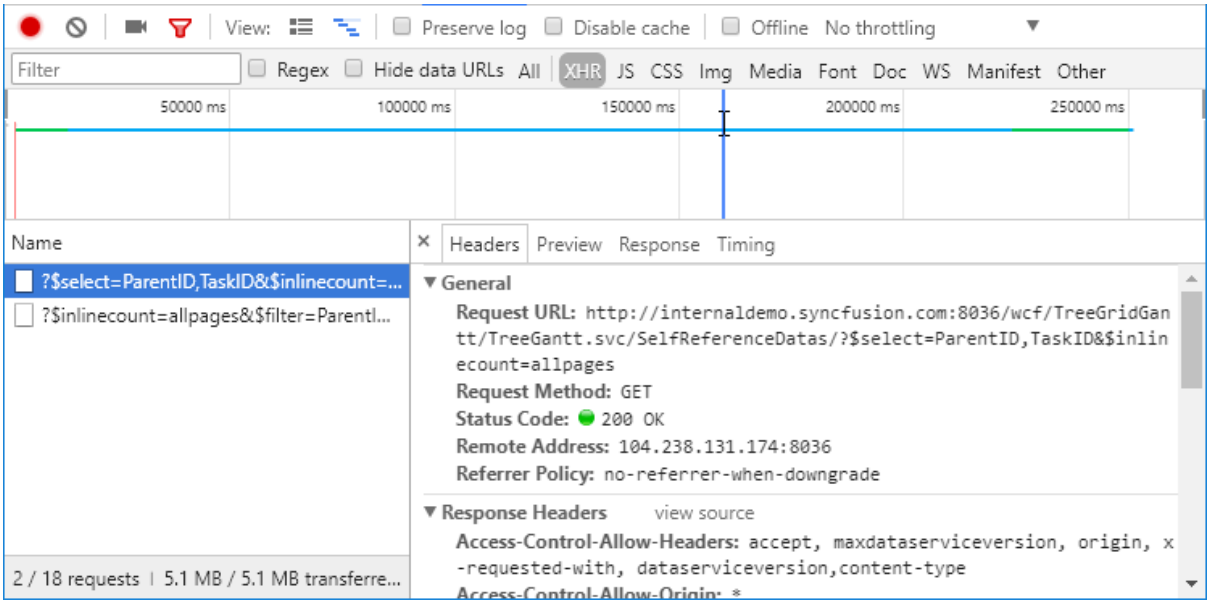
Copyright © 2001 - 2020 Syncfusion Inc.

```
.EnableLoadOnDemand(true)
.EnableVirtualization(true)
.Columns(co =>
{
co.Field("TaskID").HeaderText("Task Id").Width(45).Add();
co.Field("TaskName").HeaderText("Task Name").Add();
co.Field("StartDate").HeaderText("Start Date").Add();
co.Field("EndDate").HeaderText("End Date").Add();
co.Field("Progress").HeaderText("Progress").Add();
})
.Datasource(dataSource =>
dataSource.URL("http://js.syncfusion.com/demos/ejServices/Wcf/TreeGridGantt/TreeGantt.svc/SelfReferenceDatas").CrossDomain(true))
)
@(Html.EJ().ScriptManager())
```

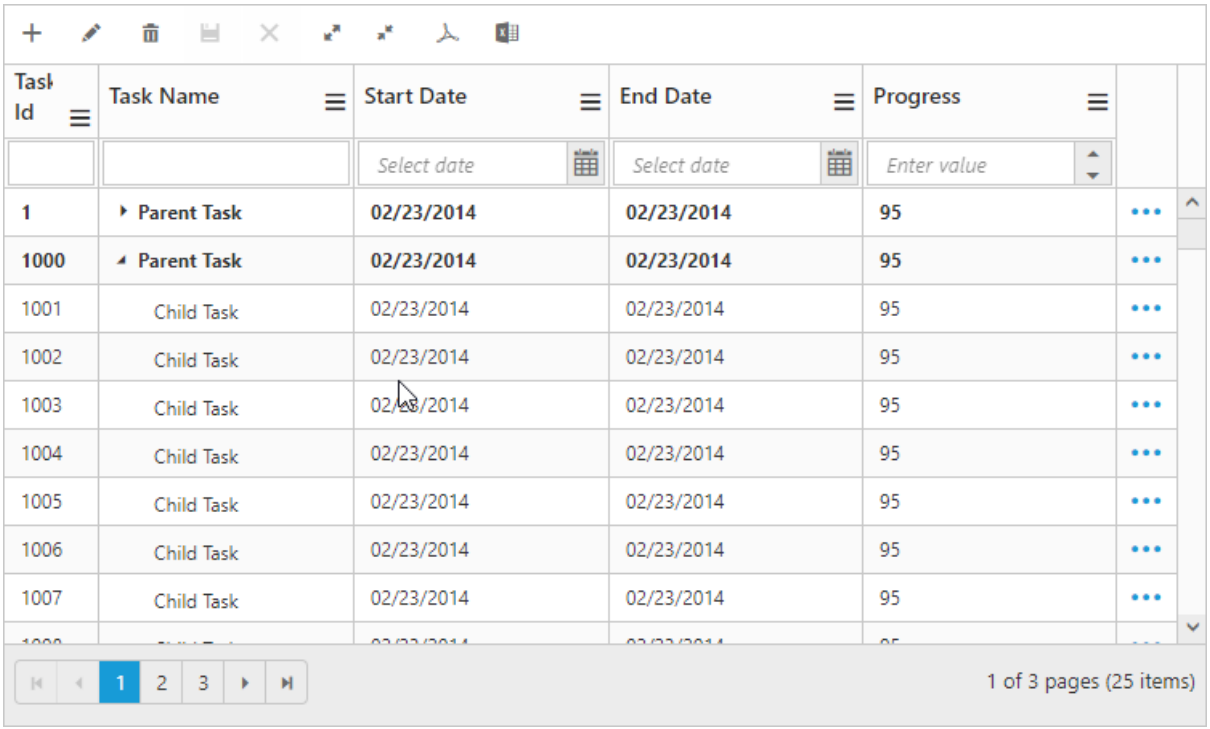
The output for load on demand support in TreeGrid:

Task Id	Task Name	Start Date	End Date	Progress
1	Parent Task	02/23/2014	02/23/2014	95
1000	Parent Task	02/23/2014	02/23/2014	95
2000	Parent Task	02/23/2014	02/23/2014	95
3000	Parent Task	02/23/2014	02/23/2014	95
4000	Parent Task	02/23/2014	02/23/2014	95
5000	Parent Task	02/23/2014	02/23/2014	95
6000	Parent Task	02/23/2014	02/23/2014	95
7000	Parent Task	02/23/2014	02/23/2014	95
8000	Parent Task	02/23/2014	02/23/2014	95
9000	Parent Task	02/23/2014	02/23/2014	95
10000	Parent Task	02/23/2014	02/23/2014	95
11000	Parent Task	02/23/2014	02/23/2014	95
12000	Parent Task	02/23/2014	02/23/2014	95

Copyright © 2001 - 2020 Syncfusion Inc.



The following output shows how load on demand works for expanding action



Click here to view the online demo sample for Load on demand.

Load at once:

On remote data binding, for every action such as paging, sorting, filtering the data will be fetched from the remote server each time. To avoid requesting the data from the remote server for each action, we can set TreeGrid to load all the data on initialization and make all the data operations in client side. To enable this, we have to set `Offline` property of `ej.DataManager` as `true`, the following code example explains this.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.IdMapping("TaskID")
.ParentIdMapping("ParentID")
.HasChildMapping("isParent")
.EnableVirtualization(true)
.Columns(co =>
{
co.Field("TaskID").HeaderText("Task Id").Width(45).Add();
co.Field("TaskName").HeaderText("Task Name").Add();
co.Field("StartDate").HeaderText("Start Date").Add();
co.Field("EndDate").HeaderText("End Date").Add();
co.Field("Progress").HeaderText("Progress").Add();
})
.Datasource(dataSource =>
dataSource.URL("http://js.syncfusion.com/demos/ejServices/Wcf/TreeGridGan
tt/TreeGantt.svc/SelfReferenceDatas").Offline(true))
)
@(Html.EJ().ScriptManager())
```

Please refer the link for further reference on offline property

Limitations:

1. Mapping the expand state of a record using ExpandStateMapping property is not supported in load on demand feature.
2. If a root or parent node is in collapsed state (child nodes not yet loaded), then that parent node will not be expanded while inserting new child to that parent node using toolbar icon or drag and drop actions.

Virtual rendering

Virtualization support is used to render large number of records in TreeGrid with effective performance. In this mode all the records are fetched from data source initially, but only few records will be displayed in the document object model (DOM) which should be visible to the user. While scrolling, the visible records are updated in DOM as per the scrolled position. This mode can be enabled by setting EnableVirtualization property as true.

The below code example shows how to use this property.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
.EnableVirtualization(true)
)
@(Html.EJ().ScriptManager())
```

Click here to view the online demo sample for virtualization.

Columns

Column definitions specified in the Columns option defines how the data in the **DataSource** have to be displayed, formatted and edited in TreeGrid. The values in the **DataSource** can be mapped to the appropriate column using the Field property of the corresponding column object.

Copyright © 2001 - 2020 Syncfusion Inc.

Editing type

The edit type of a column can be defined using the EditType property of the column object.

The following example shows how to define the EditType in a column,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col=>
{
col.EditType(TreeGridEditingType.Boolean).Add();
col.EditType(TreeGridEditingType.Numeric).Add();
})
@(Html.EJ().ScriptManager())
```

The column editors can be further customized by using the EditOptions property of column object.

The following example shows how to define additional properties to the date picker control,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("StartDate").EditType(TreeGridEditingType.Datepicker).DateEditO
ptions(new Syncfusion.JavaScript.Models.DatePickerProperties
{
HighlightWeekend = true
}).Add();
})
)
@(Html.EJ().ScriptManager())
```

Formatting

The values in each column can be formatted using the Format property of the column object.

The following code example shows how to format the numeric and date values in TreeGrid column,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("Percentage").HeaderText("Percentage").Format("{0:P0}").Add();
col.Field("Currency").HeaderText("Currency").Format("{0:C2}").Add();
col.Field("startDate").HeaderText("Start
Date").Format("{0:MM/dd/yyyy}").Add();
col.Field("endDate").HeaderText("End Date").Format("{0:MM/dd/yyyy
hh:mm:ss}").Add();
})
)
@(Html.EJ().ScriptManager())
```

Note: 1.For more numeric format strings, please refer this link.

2.For more date format strings, please refer this link.

Copyright © 2001 - 2020 Syncfusion Inc.

Defining column width

In TreeGrid, it is possible to define width for a specific column by setting Width property to the column object.

The below code snippet shows how to set width for specific column,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("taskID").HeaderText("Task Id").Width(50).Add();
col.Field("taskName").HeaderText("Task Name").Width(150).Add();
col.Field("startDate").HeaderText("Start Date").Width(100).Add();
col.Field("endDate").HeaderText("End Date").Width(100).Add();
col.Field("duration").HeaderText("Duration").Width(100).Add();
})
)
@(Html.EJ().ScriptManager())
```

The below screenshot shows the TreeGrid rendered with specific column width values.

Task Id	Task Name	Start Date	End Date	Duration
1	Planning	2/3/2014	2/7/2014	5
2	Plan timeline	2/3/2014	2/7/2014	5
3	Plan budget	2/3/2014	2/7/2014	5
4	Allocate resources	2/3/2014	2/7/2014	5
5	Planning complete	2/7/2014	2/7/2014	0
6	Design	2/10/2014	2/14/2014	3
12	Implementation Phase	2/17/2014	2/27/2014	11
13	Phase 1	2/17/2014	2/27/2014	11
14	Implementation Modul	2/17/2014	2/27/2014	11
15	Development Task 1	2/17/2014	2/19/2014	3
16	Development Task 2	2/17/2014	2/19/2014	3
17	Testing	2/20/2014	2/21/2014	2

Defining common width for the columns

The TreeGrid control provides the support to set same width for all the available columns and this can be done by using CommonWidth property.

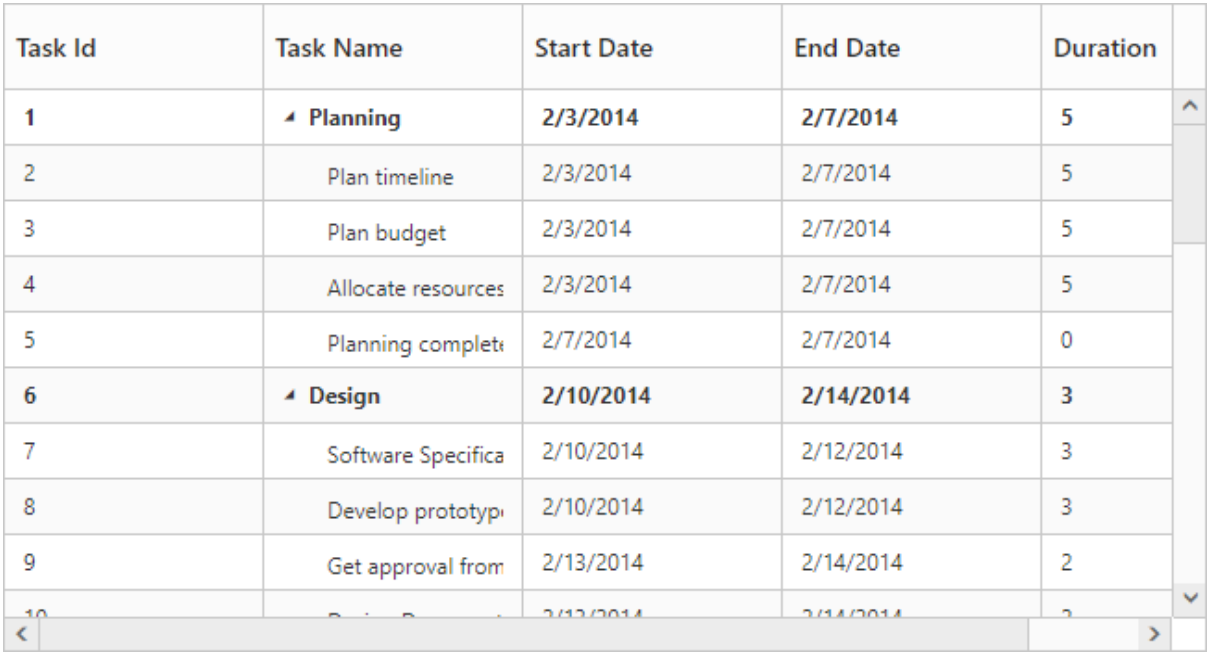
ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.CommonWidth(140)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().ScriptManager())
```

The below screenshot shows TreeGrid render with common width.



Headers

Header text

Using the HeaderText property, you can provide the title for a specific column. The below code snippet shows how to set HeaderText for TreeGrid columns.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("taskID").HeaderText("Task Id").Add();
col.Field("taskName").HeaderText("Task Name").Add();
col.Field("startDate").HeaderText("Start Date").Add();
col.Field("endDate").HeaderText("End Date").Add();
})
)
@(Html.EJ().ScriptManager())
```

Text wrapping

It is possible to wrap the header text or the title of the column when the content exceeds the column width using HeaderTextOverflow property. By default this property is set to **None**.

To enable wrapping of header text, you have to set the HeaderTextOverflow property as **Wrap**.

The below code snippet demonstrates this.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.HeaderTextOverflow(TreeGridHeaderTextOverflow.Wrap)
)
@(Html.EJ().ScriptManager())
```

Click here to view the online demo sample for text wrapping.

Header Template

TreeGrid column's header template was defined by using HeaderTemplateID property. The value of this property should be a valid JsRender template.

The following code snippet shows how to set the header template for TreeGrid columns,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("taskName").EditType(TreeGridEditingType.String).HeaderTemplate
ID("#projectName").Add();
col.Field("startDate").EditType(TreeGridEditingType.Datepicker).Add();
col.Field("resourceId").EditType(TreeGridEditingType.Dropdown).DropDownDa
ta((IEnumerable<object>)ViewBag.projectResources).HeaderTemplateID("#reso
urce").Add();
col.Field("progress").EditType(TreeGridEditingType.Numeric).Add();
})
)
@(Html.EJ().ScriptManager())
<script type="text/x-jsrender" id="resource">
<div>
<div class="name">
<img src="13.4.0.53/themes/web/images/treegrid/icon-03.png" width="20"
height="20" />
</div>
<div style="position:relative; top:3px;">
Resources
</div>
</div>
</script>
<script type="text/x-jsrender" id="projectName">
<div>
<div>
<img src="13.4.0.53/themes/web/images/treegrid/icon-01.png" width="20"
height="20" />
</div>
<div style="position:relative; top:3px;">
Task Name
</div>
</div>
</script>
```

The below screenshot depicts column headers with custom templates.

Copyright © 2001 - 2020 Syncfusion Inc.

Task Name	startDate	Resources	progress
Planning	02/03/2014		
Plan timeline	02/03/2014	Software Analyst	100
Plan budget	02/03/2014	Project Manager	100
Allocate resources	02/03/2014	Project Manager	100

Click here to view the online demo sample for header template.

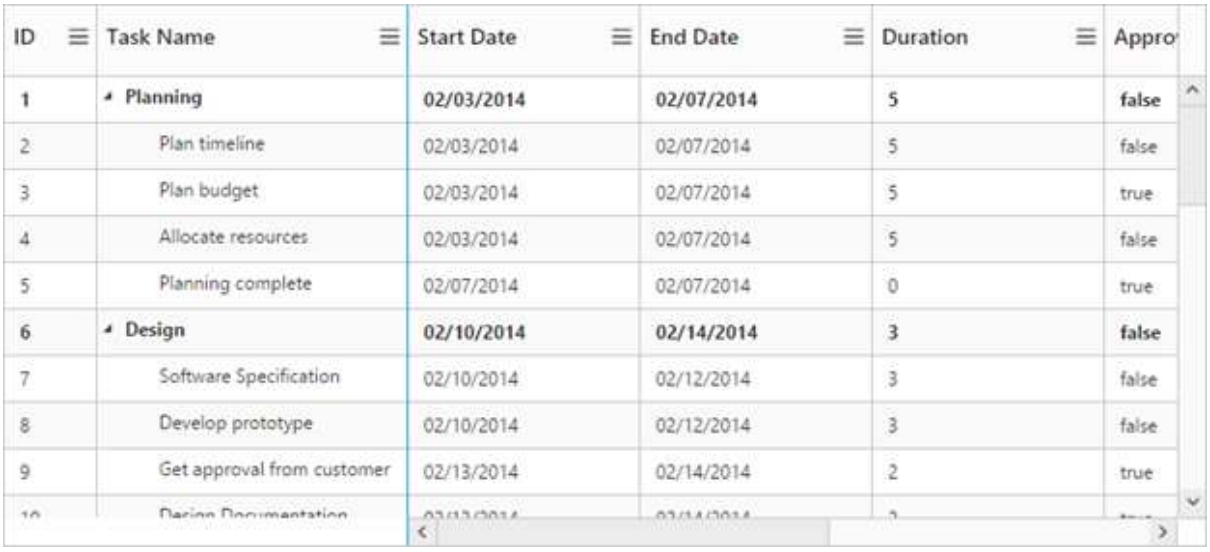
Frozen Columns

Specific columns can be frozen by enabling the IsFrozen property of the respective column object. The columns which are frozen remain static while scrolling the content horizontally. You can also freeze or unfreeze a column during runtime, by selecting Freeze or Unfreeze menu item in the column menu. These set of menu options will be displayed in all the columns when the IsFrozen property is enabled in any of the columns. However you can control the visibility of these menu options in a particular column by enabling/disabling the AllowFreezing property of that specific column.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowColumnChooser(true)
.Columns(co =>
{
co.Field("TaskId").HeaderText("ID").Width(100).IsFrozen(true).AllowFreezi
ng(false).Add();
co.Field("TaskName").HeaderText("Task
Name").Width(200).IsFrozen(true).Add();
co.Field("StartDate").HeaderText("Start Date").Add();
co.Field("EndDate").HeaderText("End Date").Add();
co.Field("Duration").HeaderText("Duration").Add();
})
)
@(Html.EJ().ScriptManager())
```

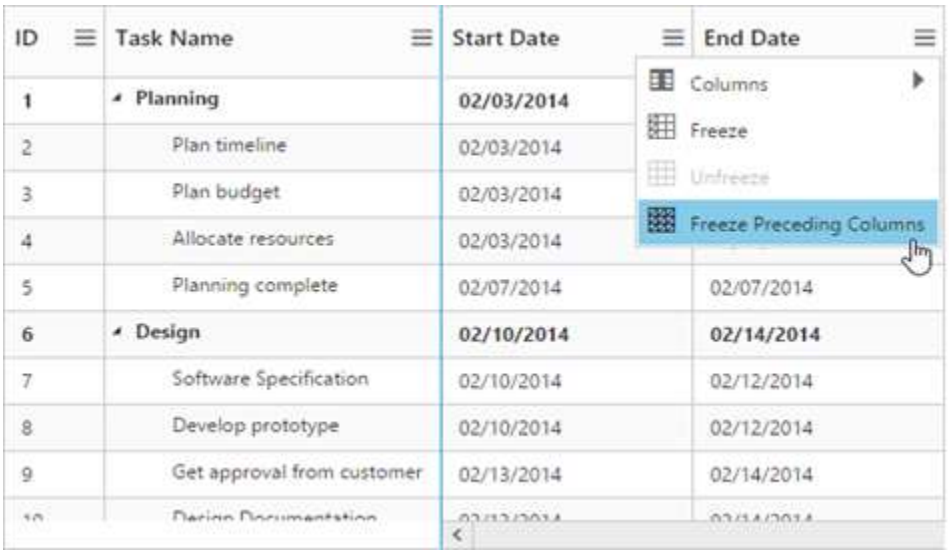
The below screenshot depicts TreeGrid with frozen columns,



ID	Task Name	Start Date	End Date	Duration	Appro
1	Planning	02/03/2014	02/07/2014	5	false
2	Plan timeline	02/03/2014	02/07/2014	5	false
3	Plan budget	02/03/2014	02/07/2014	5	true
4	Allocate resources	02/03/2014	02/07/2014	5	false
5	Planning complete	02/07/2014	02/07/2014	0	true
6	Design	02/10/2014	02/14/2014	3	false
7	Software Specification	02/10/2014	02/12/2014	3	false
8	Develop prototype	02/10/2014	02/12/2014	3	false
9	Get approval from customer	02/13/2014	02/14/2014	2	true

Copyright © 2001 - 2020 Syncfusion Inc.

It is also possible to freeze all the preceding columns at run-time by choosing **Freeze Preceding Columns** option in the column menu or by using the freezePrecedingColumns method, the column field name, for which the columns preceding it to be frozen should be passed as the method parameter.



Freeze columns using method

Columns can also be frozen or unfrozen on any custom actions using the freezeColumn method.

The column's field name which is to be frozen/unfrozen should be passed as the method parameter, along with the freeze state.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//.
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
var treegridObj = $("#TreeGridContainer").data("ejTreeGrid");
treegridObj.freezeColumn(field, true);
</script>
```

Click here to view the online demo sample for frozen column.

Resizing

You can resize the column width to view the hidden text of the cell. This feature can be enabled by setting the AllowColumnResize property to true.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowColumnResize(true)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

Column resize mode

In TreeGrid, it is possible to provide different column resizing mode by using ResizeMode property of ColumnResizeSettings property.

The below are the types of column resize modes available in TreeGrid,

- Normal - Columns are stretched with control width at load time. When resizing the column, the current column width is updated based on next column.
- Next column - Columns are stretched with control width at load time. When resize the column the current column width is updated based on stretching columns in control width.
- Fixed Columns - Column are rendered with given width value at load time. Only the current column width is changed while resizing the column.

The following code snippet explains how to set column resize mode in TreeGrid,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ColumnResizeSettings(cr=>
{
cr.ResizeMode(TreeGridColumnResizeMode.FixedColumns);
})
)
@(Html.EJ().ScriptManager())
```

Task Id	Task Name	Start Date	End Date	Duration
1	**Planning**	**2/3/2014**	**2/7/2014**	**5**
2	Plan timeline	2/3/2014	2/7/2014	5
3	Plan budget	2/3/2014	2/7/2014	5
4	Allocate resources	2/3/2014	2/7/2014	5
5	Planning complete	2/7/2014	2/7/2014	0
6	**Design**	**2/10/2014**	**2/14/2014**	**3**
7	Software Specificati	2/10/2014	2/12/2014	3
8	Develop prototype	2/10/2014	2/12/2014	3
9	Get approval from c	2/13/2014	2/14/2014	2
10	Design Documentat	2/13/2014	2/14/2014	2

The above screenshot shows the TreeGrid rendered with FixedColumns resize mode.

Click here to view the online demo sample for column resizing.

Checkbox column

It is possible to display a column value as checkbox in TreeGrid by enabling the DisplayAsCheckbox property and by setting the EditType property as Boolean for that column.

Copyright © 2001 - 2020 Syncfusion Inc.

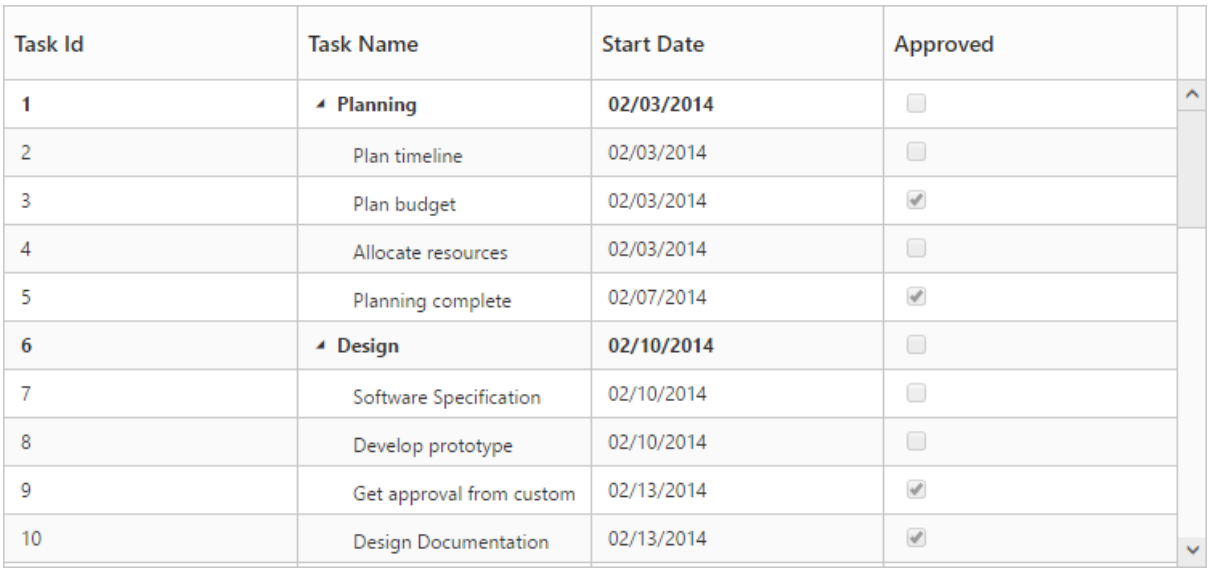
If the DisplayAsCheckbox property was set as false, then the column value will be displayed as string with the value mapped from the data source.

The following code snippet explains how to display a checkbox column in TreeGrid,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("approved").HeaderText("Approved").EditType(TreeGridEditingType
.Boolean).DisplayAsCheckbox(true).Add();
})
)
@(Html.EJ().ScriptManager())
```

The below screen shot depicts the Approved column in TreeGrid displayed as a checkbox column.



Task Id	Task Name	Start Date	Approved
1	Planning	02/03/2014	
2	Plan timeline	02/03/2014	
3	Plan budget	02/03/2014	
4	Allocate resources	02/03/2014	
5	Planning complete	02/07/2014	
6	Design	02/10/2014	
7	Software Specification	02/10/2014	
8	Develop prototype	02/10/2014	
9	Get approval from custom	02/13/2014	
10	Design Documentation	02/13/2014	

Column Template

Column Template is used to customize the column's look and feel based on requirement.

The following code example shows you how to display the icon in the TreeGrid column,

- TemplateID - Using the TemplateID property, you can specify the Id of the script element, which contains the template for the column.
- Template - HTML templates can be specified in the Template property of the particular column as a string (HTML element).

Column template support was enabled for that column by setting IsTemplateColumn as true.

The following code example show how to define template for the column,

ASPX-CS

```
// JsRender template definition.
<script type="text/x-jsrender" id="columnTemplate">
{{if #data['resourceNames']}}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div style="display:inline-block;position:relative;left:10px;top:1px">
<img src="../images/gantt/{{:#data['resourceNames']}}.png" height="40" />
</div>
{{/if}}
</script>
@(Html.EJ().TreeGrid("TreeGridContainer")
.RowHeight(50)
.Columns(col =>
{
col.Field("taskID").HeaderText("Task Id").Width(45).Add();
col.Field("taskName").HeaderText("Task Name").Add();
col.HeaderText("Resource").IsTemplateColumn(true).TemplateID("columnTempl
ate").TextAlign(TextAlign.Center).Add();
col.Field("resourceNames").HeaderText("Resource Name").Add();
})
)
@(Html.EJ().ScriptManager())
```

Click here to view the online demo sample for frozen column.

Column Menu

Column menu can be displayed in column header by setting ShowColumnChooser property as true.

The following are the items displayed in the column menu,

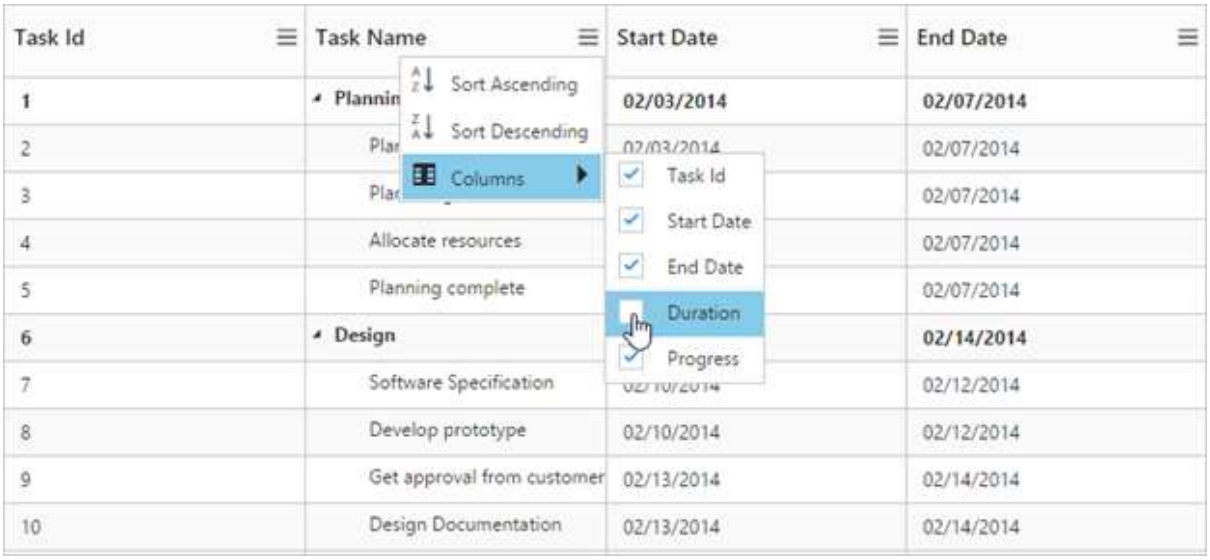
- **Column Chooser** – Displays all the column names, you can enable or disable a column by check or uncheck the respective column name in the column chooser menu.
- **Sort Ascending & Sort Descending** – Used to sort the items in the column. These menu options will be displayed only when you set the AllowSorting property as true. To perform multilevel sorting, the AllowMultiSorting property should be enabled.

Copyright © 2001 - 2020 Syncfusion Inc.

- **Freeze, Unfreeze & Freeze Preceding Columns** – Used to freeze or unfreeze the columns. These set of menu options will be displayed in all the columns when the IsFrozen property is enabled in any of the columns. However, you can control the visibility of these menu options in a particular column by enabling/disabling the AllowFreezing property of that specific column.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowColumnChooser(true)
.AllowSorting(true)
.AllowMultiSorting(true)
.Columns(col =>
{
col.Field("duration").HeaderText("Duration").Visible(false).Add();
})
)
@(Html.EJ().ScriptManager())
```



The column menu also provides support for some of the additional column options such as,

- Insert column left
- Insert column right
- Delete column
- Rename column

The column options can be enabled or disabled with the ShowColumnOptions property, default value of this property is false.

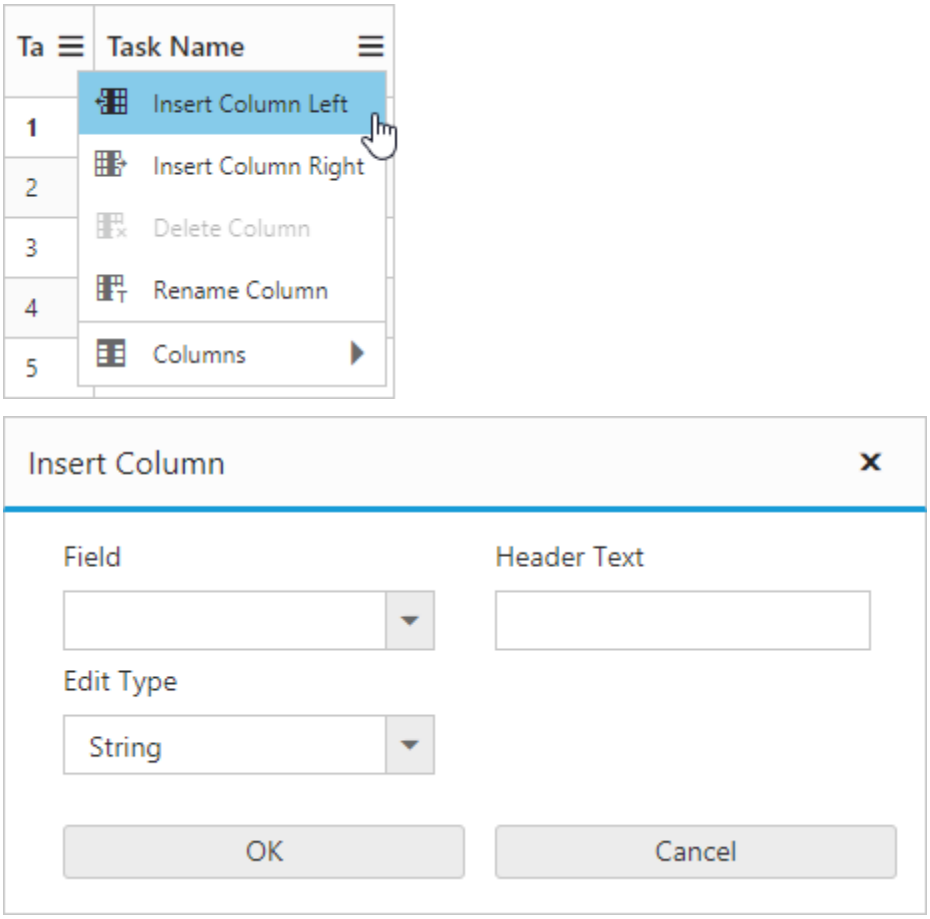
The following code example shows how to enable the column option in TreeGrid,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowColumnOptions(true)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().ScriptManager())
```



The above screenshot shows insert column dialog in TreeGrid

The TreeGrid columns can also be renamed or deleted at run-time on any custom actions using the renameColumn and deleteColumn methods.

Customize insert column dialog fields

It is possible to add or remove the Columns properties in insert column dialog using ColumnDialogFields property. In insert column dialog Field, HeaderText and EditType properties are necessary to create a new column, so these fields are unable to remove from insert column option.

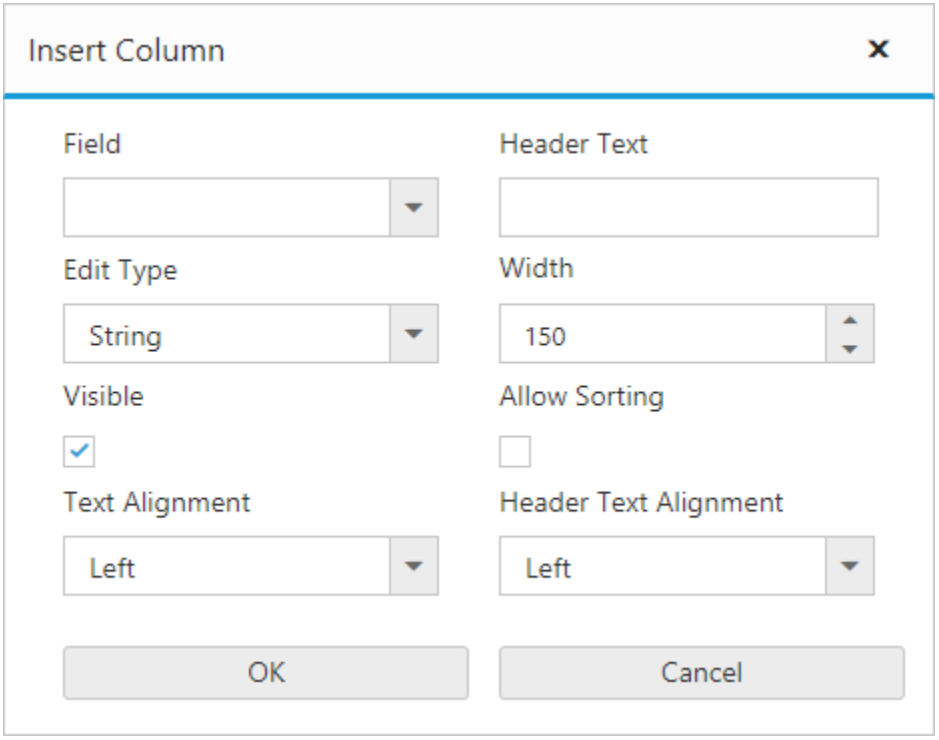
The following code example shows how to customize the insert column option in TreeGrid,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowSorting(true)
.ShowColumnOptions(true)
.ColumnDialogFields(new List<TreeGridColumnDialogFields>()
{
TreeGridColumnDialogFields.Field,
TreeGridColumnDialogFields.HeaderText,
TreeGridColumnDialogFields.EditType,
TreeGridColumnDialogFields.Width,
TreeGridColumnDialogFields.Visible,
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
TreeGridColumnDialogFields.AllowSorting,
TreeGridColumnDialogFields.TextAlign,
TreeGridColumnDialogFields.HeaderTextAlign
})
)
@(Html.EJ().ScriptManager())
```



The above screenshot shows customized insert column dialog in TreeGrid.

Hide specific column in column chooser list

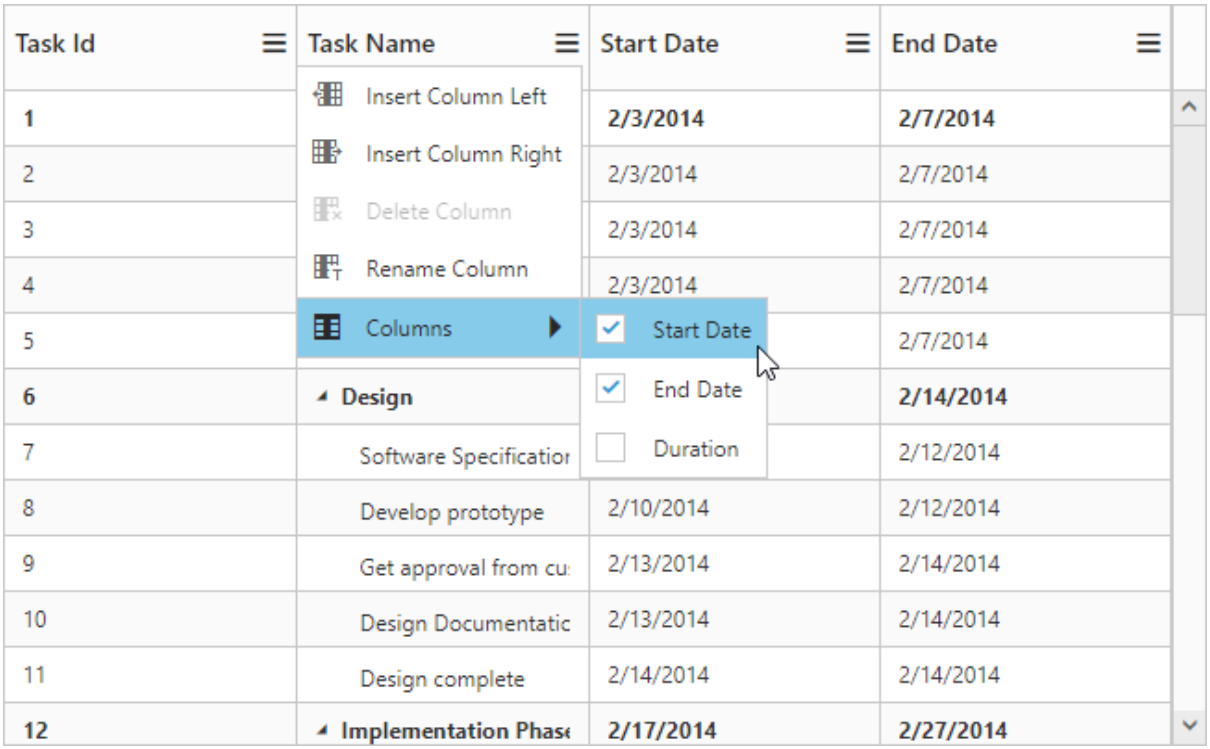
It is possible to hide the specific column in column chooser list by settings ShowInColumnChooser as false in the column definition.

The following code example shows how to hide specific column in column chooser list,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowColumnChooser(true)
.Columns(col =>
{
col.Field("taskID").HeaderText("Task
Id").ShowInColumnChooser(false).Add();
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screenshot shows TreeGrid column chooser rendered without Task Id column.

Show/Hide columns using method

It is possible to toggle the visibility of the columns using the hideColumn and showColumn methods. The column's header text should be passed as the method parameter which is to be shown/hidden.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//.
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
var treegridObj = $("#TreeGridContainer").data("ejTreeGrid");
treegridObj.hideColumn("Task Name");
treegridObj.showColumn("Order ID");
</script>
```

Click here to view the online demo sample for column menu.

Command Column

Default action buttons

Using command columns in TreeGrid, we can display a separate column to perform CRUD operations. It is also possible to perform any custom actions by using custom command buttons. Command column can be defined in TreeGrid by using the Commands property.

A command column can be customized by using the Type and ButtonOptions properties.

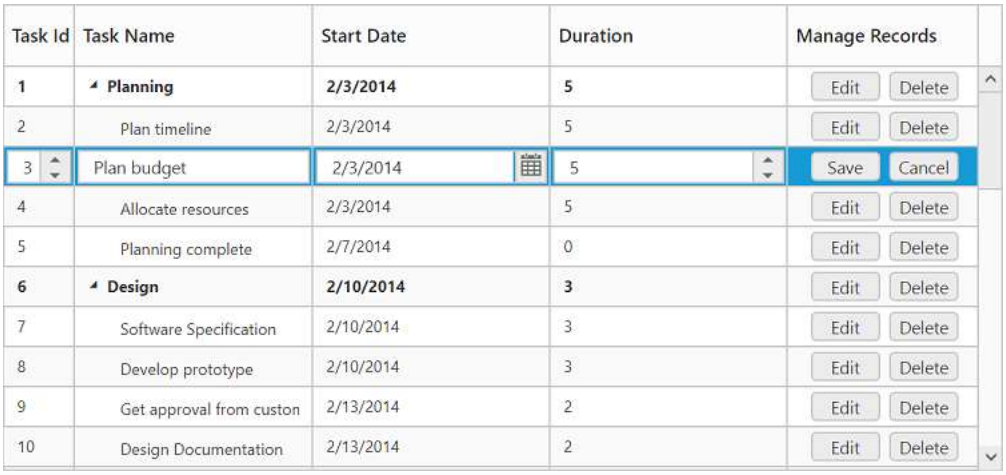
- **Type**: Using this property we can add required action buttons in TreeGrid command column such as edit,delete,save and cancel.

Copyright © 2001 - 2020 Syncfusion Inc.

- **ButtonOptions**: Using this property we can customize the button in the command column with the properties available in Button.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(co =>
{
co.HeaderText("Manage Records").Commands(command =>
{
command.Type(TreeGridUnboundType.Edit)
.ButtonOptions(new ButtonProperties()
{
Text = "Edit",
Width="58"
}).Add();
command.Type(TreeGridUnboundType.Delete)
.ButtonOptions(new ButtonProperties()
{
Text = "Delete",
Width = "58"
}).Add();
command.Type(TreeGridUnboundType.Save)
.ButtonOptions(new ButtonProperties()
{
Text = "Save",
Width = "58"
}).Add();
command.Type(TreeGridUnboundType.Cancel)
.ButtonOptions(new ButtonProperties()
{
Text = "Cancel",
Width = "58"
}).Add();
}).Add();
})
)
@(Html.EJ().ScriptManager())
```



Copyright © 2001 - 2020 Syncfusion Inc.

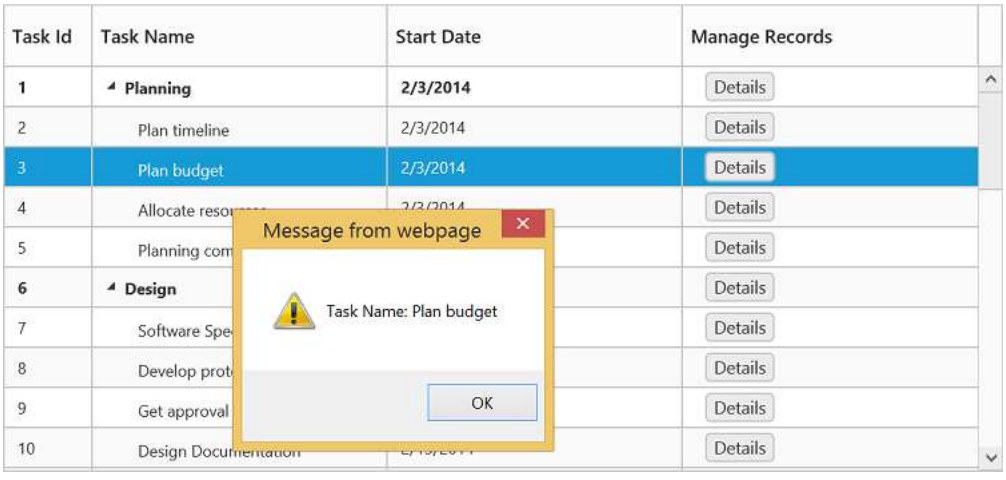
Click here to view the online demo sample for command column.

Custom buttons

We can also add custom buttons to the command column by specifying text value other than default buttons to the type property. We can also bind actions to the custom button using the Click client-side event of Button.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(co =>
{
co.HeaderText("Manage Records").Commands(command =>
{
command.Type("Details")
.ButtonOptions(new ButtonProperties()
{
Text = "Details",
Width = "58",
Click = "onClick"
}).Add();
}).Add();
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function onClick(args) {
var $tr = $(args.e.target).closest('tr'),
treeObj = $("#TreeGridContainer").data("ejTreeGrid"),
rowIndex = treeObj.getIndexByRow($tr),
record = treeObj.model.currentViewData[rowIndex];
alert("Task Name: " + record.item.TaskName);
}
</script>
```



Tree column/ Expander column

The position of the expander column/tree column can be changed by using the TreeColumnIndex property.

The following code example shows how to change the position of the expander column,

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.TreeColumnIndex(2)
)
@(Html.EJ().ScriptManager())
```

The TreeColumnIndex can also be changed at run-time by using the columnIndex method.

Visibility

The visibility of TreeGrid column can be customized by usingVisible property. TreeGrid columns column be hidden by setting Visible property as false.

The following code example explains how to hide the fourth column,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("taskID").HeaderText("Task Id").Width(45).Add();
col.Field("taskName").HeaderText("Task Name").Add();
col.Field("startDate").HeaderText("Start Date").Add();
col.Field("endDate").HeaderText("End Date").Visible(false).Add();
col.Field("progress").HeaderText("Progress").Add();
})
)
@(Html.EJ().ScriptManager())
```

Task Id	Task Name	Start Date	Progress
1	Planning	02/03/2014	100
2	Plan timeline	02/03/2014	100
3	Plan budget	02/03/2014	100
4	Allocate resources	02/03/2014	100
5	Planning complete	02/07/2014	0
6	Design	02/10/2014	86
7	Software Specification	02/10/2014	60
8	Develop prototype	02/10/2014	100
9	Get approval from customer	02/13/2014	100
10	Design Documentation	02/13/2014	100

Read-only

A column can be made read-only by setting the AllowEditing property as false.

Note: By setting Columns.AllowEditing as false that specific column alone is made as read-only, and by setting the EditSettings.AllowEditing as false the entire TreeGrid is made read-only.

The below code snippet demonstrates this,

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("taskID").HeaderText("Task Id").Width(45).Add();
col.Field("taskName").HeaderText("Task Name").AllowEditing(false).Add();
col.Field("startDate").HeaderText("Start Date").Add();
col.Field("endDate").HeaderText("End Date").Add();
})
)
@(Html.EJ().ScriptManager())
```

Validation Rules

At some occasions, we will need to validate the data before updating it to the database. In TreeGrid it is possible to validate the data while performing adding and editing actions. The validation rules must be provided in the column definition using ValidationRules property. TreeGrid has built-in support for the below validation rules.

- **maxlength** – Makes the value require a given maximum text length.
- **minlength** – Makes the value require a given minimum text length.
- **required** – Makes the value required.
- **number** – Makes the value require a decimal number.
- **range** – Makes the value require a given value range.

The below code example explains defining the validation rules for the column.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("taskID").HeaderText("Task Id").Width(45).ValidationRules(v=>
v.AddRule("required",true)).Add();
col.Field("taskName").HeaderText("Task Name").ValidationRules(v =>
v.AddRule("maxlength",5).AddRule("minlength",2)).Add();
col.Field("progress").HeaderText("Progress").ValidationRules(v =>
v.AddRule("range", new List<object>() { -1, 101 })).Add();
})
)
@(Html.EJ().ScriptManager())
```

Custom validation error messages can also be defined in the column object. The below code example explains defining the custom error message.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("taskID").HeaderText("Task Id").Width(45).ValidationRules(v=>
v.AddRule("required",true).AddRule("number",true).AddRule("messages", new
Dictionary<string, object>() { { "required", "This field was must" }
})).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
)
@(Html.EJ().ScriptManager())
```

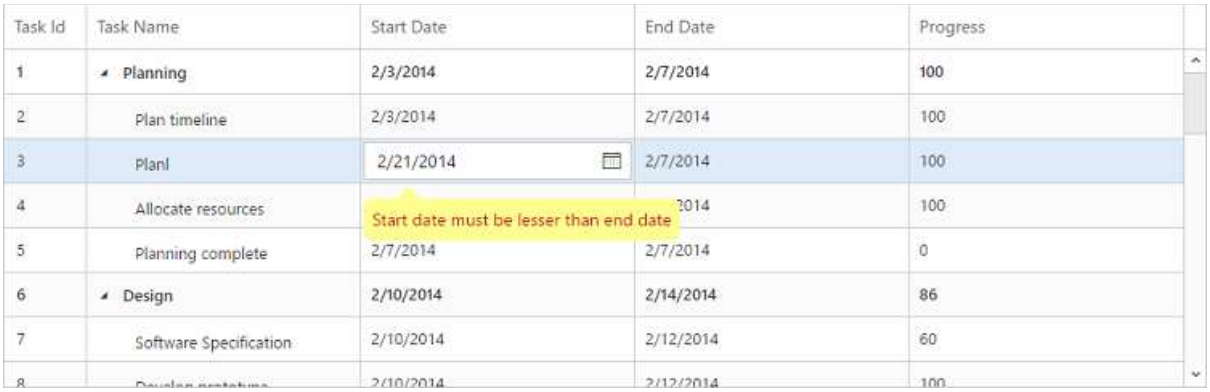
Custom Validation rules

Apart by the in-built validation rules, any custom validation rules can also be defined for the column. The below code example explains defining custom validation rule for a column.

ASPX-CS

```
<script type="text/javascript">
// Custom validation rule definition
$.validator.addMethod("customCompare", function(value, element, params) {
return element.value > params[0] && element.value < params[1]
}, "progress value must be between 0 and 100");
</script>
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("Progress").HeaderText("Progress").EditType(TreeGridEditingType
.Numeric).ValidationRules(v => v.AddRule("customCompare", new
List<object>() { -1, 101 })).Add();
})
)
@(Html.EJ().ScriptManager())
```

The below image displays the TreeGrid with validation rule applied for a date column.



Click here to view the online demo sample for TreeGrid validation support.

Column Reorder

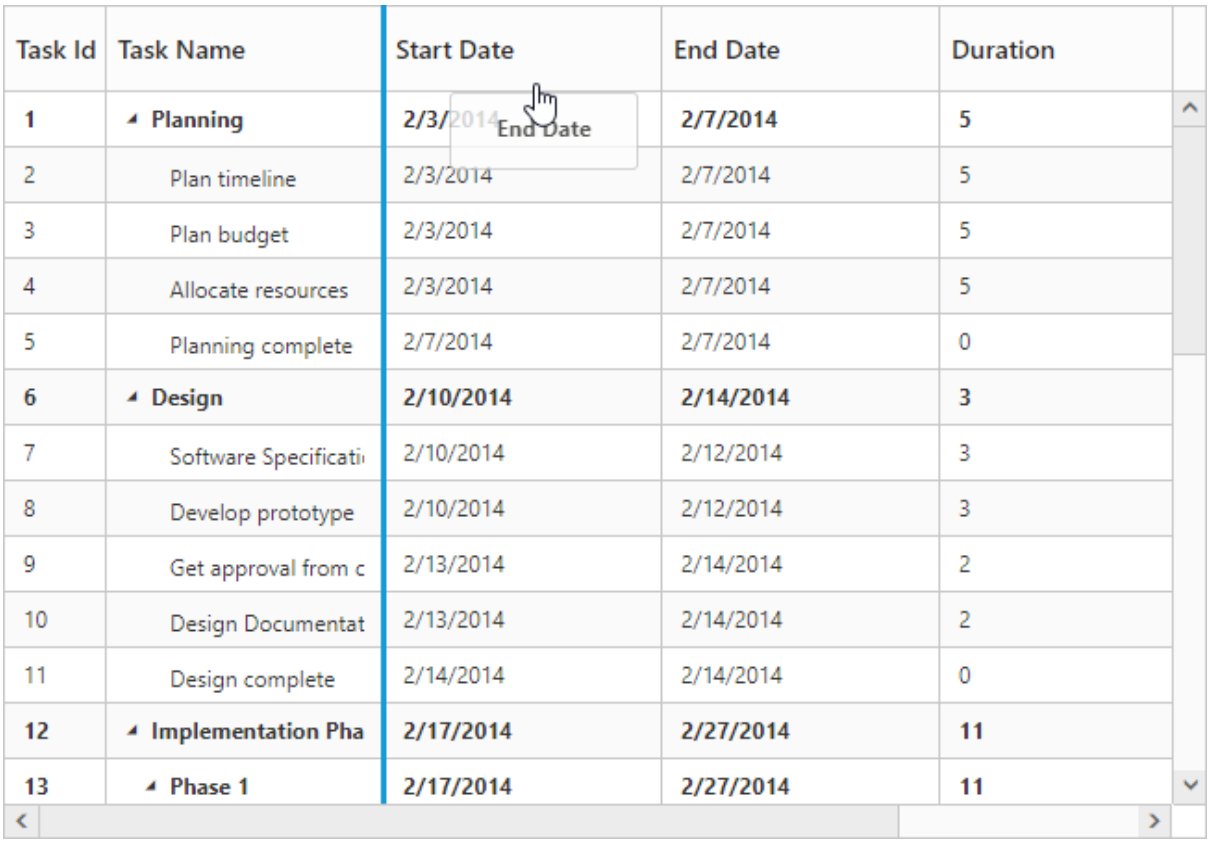
Column reorder support was used to change the order of the column by mouse interactions. In TreeGrid, AllowColumnReordering property was used to enable this support and the default value of this property was false.

The following code example explains how to enable column reorder in TreeGrid,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowColumnReordering(true)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screenshot shows the column reorder in TreeGrid.

The TreeGrid columns can also be reordered by using the reorderColumn method, where the column field name and the target index should be passed as the method parameters.

Click here to view the online demo sample for column re-ordering.

Text Alignment

In TreeGrid, it is possible to align both content and header text of particular column by using the `TextAlign` and `HeaderTextAlign` property of columns.

There are four possible ways to align content and header text of column, they are

1. Left
2. Right
3. Center
4. Justify

Note: The `TextAlign` property will affect both content and header text of the TreeGrid, when `HeaderTextAlign` is not set in the column definition.

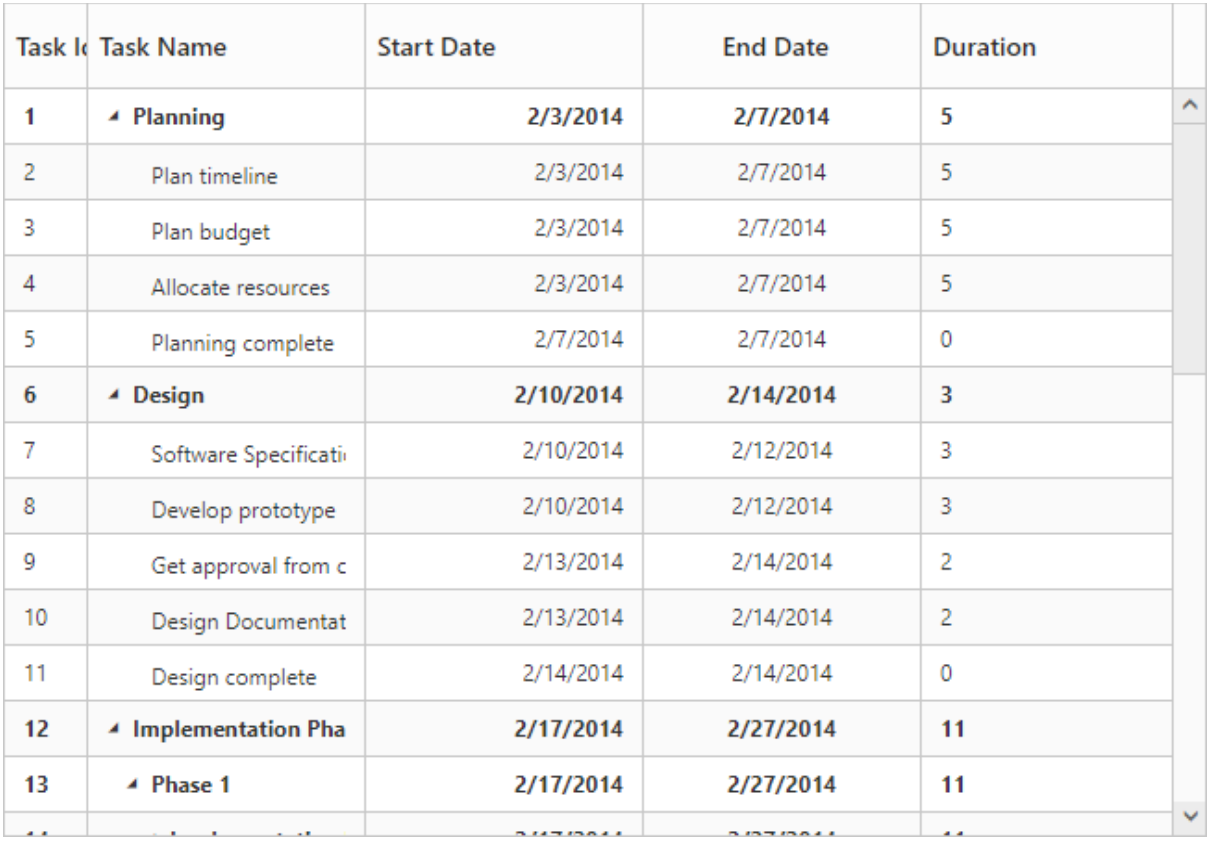
The following code example explains how to set text alignment for content and header text in TreeGrid,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Columns(col =>
{
col.Field("taskID").HeaderText("Task Id").Add();
col.Field("taskName").HeaderText("Task Name").Add();
col.Field("startDate").HeaderText("Start
Date").TextAlign(TextAlign.Right).HeaderTextAlign(TextAlign.Left).Add();
col.Field("endDate").HeaderText("End
Date").TextAlign(TextAlign.Center).Add();
col.Field("duration").HeaderText("Duration").Add();
})
)
@(Html.EJ().ScriptManager())
```



Task Id	Task Name	Start Date	End Date	Duration
1	**Planning**	**2/3/2014**	**2/7/2014**	**5**
2	Plan timeline	2/3/2014	2/7/2014	5
3	Plan budget	2/3/2014	2/7/2014	5
4	Allocate resources	2/3/2014	2/7/2014	5
5	Planning complete	2/7/2014	2/7/2014	0
6	**Design**	**2/10/2014**	**2/14/2014**	**3**
7	Software Specificati	2/10/2014	2/12/2014	3
8	Develop prototype	2/10/2014	2/12/2014	3
9	Get approval from c	2/13/2014	2/14/2014	2
10	Design Documentat	2/13/2014	2/14/2014	2
11	Design complete	2/14/2014	2/14/2014	0
12	**Implementation Pha**	**2/17/2014**	**2/27/2014**	**11**
13	**Phase 1**	**2/17/2014**	**2/27/2014**	**11**

The above screenshot shows TreeGrid render with text alignment and header text alignment.

Customize the column at initial load

In TreeGrid, it is possible to customize the column at load time using Load event.

The following code examples shows how to customize the column at load time,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(col =>
{
col.Field("taskID").HeaderText("Task Id").Add();
col.Field("taskName").HeaderText("Task Name").Add();
col.Field("startDate").HeaderText("Start Date").Add();
col.Field("endDate").HeaderText("End Date").Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Field("duration").HeaderText("Duration").Add();
})
.ClientSideEvents(eve=>
{
eve.Load("load");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function load(args) {
var columns = args.model.columns;
columns[0].isFrozen = true;
columns[3].textAlign = "center";
columns[4].visible = false;
}
</script>
```

Task Id	Task Name	Start Date	End Date
1	Planning	2/3/2017	2/7/2017
2	Plan timeline	2/3/2017	2/7/2017
3	Plan budget	2/3/2017	2/7/2017
4	Allocate resources	2/3/2017	2/7/2017
5	Planning complete	2/7/2017	2/7/2017
6	Design	2/10/2017	2/14/2017
7	Software Specification	2/10/2017	2/12/2017
8	Develop prototype	2/10/2017	2/12/2017
9	Get approval from customer	2/13/2017	2/14/2017
10	Design Documentation	2/13/2017	2/14/2017

The above screenshot shows TreeGrid rendered with customized column.

Get Column Object

The column object which consists the list of columns available in TreeGrid and we can get the particular column details by using the getColumnByHeaderText and getColumnByField methods.

Similarly we can get the column index by using the getColumnIndexByField method. To use this method we have to pass the field name as parameter. And we can get the field name of the column by using its `HeaderText` value by using getFieldNameByHeaderText method.

Rows

The TreeGrid rows displays the information of each row from the bounded data source.

Row Template

Row template is used to customize the TreeGrid rows based on requirements. In TreeGrid, `RowTemplateId` and `AltRowTemplateId` properties are used for customizing the row.

Copyright © 2001 - 2020 Syncfusion Inc.

- **RowTemplateId** is used to customize all the rows in TreeGrid. For this property, ID of the row template is to be provided.
- **AltRowTemplateId** is used to customize the alternative rows in TreeGrid. For this property, ID of the alternative row template is to be provided.

ASPX-CS

```
<style>
.border {
border-color: #BDBDBD;
border-width: 1px;
border-style: solid;
}
</style>
<script id="rowTemplateScript" type="text/x-jsrender">

{
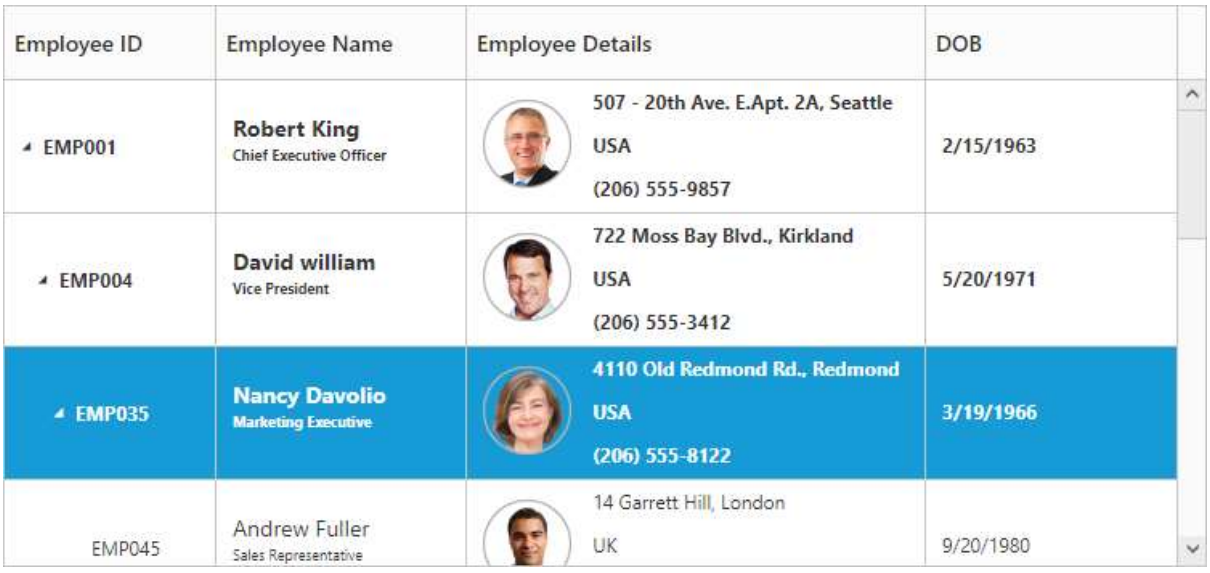
Name = "David William",
FullName = "David William",
Designation = "Vice President",
EmployeeID = "EMP004",
Address = "722 Moss Bay Blvd., Kirkland",
Country = "USA",
Contact = "(206) 555-3412",
DOB = "5/20/1971",
DOJ = "1/5/1991",
Children = new List<RowData>()
};
//..
Record1.Children.Add(parent);
//..
return DataCollection;
}
public class RowData
{
public string Name { get; set; }
public string FullName { get; set; }
public string Designation { get; set; }
public string EmployeeID { get; set; }
public string Address { get; set; }
public string Contact { get; set; }
public string DOB { get; set; }
public string DOJ { get; set; }
public string Country { get; set; }
public List<RowData> Children { get; set; }
}
```

The output of TreeGrid with Row Template is as follows.



Click here to view online sample for TreeGrid Row Template

Copyright © 2001 - 2020 Syncfusion Inc.

Note: In TreeGrid, the given row template is parsed for default row functionality like row selection, alt row and other default row customization. Using ParseRowTemplate property we can disable the row template parsing. If we disable that property, TreeGrid is rendered with given row template.

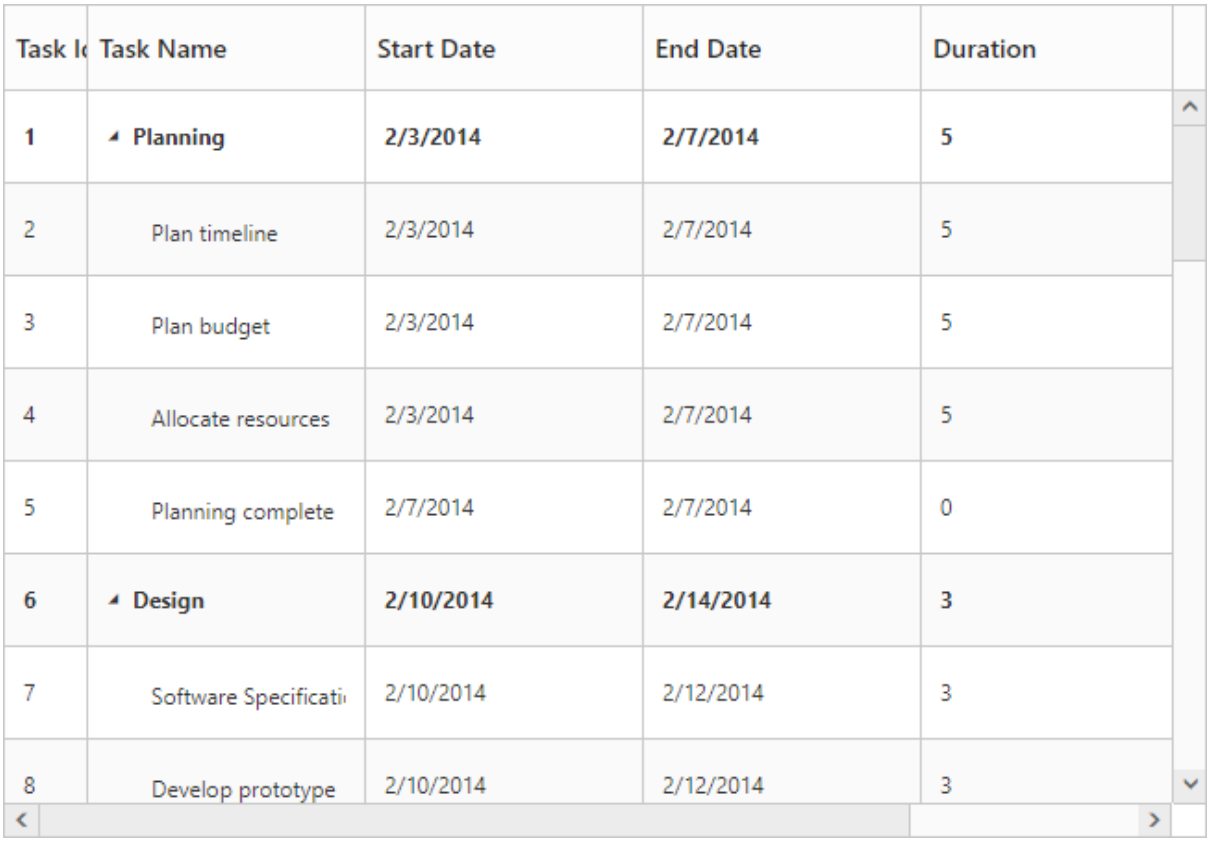
Row Height

The RowHeight property is used to change the height of row in TreeGrid, default value of this property is 30.

The following code example explains how to change the row height in TreeGrid

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.RowHeight(50)
//.
)
@(Html.EJ().ScriptManager())
```



Task Id	Task Name	Start Date	End Date	Duration
1	**Planning**	**2/3/2014**	**2/7/2014**	**5**
2	Plan timeline	2/3/2014	2/7/2014	5
3	Plan budget	2/3/2014	2/7/2014	5
4	Allocate resources	2/3/2014	2/7/2014	5
5	Planning complete	2/7/2014	2/7/2014	0
6	**Design**	**2/10/2014**	**2/14/2014**	**3**
7	Software Specificati	2/10/2014	2/12/2014	3
8	Develop prototype	2/10/2014	2/12/2014	3

The above screenshot shows TreeGrid render with row height of 50.

Alternate row styling

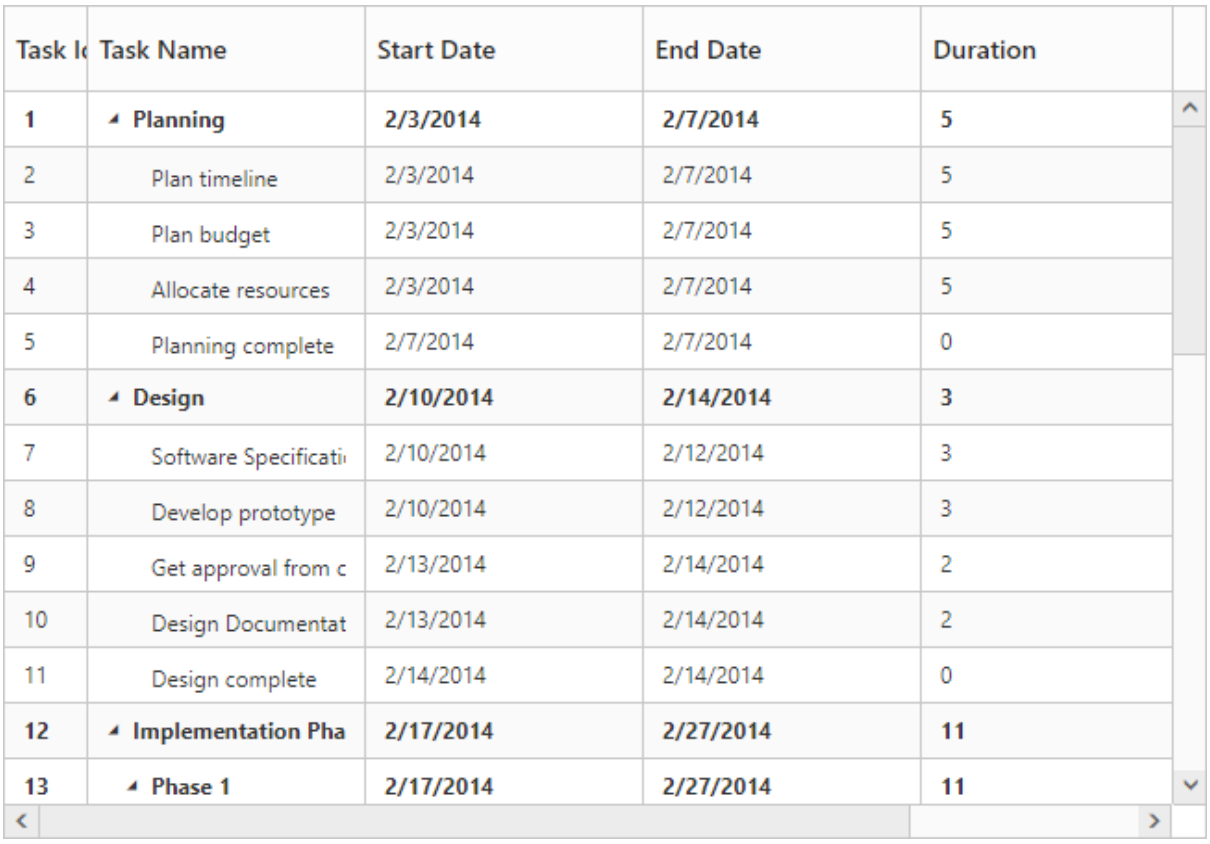
Alternate row style is used to enable the different background color for every alternate row. The EnableAltRow property is used to enable the alternate row style in TreeGrid, default value of this property is true.

The following code explains about enabling the alternate row style in TreeGrid

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EnableAltRow(true)
//.
)
@(Html.EJ().ScriptManager())
```



The above screenshot shows TreeGrid with alternate row style.

Row Drag and Drop

It is possible to dynamically re-arrange the rows in the TreeGrid control by using the AllowDragAndDrop property. Using this property row drag option can be enabled or disabled. Rows can be inserted above, below or as a sibling or as a child to the existing row with the help of this feature. A default tooltip is rendered while dragging the TreeGrid row and this tooltip can be customized by the DragTooltip property. This property has inner properties such as ShowTooltip, TooltipItems and TooltipTemplate.

The ShowTooltip property is used to enable or disable the tooltip and the default value of this property is false.

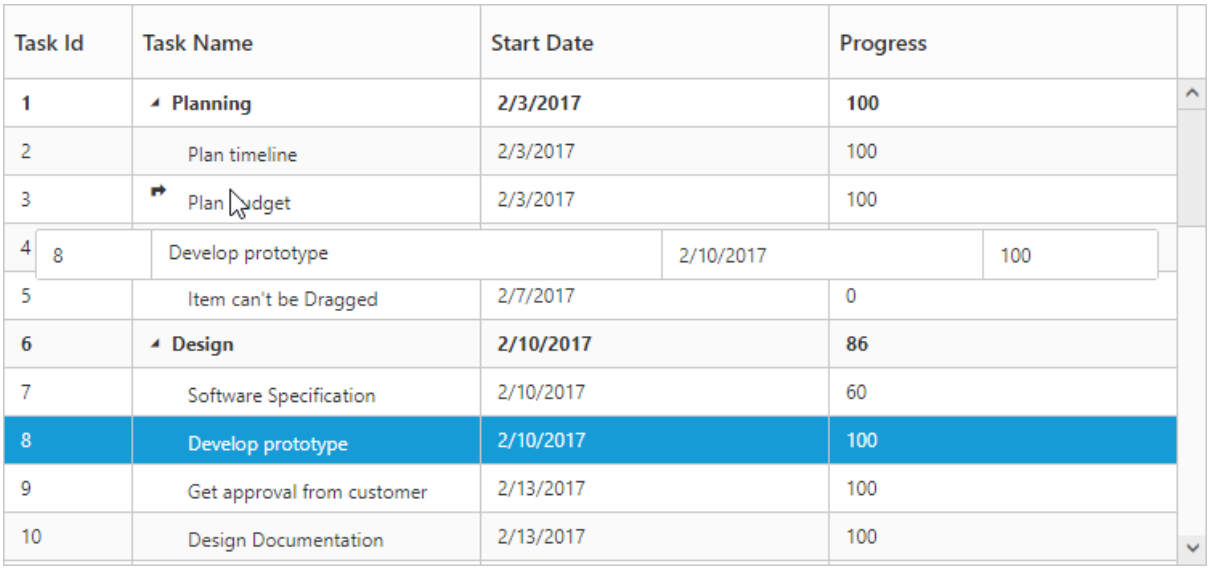
The following code explains about enabling the row drag and drop with the default tooltip in the TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(co =>
{
```

```
co.Field("TaskId").headerText("Task Id"). Add();
co.Field("TaskName").headerText("Task Name").Add();
})
.AllowDragAndDrop(true)
.DragTooltip(tooltip =>
{
tooltip.ShowTooltip(true);
}))
@(Html.EJ().ScriptManager())
```

The following screenshot depicts a row drag and drop in the TreeGrid.



Customizing Drag tooltip

The default drag tooltip in TreeGrid can be customized by using TooltipTemplate property. We can provide JsRender template or HTML formatted string as the value for this property.

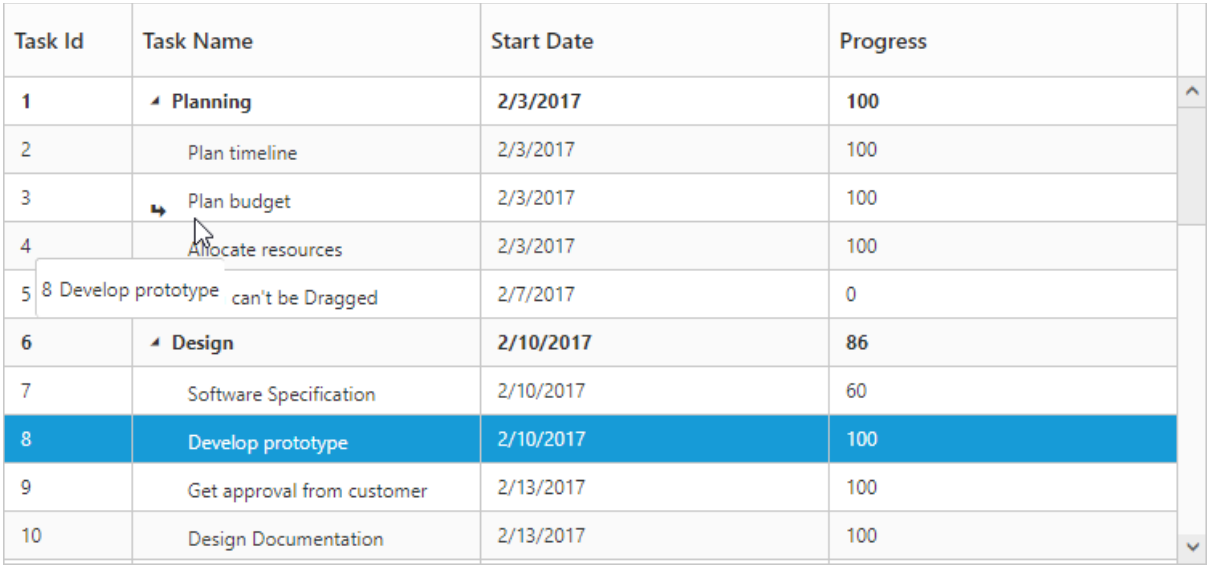
The following code shows how to render row drag tooltip with JsRender template.

ASPX-CS

```
<script id="customTooltip" type="text/x-jsrender">
<tr>
<td style='height:30px'>
<div>{{"{{"}}:#data['TaskId']{{}}}}</div>
</td>
<td style='height:30px'>
<div>{{"{{"}}:#data['TaskName']{{}}}}</div>
</td>
</tr>
</script>
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.DragTooltip(tt =>
{
tt.ShowTooltip(true);
tt.TooltipTemplate("#customTooltip");
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
@(Html.EJ().ScriptManager())
```



Multiple row drag and drop

TreeGrid provides support for multiple row reordering with mouse drag and drop interaction. The selected rows can be dropped above and below as siblings or as child records similar to single row reordering.

In TreeGrid we can enable the multiple row drag and drop by setting SelectionSettings.SelectionType as Multiple or Checkbox and also we should enable the AllowDragAndDrop.

Please find the code example below to enable multiple drag and drop in TreeGrid.

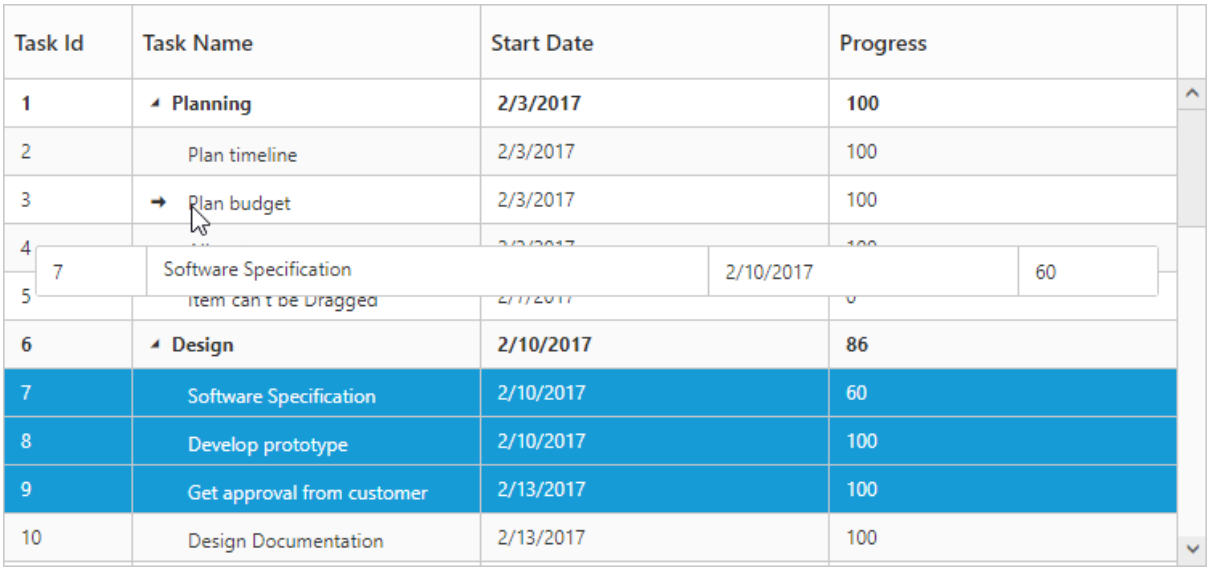
ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowDragAndDrop(true)
.SelectionSettings(ss=>
ss.SelectionType(TreeGridSelectionType.Multiple))
)
```

We can also customize row drag and drop actions by using below properties

- canDrag – It is used to enable/disable the row drag action for draggedRecords collection in RowDragStart client side event.
- canDrop – It is used to enable/disable the row drop action for draggedRecords collection in RowDropActionBegin client side event.

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the demo sample for multiple drag and drop action.

Details row

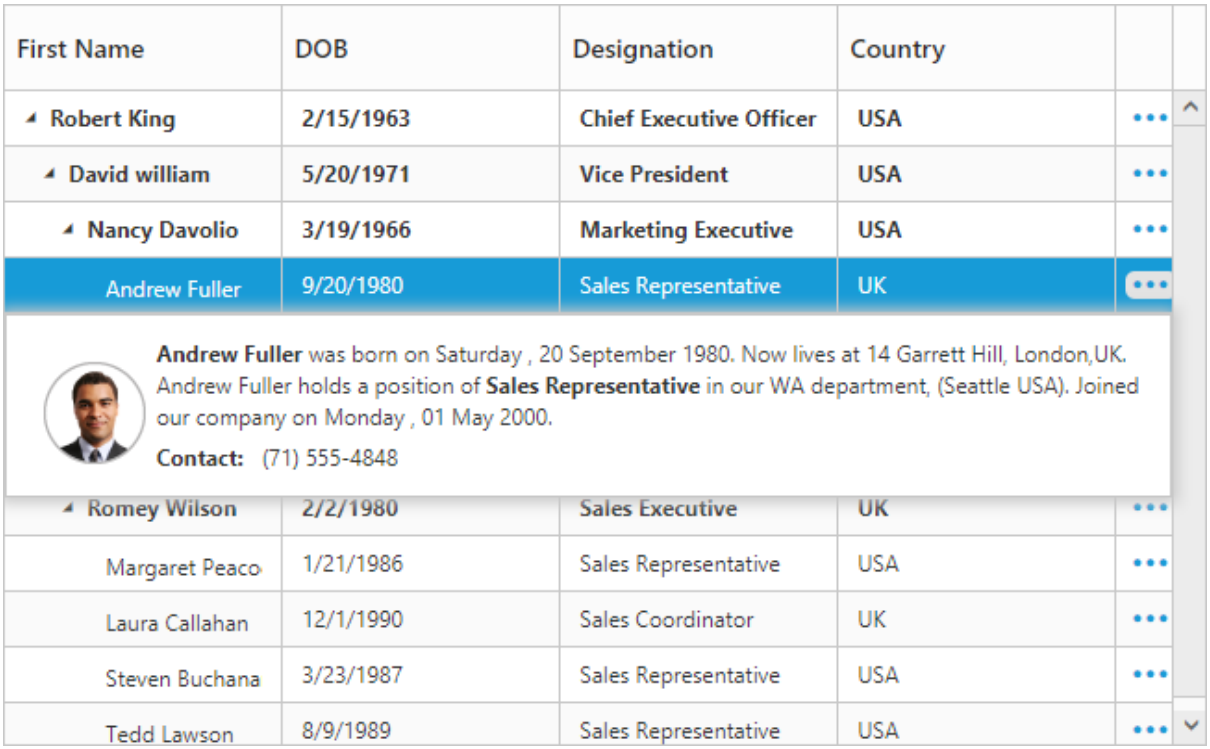
Details row is used to provide a additional information about each row of TreeGrid. You can specify the detail row JsRender template id or HTML element as string to `DetailsTemplate` property. However you need to enable the details template by setting `ShowDetailsRow` property as `true`.

The following code example shows how to enable details tow in TreeGrid.

ASPX-CS

```
<script id="descriptionTemplate" type="text/x-jsrender">
<div style="position: relative; display: inline-block; float: left; font-weight: bold; width: 10%">
<img src="../images/treegrid/{{"{{"}}:Name{{}}}}.png" style="margin-left: 10px;margin-top:15px;" />
</div>
<div style="padding-left: 10px; display: inline-block; width: 88%; text-wrap: normal;font-size:12px;font-family:'Segoe UI';margin-top:2px;">
<div class="e-description" style="word-wrap: break-word;">
<b>{{"{{"}}:Name{{}}}}</b> was born on
{{"{{"}}:~_treeGridDateFormatter("DOB"){{}}}}. Now lives at
{{"{{"}}:Address{{}}}},{{"{{"}}:Country{{}}}}. {{"{{"}}:Name{{}}}} holds
a position of <b>{{"{{"}}:Designation{{}}}}</b> in our WA department,
(Seattle USA). Joined our company on
{{"{{"}}:~_treeGridDateFormatter("DOJ"){{}}}}.
</div>
<div class="e-description" style="word-wrap: break-word;margin-top:5px;">
<b style="margin-right:10px;">Contact:</b>{{"{{"}}:Contact{{}}}}
</div>
</div>
</script>
@(Html.EJ().TreeGrid("TreeGridRowDetails")
.DetailsTemplate("descriptionTemplate")
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screenshot shows details row in TreeGrid.

The visibility of the details view of a record can also be toggled with any custom actions by using the method ShowHideDetailsRow.

Click here to view the demo sample for details row template.

Disable details row info column

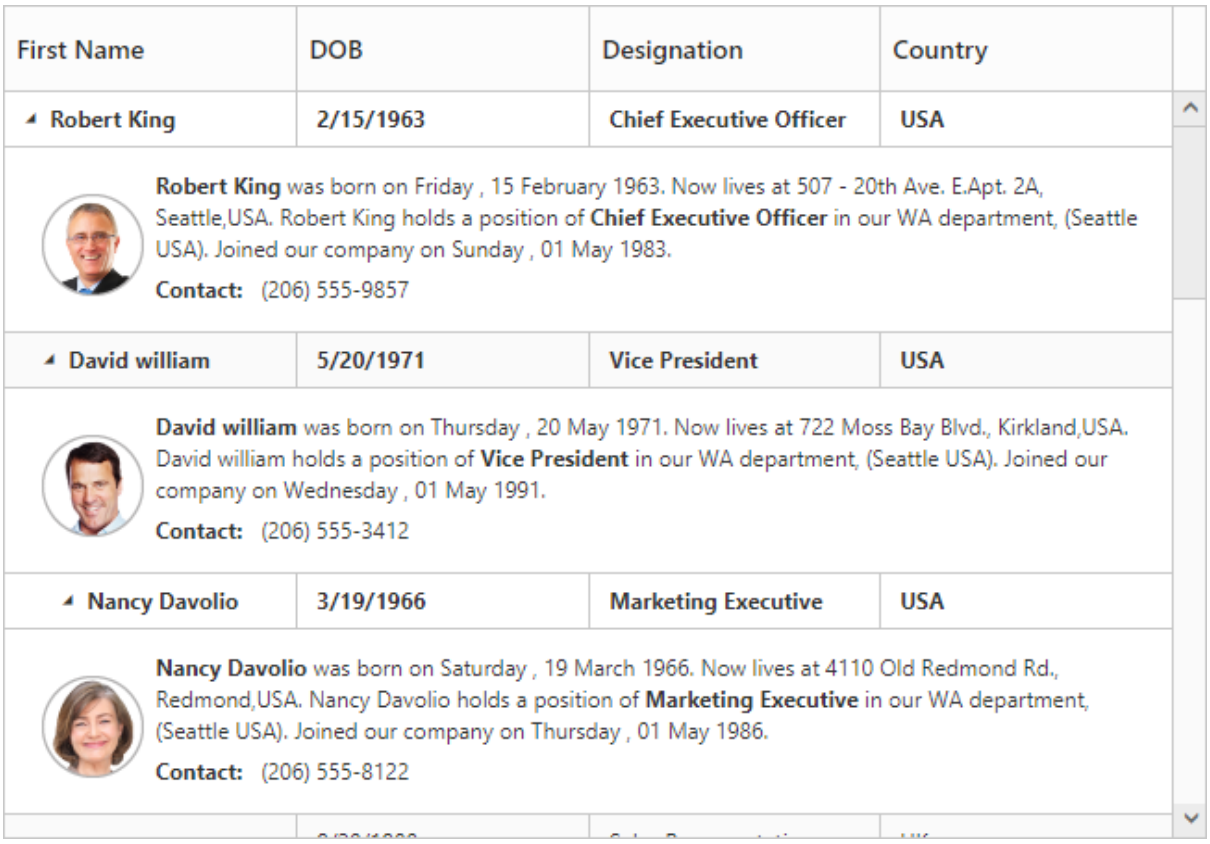
On enabling details template, details row info column will be added in TreeGrid. It is used for show or hide the detail row of respective row.

You can disable that column while enabling details template using ShowDetailsRowInfoColumn property. If you disable details row info column, then the details row will render next to the respective row.

The following code example shows how to hide detail info column in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridRowDetails")
.DetailsTemplate("descriptionTemplate")
.ShowDetailsRowInfoColumn(false)
)
@(Html.EJ().ScriptManager())
```



The above screenshot shows details row rendered next to the respective row.

Defining row height for detail template

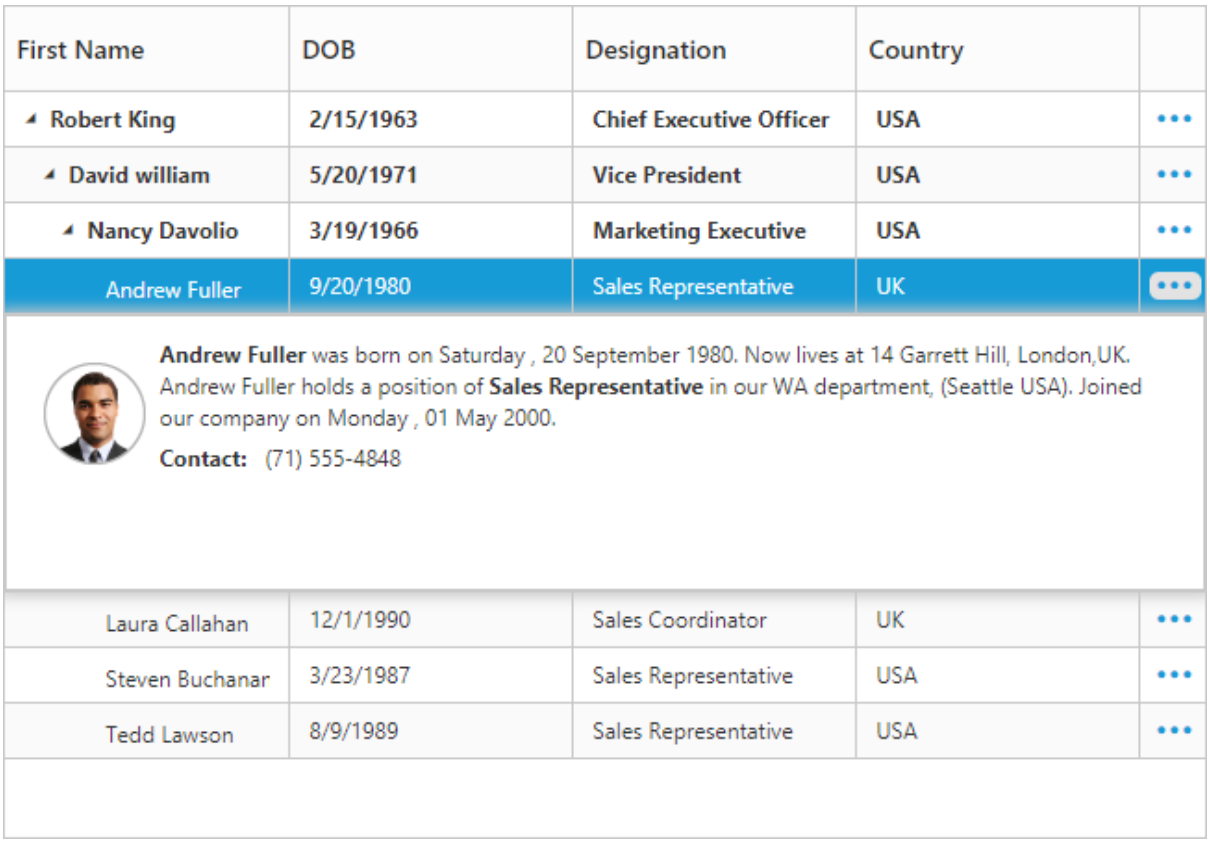
In TreeGrid, it is provide a support to change the detail template height using DetailsRowHeight property.

The following code example shows how to set details row height in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridRowDetails")
.DetailsTemplate("descriptionTemplate")
.DetailsRowHeight(150)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screenshot shows details row rendered with height of 150px.

Customize detail row

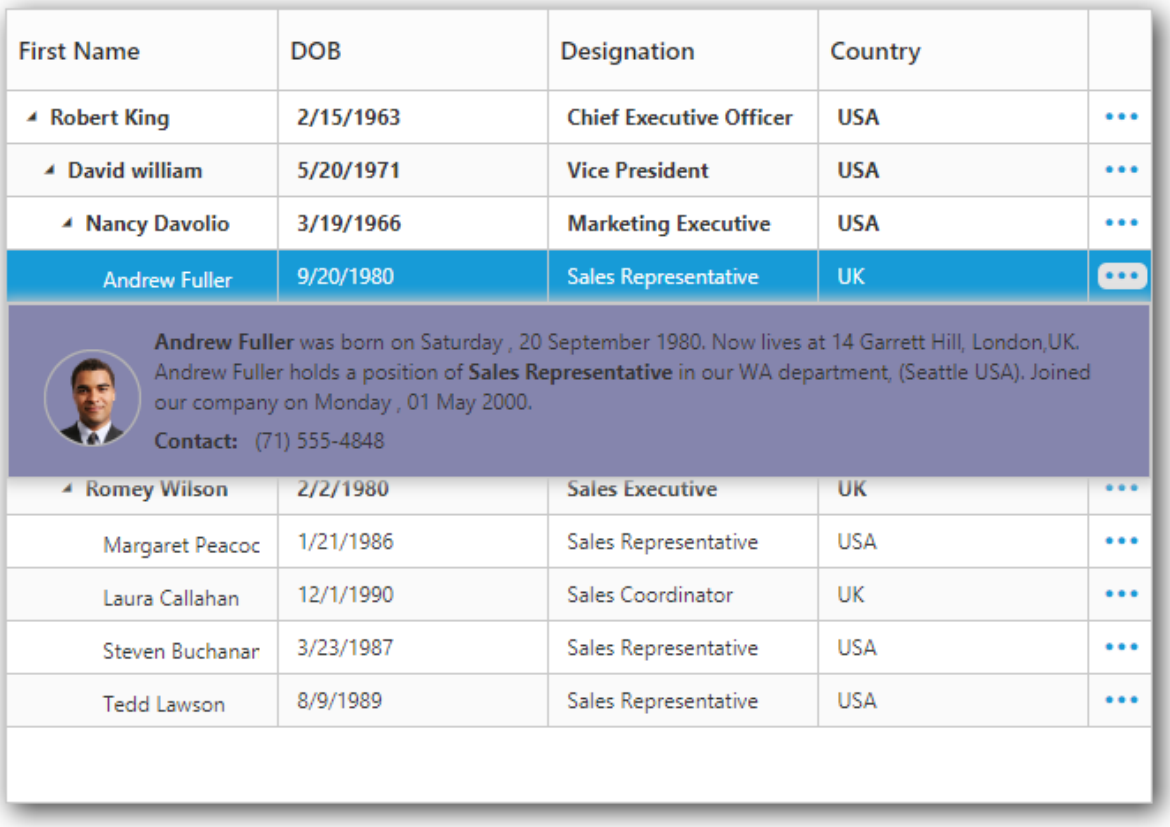
In TreeGrid, while rendering the details row the DetailsDataBound event will be triggered. Using this event we can customize the detail template for specific row.

The below code example shows how to customize details row for specific row.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.DetailsTemplate("descriptionTemplate")
.ClientSideEvents(cs =>
{
cs.DetailsDataBound("detailsDataBound");
}))
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function detailsDataBound(args) {
if (args.data.Name == "Andrew Fuller")
$(args.detailsElement).css("background-color", "rgba(133, 133, 173,1)");
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screenshot shows details row customization for specific row.

While opening and closing the details row, the DetailsShown and DetailsHidden events are triggered. Using this event we can prevent the details row show and hide action for specific row.

The below code example shows how to prevent details row show action for specific row.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.DetailsTemplate("descriptionTemplate")
.ClientSideEvents(cs =>
{
cs.DetailsShown("detailsShown");
}))
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function detailsShown(args) {
if (args.data.Name == "Andrew Fuller")
args.cancel = true;
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Expand/Collapse Row

In TreeGrid, parent rows are expanded/collapsed by using expand/collapse icons, expand all/collapse all toolbar items and by using the expandCollapseRow method. By default all records in TreeGrid will be rendered in expanded state.

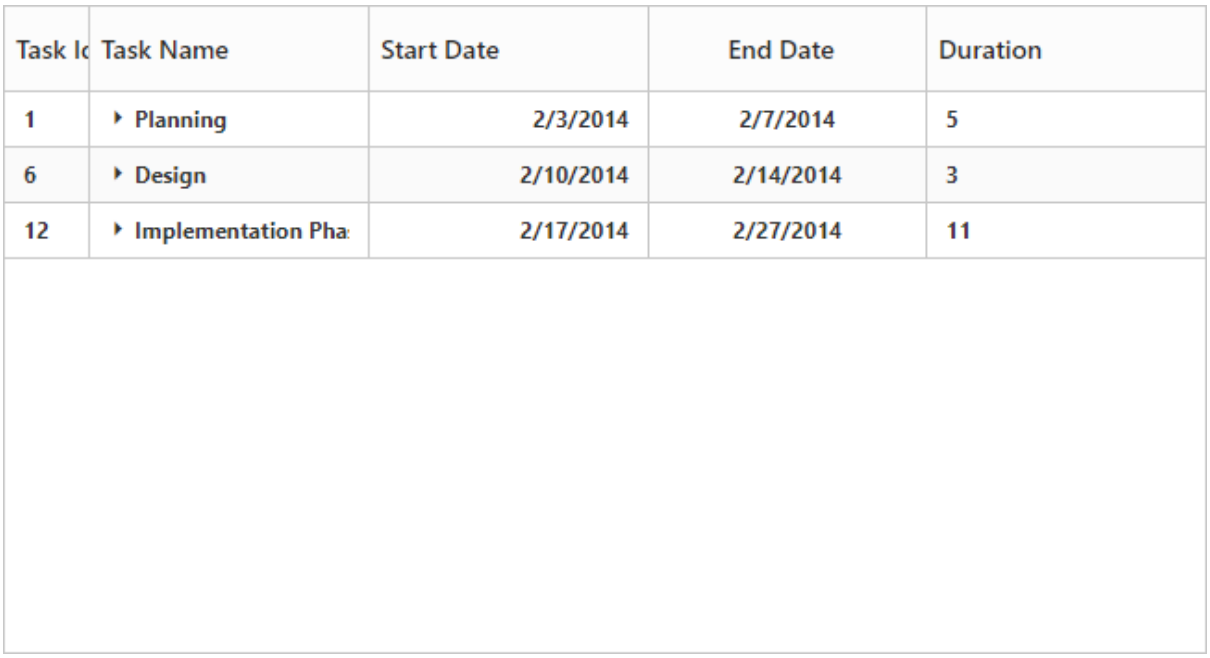
Collapse parent records at initial load

It is possible to display all the records in collapsed state by setting EnableCollapseAll property as true.

The following code example shows how to use this property.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
.EnableCollapseAll(true)
)
@(Html.EJ().ScriptManager())
```



Task Id	Task Name	Start Date	End Date	Duration
1	Planning	2/3/2014	2/7/2014	5
6	Design	2/10/2014	2/14/2014	3
12	Implementation Pha	2/17/2014	2/27/2014	11

The above screenshot shows TreeGrid render with collapsed state.

Define expand/collapse state of every record

In TreeGrid, it is possible to render records either in collapsed state or in expanded state, and this can done by mapping the expand state to the records from the data source by using ExpandStateMapping property.

The following code example shows how to use this property.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
.ExpandStateMapping("expandState")
.Datasource(ViewBag.datasource)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

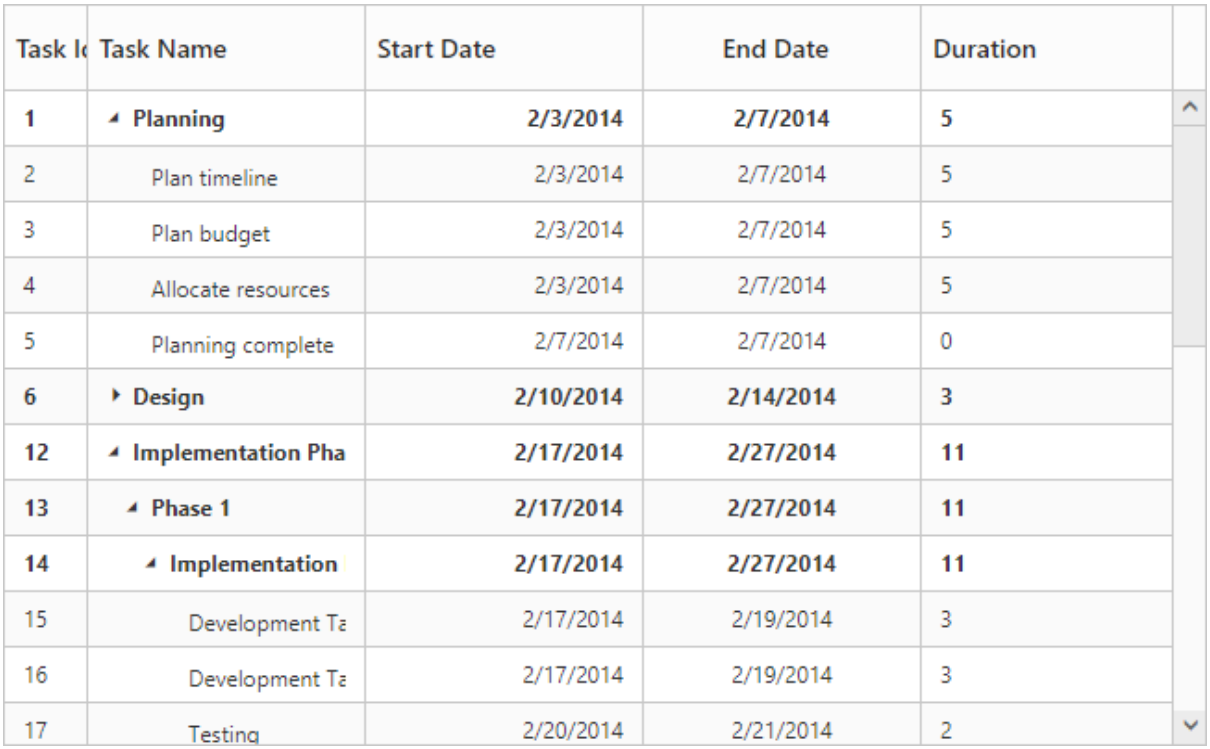
```
@(Html.EJ().ScriptManager())
```

C#

```
public class TreeGridController : Controller
{
//
// GET: /Default/
public ActionResult Default()
{
var DataSource = TreeGridDefaultData.GetData();
ViewBag.datasource = DataSource;
return View();
}
public class TreeGridDefaultData
{
public static List<DefaultData> GetData()
{
List<DefaultData> list = new List<DefaultData>();
list.Add(new DefaultData()
{
Id = 6,
Name = "Design",
ExpandState = false,
Children = (new List<DefaultData>()
{
new DefaultData()
{
Id = 7,
Name = "Software Specification",
ExpandState = false,
},
//..
})
});
return list;
}
}
}
```

The below screenshot shows the output of above code example..

Copyright © 2001 - 2020 Syncfusion Inc.



Task Id	Task Name	Start Date	End Date	Duration
1	Planning	2/3/2014	2/7/2014	5
2	Plan timeline	2/3/2014	2/7/2014	5
3	Plan budget	2/3/2014	2/7/2014	5
4	Allocate resources	2/3/2014	2/7/2014	5

Expand/Collapse all the rows dynamically

All the rows in TreeGrid will be expanded/collapsed by clicking ExpandAll and CollapseAll toolbar items or by using expandAll and collapseAll methods. We can invoke this methods

dynamically on any action like external button click.

The below code example shows how to use this methods.

ASPX-CS

```
<button id="expandAll">Expand All</button>
<button id="collapseAll">Collapse All</button>
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<TreeGridToolBarItems>()
{
TreeGridToolBarItems.ExpandAll,
TreeGridToolBarItems.CollapseAll,
});
}))
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#expandAll").click(function () {
var treegridObj = $("#TreeGridContainer").ejTreeGrid("instance");
treegridObj.expandAll();
});
$("#collapseAll").click(function () {
var treegridObj = $("#TreeGridContainer").ejTreeGrid("instance");
treegridObj.collapseAll();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
});
</script>
```

Dynamically expand/Collapse the specific level row

The TreeGrid control provides the support to dynamically expand/collapse the specific level of rows by using expandAtLevel and collapseAtLevel methods. This methods are used to expand/collapse the rows which are in specific level.

The below code example shows how to use this methods.

ASPX-CS

```
<button id="expandAtLevel">Expand At Level</button>
<button id="collapseAtLevel">Collapse At Level</button>
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#expandAtLevel").click(function () {
var treegridObj = $("#TreeGridContainer").ejTreeGrid("instance");
treegridObj.expandAtLevel(1);
});
$("#collapseAtLevel").click(function () {
var treegridObj = $("#TreeGridContainer").ejTreeGrid("instance");
treegridObj.collapseAtLevel(1);
});
</script>
```

Customize expand/collapse action

In TreeGrid, while expanding the parent row Expanding and Expanded event will be triggered with current expanding row detail. Similarly Collapsing and Collapsed event will be triggered while collapsing the parent row. Using this event and its arguments we can customize the expand/collapse action.

The following code example shows how to prevent the particular row from expand/collapse action using Expanding and Collapsing event.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.DetailsTemplate("descriptionTemplate")
.ClientSideEvents(cs =>
{
cs.Collapsing("collapsing");
cs.Expanding("expanding");
}))
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function expanding(args) {
if(args.data.progress < 50) // we can't collapse the record which has
progress is less than 50
args.cancel = true;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
function collapsing(args) {
if(args.data.duration > 5) // we can't expand the record which has
duration is greater than 5
args.cancel = true;
}
</script>
```

Cell

Tooltip

In TreeGrid tooltip can be enabled using the ShowGridCellTooltip property. Using this property tooltip can be enabled for cells both header and content.

Please find the example describes the above behavior.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowGridCellTooltip(true)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following output shows the result of above code example.

Task Id	Task Name	Start Date	End Date	Duration	Progress
1	Planning	2/3/2014	2/7/2014	5	100
2	Plan timeline	2/3/2014	2/7/2014	5	100

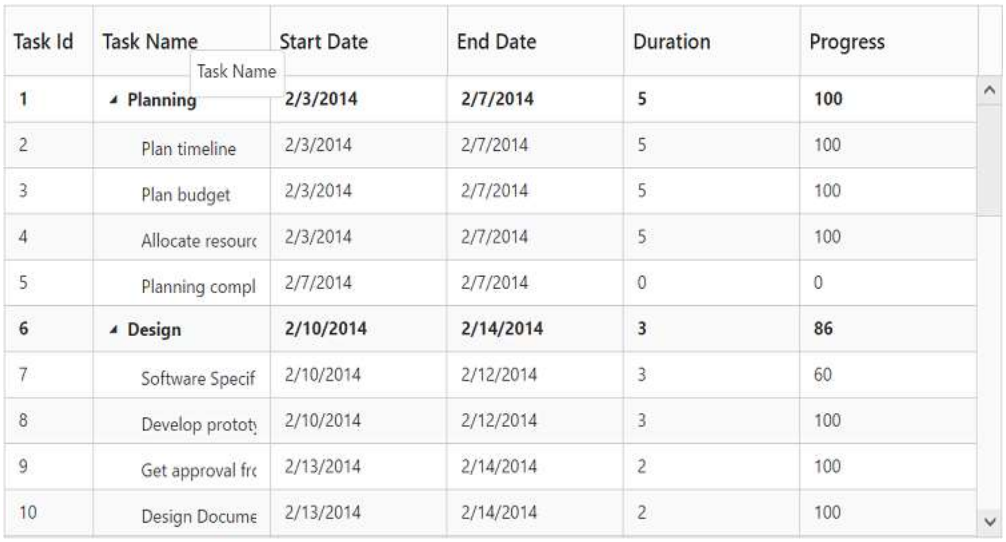
Cell Tooltip

Copyright © 2001 - 2020 Syncfusion Inc.



Header Tooltip

Tooltip Template

It is possible to display a custom tooltip across all the TreeGrid cells using the property CellTooltipTemplate with the property ShowGridCellTooltip enabled. We need to set the template of the custom tooltip to this property.

Please find code example that describes the cell tooltip template support below.

ASPX-CS

```
<script type="text/x-jsrender" id="cellTooltipTemplate">
<table>
<tr>
<td style='padding:5px;font-weight: bold;'>
Task ID
</td>
<td style='padding:5px;'>
: {{"{{"}}:#data['record']['taskID']{{}}}}
</td>
</tr>
<tr>
<td style='padding:5px;font-weight: bold;'>
Task Name
</td>
<td style='padding:5px;'>
: {{"{{"}}:#data['record']['taskName']{{}}}}
</td>
</tr>
<tr>
<td style='padding:5px;font-weight: bold;'>
Start Date
</td>
<td style='padding:5px;'>
: {{"{{"}}:#data['record']['startDate']{{}}}}
</td>
</tr>
<tr>
<td style='padding:5px;font-weight: bold;'>
```

```
End Date
</td>
<td style='padding:5px;'>
: {{"{{"}}:#data['record']['endDate']{{}}}}
</td>
</tr>
<tr>
<td style='padding:5px;font-weight: bold;'>
Duration
</td>
<td style='padding:5px;'>
: {{"{{"}}:#data['record']['duration']{{}}}}
</td>
</tr>
<tr>
<td style='padding:5px;font-weight: bold;'>
Progress
</td>
<td style='padding:5px;'>
: {{"{{"}}:#data['record']['progress']{{}}}}
</td>
</tr>
</table>
</script>
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
.ShowGridCellTooltip(true)
.CellTooltipTemplate("cellTooltipTemplate")
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following output shows the result of above code example.

Task Id	Task Name	Start Date	End Date	Duration	Progress
1	**Planning**	**2/3/2014**	**2/7/2014**	**5**	**100**
2	Plan timeline	2/3/2014	2/7/2014	5	100

Column tooltip

By using the property the Columns.Tooltip it is possible to display a custom tooltip for a specific column. The ID of the script template must be set to the Columns.Tooltip property.

Please refer to the following code example for setting a custom tooltip for a specific column.

ASPX-CS

```
<script type="text/x-jsrender" id="template">
<div style='padding:10px;color:red;font-weight: bold;'>
{{"{{"}}:#data['record']['taskName']{{}}}}
</div>
</script>
@(Html.EJ().TreeGrid("TreeGridContainer")
.ChildMapping("Children")
.Columns(co =>
{
//..
co.Field("taskName").headerText("Task Name").Tooltip("template").Add();
//..
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following output shows the output of above code snippets.

Task Id	Task Name	Start Date	End Date	Duration	Progress
1	Planning	2/3/2014	2/7/2014	5	100
2	Plan timeline	2/3/2014	2/7/2014	5	100
3	Plan budget	2/3/2014	2/7/2014	5	100

Plan budget

Note: Template element should be enclosed with <script> tag with type as “text/x-jsrender”.

Header tooltip

By using the property the Columns.HeaderTooltip it is possible to display a custom tooltip for a specific column header. The ID of the script template must be set to the Columns.HeaderTooltip property.

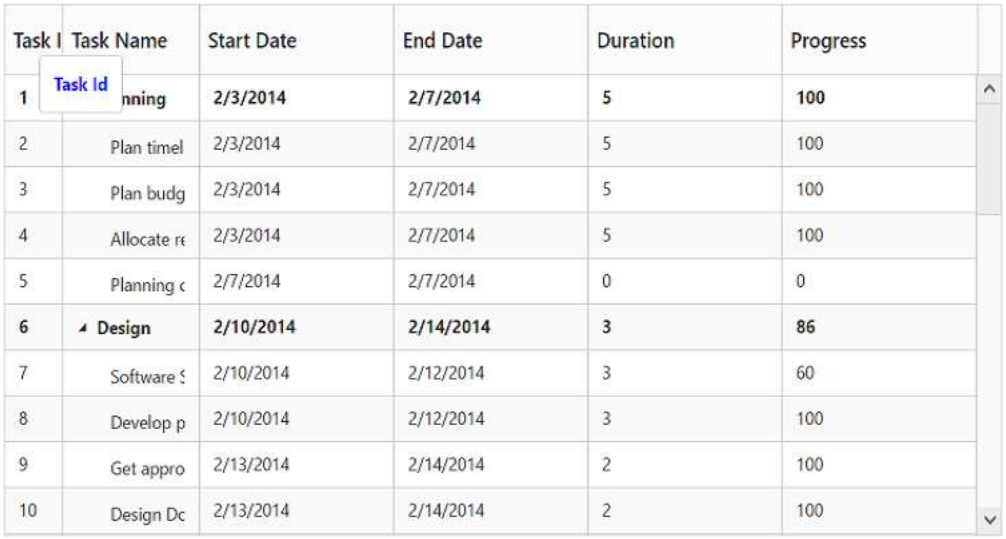
Copyright © 2001 - 2020 Syncfusion Inc.

Please refer to the following code example for setting a custom tooltip for a specific column header.

ASPX-CS

```
<script type="text/x-jsrender" id="template">
<div style='padding:10px;color:blue;font-weight: bold;'>
{{"{{"}}:#data['column']['headerText']{{}}}}
</div>
</script>
@(Html.EJ().TreeGrid("TreeGridContainer")
.ChildMapping("Children")
.Columns(co =>
{
//..
co.Field("taskID").headerText("Task Id").HeaderTooltip("template").Add();
//..
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following output shows the result of above code example.



Clip Mode

Clip mode enables the TreeGrid to clip cell content and header content when the content exceeds the boundary of the cell width.

We can specify the type of clip mode using the Columns.ClipMode property, clip mode will be enabled for both TreeGrid content and header of that specific column.

The below are the available clipping modes in TreeGrid.

1. Clip
2. Ellipsis

Copyright © 2001 - 2020 Syncfusion Inc.

Clip

When ClipMode of Columns property set as the TreeGridColumnClipMode.Clip, then it truncates the overflown text in the cell.

Note: 1. By default the ClipMode will be set as theTreeGridColumnClipMode.Clip.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ChildMapping("Children")
.Columns(co =>
{
//..
co.Field("taskID").headerText("Task
Id").ClipMode(TreeGridColumnClipMode.Clip).Add();
//..
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following output shows the result of above code example.

Task Id	Task Name	Start Date	End Date	Duration	Progress
1	**Planning**	**2/3/2014**	**2/7/2014**	**5**	**100**
2	Plan timeline	2/3/2014	2/7/2014	5	100
3	Plan budget	2/3/2014	2/7/2014	5	100
4	Allocate resource	2/3/2014	2/7/2014	5	100
5	Planning comple	2/7/2014	2/7/2014	0	0

12	**Implementation F**	**2/17/2014**	**2/27/2014**	**11**	

Ellipsis

When the Columns.ClipMode property is set as TreeGridColumnClipMode.Ellipsis then it shows ellipsis for the overflown cell.

The following code example describes the above behavior.

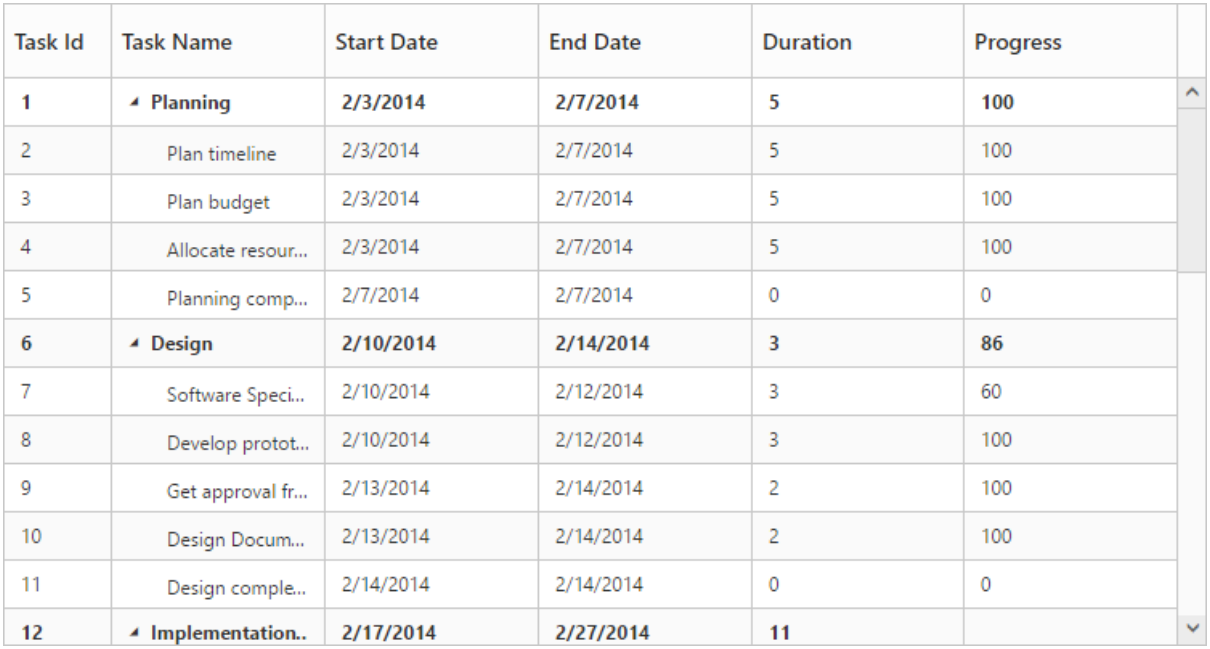
ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ChildMapping("Children")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Columns(co =>
{
//..
co.Field("taskID").headerText("Task
Id").ClipMode(TreeGridColumnClipMode.Ellipsis).Add();
//..
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following output is shows the result of the above code example.



Task Id	Task Name	Start Date	End Date	Duration	Progress
1	**Planning**	**2/3/2014**	**2/7/2014**	**5**	**100**
2	Plan timeline	2/3/2014	2/7/2014	5	100

Text Wrap

Text wrap enables the TreeGrid to wrap cell content or header content to next line when the content exceeds the boundary of the cell width.

Header Text Wrap

To enable header cell text wrap, set the HeaderTextOverflow property as TreeGridHeaderTextOverflow.Wrap.

Note: By default the HeaderTextOverflow will be set as TreeGridHeaderTextOverflow.None.

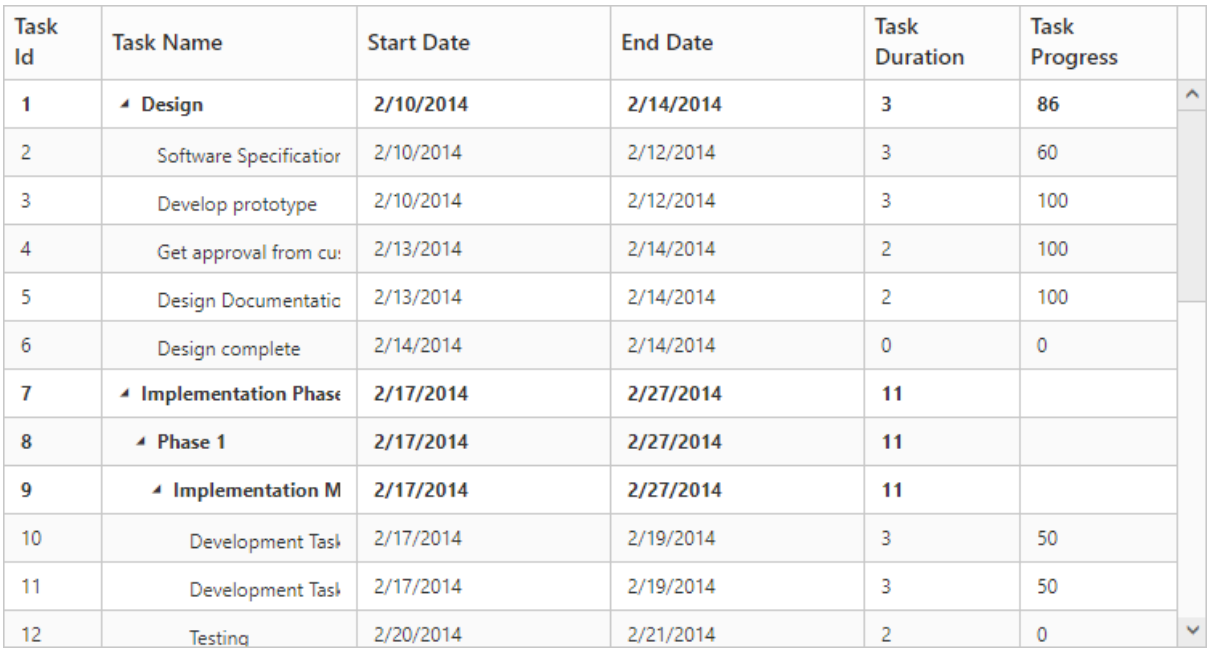
The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
.HeaderTextOverflow(TreeGridHeaderTextOverflow.Wrap)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following output shows the result of above code example.



Task Id	Task Name	Start Date	End Date	Task Duration	Task Progress
1	**Design**	**2/10/2014**	**2/14/2014**	**3**	**86**

12	Testing	2/20/2014	2/21/2014	2	0

Content Text Wrap

To enable cell text wrap, set the `AllowTextWrap` property as `true`.

Note: 1.By default the `AllowTextWrap` will be set as `false`.

Note: 2.The text wrap feature provide only limited support in virtualization mode.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
.AllowTextWrap(true)
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The following output shows the result of above code example.

Editing

TreeGrid provides support to add, edit and delete the records dynamically using EditSettings property.

Add new record

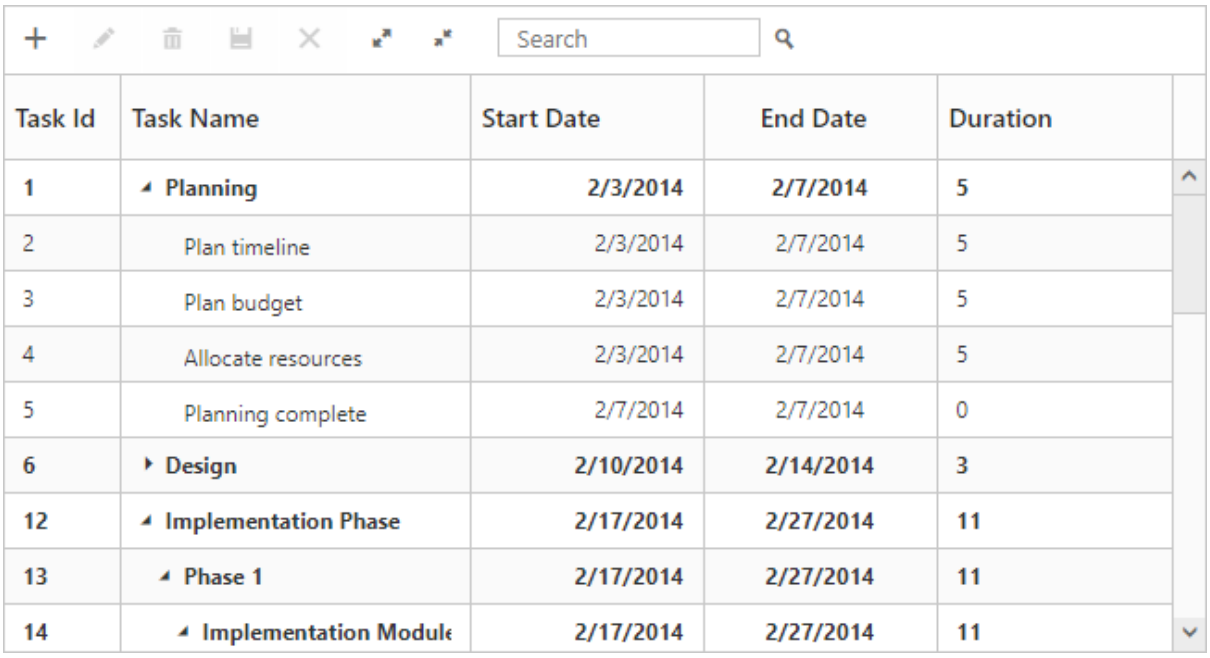
TreeGrid provides support for adding a new record by setting AllowAdding property as true. You can add new record by toolbar add item click or context menu.

The below code example shows how to enable add option in TreeGrid.

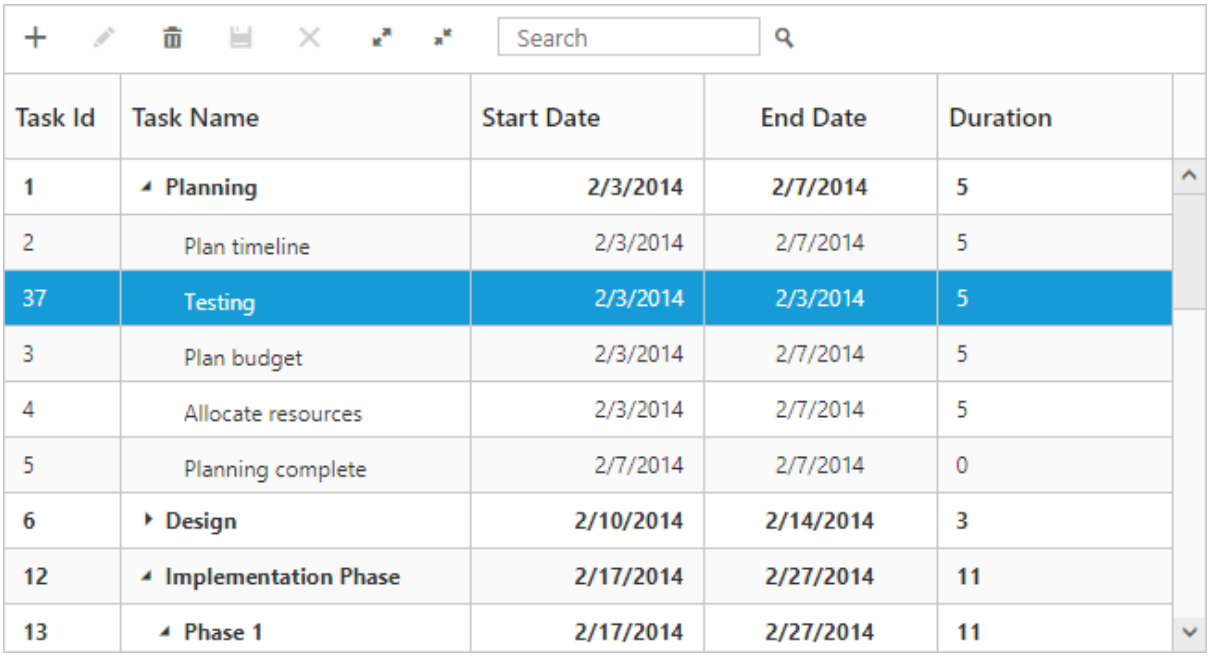
ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
{
edit.AllowAdding(true);
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screenshot shows before add a new record in TreeGrid.



The above screenshot shows after add a new record in TreeGrid.

Add row position

Using the EditSettings.RowPosition parameter, user can able to insert the record at any desired index at run-time. The user can insert a record dynamically in the following positions

- Top: Top to all the existing records
- Bottom: Bottom to all the existing records
- AboveSelectedRow: Above to the selected row
- BelowSelectedRow: Below to the selected row

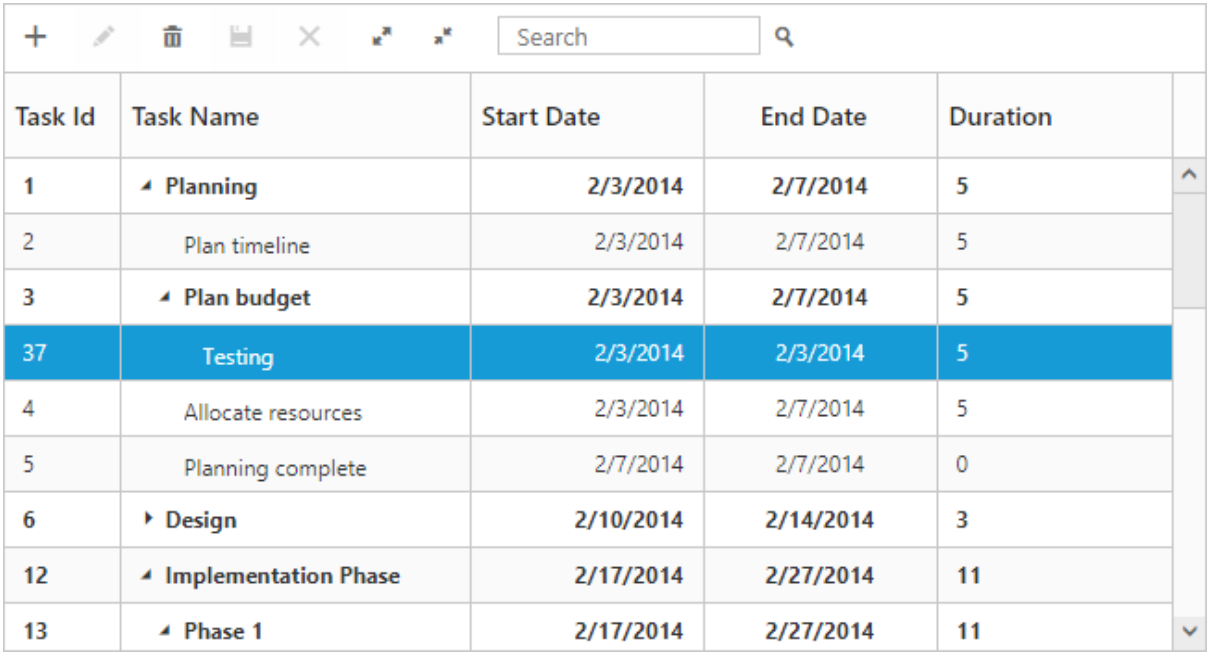
Copyright © 2001 - 2020 Syncfusion Inc.

- Child: As a child to the selected row

The below code example shows how to set row position for new record add in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
{
edit.AllowAdding(true);
edit.RowPosition(TreeGridRowPosition.Child);
})
)
@(Html.EJ().ScriptManager())
```



The above screenshot shows new record added in row position of Child.

Adding records using method

Using addRow method records can be added dynamically to the TreeGrid. Before calling this method, you should enable the AllowAdding property.

The below code snippet explains dynamically inserting a record in TreeGrid. The record will be inserted as a child node to the current selected record.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
{
edit.AllowAdding(true);
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
```

```
$("#add").click(function () {
var treeGridObj = $("#TreeGridContainer").data("ejTreeGrid");
var data = {
taskId: "40",
taskName: "New Task 40",
startDate: "2/20/2014",
startDate: "2/25/2014"
};
treeGridObj.addRow(data, ej.TreeGrid.RowPosition.Child); // To add a task
})
</script>
```

Edit modes

TreeGrid supports the below editModes,

- Cell Editing
- Row Editing
- Dialog Editing
- Batch Editing

You can enable editing in TreeGrid by enabling the property AllowEditing.

Cell Editing

Update the record through editing a cell by setting EditMode as the CellEditing.

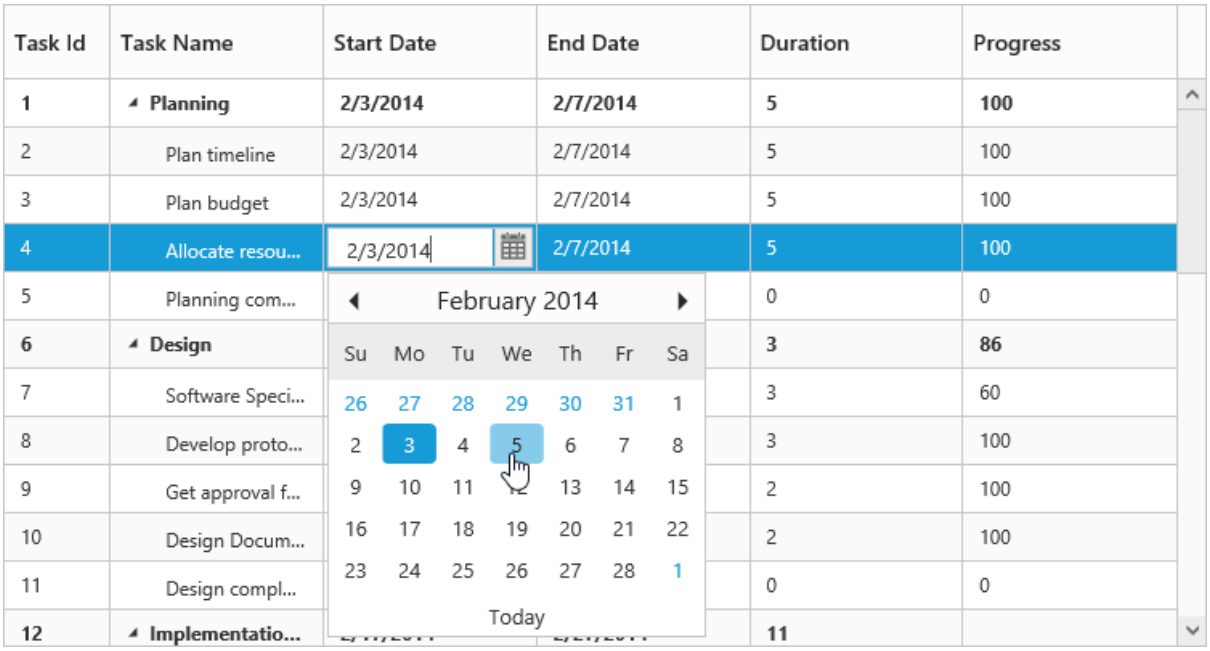
The following code example shows you how to enable the CellEditing in TreeGrid control.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
{
edit.AllowEditing(true);
edit.EditMode(TreeGridEditMode.CellEditing);
})
)
@(Html.EJ().ScriptManager())
```

The output of TreeGrid with CellEditing is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Prevent cell editing

In cell edit action BeginEdit and EndEdit events are triggered before and after the editing action. Cell editing for specific cell can be prevented by using BeginEdit event.

The following code example show, how to prevent cell editing in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
{
edit.AllowEditing(true);
edit.EditMode(TreeGridEditMode.CellEditing);
})
.ClientSideEvents(eve=>
{
eve.BeginEdit("beginEdit");
eve.EndEdit("endEdit");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function beginEdit(args) {
if (args.columnIndex == 1)
args.cancel = true;
}
function endEdit(args) {
//To perform actions after editing
}
</script>
```

Row Editing

It is possible to make the entire row to editable state and to update a record by setting EditMode as RowEditing.

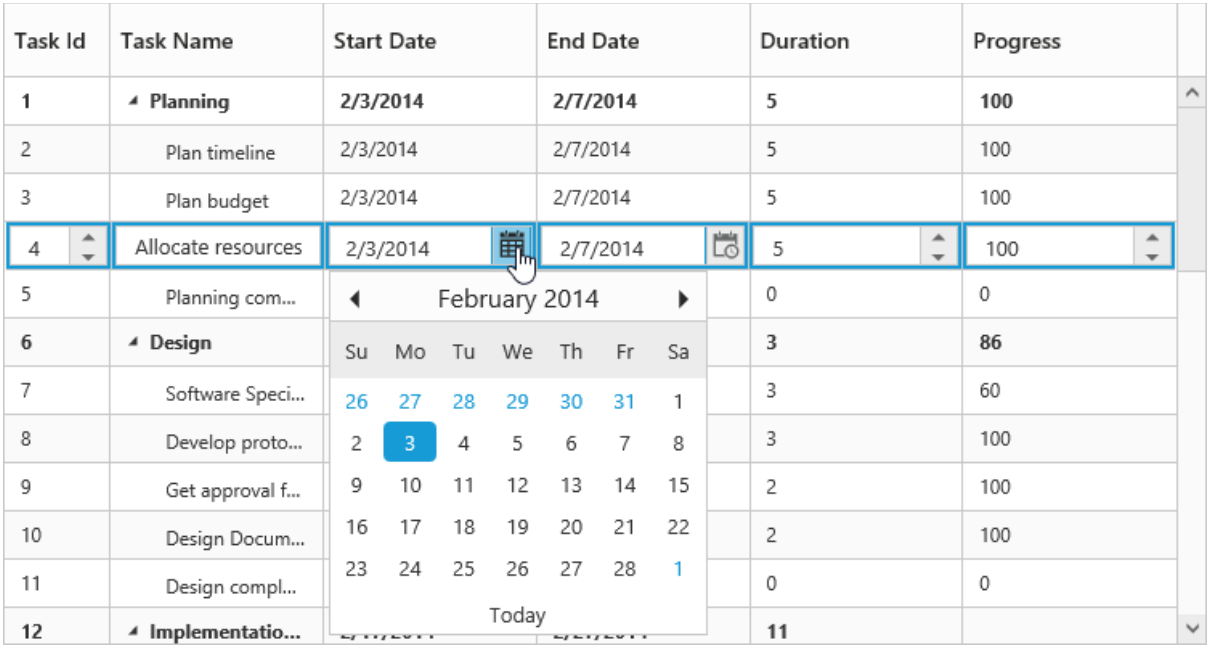
Copyright © 2001 - 2020 Syncfusion Inc.

The following code example shows you how to enable RowEditing in TreeGrid control.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
{
edit.AllowEditing(true);
edit.EditMode(TreeGridEditMode.RowEditing);
})
)
@(Html.EJ().ScriptManager())
```

The following output is displayed as a result of the above code example.



Dialog Editing

Set the EditMode as DialogEditing to edit/add a record using dialog.

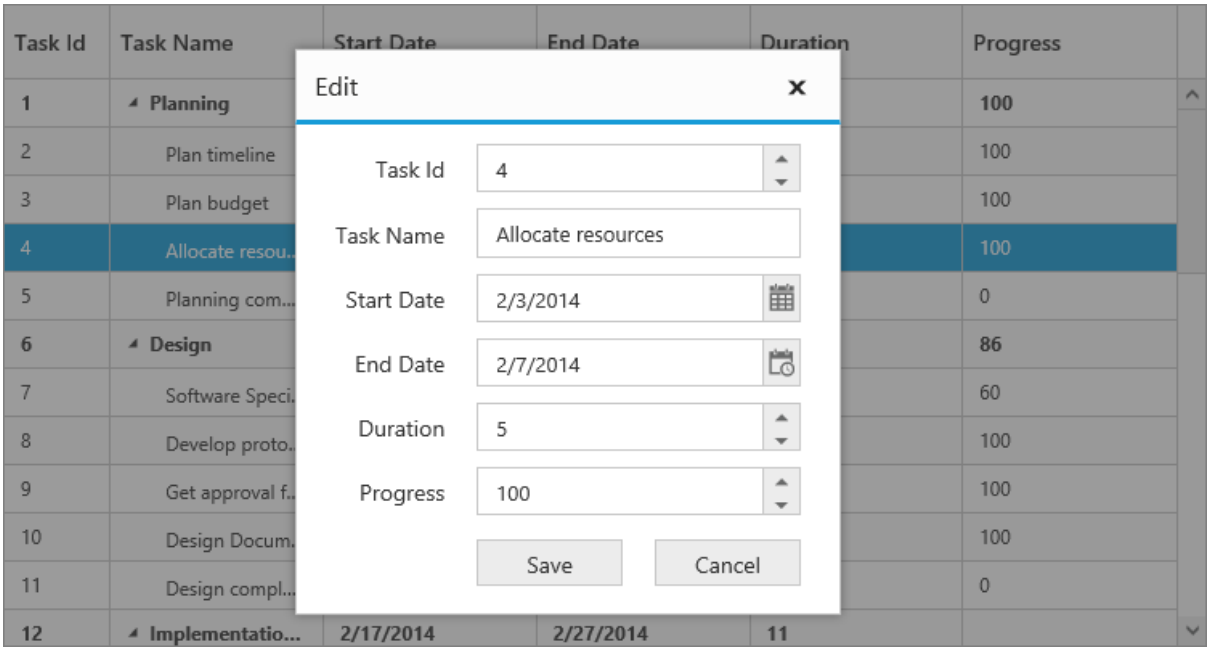
The following code example shows you how to enable the DialogEditing in TreeGrid control.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
{
edit.AllowEditing(true);
edit.EditMode(TreeGridEditMode.DialogEditing);
})
)
@(Html.EJ().ScriptManager())
```

The output of the TreeGrid with DialogEditing is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



The add and edit dialogs can be opened on custom actions instead of toolbar icons using the methods showAddDialog and showEditDialog.

Prevent dialog editing

In dialog editing action ActionBegin and ActionComplete client side events are triggered before and after the edit action. Dialog editing for specific row can be prevented by using ActionBegin event.

The following code example show, how to prevent dialog editing in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
{
edit.AllowEditing(true);
edit.EditMode(TreeGridEditMode.DialogEditing);
})
.ClientSideEvents(eve=>
{
eve.ActionBegin("actionBegin");
eve.ActionComplete("actionComplete");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function actionBegin(args) {
if(args.requestType == "beforeOpenEditDialog")
{
if(args.data.taskID == 4)
args.cancel = true;
}
}
function actionComplete(args) {
//To perform actions on action complete
}
```

```
</script>
```

Note: While saving the edited record ActionComplete event will be triggered with updated record value in data argument and requestType as recordUpdate. Using this event we can update the database.

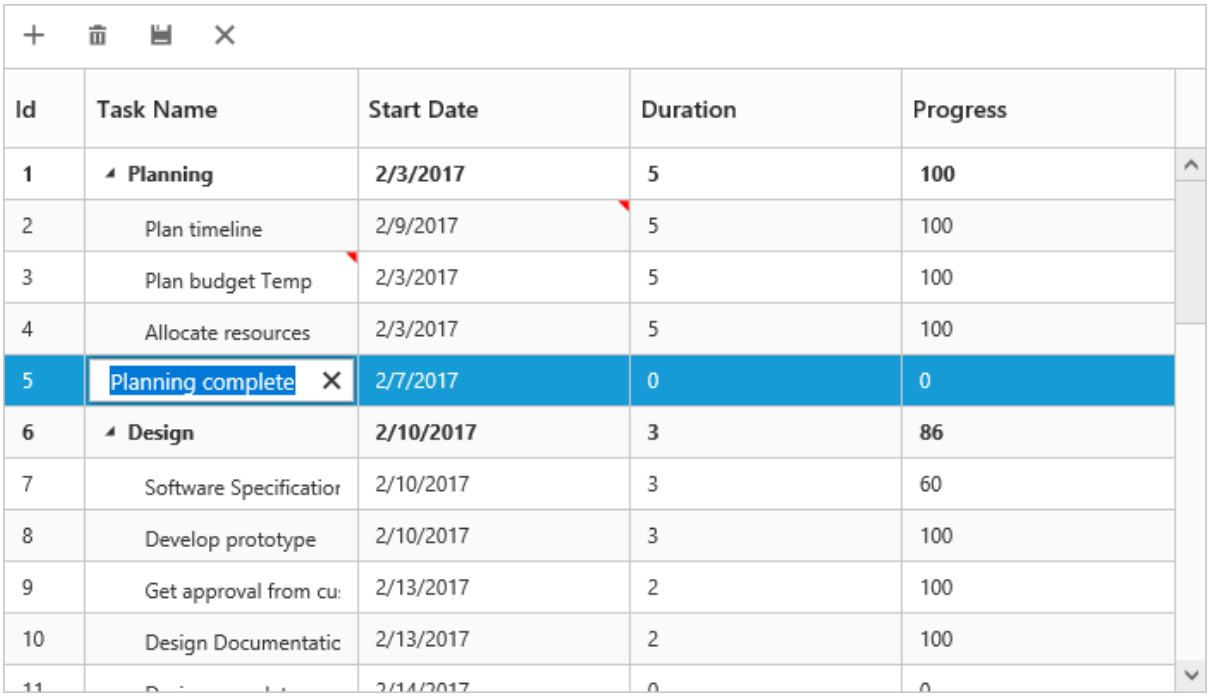
Batch Editing

The batch editing support in the tree grid is used to save all added, edited, and deleted changes to the database with a single action. This can be enabled by setting the EditMode property to BatchEditing. The following code example shows how to enable the BatchEditing in the tree grid control.

HTML

```
@(Html.EJ().TreeGrid("TreeGrid")
.EditSettings(ed =>
.EditMode(TreeGridEditMode.BatchEditing))
)
```

The output of a tree grid with BatchEditing is as follows.



In batch editing, the edit mode can be changed to **Cell** or **Row** or **Dialog** with the BatchEditSettings.EditMode property. The following code snippet shows how to set the editMode to row in the BatchEditSettings property.

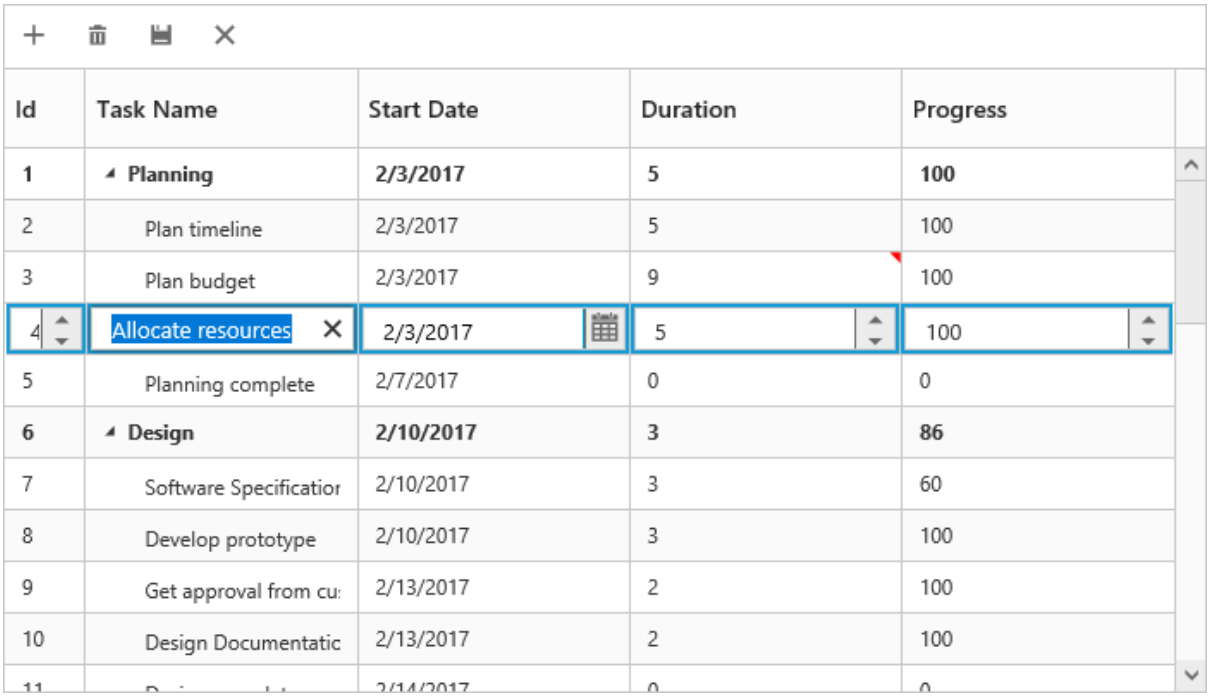
JS

```
@(Html.EJ().TreeGrid("TreeGrid")
.EditSettings(ed =>
ed.BatchEditSettings(ba =>
ba.EditMode(TreeGridBatchEditMode.Row))
.EditMode(TreeGridEditMode.BatchEditing))
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
```

The output of a tree grid with BatchEditSettings and EditMode set as Row is as follows.



Note: After modifying all changes in the tree grid, click the save button in the toolbar. The ActionComplete event will be triggered with updated records in the batchChanges argument with requestType argument as batchSave. Using this event, you can update all the modified records to the database.

Edit type and its params

The edit type of columns can be customized using EditType property of Columns. The following controls are supported built-in by EditType. You can set the EditType based on specific data type of the column.

- **CheckBox** control for boolean data type.
- **NumericTextBox** control for integers, double, and decimal data types.
- **InputTextBox** control for string data type.
- **DatePicker** control for date data type.
- **DateTimePicker** control for date-time data type.
- **DropDownList** control for list of data type.

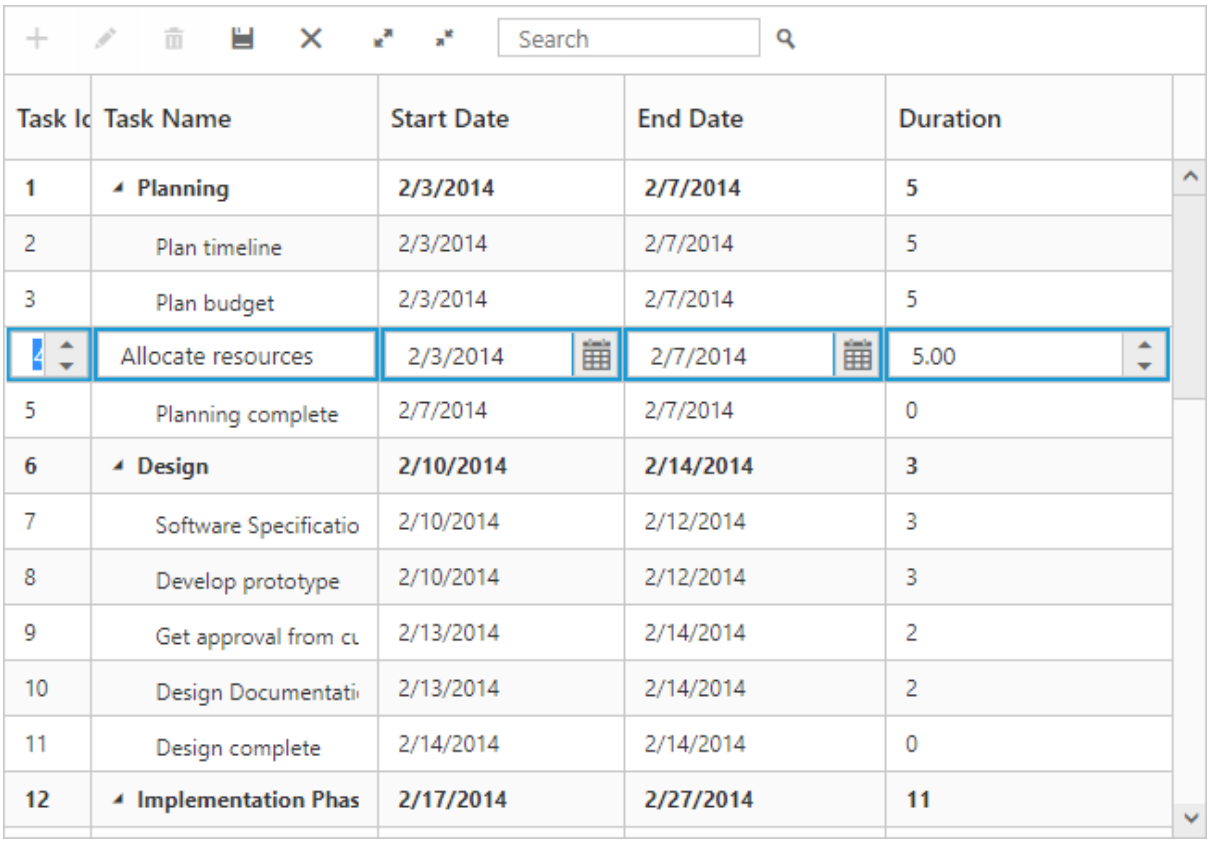
And also you can define the model for all the EditTypes controls while editing through EditOptions property of Columns.

The following code example describes the above behavior.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(co =>
```

```
{
co.Field("taskID").HeaderText("Task
Id").EditType(TreeGridEditingType.Numeric).Add();
co.Field("taskName").HeaderText("Task
Name").EditType(TreeGridEditingType.String).Add();
co.Field("startDate").HeaderText("Start
Date").EditType(TreeGridEditingType.Datepicker).Add();
co.Field("endDate").HeaderText("End
Date").EditType(TreeGridEditingType.Datepicker).Add();
co.Field("duration").HeaderText("Duration").EditType(TreeGridEditingType.
Numeric)
.NumericEditOptions(new EditorProperties { DecimalPlaces= 2 }).Add();
})
)
@(Html.EJ().ScriptManager())
```



The above screenshot shows TreeGrid with different Edit type.

Assign data source for drop down edit type

In TreeGrid, we need to assign the data source for drop down list control to populate the suggestion list while editing the column in TreeGrid. The DropdownData property is used to set the drop down list data source in TreeGrid control.

The following code example shows how to set data source for drop down edit type.

C#

```
public class TreeGridController : Controller
```

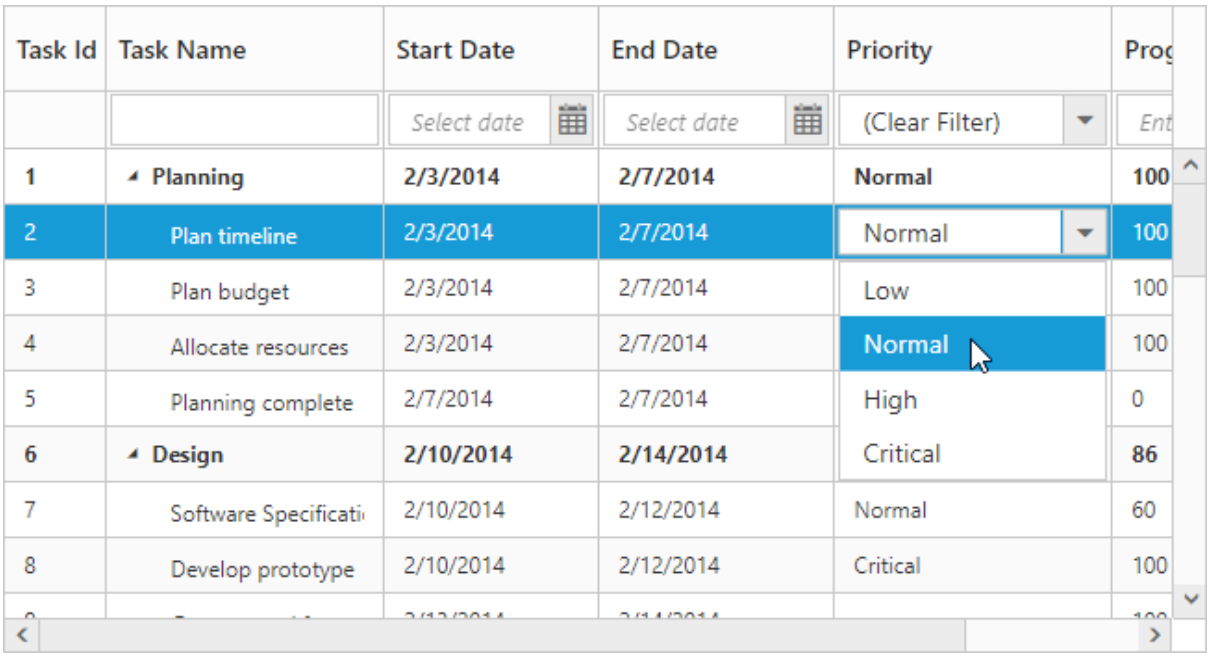
Copyright © 2001 - 2020 Syncfusion Inc.

```
{
//
// GET: /TreeGridColumn/
public ActionResult TreeGridColumn()
{
//..
StageDetails stages = new StageDetails();
ViewBag.dropData = stages.GetStageCollection();
return View();
}
public class Stage
{
public int id { get; set; }
public string text { get; set; }
public string value { get; set; }
}
public class StageDetails
{
public List<Stage> GetStageCollection()
{
List<Stage> stageCollection = new List<Stage>();
stageCollection.Add(new Stage() { id = 1, text = "Low", value = "Low" });
stageCollection.Add(new Stage() { id = 2, text = "Normal", value =
"Normal" });
stageCollection.Add(new Stage() { id = 3, text = "High", value = "High"
});
stageCollection.Add(new Stage() { id = 4, text = "Critical", value =
"Critical" });
return stageCollection;
}
}
}
```

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(co =>
{
co.Field("Priority").HeaderText("Priority").EditType(TreeGridEditingType.
Dropdown).DropDownData((IEnumerable<object>)ViewBag.dropData).Add();
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screenshot shows drop down edit type in TreeGrid.

Dialog Template

You can edit any of the fields pertaining to a single record of data and apply it to a template so that the same format is applied to all the other records that you may edit later.

Using this template support, you can edit/add the fields that are not bound to TreeGrid columns.

To edit/add the records using dialog template form, set `EditMode` as `DialogEditing` and specify the template id to `DialogEditorTemplateID` property of `EditSettings`.

Note: The `value` attribute is used to bind the corresponding field value while editing.

The `name` attribute is used to get the changed field values while saving the edited record.

The `id` attribute must to be set in the format of (treegrid control id + fieldname).

The following code example describes the above behavior.

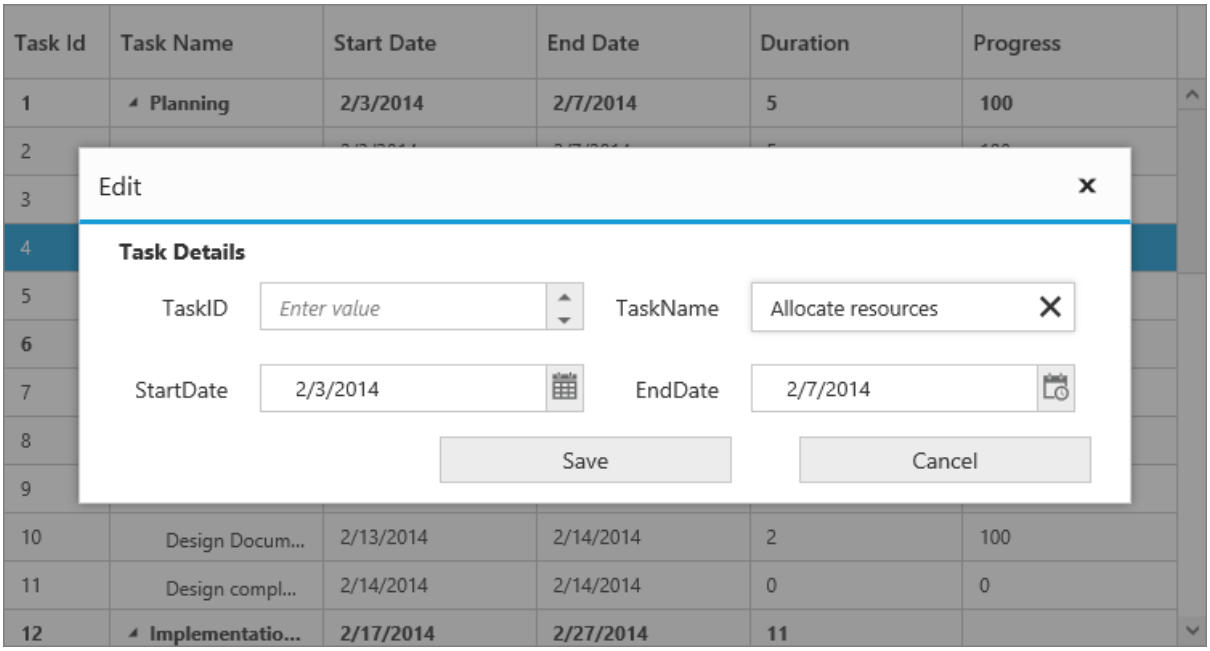
ASPX-CS

```
<script type="text/x-jsrender" id="template">
<div>
<b>Task Details</b>
<table cellspacing="10" class="beta">
<tr>
<td style="text-align:right;padding: 10px;">
TaskID
</td>
<td style="text-align: left;padding: 10px;">
<input id="TreeGridContainertaskID" type="number" name="taskID"
value="{{'{{'}}:taskID{{}}}}" disabled="disabled" class="e-field e-
ejinputtext valid e-disable"/>
</td>
<td style="text-align: right;padding: 10px;">
TaskName
```

```
</td>
<td style="text-align: left;padding: 10px;">
<input id="TreeGridContainertaskName" name="taskName"
value="{{'{{'}}:taskName{{}}}}" class="e-field e-ejinputtext valid"/>
</td>
</tr>
<tr>
<td style="text-align: right;padding: 10px;">
StartDate
</td>
<td style="text-align: left;padding: 10px;">
<input type="text" id="TreeGridContainerstartDate" name="startDate"
value="{{'{{'}}:startDate{{}}}}" class="e-field e-ejinputtext valid" />
</td>
<td style="text-align: right;padding: 10px;">
EndDate
</td>
<td style="text-align: left;padding: 10px;">
<input id="TreeGridContainerendDate" type="text" name="endDate"
value="{{'{{'}}:endDate{{}}}}" class="e-field e-ejinputtext valid"  />
</td>
</tr>
</table>
</div>
</script>
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
{
edit.AllowEditing(true);
edit.EditMode(TreeGridEditMode.DialogEditing);
edit.DialogEditorTemplateID("#template");
})
)
@(Html.EJ().ScriptManager())
```

The following output is displayed as a result of the above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the online demo sample for Dialog Template.

Using methods to open dialog

It is possible to open the add dialog dynamically using showAddDialog method.

Similarly, open the edit dialog dynamically using the method showEditDialog(index), with the index of the row to be edited as parameter.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
$("#add").click(function () {
treegridObj = $("#TreeGridContainer").data("ejTreeGrid");
treegridObj.showAddDialog();
})
$("#edit").click(function () {
treegridObj = $("#TreeGridContainer").data("ejTreeGrid");
treegridObj.showEditDialog(3);
})
</script>
```

BeginEditAction - edit cell/row by single/double click

In TreeGrid we can perform edit action by single or double click using `BeginEditAction` , default value of this property is `DblClick`.

The following code example shows how to enable single click edit in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
//..
edit.BeginEditAction(TreeGridBeginEditAction.Click);
})
)
@(Html.EJ().ScriptManager())
```

Cell Edit Template

Edit template is used to create custom editor for editing the column values. This can be achieved by using Columns.EditTemplate.

Following functions required to render edit template in TreeGrid,

- Create - It is used to create the control on initialization.
- Read - It is used to read the input value on save.
- Write - It is used to assign the value to control on editing.

The following code example describes edit template behavior

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.Columns(co =>
{
co.Field("TaskName").HeaderText("Task Name").EditTemplate(new
TreeGridEditTemplate() { Create="create",Write="write",Read="read"
}).Add();
})
)
@(Html.EJ().ScriptManager())
```

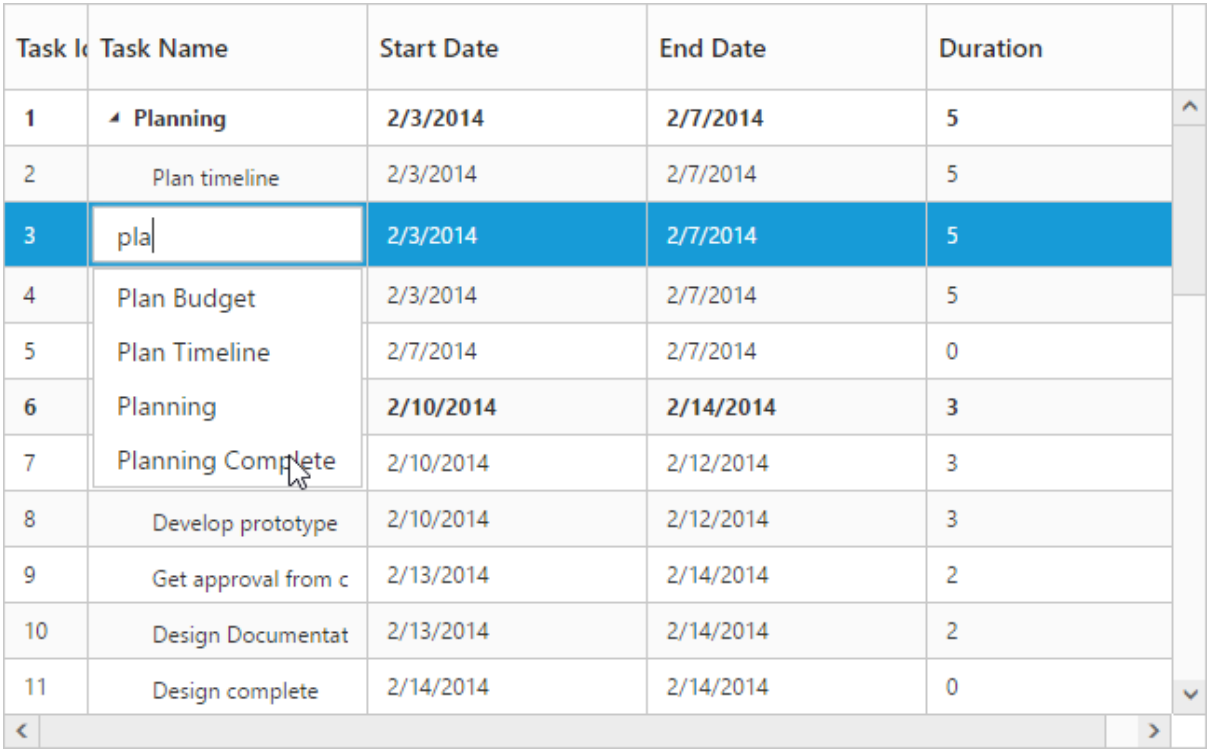
JS

```
<script>
var autocompleteData = ["Planning", "Plan Timeline", "Plan Budget",
"Allocate Resources", "Planning Complete"];
function create()
{
return "<input>";
}
function write(args)
{
args.element.ejAutocomplete({
width: "100%",
dataSource: autocompleteData,
enableDistinct: true,
value: args.rowData !== undefined ? args.rowData["taskName"] : ""
});
}
function read(args)
{
args.ejAutocomplete('suggestionList').css('display', 'none');
return args.ejAutocomplete("getValue");
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</script>
```

The output of the TreeGrid width EditTemplate as follows



The updated record values are maintained in collection in TreeGrid, and the user can retrieve the updated record collection at any time by using the getUpdatedRecords method.

Click here to view the online demo sample for Edit Template.

Delete record

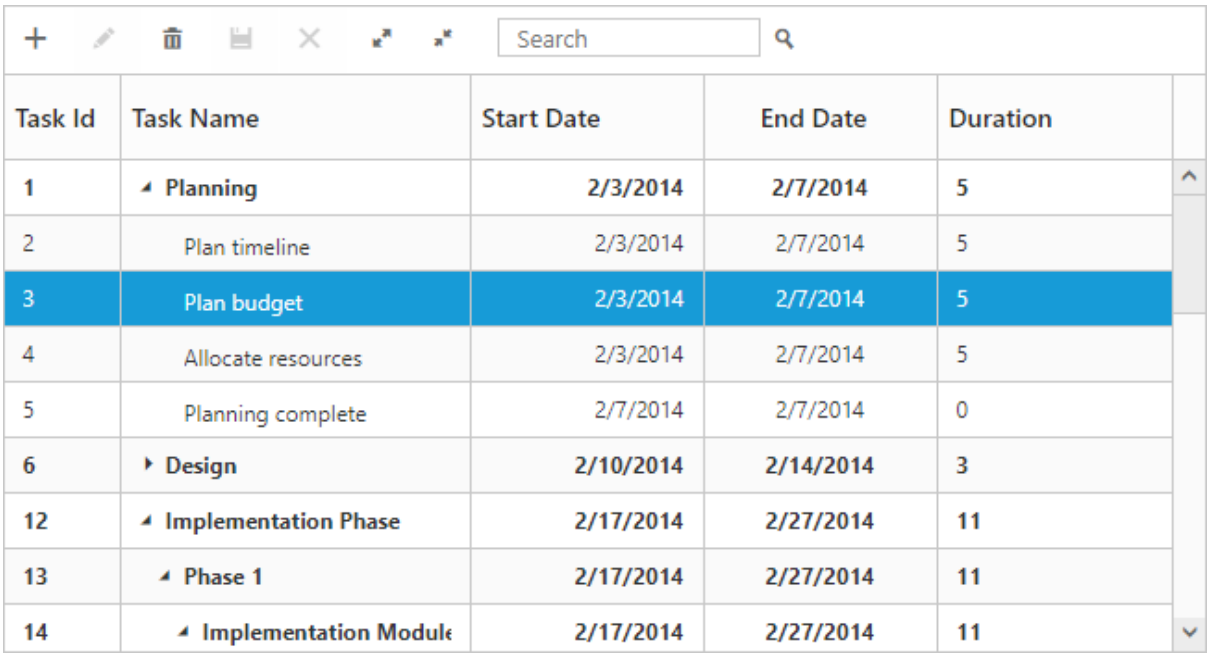
TreeGrid provides support to delete a record by enabling AllowDeleting property.

The below code example shows how to enable delete option in TreeGrid.

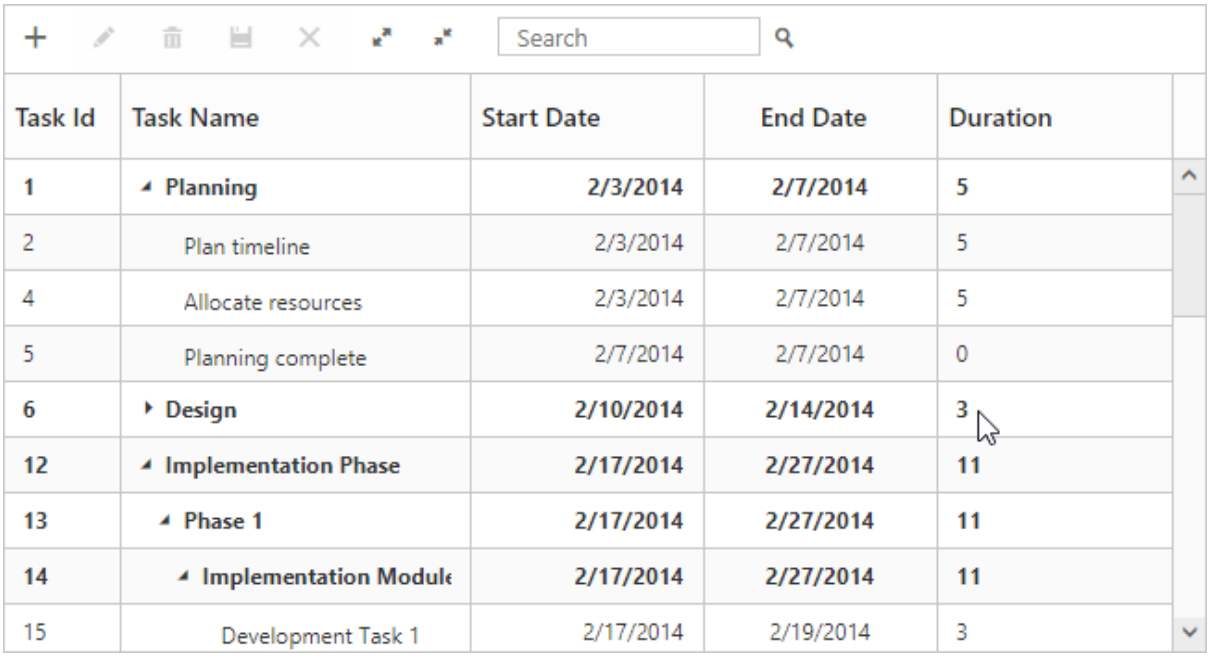
ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.EditSettings(edit=>
{
edit.AllowDeleting(true);
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screenshot shows before delete a record in TreeGrid.



The above screenshot shows after delete a record in TreeGrid.

Delete confirmation message

Delete confirmation message is used to get the confirmation from the user before deleting action. This confirmation message can be enabled by setting `ShowDeleteConfirmDialog` property as `true`.

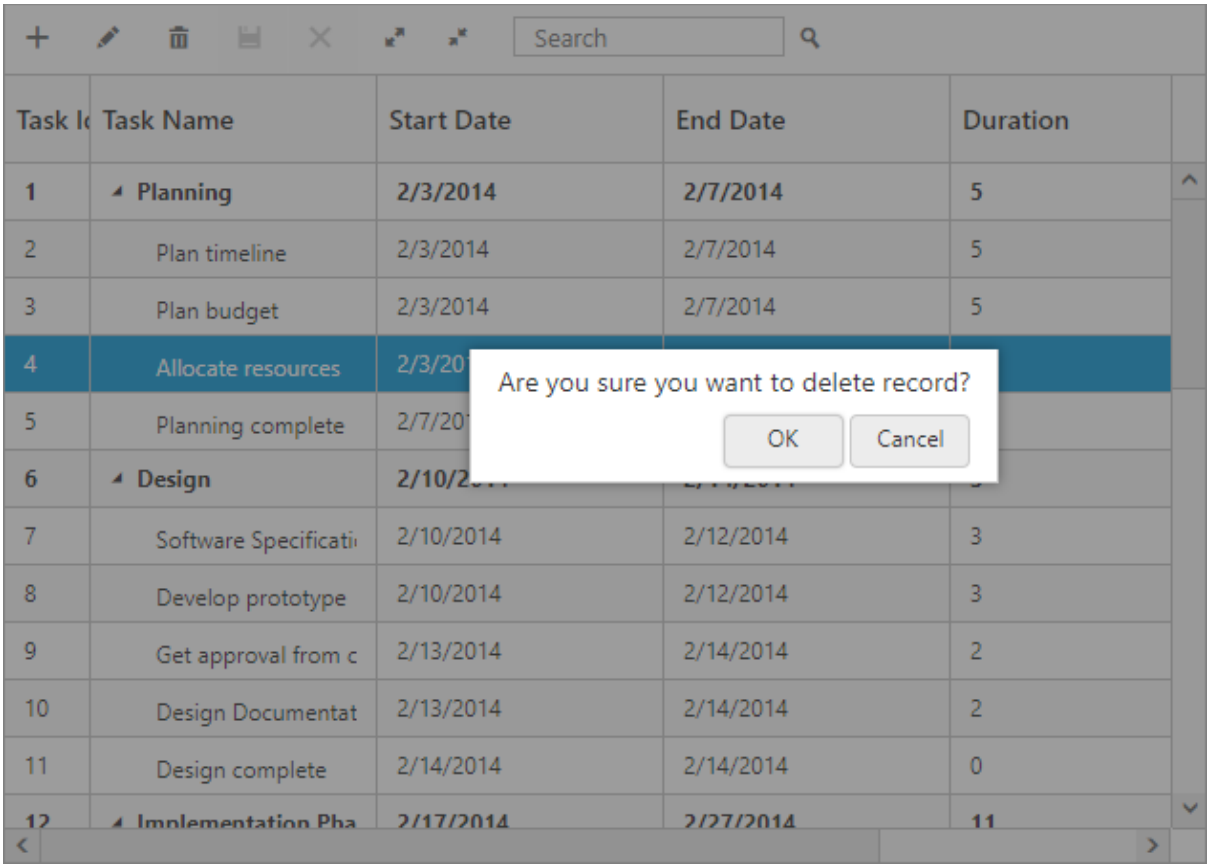
The following code snippet explains how to enable delete confirmation message in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.EditSettings(edit=>
{
edit.AllowDeleting(true);
edit.ShowDeleteConfirmDialog(true);
})
)
@(Html.EJ().ScriptManager())
```



Click here to view the online demo sample for Editing.

Filtering

Filtering helps to view specific or related records from data source which meets a given filtering criteria. To enable filtering in TreeGrid, set the `AllowFiltering` as `true`.

The `FilterSettings` property is used to customize the filtering in TreeGrid.

TreeGrid provides support for the following filtering modes.

- FilterBar
- Menu
- Excel

Also, the following filtering types are available in TreeGrid.

- String

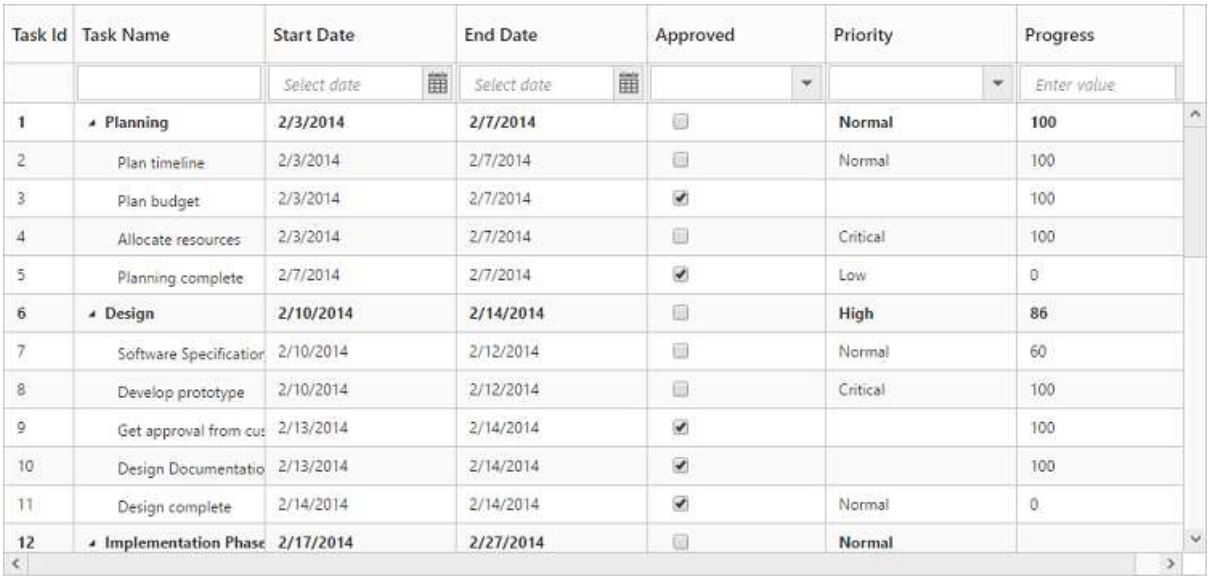
- Boolean
- Date
- Numeric
- Dropdown

The below code explains how to enable filtering in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowFiltering(true)
)
@(Html.EJ().ScriptManager())
```

The output of the TreeGrid with filtering enabled is as follows.



Task Id	Task Name	Start Date	End Date	Approved	Priority	Progress
		Select date	Select date			Enter value
1	Planning	2/3/2014	2/7/2014	☐	Normal	100
2	Plan timeline	2/3/2014	2/7/2014	☐	Normal	100
3	Plan budget	2/3/2014	2/7/2014	☑		100
4	Allocate resources	2/3/2014	2/7/2014	☐	Critical	100
5	Planning complete	2/7/2014	2/7/2014	☑	Low	0
6	Design	2/10/2014	2/14/2014	☐	High	86
7	Software Specificatior	2/10/2014	2/12/2014	☐	Normal	60
8	Develop prototype	2/10/2014	2/12/2014	☐	Critical	100
9	Get approval from cus	2/13/2014	2/14/2014	☑		100
10	Design Documentatio	2/13/2014	2/14/2014	☑		100
11	Design complete	2/14/2014	2/14/2014	☑	Normal	0
12	Implementation Phase	2/17/2014	2/27/2014	☐	Normal	

The TreeGrid allows the user to filter the columns with custom actions by using the method filterColumn. And it is possible to clear the filter for a specific column by using the method clearFilter.

Filtering Modes

Filter Bar

This is the default filtering mode in TreeGrid. It can also be enabled by setting the `FilterSettings.FilterType` as `FilterBar`. When this filtering mode is enabled, a filter row will be displayed below the column header, in which we can provide the filter query.

There are two types of actions available to initiate the filtering process in the filter bar mode, we can set the filter bar mode using `FilterSettings.FilterBarMode` property.

`Immediate`: Filtering action will be initiated immediately on key press, for each character being typed in the filter bar.

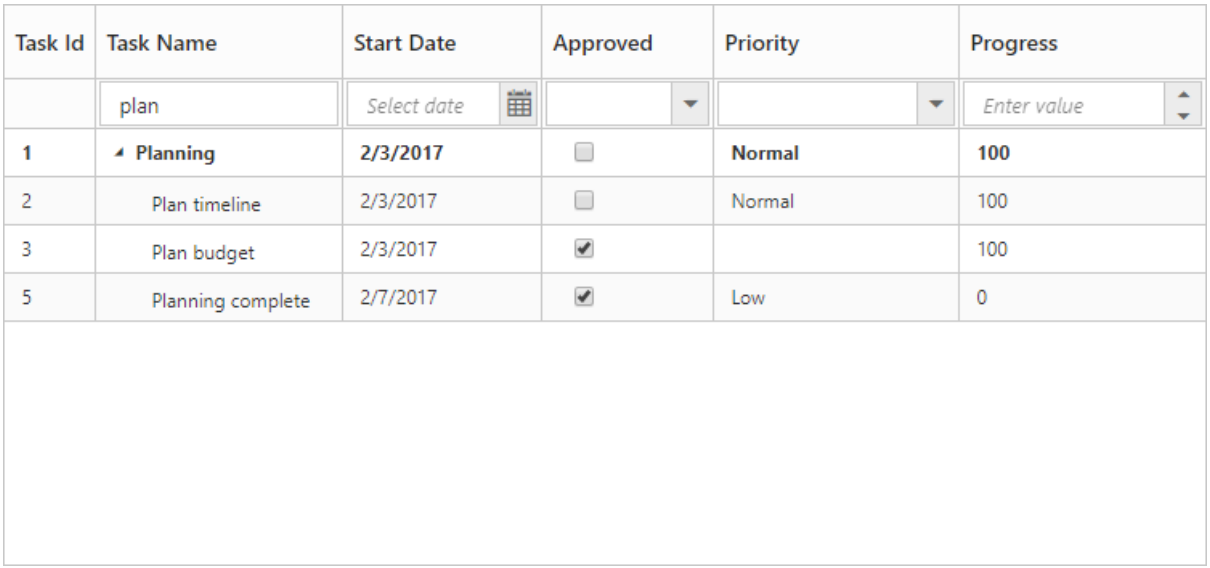
`OnEnter`: Filtering action will be initiated only on enter key press in the filter bar.

The below code snippet explains the above behavior.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowFiltering(true)
.FilterSettings(filtered=>
{
filtered.FilterType(TreeGridFilterType.FilterBar);
filtered.FilterBarMode(TreeGridFilterBarMode.OnEnter);
})
)
@(Html.EJ().ScriptManager())
```

The output of the filtering with filter bar enabled is as follows.



Menu filtering

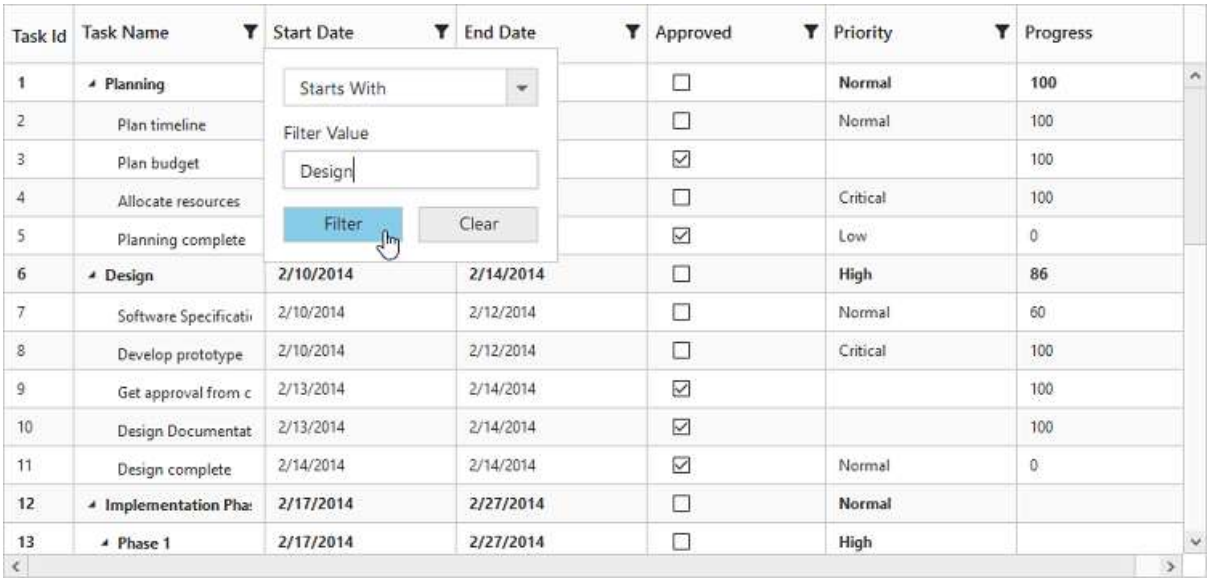
Menu filtering can be enabled by setting the FilterSettings.FilterType property as Menu. The below code snippet explains how to enable menu filtering in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowFiltering(true)
.FilterSettings(filtered=>
{
filtered.FilterType(TreeGridFilterType.Menu);
})
)
@(Html.EJ().ScriptManager())
```

The output of the filtering with filter menu enabled is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Excel Filtering

Excel filtering can be enabled by setting the FilterSettings.FilterType property as Excel. The excel menu contains options such as sorting, clear filter and advance filtering options.

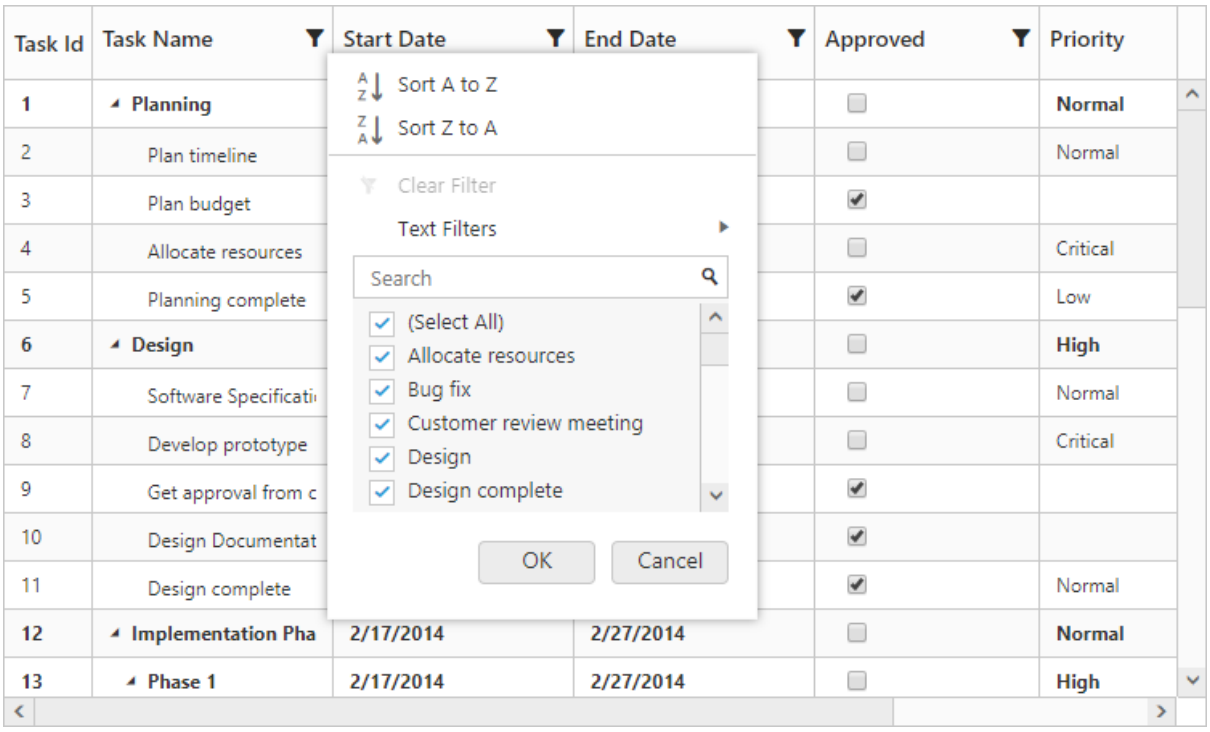
The below code snippet explains how to enable excel filtering in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowFiltering(true)
.FilterSettings(filtered=>
{
filtered.FilterType(TreeGridFilterType.Excel);
})
)
@(Html.EJ().ScriptManager())
```

The output of the filtering with excel filter enabled is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Checkbox list generation

By default, the checkbox list is generated from distinct values of the filter column from `Datasource` which gives an option to search and select the required items.

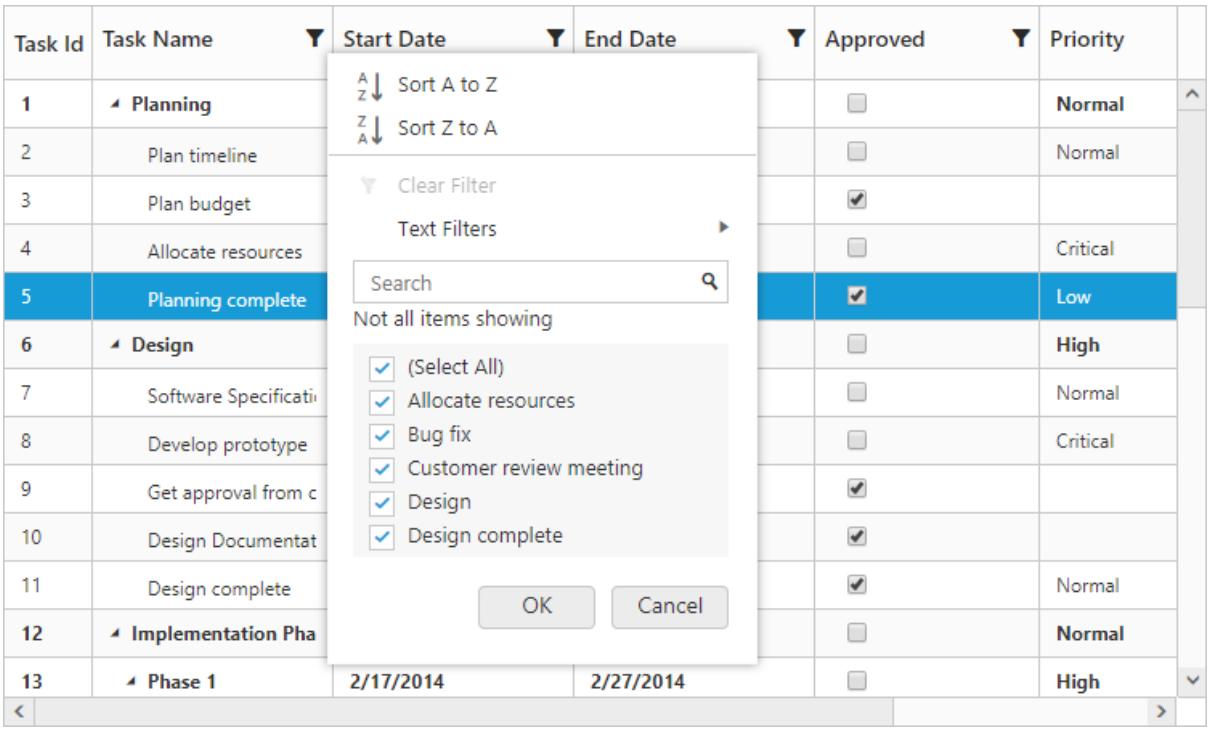
If the number of distinct values are greater than 1000, then the excel filter will display only first 1000 values and show "Not all items shown" label to ensure the best performance on rendering and searching. However, this limit has been customized according to your requirement by setting the `MaxFilterChoices` with required limit in integer.

The below code snippet explains how to change the max filter choices value.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowFiltering(true)
.FilterSettings(filtered=>
{
filtered.FilterType(TreeGridFilterType.Excel);
filtered.MaxFilterChoices(5);
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screen shot shows TreeGrid with MaxFilterChoices as 5.

Case Sensitivity

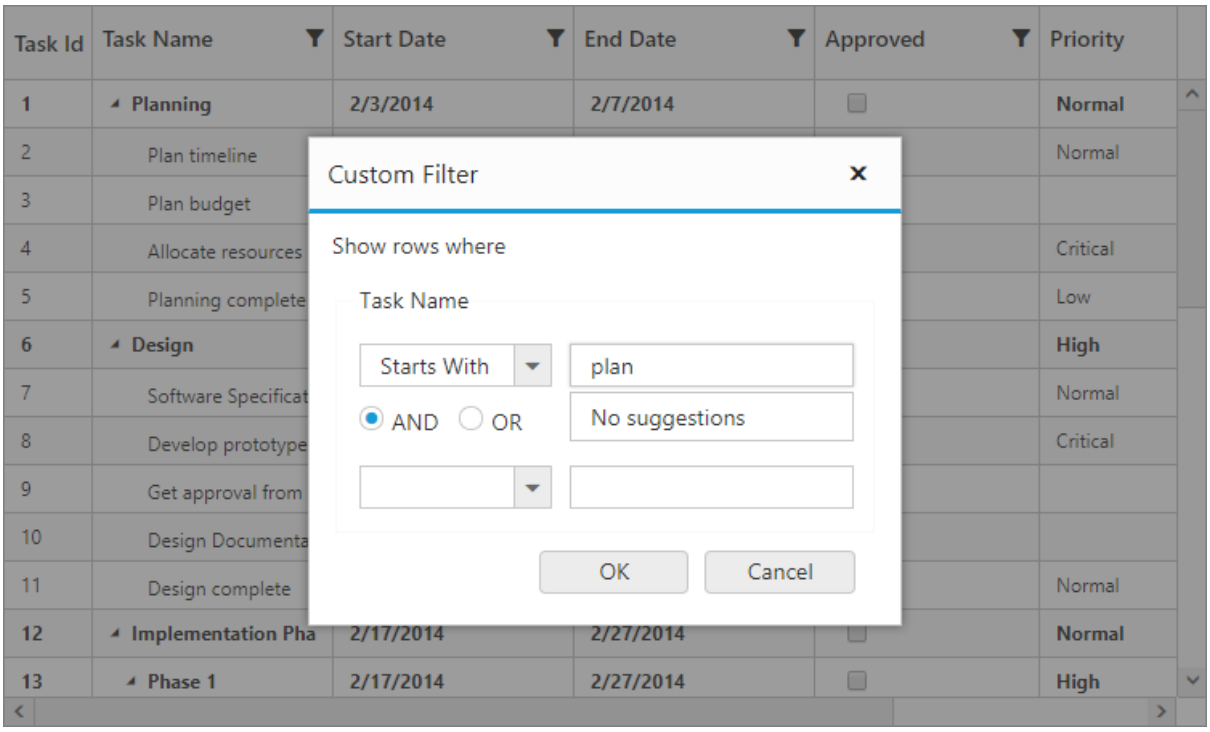
To perform filter operation with case sensitive in excel styled filter menu mode by setting the EnableCaseSensitivity as true.

The below code snippet explains how to enable the case sensitivity in excel filter.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowFiltering(true)
.FilterSettings(filtered=>
{
filtered.FilterType(TreeGridFilterType.Excel);
filtered.EnableCaseSensitivity(true);
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screen shot shows TreeGrid with EnableCaseSensitivity set as false in search action.

Change filter mode for specific column

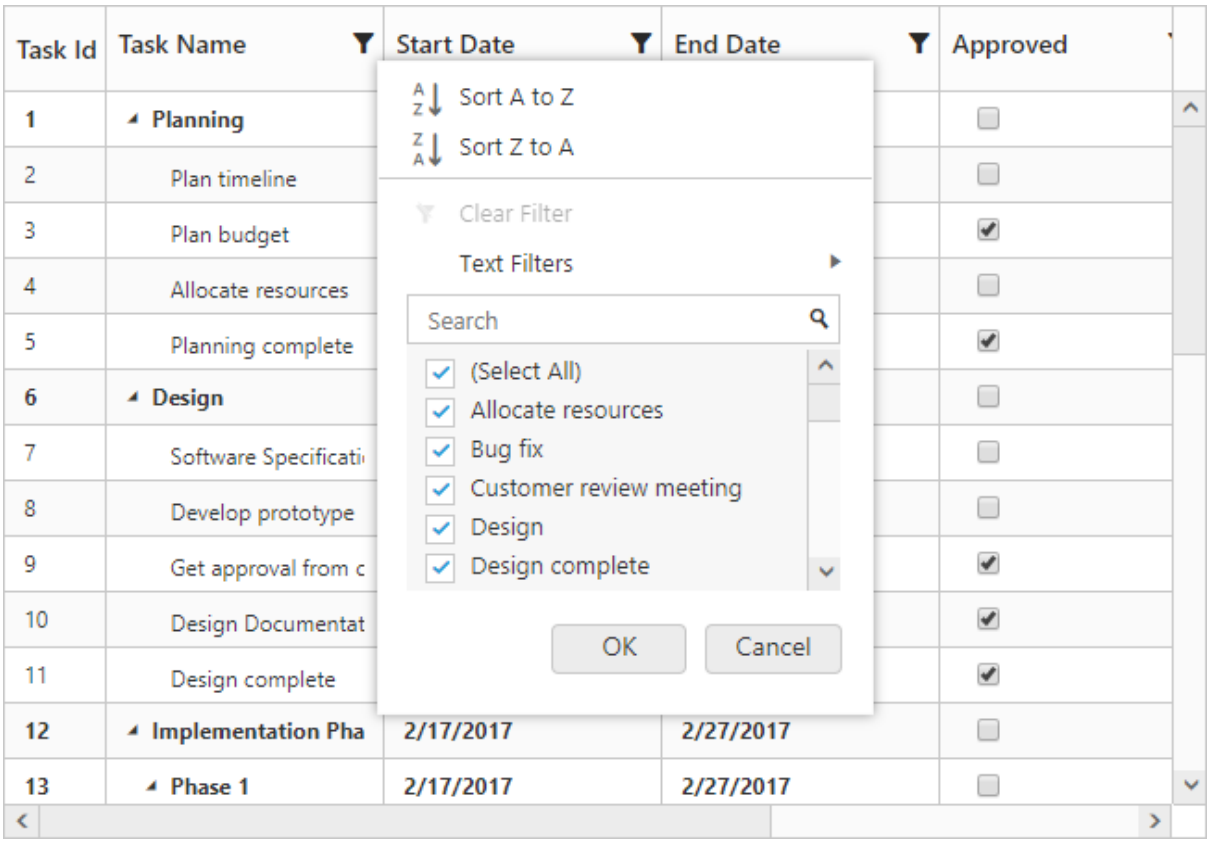
TreeGrid provides option for changing the filter mode for specific column by using Columns.FilterType property. Using this property we can either set Menu or Excel filter mode when FilterSettings.FilterType property as Menu or Excel.

The following code example show, how to change filter mode for specific column.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowFiltering(true)
.FilterSettings(filtered=>
{
filtered.FilterType(TreeGridFilterType.Menu);
})
.Columns(co =>
{
co.Field("taskName").HeaderText("Task
Name").EditType(TreeGridEditingType.String).FilterType(TreeGridFilterOpti
on.Excel).Add();
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.



The above screen shot shows TreeGrid with excel filter mode for Task Name column only.

Filtering types

By default, the filtering type for a column is inherited from the Columns.EditType property. You can also define a specific filtering type for a column using the Columns.FilterEditType property.

The below code snippet explains on how to set a filtering type for a column.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowFiltering(true)
.Columns(co =>
{
co.Field("taskID").AllowFiltering(false).Add();
co.Field("taskName").EditType(TreeGridEditingType.String).FilterEditType(
TreeGridFilterEditType.String).Add();
co.Field("startDate").EditType(TreeGridEditingType.Datepicker).Format("{0
:MM/dd/yyyy}").FilterEditType(TreeGridFilterEditType.Datepicker).Add();
co.Field("priority").EditType(TreeGridEditingType.Dropdown).DropDownData(
(IEnumerable<object>)ViewBag.dropData).FilterEditType(TreeGridFilterEditT
ype.Dropdown).Add();
co.Field("progress").EditType(TreeGridEditingType.Numeric).FilterEditType
(TreeGridFilterEditType.Numeric).Add();
})
)
@(Html.EJ().ScriptManager())
```

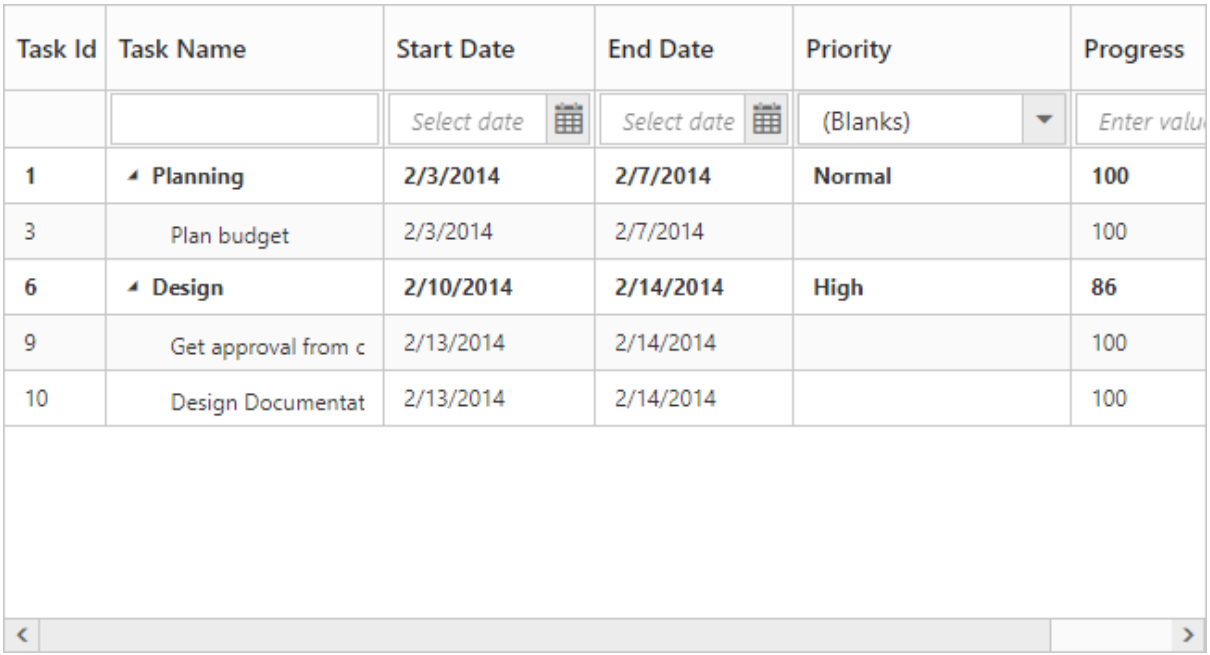
Copyright © 2001 - 2020 Syncfusion Inc.

Filtering blank values in drop down filtering

In TreeGrid, it is possible to filter the null or empty string value in drop down filter type by setting `AllowFilteringBlankContent` as `true` in the column definition.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowFiltering(true)
.Columns(co =>
{
co.Field("priority").HeaderText("Priority").FilterEditType(TreeGridFilter
EditType.Dropdown).AllowFilteringBlankContent(true).Add();
})
)
@(Html.EJ().ScriptManager())
```



The above screenshot shows TreeGrid with filtering blank content.

Filter Hierarchy Modes

TreeGrid provides support for a set of filtering modes with `FilterSettings.FilterHierarchyMode` property.

The below are the type of filter mode available in TreeGrid.

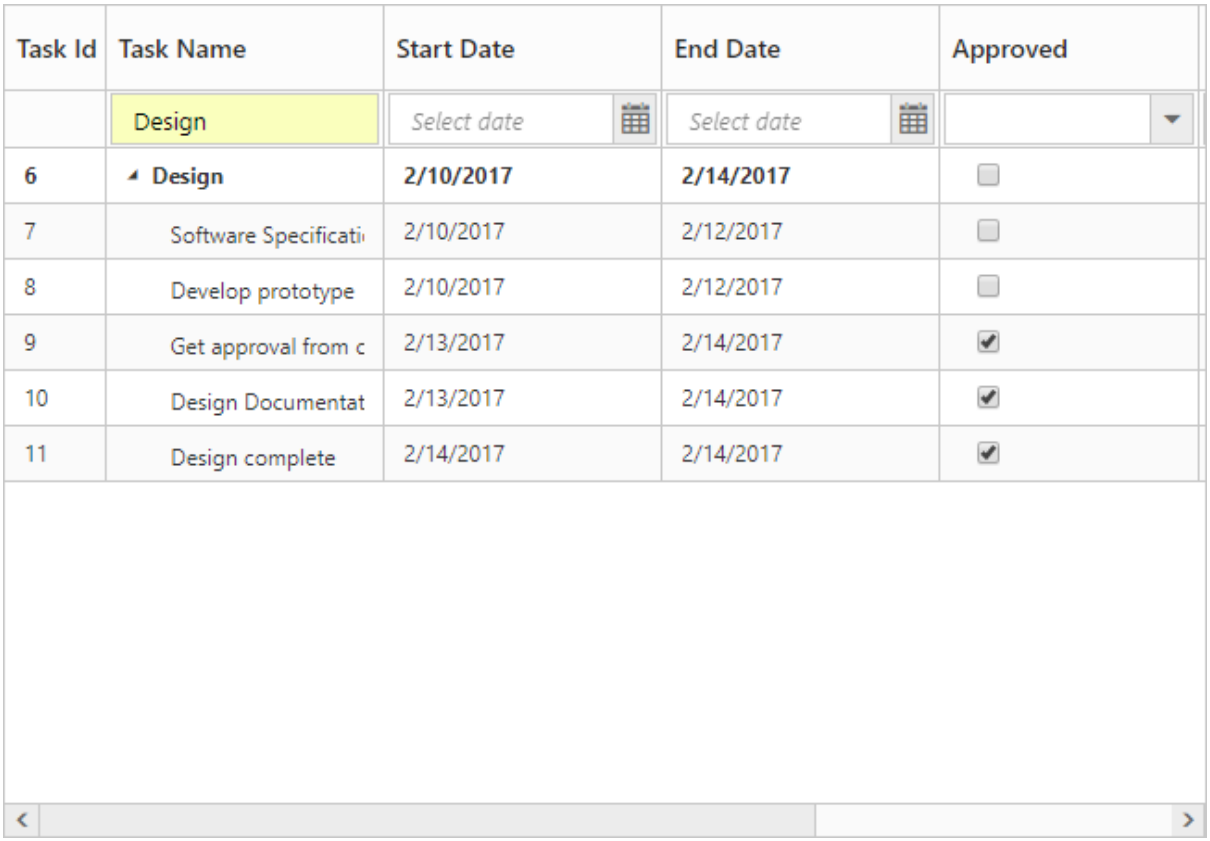
- **Parent**: This is the default filter hierarchy mode in TreeGrid. The filtered record displayed with its parent records, if the filtered records not have any parent record then the filtered record only displayed.
- **Child** : The filtered record displayed with its child record, if the filtered records not have any child record then the filtered record only displayed.
- **Both** : The filtered record displayed with its both parent and child record, if the filtered records not have any parent and child record then the filtered record only displayed.
- **None** : The filtered record only displayed.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example shows how to set filter mode in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.FilterSettings(filtered =>
{
filtered.FilterHierarchyMode(TreeGridFilterHierarchyMode.Child);
})
)
@(Html.EJ().ScriptManager())
```



The above screenshot shows TreeGrid filter with Child filter mode.

Filter columns at initial load

It is also possible to filter one or more columns at load time by providing the FilterSettings.FilteredColumns.Field, FilterSettings.FilteredColumns.Value, FilterSettings.FilteredColumns.Predicate and FilterSettings.FilteredColumns.Operator to the FilterSettings.FilteredColumns property. The following code example explains how to filter a column on initial load.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.FilterSettings(filtered =>
{
filtered.FilteredColumns(filtered =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
filtered.Field("taskName").Value("plan").Predicate("and").Operator(Filter
OperatorType.StartsWith).Add();
});
})
)
@(Html.EJ().ScriptManager())
```

Disabling filtering for a specific column

It is possible to disable filtering for a specific column by setting the Columns.AllowFiltering as false in the column definition.

The below code snippet explains the above behavior.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowFiltering(true)
.Columns(co =>
{
co.Field("taskID").AllowFiltering(false).Add();
})
)
@(Html.EJ().ScriptManager())
```

The output of the filtering enabled for only one column is as follows.

Task Id	Task Name	Start Date	End Date	Approved	Priority
1	Planning	2/3/2014	2/7/2014	☐	Normal
2	Plan timeline	2/3/2014	2/7/2014	☐	Normal
3	Plan budget	2/3/2014	2/7/2014	☑	
4	Allocate resources	2/3/2014	2/7/2014	☐	Critical
5	Planning complete	2/7/2014	2/7/2014	☑	Low
6	Design	2/10/2014	2/14/2014	☐	High
7	Software Specificati	2/10/2014	2/12/2014	☐	Normal
8	Develop prototype	2/10/2014	2/12/2014	☐	Critical
9	Get approval from c	2/13/2014	2/14/2014	☑	
10	Design Documentat	2/13/2014	2/14/2014	☑	
11	Design complete	2/14/2014	2/14/2014	☑	Normal
12	Implementation Pha:	2/17/2014	2/27/2014	☐	Normal

Click to find the demo sample for filtering in TreeGrid

Toolbox searching

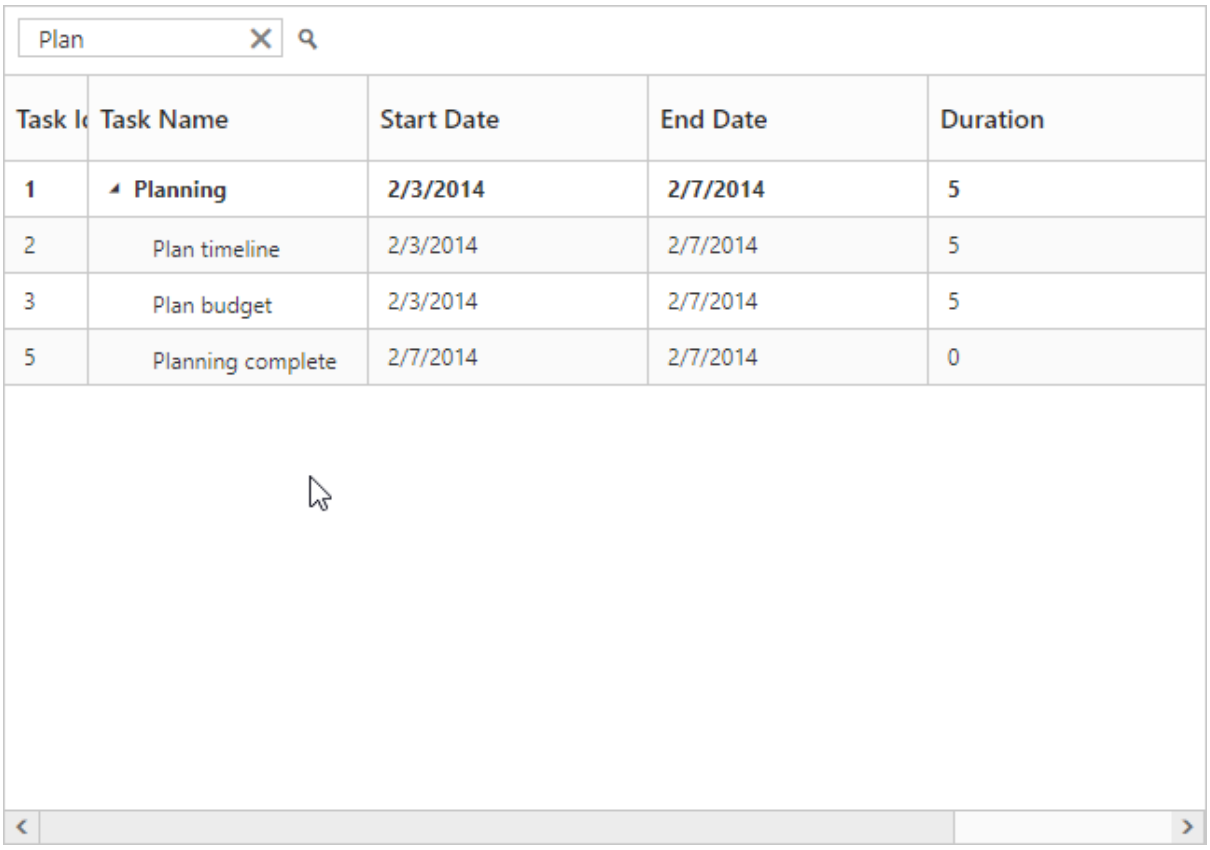
The TreeGrid control has an option to search its content using toolbar search box. The toolbar search box can be enabled by using the ToolbarSettings.ToolbarItems property.

Copyright © 2001 - 2020 Syncfusion Inc.

The following code example explains how to integrate search text box in toolbar.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<TreeGridToolBarItems>()
{
TreeGridToolBarItems.Search
});
})
)
@(Html.EJ().ScriptManager())
```



The above screen shot shows TreeGrid search with **Plan** key word.

The toolbox searching can be customized using the SearchSettings property. It is possible to search the TreeGrid content with the specific column values as the query for searching, using the property SearchSettings.Field.

The below code example explains searching the TreeGrid content across the "TaskId" and "TaskName" columns.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.SearchSettings(ss =>
{
ss.Fields(new List<string> { "TaskId", "TaskName" });
})
)
@(Html.EJ().ScriptManager())
```

It is possible to filter the TreeGrid contents at initial load using the toolbar search, with the SearchSettings.Key property.

The below code example explains filtering the TreeGrid contents at initial load with a search key, which will be applied across all the columns.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.SearchSettings(ss =>
{
ss.Key("task 1");
})
)
@(Html.EJ().ScriptManager())
```

TreeGrid provides support for conditional searching with operators in toolbar search using the property SearchSettings.Operator. And case sensitivity for the search query can be ignored using the property SearchSettings.IgnoreCase.

The below code example explains filtering the TreeGrid content using toolbar search with operators

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.SearchSettings(ss =>
{
ss.Fields(new List<string> { "TaskName" }).Key("Task
1").Operator(TreeGridSearchOperator.StartsWith).IgnoreCase(false);
})
)
@(Html.EJ().ScriptManager())
```

If the toolbar search textbox is not enabled in TreeGrid, and still if the contents need to be filtered at initial load using the SearchSettings property, then the user should enable the AllowSearching property along with search settings.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowSearching(true)
.SearchSettings(ss =>
{
ss.Key("Plan");
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

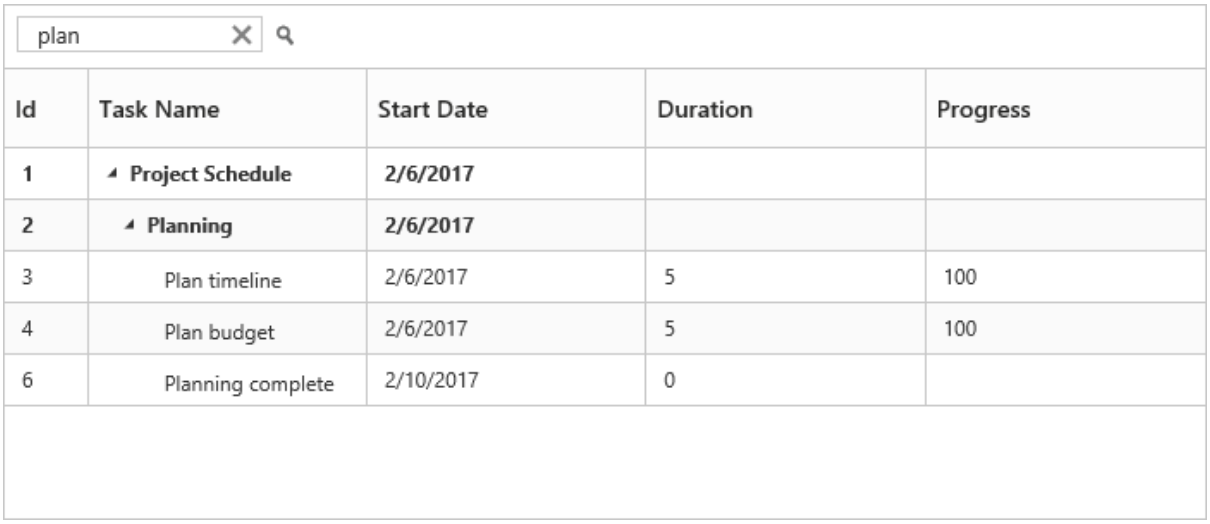
Searching

The TreeGrid control has an option to search its content using toolbar search box. The toolbar search box can be enabled by using the ToolbarSettings.ToolbarItems property. The following code example explains how to integrate search textbox in toolbar.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<TreeGridToolBarItems>()
{
TreeGridToolBarItems.Search,
});
})
)
```

The below screenshot shows TreeGrid search with plan key word.



Search Hierarchy Modes

The tree grid supports different types of search mode through the SearchSettings.SearchHierarchyMode property.

The following are the types of search modes available in the tree grid.

Parent: This is the default search hierarchy mode in the tree grid. It displays a searched record with its parent records. If the searched records do not have any parent record, it displays only the searched record.

Child: Displays the searched record with its child record. If the searched records do not have any child record, it displays only the searched record.

Both: Displays the searched record with both its parent and child records. If the searched records do not have any parent and child records, it displays only the searched record.

None: Displays only the searched record.

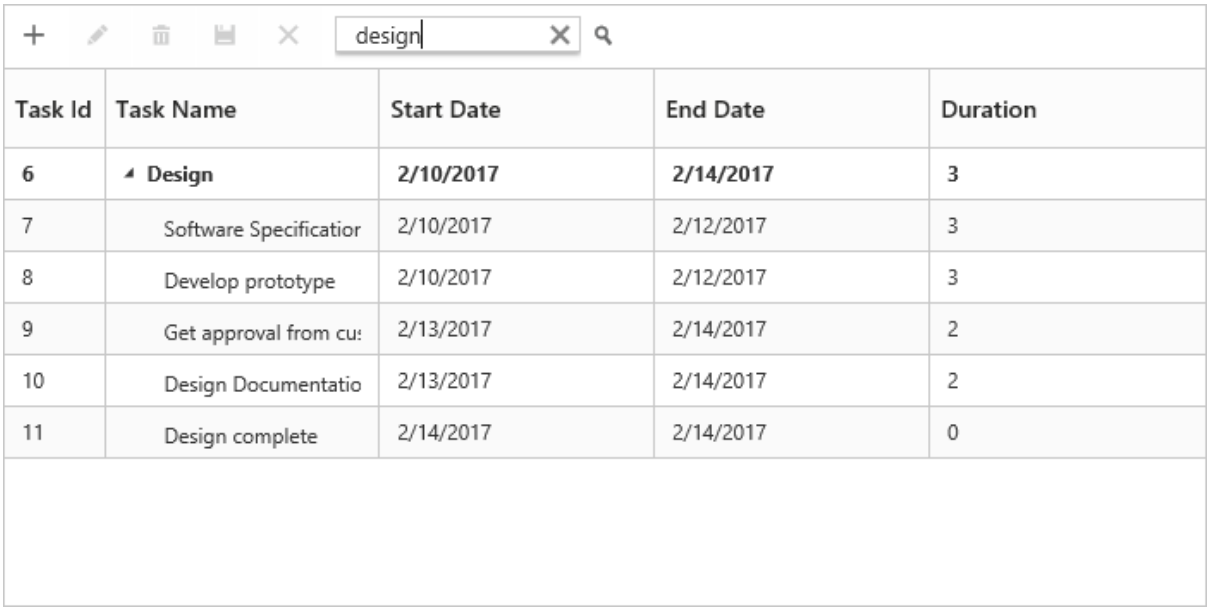
Copyright © 2001 - 2020 Syncfusion Inc.

The following code example shows how to set the SearchHierarchyMode in the tree grid.

HTML

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.SearchSettings(se => {
se.SearchHierarchyMode(TreeGridSearchHierarchyMode.Child);
})
.Datasource(ViewBag.datasource)
)
```

The following image depicts the output of the previous code example.



The above screenshot shows Tree Grid with Child search mode.

Summary Row

Summary rows in TreeGrid are used to summarize every hierarchy with the set of predefined summary types using the column values. Using the SummaryRows property, user can define the summary rows in TreeGrid and the title for each summary row can be defined using the SummaryRows.Title property. And summary for the columns in TreeGrid can be defined by using the SummaryRows.SummaryColumns property. Summary rows are enabled by setting the ShowSummaryRow property as true. The total summary row is the overall summary row displayed for all the rows in the TreeGrid and its visibility can be defined by using the ShowTotalSummary property.

Defining summary columns

Using the **SummaryType** property, user can define the type of summary to be displayed in a column.

The **DataMember** property is used the map the field values which is used for summary calculations.

The **DisplayColumn** property is used to specify the column in which the summary to be displayed.

The **Prefix** and **Suffix** properties are used to define the text should be displayed along with the summary column value.

Copyright © 2001 - 2020 Syncfusion Inc.

The **Format** property is used for formatting the summary column value.

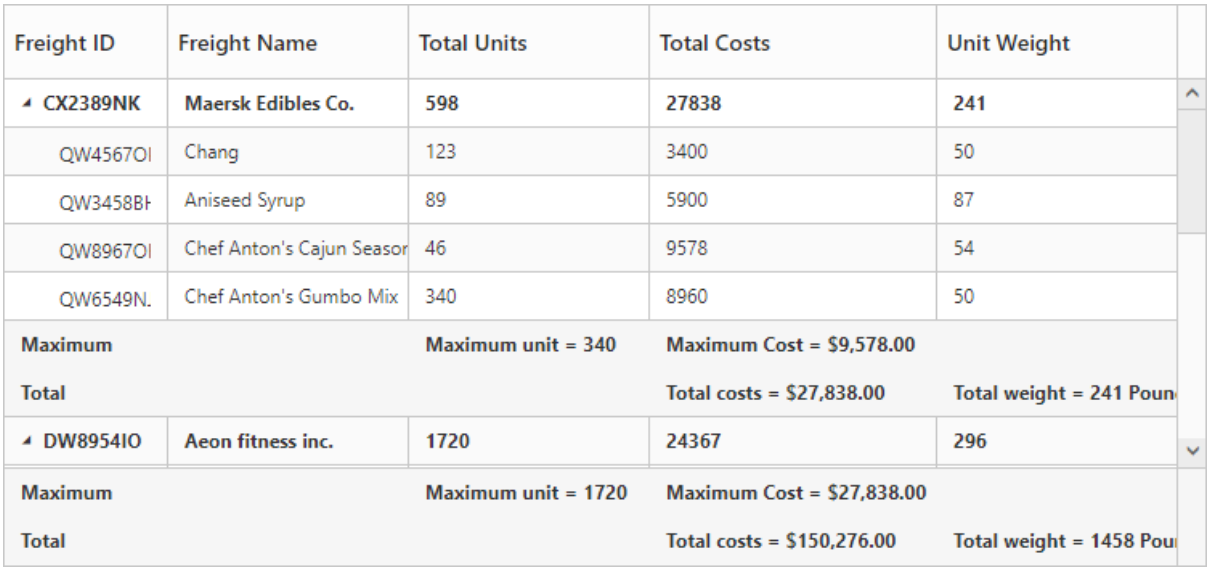
The below code snippet explains defining a summary row in TreeGrid,

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowSummaryRow(true)
.ShowTotalSummary(true)
.SummaryRows(rows =>
{
rows.Title("Maximum").SummaryColumns(col =>
{
col.SummaryType(TreeGridSummaryType.Maximum)
.DataMember("TotalUnits")
.Prefix("Maximum unit = ")
.DisplayColumn("TotalUnits").Add();
col.SummaryType(TreeGridSummaryType.Maximum)
.DataMember("TotalCosts")
.Prefix("Maximum Cost = ")
.DisplayColumn("TotalCosts")
.Format("{0:C}").Add();
}).Add();
rows.Title("Total").SummaryColumns(summary =>
{
summary.SummaryType(TreeGridSummaryType.Sum)
.DataMember("TotalCosts")
.Prefix("Total costs = ")
.DisplayColumn("TotalCosts")
.Format("{0:C}").Add();
summary.SummaryType(TreeGridSummaryType.Sum)
.DataMember("UnitWeight")
.Prefix("Total weight = ")
.DisplayColumn("UnitWeight")
.Suffix("Pounds").Add();
}).Add();
})
)
@(Html.EJ().ScriptManager())
```

The below screenshot shows the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.



Freight ID	Freight Name	Total Units	Total Costs	Unit Weight
CX2389NK	Maersk Edibles Co.	598	27838	241
QW4567OI	Chang	123	3400	50
QW3458BH	Aniseed Syrup	89	5900	87
QW8967OI	Chef Anton's Cajun Seasor	46	9578	54
QW6549N.	Chef Anton's Gumbo Mix	340	8960	50
Maximum		Maximum unit = 340	Maximum Cost = $9,578.00	
Total			Total costs = $27,838.00	Total weight = 241 Poun
DW8954IO	Aeon fitness inc.	1720	24367	296
Maximum		Maximum unit = 1720	Maximum Cost = $27,838.00	
Total			Total costs = $150,276.00	Total weight = 1458 Pou

Customize height of total summary

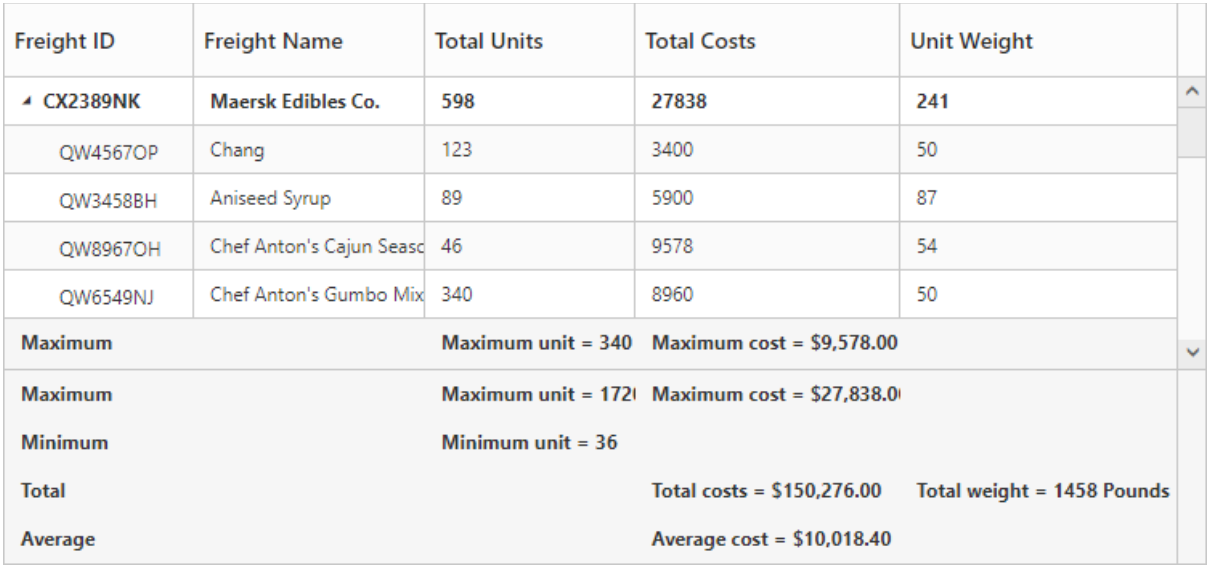
Using TotalSummaryHeight property we can customize the height of the total summary container.

The below code example shows how to update the footer summary container height.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowSummaryRow(true)
.ShowTotalSummary(true)
.TotalSummaryHeight(120)
)
@(Html.EJ().ScriptManager())
```

The below screenshot shows the output of above code example.



Freight ID	Freight Name	Total Units	Total Costs	Unit Weight
CX2389NK	Maersk Edibles Co.	598	27838	241
QW4567OP	Chang	123	3400	50
QW3458BH	Aniseed Syrup	89	5900	87
QW8967OH	Chef Anton's Cajun Seasc	46	9578	54
QW6549NJ	Chef Anton's Gumbo Mix	340	8960	50
Maximum		Maximum unit = 340	Maximum cost = $9,578.00	
Maximum		Maximum unit = 172	Maximum cost = $27,838.0	
Minimum		Minimum unit = 36		
Total			Total costs = $150,276.00	Total weight = 1458 Pounds
Average			Average cost = $10,018.40	

Expand/collapse total summary row

We can expand/collapse the total summary rows in TreeGrid using following methods.

Copyright © 2001 - 2020 Syncfusion Inc.

- Using Expander Icon
- Using Method

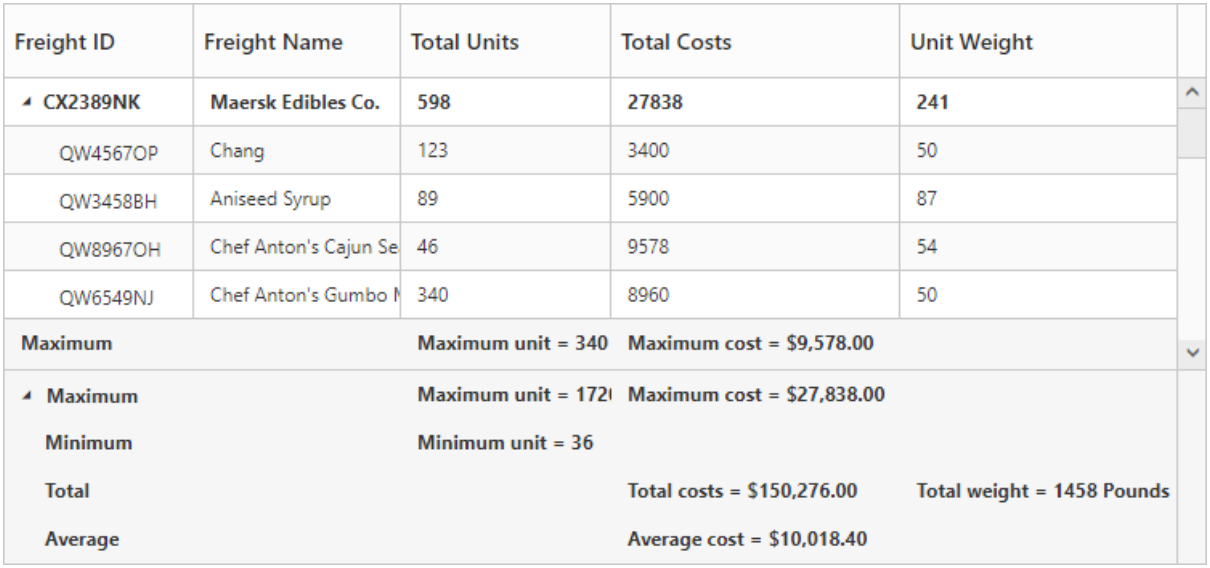
Using Expander Icon

We can enable expander icon in total summary row by using CollapsibleTotalSummary property. By default expander icon will be rendered in first row of 0th column in total summary rows.

Please find the below code example to enable collapsible total summary row in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowSummaryRow(true)
.ShowTotalSummary(true)
.TotalSummaryHeight(120)
.CollapsibleTotalSummary(true)
)
@(Html.EJ().ScriptManager())
```



Freight ID	Freight Name	Total Units	Total Costs	Unit Weight
CX2389NK	Maersk Edibles Co.	598	27838	241
QW4567OP	Chang	123	3400	50
QW3458BH	Aniseed Syrup	89	5900	87
QW8967OH	Chef Anton's Cajun Se	46	9578	54
QW6549NJ	Chef Anton's Gumbo M	340	8960	50
Maximum		Maximum unit = 340	Maximum cost = $9,578.00	
Maximum		Maximum unit = 172	Maximum cost = $27,838.00	
Minimum		Minimum unit = 36		
Total			Total costs = $150,276.00	Total weight = 1458 Pounds
Average			Average cost = $10,018.40	

Note: We can also customize the expander icon column in total summary row by using _summaryColumnIndex property and Load event.

Using Method

Total summary rows in TreeGrid can be expanded/collapsed by using expandCollapseTotalSummary method.

Please find the code example to collapse the total summary rows below.

ASPX-CS

```
<button onclick="expandCollapse()">expandCollapse</button>
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowSummaryRow(true)
.ShowTotalSummary(true)
.TotalSummaryHeight(120)
.CollapsibleTotalSummary(true)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().ScriptManager())
function expandCollapse() {
var treeObj = $("#TreeGridContainer").data("ejTreeGrid");
treeObj.expandCollapseTotalSummary(false);
}
```

Click here to view the demo sample for summary row in TreeGrid.

Custom Summary

Custom summary can be used to create summary values based on your required custom logic and calculations. To enable the custom summary, the SummaryType should be set to 'Custom' and the CustomSummaryValue property should be defined as function. After the custom calculation, the returned value will be displayed in the corresponding summary cell.

HTML

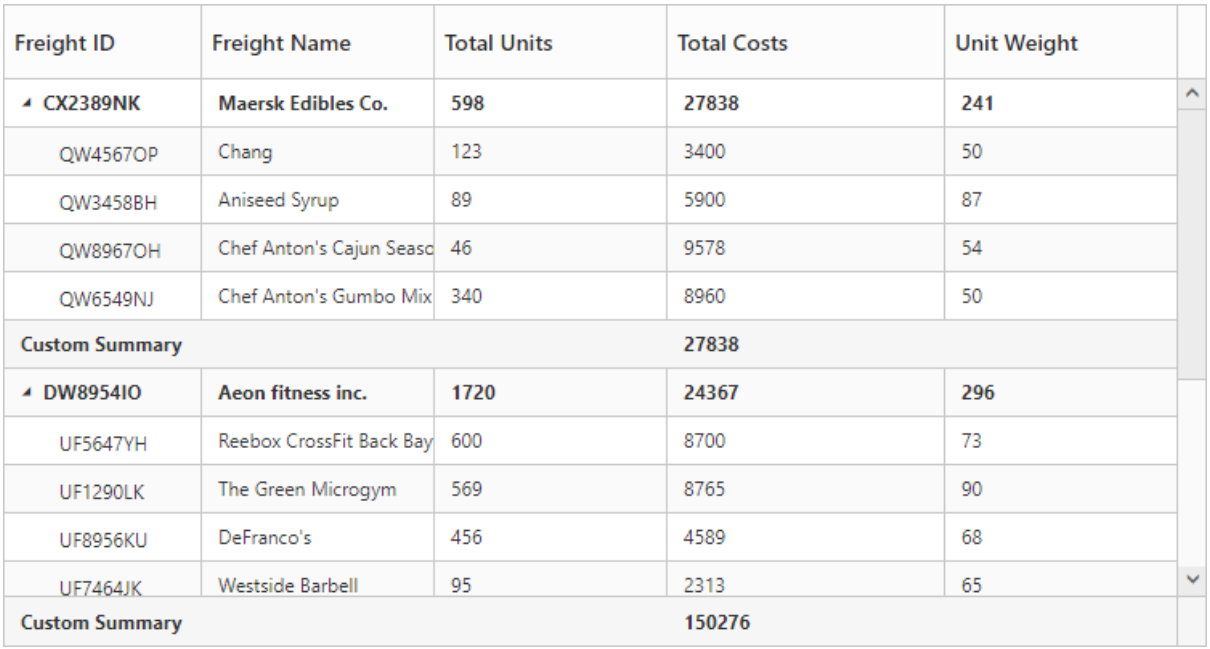
```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ShowSummaryRow(true)
.SummaryRows(su =>
{
su.Title("Custom Summary").
SummaryColumns(
summary =>
{
summary.SummaryType(TreeGridSummaryType.Custom)
.CustomSummaryValue("sum")
.DisplayColumn("Progress").Add();
}).Add();
})
)
```

JS

```
<script>
function sum(args, data) {
//ej.sum is aggregate to add data of total costs from datasource
return ej.sum(data, "TotalCosts");
}
</script>
```

The output of the tree grid with custom summary value is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.



Freight ID	Freight Name	Total Units	Total Costs	Unit Weight
CX2389NK	**Maersk Edibles Co.**	**598**	**27838**	**241**
QW4567OP	Chang	123	3400	50
QW3458BH	Aniseed Syrup	89	5900	87
QW8967OH	Chef Anton's Cajun Seaso	46	9578	54
QW6549NJ	Chef Anton's Gumbo Mix	340	8960	50
Custom Summary			**27838**	
DW8954IO	**Aeon fitness inc.**	**1720**	**24367**	**296**
UF5647YH	Reebox CrossFit Back Bay	600	8700	73
UF1290LK	The Green Microgym	569	8765	90
UF8956KU	DeFranco's	456	4589	68
UF7464JK	Westside Barbell	95	2313	65
Custom Summary			**150276**	

Responsive

The TreeGrid control has support for responsive behavior based on client browser's width and height. To enable responsive support in TreeGrid, IsResponsive property must be enabled.

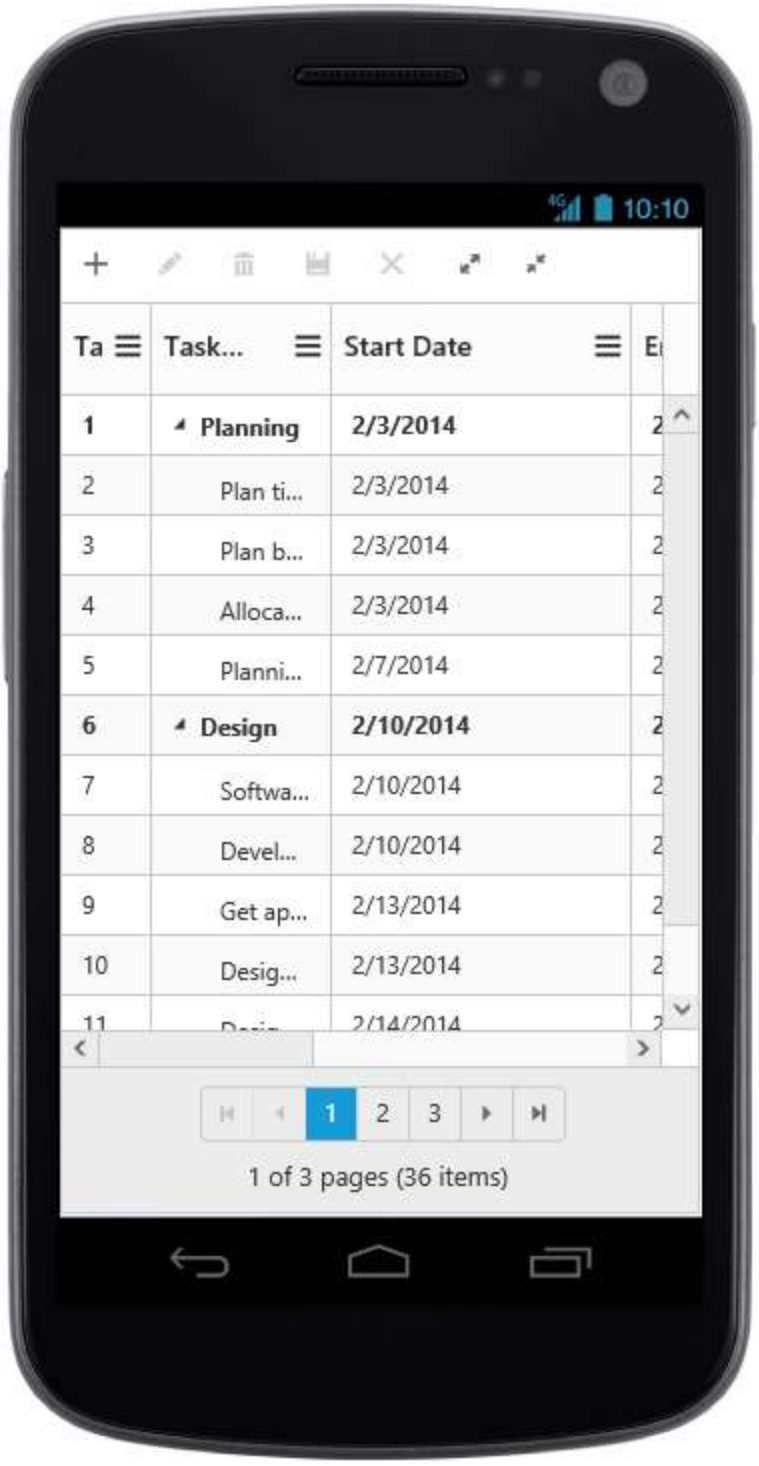
Please find the example describes the above behavior.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.IsResponsive(true)
)
@(Html.EJ().ScriptManager())
```

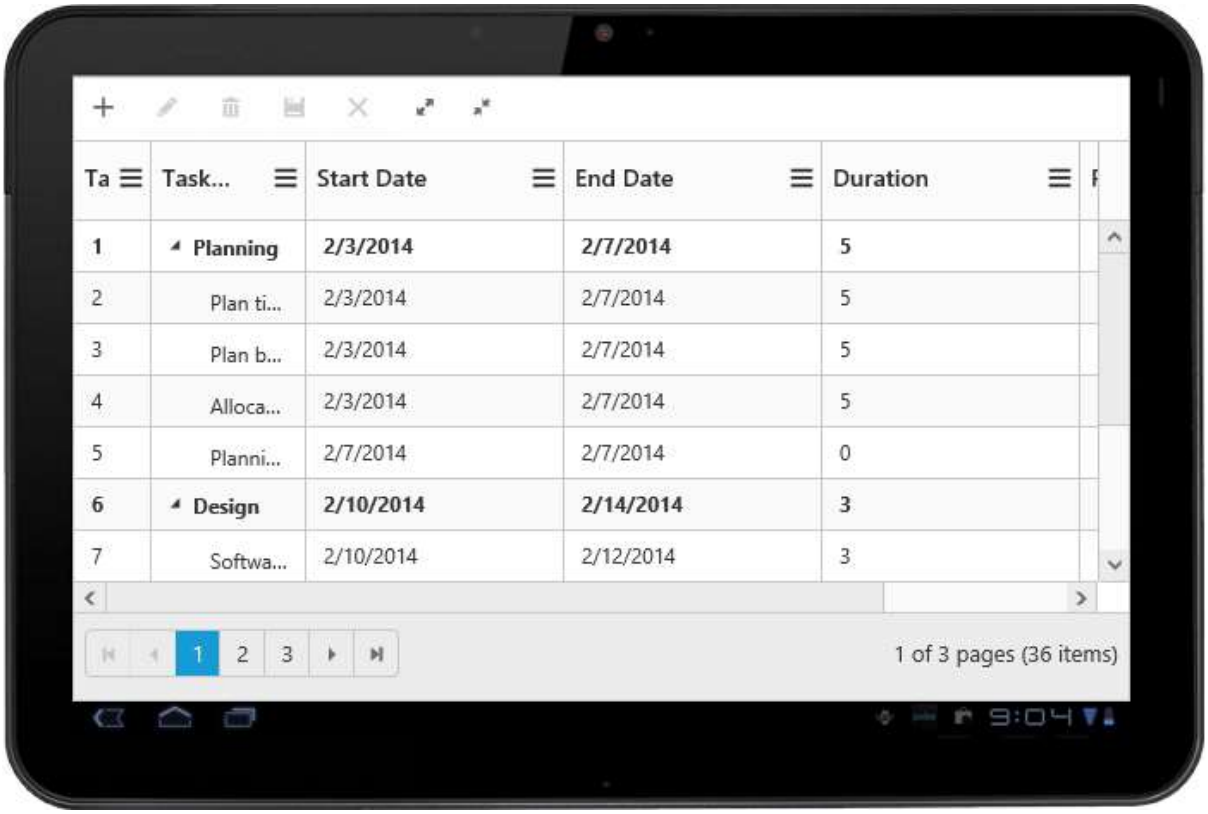
The following output is displayed as a result of the above code example

Copyright © 2001 - 2020 Syncfusion Inc.



Responsive TreeGrid in Mobile layout.

Copyright © 2001 - 2020 Syncfusion Inc.



Responsive TreeGrid in tablet layout.

Layout

Below are the modes of responsive layout available in TreeGrid based on client width,

- Mobile(<321px)
- Tablet(321px to 768px)
- Desktop(>768px)

Mobile Layout

The customized layout for filtering, column chooser operations and add/edit operations in mobile device can be seen in the following screen shots.

Insert column options in tablet layout

Changing responsive width using method

You can change the minimum responsive width dynamically by using public method updateResponsiveMinWidth(width) by passing the width as an argument.

The TreeGrid control get works in responsive mode only when the window width is below the minimum responsive width.

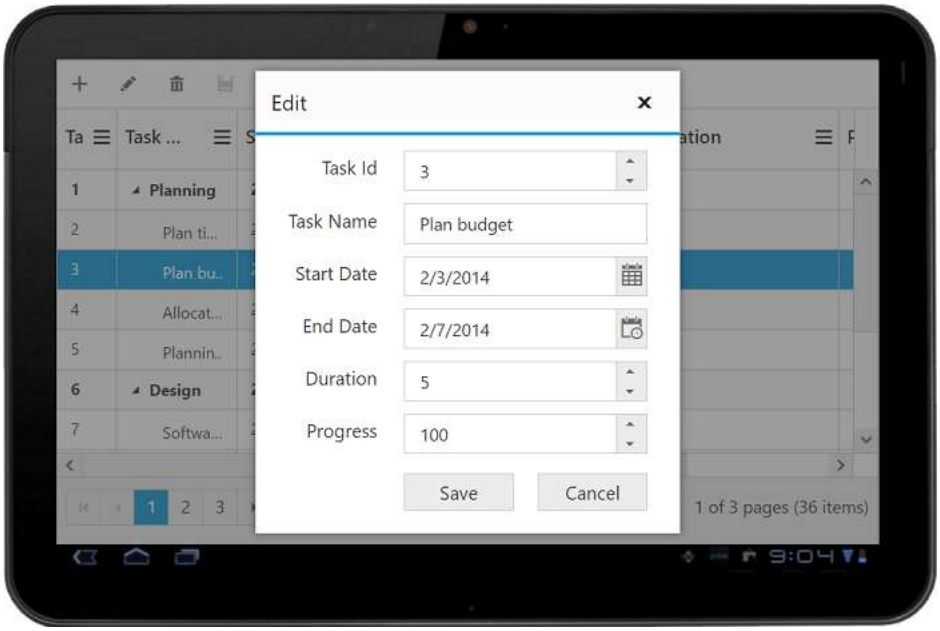
Please find the example describes the above behavior.

ASPX-CS

```
<button id="minResponsiveWidth">minResponsiveWidth</button>
@(Html.EJ().TreeGrid("TreeGridContainer")
.IsResponsive(true)
)
@(Html.EJ().ScriptManager())
$("#minResponsiveWidth").click(function (args) {
treegridObj = $("#TreeGridContainer ").data("ejTreeGrid");
treegridObj.updateResponsiveMinWidth(600);
});
```

The following output is displayed as a result of the above code example

Copyright © 2001 - 2020 Syncfusion Inc.



Priority for columns

Column priorities are used to show or hide the columns based on priority values and browser width to best accommodate the possible columns. Priority value of the column is set by Columns.Priority property and the value ranges from one to six.

The following code example explains how to set priority for column

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.IsResponsive(true)
.Columns(co =>
{
co.Field("TaskId").HeaderText("Task Id").Width(45).Add();
co.Field("TaskName").HeaderText("Task Name").Add();
co.Field("StartDate").HeaderText("Start Date").Add();
co.Field("EndDate").HeaderText("End Date").Priority(5).Add();
co.Field("Duration").HeaderText("Duration").Priority(6).Add();
co.Field("Progress").HeaderText("Progress").Priority(6).Add();
})
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

Task Id	Task Name	Start Date
1	**Planning**	**2/3/2014**
2	Plan timeline	2/3/2014

12	**Implementation Phase**	**2/17/2014**

The above screen shot show TreeGrid rendered in browser width of 640 pixels.

Selection

The TreeGrid control provides support for row and cell selections using SelectionSettings property.

Row selection

You can enable or disable the row selection in TreeGrid, using the AllowSelection property. By default row selection is enabled in TreeGrid.

The following code example shows, how to disable the row selection in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.AllowSelection(true)
)
@(Html.EJ().ScriptManager())
```

The output of the TreeGrid with row selection is as follows.

Selecting a row at initial load

You can select a row at initial load by setting the index of the row to the SelectedRowIndex property.

Find the following code for selecting a row at initial load.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.SelectedRowIndex(3)
)
@(Html.EJ().ScriptManager())
```

Multiple row selection

It is also possible to select multiple rows by setting the SelectionType as Multiple. You can select more than one row by holding down **CTRL** key and to click on the rows.

The following code example explains how to enable multiple selection in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.SelectionSettings(ss=>
{
ss.SelectionMode(TreeGridSelectionMode.Row);
ss.SelectionType(TreeGridSelectionType.Multiple);
}))
@(Html.EJ().ScriptManager())
```

The output of the TreeGrid with multiple row selection is as follows.

10	Design Documentation	02/13/2014	02/14/2014	2
11	Design complete	02/14/2014	02/14/2014	0
12	Implementation Phase	02/17/2014	02/27/2014	11

Selecting a row programmatically

You can select a row programmatically by setting the row index value to the SelectedRowIndex property.

The following code shows on how to select a row programmatically with button click action.

ASPX-CS

```
<button id="selectRow">SelectRow</button>
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
)
@(Html.EJ().ScriptManager())
$("#selectRow").click(function (args) {
$("#TreeGridContainer").ejTreeGrid("option", "selectedRowIndex", 4);
})
```

Customize row selection action

While selecting a row in TreeGrid, RowSelecting and RowSelected event will be triggered. Row selecting event will be triggered on initialization of row selection action. In RowSelecting event we can get the previously selected row and current selecting row's information, using this information we can prevent selection of particular row. The RowSelected event will be triggered on completion of row selection action, in this event we can get the current selected row's information.

The following code example shows how to prevent the selection of particular row using RowSelecting event.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.ClientSideEvents(cs =>
{
cs.RowSelecting("rowSelecting");
}))
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function rowSelecting(args) {
if(args.data.taskID == 5) // prevent selection of Task id 5
args.cancel = true;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
</script>
```

Get record details

In TreeGrid, It is possible to get the record detail when **click** and **dblClick** the row using RecordClick and RecordDoubleClick event, using this method we can get the record details even AllowSelection is false.

The below code example show, how to get record details when **click** the row.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.ClientSideEvents(cs =>
{
cs.RecordClick("recordClick");
}))
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function recordClick(args) {
// Perform action for recordClick
}
</script>
```

Cell selection

You can select cells in TreeGrid by setting the SelectionMode property as Cell.

And you can able to get the selected cell information using the SelectedCellIndexes property from the TreeGrid object.

The SelectedCellIndexes is an object collection, which has the CellIndex and RowIndex information of the selected cells.

Find the code example below to enable the cell selection in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.SelectionSettings(ss=>
{
ss.SelectionMode(TreeGridSelectionMode.Cell);
}))
@(Html.EJ().ScriptManager())
```

The output of the TreeGrid with cell selection is as follows.

Copyright © 2001 - 2020 Syncfusion Inc.

12	Implementation Phase	02/17/2014	02/27/2014	11

It is possible to get the list of HTML elements of the selected cells at run-time using the getSelectedCells method.

Select cells dynamically

You can select the cells programmatically using the selectCells public method. Find the code example below for details.

ASPX-CS

```
<button id="selectCells">Select Cells</button>
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.SelectionSettings(ss=>
{
ss.SelectionMode(TreeGridSelectionMode.Cell);
ss.SelectionType(TreeGridSelectionType.Multiple);
}))
@(Html.EJ().ScriptManager())
$("#selectCells").click(function () {
var treegridObj = $("#TreeGridContainer").ejTreeGrid("instance");
var cellIndex = [{
rowIndex: 2,
cellIndex: 1
}, {
rowIndex: 3,
cellIndex: 1
}];
treegridObj.selectCells(cellIndex);
})
```

Disabling cell selection for specific column

It is possible to disable cell selection for a specific column by setting `AllowCellSelection` as `false` in the column definition.

The below code snippet explains how to disable cell selection for specific column in TreeGrid

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.Columns(co =>
{
//..
co.Field("TaskId").AllowCellSelection(false).Add();
}))
@(Html.EJ().ScriptManager())
```

Multiple cell selection

You can also select multiple cell by setting the `SelectionType` property as `Multiple`.

Multiple selection can be done by holding the **CTRL** key and to click the required cells.

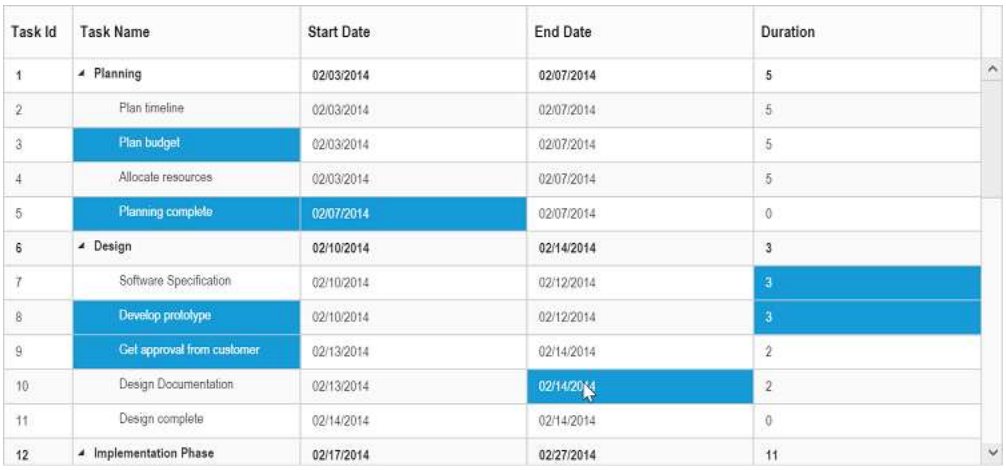
The following code example shows you to select multiple cells.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.SelectionSettings(ss=>
{
ss.SelectionMode(TreeGridSelectionMode.Cell);
ss.SelectionType(TreeGridSelectionType.Multiple);
}))
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

The output of the TreeGrid with multiple cell selection is as follows.



Task Id	Task Name	Start Date	End Date	Duration
1	Planning	02/03/2014	02/07/2014	5
2	Plan timeline	02/03/2014	02/07/2014	5

12	Implementation Phase	02/17/2014	02/27/2014	11

Customize cell selection action

While selecting a cell in TreeGrid, CellSelecting and CellSelected event will be triggered. Cell selecting event will be triggered on initialization of cell selection action. In CellSelecting event we can get the current selecting cell information, using this information we can prevent selection of particular cell in particular row. The CellSelected event will be triggered on completion of cell selection action, in this event we can get the current selected cell's information.

The following code example shows how to prevent the selection of particular cell using CellSelecting event.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.ClientSideEvents(cs =>
{
cs.CellSelecting("cellSelecting");
}))
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function cellSelecting(args) {
if(args.data.taskID == 5 && args.cellIndex == 1) // prevent selection of
Task Name cell of Task id 5
args.cancel = true;
}
</script>
```

Checkbox selection

TreeGrid supports checkbox selection and to enable the checkbox selection, you need to set the SelectionType property to Checkbox and the SelectionMode property as Row. By default, checkbox column will be displayed as the left most column, on enabling the checkbox selection in TreeGrid.

Column header checkbox

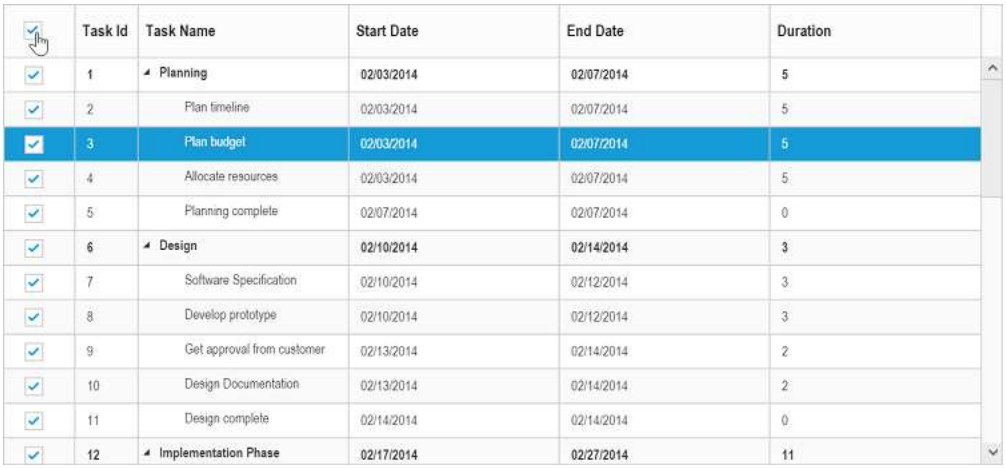
It is possible to select/unselect all the TreeGrid rows using column header checkbox. To enable this you need to set the EnableSelectAll property as true. The following code snippet explains how to enable the column header checkbox.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
.SelectionSettings(ss=>
{
ss.SelectionMode(TreeGridSelectionMode.Row);
ss.SelectionType(TreeGridSelectionType.Checkbox);
ss.EnableSelectAll(true);
})
)
@(Html.EJ().ScriptManager())
```

The output of the TreeGrid with checkbox enabled in column header.



Task Id	Task Name	Start Date	End Date	Duration
1	Planning	02/03/2014	02/07/2014	5
2	Plan timeline	02/03/2014	02/07/2014	5

12	Implementation Phase	02/17/2014	02/27/2014	11

Hierarchy selection

It is possible to select the rows hierarchically using checkboxes in TreeGrid by enabling the EnableHierarchySelection property.

In this selection the hierarchy between the records will be retained, where the child records will get selected on selecting its parent record's checkbox and parent record checkbox will get selected on checking all of its child items.

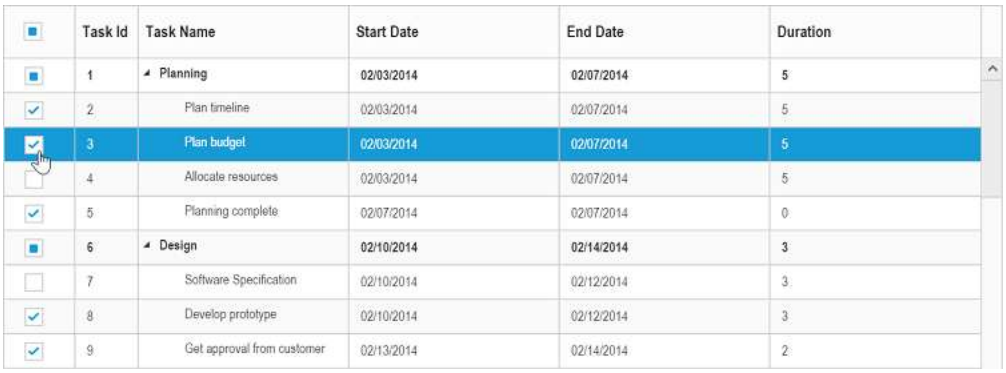
Following code snippet explains on enabling hierarchy selection in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
.SelectionSettings(ss=>
{
ss.SelectionMode(TreeGridSelectionMode.Row);
ss.SelectionType(TreeGridSelectionType.Checkbox);
ss.EnableHierarchySelection(true);
})
)
@(Html.EJ().ScriptManager())
```

The output of the TreeGrid with hierarchy selection enabled.

Copyright © 2001 - 2020 Syncfusion Inc.



Task Id	Task Name	Start Date	End Date	Duration

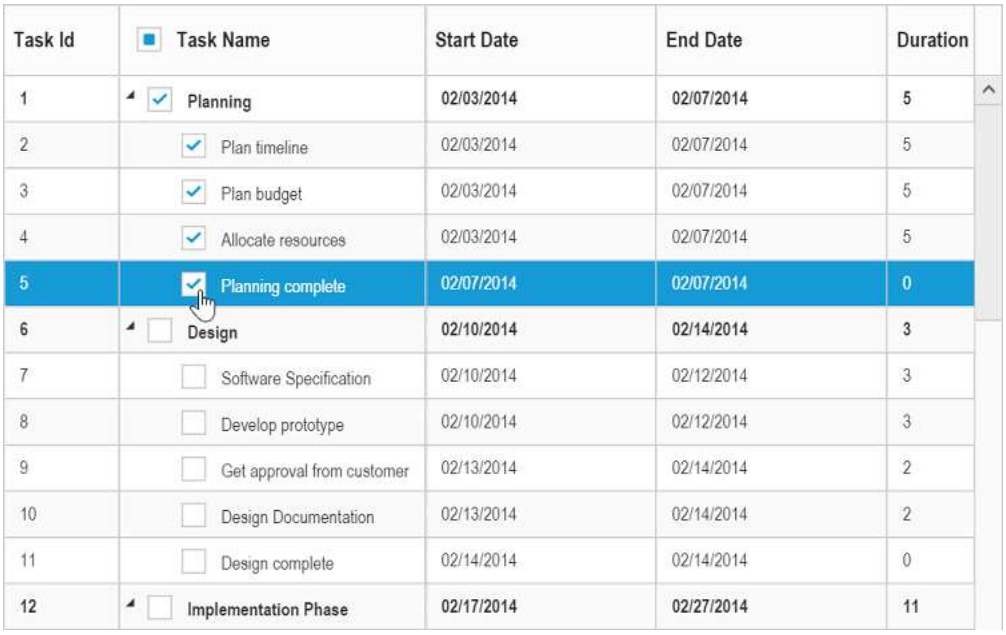
Checkbox column

It is possible to change the default index of the checkbox column and we can display the checkboxes in any of the existing column. And to enable the checkbox in any of the column, we need to set `Columns.ShowCheckbox` property as true in the column object.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//..
.SelectionSettings(ss=>
{
ss.SelectionMode(TreeGridSelectionMode.Row);
ss.SelectionType(TreeGridSelectionType.Checkbox);
})
.Columns(co =>
{
co.Field("taskName").HeaderText("Task Name").ShowCheckbox(true).Add();
})
)
@(Html.EJ().ScriptManager())
```

The output of the TreeGrid with checkbox enabled in task name column.



Task Id	Task Name	Start Date	End Date	Duration

12	Implementation Phase	02/17/2014	02/27/2014	11

Copyright © 2001 - 2020 Syncfusion Inc.

The index of the checkbox column can be changed at run-time using the updateCheckboxColumn method. The index of the column in which the checkbox should be displayed is passed as the method parameter.

MultiSelection – Touch Option

It is possible to select cells using touch action in TreeGrid. TreeGrid provides support for both single selection and multiple cell selection using touch action. For multiple cell selection, when we tap on a cell a helper icon will be displayed using that we can select multiple cells.

The following code example describes how to enable multiple selection in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.SelectionSettings(ss=>
{
ss.SelectionType(TreeGridSelectionType.Multiple);
}))
@(Html.EJ().ScriptManager())
```

The following output is displayed the result of multiple selection in touch device environment.

Task Id	Task Name	Start Date	End Date	Duration	Progress

Clear selection using method

It is possible to clear the selection in TreeGrid at run-time using the clearSelection method.

The specific row will be deselected when the row index is passed as the method parameter. If the index is not passed, then all the selected rows in TreeGrid will be deselected.

ASPX-CS

```
<button id="clearSelection">Clear Selection</button>
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@(Html.EJ().ScriptManager())
$("#clearSelection").click(function () {
var treegridObj = $("#TreeGridContainer").data("ejTreeGrid");
treegridObj.clearSelection(2);
})
```

Export

Exporting feature provides support to export TreeGrid content to excel and PDF files. To export the contents, the ExcelExport and PdfExport toolbar items must be added in the toolbar using the ToolbarItems property of ToolbarSettings. When you click, the toolbar exporting icons, it internally invokes the export public method of TreeGrid object to export.

The below code snippet explains the above behavior,

C#

```
public class TreeGridController  : Controller
{
public ActionResult TreeGridExporting()
{
ViewBag.datasource = this.GetEditingDataSource();
return View();
}
public void ExportToPdf(string TreeGridModel)
{
PdfExport exp = new PdfExport();
var DataSource = this.GetEditingDataSource();
TreeGridProperties obj = ConvertTreeGridObject(TreeGridModel);
exp.Export(obj, DataSource, new TreeGridExportSettings() { Theme =
ExportTheme.FlatSaffron },"Export");
}
public void ExportToExcel(string TreeGridModel)
{
ExcelExport exp = new ExcelExport();
var DataSource = this.GetEditingDataSource();
TreeGridProperties obj = ConvertTreeGridObject(TreeGridModel);
exp.Export(obj, DataSource, "Export.xlsx", ExcelVersion.Excel2010, new
TreeGridExportSettings() { Theme = ExportTheme.FlatSaffron});
}
private TreeGridProperties ConvertTreeGridObject(string gridProperty)
{
JavaScriptSerializer serializer = new JavaScriptSerializer();
IEnumerable div = (IEnumerable)serializer.Deserialize(gridProperty,
typeof(IEnumerable));
TreeGridProperties gridProp = new TreeGridProperties();
foreach (KeyValuePair<string, object> ds in div)
{
var property = gridProp.GetType().GetProperty(ds.Key,
BindingFlags.Instance | BindingFlags.Public | BindingFlags.IgnoreCase);
if (property != null)
{
Type type = property.PropertyType;
string serialize = serializer.Serialize(ds.Value);
object value = serializer.Deserialize(serialize, type);
property.SetValue(gridProp, value, null);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
}
return gridProp;
}
}
```

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<TreeGridToolBarItems>()
{
TreeGridToolBarItems.PdfExport,
TreeGridToolBarItems.ExcelExport
});
})
.Datasource(ViewBag.datasource)
)
@(Html.EJ().ScriptManager())
```

The below screen shot shows TreeGrid with excel and PDF exporting enabled.

Task Id	Task Name	Start Date	End Date	Duration
1	Planning	02/03/2014	02/07/2014	5
2	Plan timeline	02/03/2014	02/07/2014	5

Server dependencies

Export Helper functions are available in the Assembly Syncfusion.EJ.Export, which is available in the Essential Studio & Essential ASP.NET MVC builds. The list of assemblies needed for TreeGrid Export as follows

- Syncfusion.EJ
- Syncfusion.EJ.Export
- Syncfusion.Linq.Base
- Syncfusion.Compression.Base
- Syncfusion.XlsIO.Base

Copyright © 2001 - 2020 Syncfusion Inc.

- Syncfusion.PDF.Base

Supported Export Types

Currently server helper function allows following two types of exporting.

- Excel
- PDF

Export Mapper in MVC

Mappers is used to change the default routing path for exporting. By using Mappers you can change any action name in controller and the action can be in any controller (Need not to be in TreeGrid View Page Controller).

C#

```
public  class TreeGridController : Controller
{
public void PdfAction(string TreeGridModel)
{
PdfExport exp = new PdfExport();
var DataSource = this.GetEditingDataSource();
TreeGridProperties obj = ConvertTreeGridObject(TreeGridModel);
exp.Export(obj, DataSource, new TreeGridExportSettings() { Theme =
ExportTheme.FlatSaffron },"Export");
}
public void ExcelAction(string TreeGridModel)
{
ExcelExport exp = new ExcelExport();
var DataSource = this.GetEditingDataSource();
TreeGridProperties obj = ConvertTreeGridObject(TreeGridModel);
exp.Export(obj, DataSource, "Export.xlsx", ExcelVersion.Excel2010, new
TreeGridExportSettings() { Theme = ExportTheme.FlatSaffron});
}
}
```

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.Mappers(map =>
map.ExportToPdfAction("PdfAction")).ExportToExcelAction("ExcelAction"))
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<TreeGridToolBarItems>()
{
TreeGridToolBarItems.PdfExport,
TreeGridToolBarItems.ExcelExport
});
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

Click here to view the online demo sample for Exporting.

Multiple exporting

Multiple export is used for export more than one TreeGrid object in the same file. Multiple export in TreeGrid can be enabled by setting AllowMultipleExporting property to true. TreeGrid properties of all the TreeGrid which are available in current page are passed as string array parameter to controller action method.

The following code example describes exporting multiple TreeGrid in PDF format

C#

```
public class TreeGridController : Controller
{
public ActionResult TreeGridMultipleExporting()
{
ViewBag.datasource1 = this.GetPlanDataSource();
ViewBag.datasource2 = this.GetDesignDataSource();
ViewBag.datasource3 = this.GetImplementationDataSource();
return View();
}
public void MultipleExportToPdf(string[] TreeGridModel)
{
PdfExport exp = new PdfExport();
var PlanData = this.GetPlanDataSource();
var DesignData = this.GetDesignDataSource();
var ImplementationData = this.GetImplementationDataSource();
PdfDocument document = null;
int count = 1;
foreach (string gridProperty in TreeGridModel)
{
TreeGridProperties gridProp = this.ConvertTreeGridObject(gridProperty);
if (count == 1)
{
document = exp.Export(gridProp, PlanData, new TreeGridExportSettings() {
Theme = ExportTheme.FlatSaffron }, false, "Planning Phase");
}
else if(count == 2)
{
exp.Export(gridProp, DesignData, new TreeGridExportSettings() { Theme =
ExportTheme.FlatSaffron }, "Export", document, false, "Design Phase");
}
else
{
exp.Export(gridProp, ImplementationData, new TreeGridExportSettings() {
Theme = ExportTheme.FlatSaffron }, "Export", document, true,
"Implementation Phase");
}
count++;
}
}
public void MultipleExportToExcel(string[] TreeGridModel)
{
ExcelExport exp = new ExcelExport();
IWorkbook  workbook = null;
int count = 1;
foreach (string gridProperty in TreeGridModel)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
TreeGridProperties gridProp = this.ConvertTreeGridObject(gridProperty);
if (count == 1)
{
workbook = exp.Export(gridProp, this.GetPlanDataSource(), new
TreeGridExportSettings() { Theme = ExportTheme.FlatSaffron }, true,
"Planning Phase");
}
else if (count == 2)
{
exp.Export(gridProp, this.GetDesignDataSource(), new
TreeGridExportSettings() { Theme = ExportTheme.FlatSaffron }, workbook,
true, "Design Phase");
}
else
{
exp.Export(gridProp, this.GetImplementationDataSource(),
"ExcelExport.xlsx", ExcelVersion.Excel2010, new TreeGridExportSettings()
{ Theme = ExportTheme.FlatSaffron }, workbook, false, "Implementation
Phase");
}
count++;
}
}
}
```

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.AllowMultipleExporting(true)
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<TreeGridToolBarItems>()
{
TreeGridToolBarItems.PdfExport,
TreeGridToolBarItems.ExcelExport
});
})
.Mappers(map =>
map.ExportToPdfAction("MultipleExportToPdf").ExportToExcelAction("Multipl
eExportToExcel"))
.Datasource(ViewBag.datasource1)
)
@(Html.EJ().TreeGrid("TreeGridContainer1")
//...
.AllowMultipleExporting(true)
.Datasource(ViewBag.datasource2)
)
@(Html.EJ().TreeGrid("TreeGridContainer2")
//...
.AllowMultipleExporting(true)
.Datasource(ViewBag.datasource3)
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

Click here to view the online demo sample for Multiple Exporting.

Export Theme

The TreeGrid export supports the below themes,

- flat-azure
- flat-azure-dark
- flat-lime
- flat-lime-dark
- flat-saffron
- flat-saffron-dark
- gradient-azure
- gradient-azure-dark
- gradient-lime
- gradient-lime-dark
- gradient-saffron
- gradient-saffron-dark
- bootstrap-theme

The desired theme should be passed as a parameter to the Export method and the code snippet for this as follows

C#

```
public void ExcelAction(string TreeGridModel)
{
ExcelExport exp = new ExcelExport();
var DataSource = this.GetEditingDataSource();
TreeGridProperties obj = ConvertTreeGridObject(TreeGridModel);
exp.Export(obj, DataSource, "Export.xlsx", ExcelVersion.Excel2010, new
TreeGridExportSettings() { Theme = ExportTheme.FlatSaffron});
}
```

Paging

TreeGrid provides support for displaying records in paginated view. Paging can be enabled in TreeGrid by setting the `AllowPaging` property as `true`.

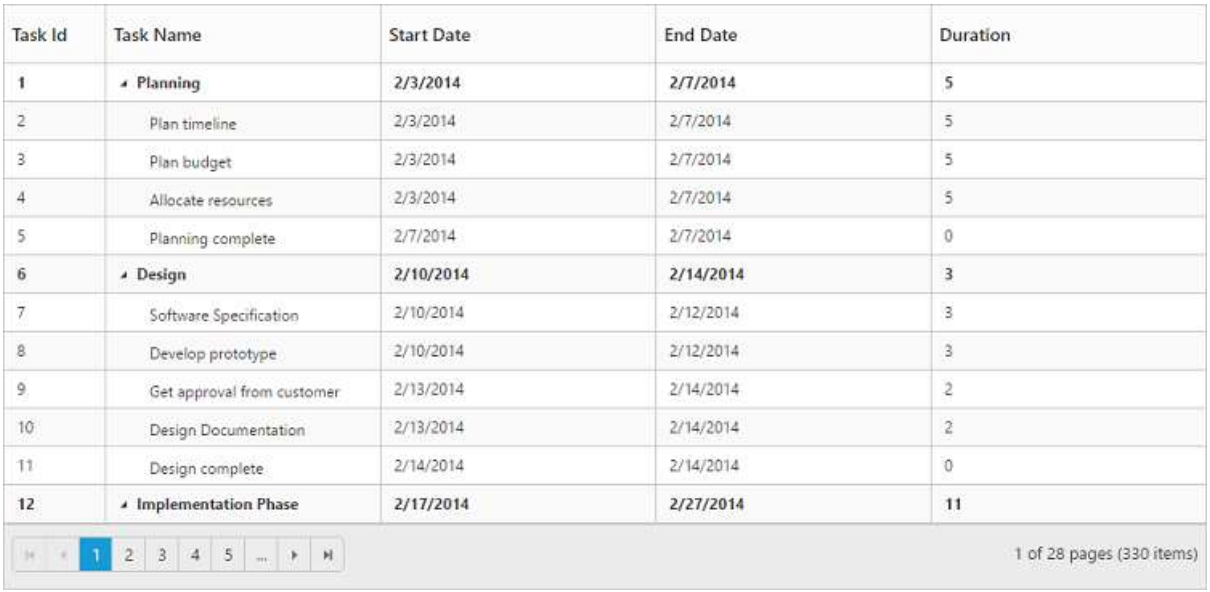
The below code snippet explains enable paging in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowPaging(true)
)
@(Html.EJ().ScriptManager())
```

The output of the TreeGrid with paging enabled is displayed below.

Copyright © 2001 - 2020 Syncfusion Inc.



Task Id	Task Name	Start Date	End Date	Duration
1	Planning	2/3/2014	2/7/2014	5
2	Plan timeline	2/3/2014	2/7/2014	5
3	Plan budget	2/3/2014	2/7/2014	5
4	Allocate resources	2/3/2014	2/7/2014	5
5	Planning complete	2/7/2014	2/7/2014	0

12	Implementation Phase	2/17/2014	2/27/2014	11

Paging settings

The paging in TreeGrid can be customized by using the PageSettings property.

- **PageSize** - Using this property we can limit the number of records to be displayed per page.
- **PageSizeMode** - By setting this property as Root we can limit the number of root nodes or the 0th level records to be displayed per page .

When the PageSizeMode property is set as Root the number of records to be displayed per page which is defined in the the PageSize property will be considered only for the root nodes or the 0th level records.

- **PageCount** - It is used to display the page number to be displayed in the pager.
- **CurrentPage** - This property is used to set the active page to be displayed initially.
- **TotalRecordsCount** - This property is used to limit the total number of records from the data source to be displayed in TreeGrid.

The following code example explains the properties in pageSettings.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowPaging(true)
.PageSettings(page=>
{
page.PageCount(5);
page.CurrentPage(3);
page.TotalRecordsCount(50);
page.PageSizeMode(TreeGridPageSizeMode.All);
page.PageSize(12);
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

Click here to find our online demo sample for Paging.

Pager Template

It is possible to customize the default pager in TreeGrid by using the PageSettings.Template property.

The below code snippet explains how to customize the default pager with template

ASPX-CS

```
<script type="text/x-jsrender" id="Template">
<div class="e-pagercontainer">
<div class="e-first e-icon e-mediaback e-firstpagedisabled e-disable"
title="Go to first page"></div><div class="e-prev e-icon e-arrowheadleft-
2x e-prevpagedisabled e-disable" style="border-right:none" title="Go to
previous page"></div>
</div>
<div class="e-pagercontainer e-currentPageContainer" style="border-
radius:0px">
<input id="currentPage" type="text" style="text-align:center;
margin:0px;border:none;width:32px;height:23px" />
</div>
<div id="totalPages" class="e-pagercontainer" style="margin-left:2px;
margin-bottom:5px;border:none">
<span></span>
</div>
<div class="e-pagercontainer">
<div class="e-nextpage e-icon e-arrowheadright-2x e-default" title="Go to
next page"></div><div class="e-lastpage e-icon e-mediaforward e-default"
title="Go to last page"></div>
</div>
</script>
@(Html.EJ().TreeGrid("TreeGridContainer")
.ClientSideEvents(eve => eve.ActionComplete("complete").Create("create"))
.AllowPaging(true)
.PageSettings(pg => pg.Template("#Template"))
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function create(args) {
//Code for navigating to the page
$("#currentPage").keydown(function (e) {
var obj = $("#TreeGridContainer").data("ejTreeGrid");
var val = parseInt($("#currentPage").val());
if (e.keyCode == 13 && !isNaN(val)) {
if (val > obj.model.pageSettings.totalPages)
val = obj.model.pageSettings.totalPages;
if (val <= 0)
val = 1;
obj.gotoPage(val);
return false;
}
});
}
function complete(args) {
$("#totalPages").find('span').text('of ' +
this.model.pageSettings.totalPages);
$(".e-pagercontainer:first").css('border-style', 'none');
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
if (args.requestType == 'paging' || args.requestType == 'refresh') {
if (this.model.pageSettings.currentPage ==
this.model.pageSettings.totalPages) {
this.element.find('.e-nextpage').addClass('e-
nextpagedisabled').removeClass('e-nextpage');
this.element.find('.e-lastpage').addClass('e-
lastpagedisabled').removeClass('e-lastpage');
}
else {
this.element.find('.e-nextpagedisabled').addClass('e-
nextpage').removeClass('e-nextpagedisabled');
this.element.find('.e-lastpagedisabled').addClass('e-
lastpage').removeClass('e-lastpagedisabled');
}
if (this.model.pageSettings.currentPage == 1) {
this.element.find('.e-prevpage').addClass('e-prevpagedisabled e-
disable').removeClass('e-prevpage');
this.element.find('.e-firstpage').addClass('e-firstpagedisabled e-
disable').removeClass('e-firstpage');
}
else {
this.element.find('.e-prevpagedisabled').addClass('e-
prevpage').removeClass('e-prevpagedisabled e-disable');
this.element.find('.e-firstpagedisabled').addClass('e-
firstpage').removeClass('e-firstpagedisabled e-disable');
}
$("#currentPage").val(this.model.pageSettings.currentPage);
}
}
</script>
```

CSS

```
#currentPage {
background-color: white;
}
.darktheme #currentPage {
background-color: black;
}
.e-pagercontainer .e-icon {
display: inline-block;
height: 8px;
}
.e-pager .e-pagercontainer {
margin: 0px;
margin-left: 6px;
}
```

Click here to find our online sample for Pager Template

The below image displays TreeGrid with paging template.

9	Get approval from customer	2/13/2014	2/14/2014	2	8
10	Design Documentation	2/13/2014	2/14/2014	2	53
11	Design complete	2/14/2014	2/14/2014	0	35
12	Implementation Phase	2/17/2014	2/27/2014	11	55

1 of 28

It is possible to navigate to a specific page with a custom action instead of clicking pager button by using the gotoPage method.

The below code snippet explains how to navigate to 3rd page in TreeGrid by using gotoPage method

ASPX-CS

```
var treeObject = $("#TreeGridContainer").data("ejTreeGrid");
treeObject.gotoPage(3);
```

Paging - Touch Option

With paging and responsive mode enabled in TreeGrid, it is possible to change the current page using swipe action.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.AllowPaging(true)
.IsResponsive(true)
)
@(Html.EJ().ScriptManager())
```

Toolbar

In TreeGrid we can show/hide the Toolbar by using ShowToolbar property.We can add default toolbar items by ToolbarItems. User can also create a custom toolbar items by using CustomToolbarItems.

Default Toolbar Items

Using TreeGrid default toolbar items we can perform below operations.

- **Add**- To add new task.
- **Edit**-To edit a selected task.
- **Delete**- To delete a selected task.
- **Cancel**- To cancel the edited changes in a task.
- **Update**- To save the edited changes in a task.

Copyright © 2001 - 2020 Syncfusion Inc.

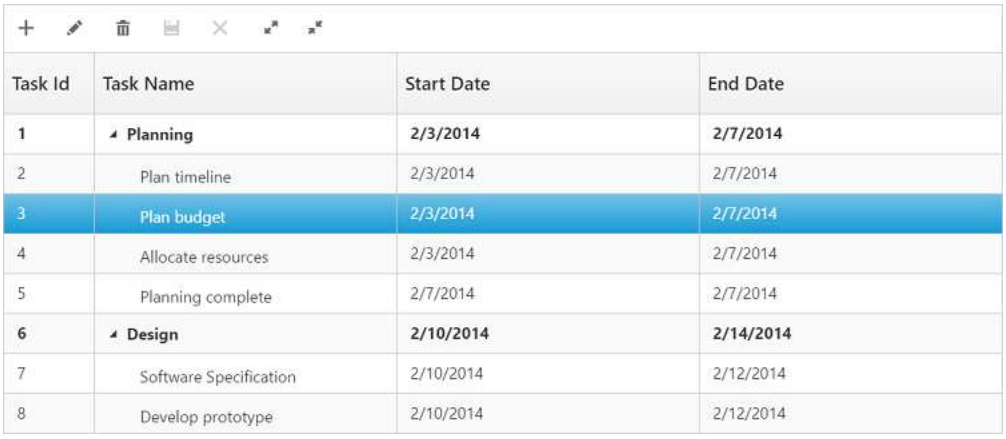
- **ExpandAll**- To expand all the TreeGrid rows.
- **CollapseAll**- To collapse all the TreeGrid rows.
- **PdfExport**- To export TreeGrid in PDF format.
- **ExcelExport**- To export TreeGrid in Excel format.

We can enable TreeGrid toolbar by using below code example:

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.ToolbarItems(new List<TreeGridToolBarItems>()
{
TreeGridToolBarItems.Add,
TreeGridToolBarItems.Edit,
TreeGridToolBarItems.Delete,
TreeGridToolBarItems.Update,
TreeGridToolBarItems.Cancel,
TreeGridToolBarItems.ExpandAll,
TreeGridToolBarItems.CollapseAll,
TreeGridToolBarItems.ExcelExport,
TreeGridToolBarItems.PdfExport
});
})
)
```

The following screenshot displays the toolbar option in TreeGrid control.



Task Id	Task Name	Start Date	End Date
1	Planning	2/3/2014	2/7/2014
2	Plan timeline	2/3/2014	2/7/2014
3	Plan budget	2/3/2014	2/7/2014
4	Allocate resources	2/3/2014	2/7/2014
5	Planning complete	2/7/2014	2/7/2014
6	Design	2/10/2014	2/14/2014
7	Software Specification	2/10/2014	2/12/2014
8	Develop prototype	2/10/2014	2/12/2014

Note: To perform add,edit,delete,cancel,update using Toolbar items we need to enable add/edit/delete using EditSettings.

Custom Toolbar Items

CustomToolbarItems allows us to insert custom icons and custom template in TreeGrid toolbar. By using below properties we can customize TreeGrid toolbar as per our requirement.

- **Text**- To insert the custom icons in toolbar using CSS class name selector.

Copyright © 2001 - 2020 Syncfusion Inc.

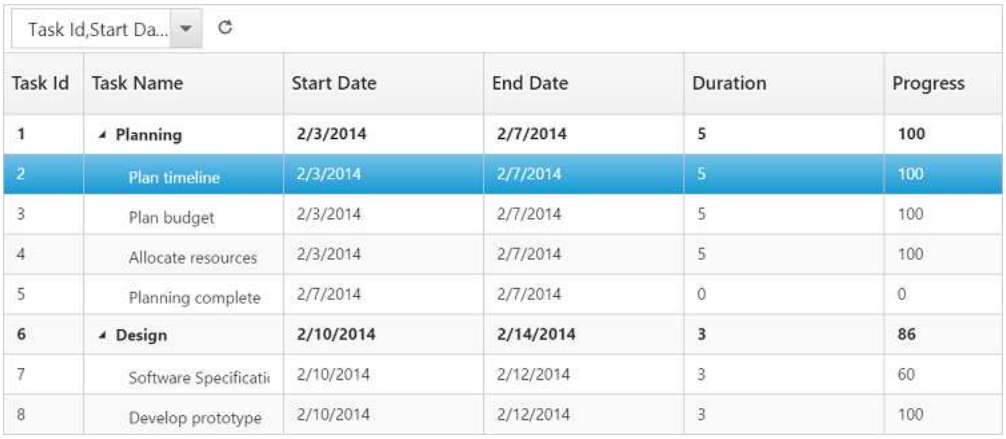
- **TemplateID**-To insert the custom icons in toolbar using script templates. Using this property we can bind HTML elements and other EJ controls to TreeGrid toolbar.
- **TooltipText**-Displays tooltip text for the custom icons.

To insert EJ Controls in TreeGrid toolbar we need to initiate the control in Create client side event.In ToolbarClick client side event we can bind actions to the custom toolbar items.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ToolbarSettings(tool =>
{
tool.ShowToolbar(true);
tool.CustomToolbarItems(ct =>
{
ct.TemplateID("#ColumnVisibility").TooltipText("Column
Visibility").Add();
ct.Text("Reset").TooltipText("Reset").Add();
});
})
.ClientSideEvents(cs =>
{
cs.Create("create");
cs.ToolbarClick("toolbarClick");
})
)
<script id="ColumnVisibility" type="text/x-jsrender">
<input id="dropdownContainer" />
</script>
<script type="text/javascript">
function toolbarClick(args) {
if (args.itemName == "Reset") {
//we can bind the custom actions here
}
}
//Here we can append custom EJ controls
function create(args) {
$("#dropdownContainer").ejDropDownList({});
}
</script>
<style type="text/css" class="cssStyles">
#TreeGridContainer_ColumnVisibility {
padding-top: 2px;
padding-bottom: 0px;
}
.Reset:before {
content: "\e677";
}
</style>
```

Copyright © 2001 - 2020 Syncfusion Inc.



Click here to view the demo sample for custom toolbar item

Sorting

The TreeGrid control for JavaScript has built-in support for Sorting one or more columns.

Sorting Columns

TreeGrid allows the items to be sorted in ascending or descending order based on the selected column by enabling the AllowSorting option in TreeGrid control. The following code example shows you how to enable Sorting in TreeGrid control.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.AllowSorting(true)
)
@(Html.EJ().ScriptManager())
```

Multicolumn sorting

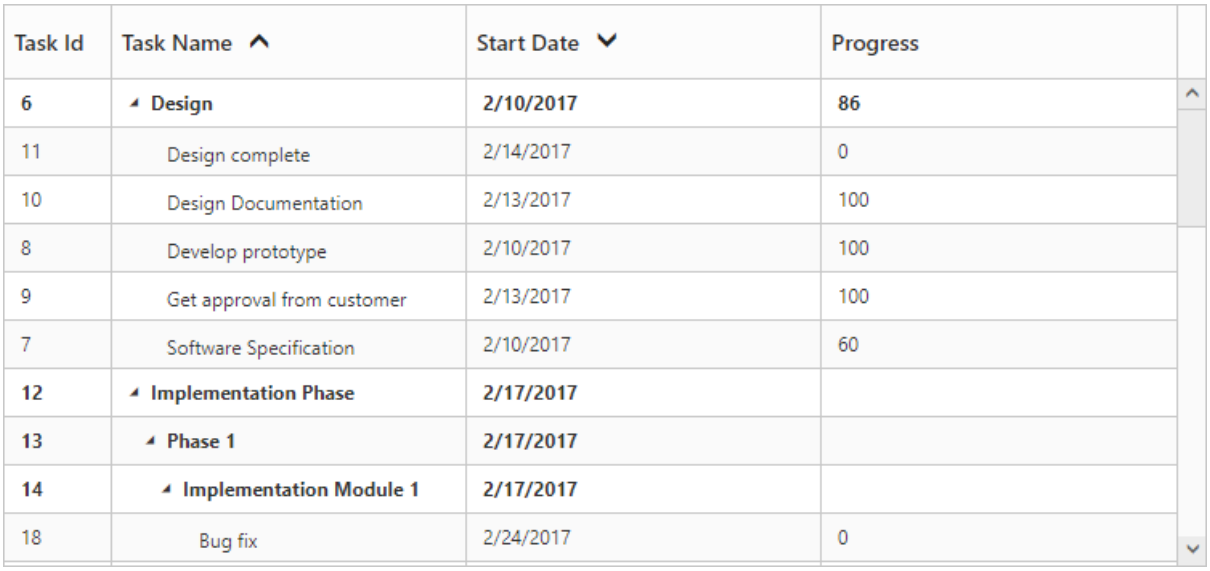
Gantt allows you to sort multiple columns by clicking the desired column headers while holding the **CTRL** key with AllowMultiSorting as true . The following code example shows you how to enable multicolumn sorting in Gantt control.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.AllowSorting(true)
.AllowMultiSorting(true)
)
@(Html.EJ().ScriptManager())
```

The following screenshot shows the output of Multicolumn sorting in TreeGrid control.

Copyright © 2001 - 2020 Syncfusion Inc.



Task Id	Task Name	Start Date	Progress
6	Design	2/10/2017	86
11	Design complete	2/14/2017	0
10	Design Documentation	2/13/2017	100
8	Develop prototype	2/10/2017	100
9	Get approval from customer	2/13/2017	100
7	Software Specification	2/10/2017	60
12	Implementation Phase	2/17/2017	
13	Phase 1	2/17/2017	
14	Implementation Module 1	2/17/2017	
18	Bug fix	2/24/2017	0

Disable sorting for specific column

It is possible to disable sorting for a specific column by setting AllowSorting as false in the column definition.

The below code snippet demonstrates this.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.AllowSorting(true)
.Columns(co =>
{
//..
co.Field("taskName").HeaderText("Task Name").AllowSorting(false).Add();
})
)
@(Html.EJ().ScriptManager())
```

Sort column at initial load

In TreeGrid, It is possible to render the control with sorted columns, this can be achieve by using SortSettings property. We can add columns which are sorted initially in SortedColumns collection. SortedColumns collection was defined with Field and Direction properties.

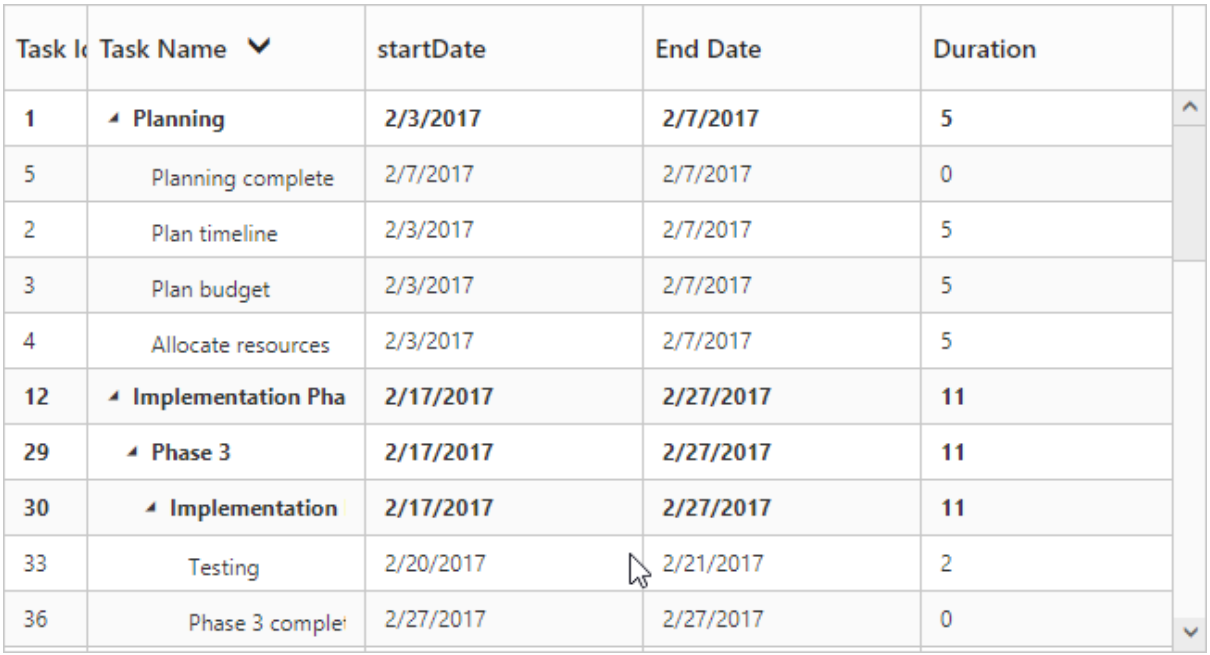
The following code shows how to add sorted column in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//...
.AllowSorting(true)
.SortSettings(ss =>
{
ss.SortedColumns(cs =>
{
cs.Field("taskName").Direction(TreeGridSortOrder.Descending).Add();
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
)
@(Html.EJ().ScriptManager())
```



Task Id	Task Name	startDate	End Date	Duration
1	Planning	2/3/2017	2/7/2017	5
5	Planning complete	2/7/2017	2/7/2017	0
2	Plan timeline	2/3/2017	2/7/2017	5
3	Plan budget	2/3/2017	2/7/2017	5
4	Allocate resources	2/3/2017	2/7/2017	5
12	Implementation Pha	2/17/2017	2/27/2017	11
29	Phase 3	2/17/2017	2/27/2017	11
30	Implementation	2/17/2017	2/27/2017	11
33	Testing	2/20/2017	2/21/2017	2
36	Phase 3 comple	2/27/2017	2/27/2017	0

The above screenshot shows TreeGrid rendered with descending order of **Task Name** column.

Stacked Headers

The stacked headers helps you to group the logical columns in treegrid. It can be shown by setting `ShowStackedHeader` as `true` and by defining `StackedHeaderRows`.

Adding Stacked header columns

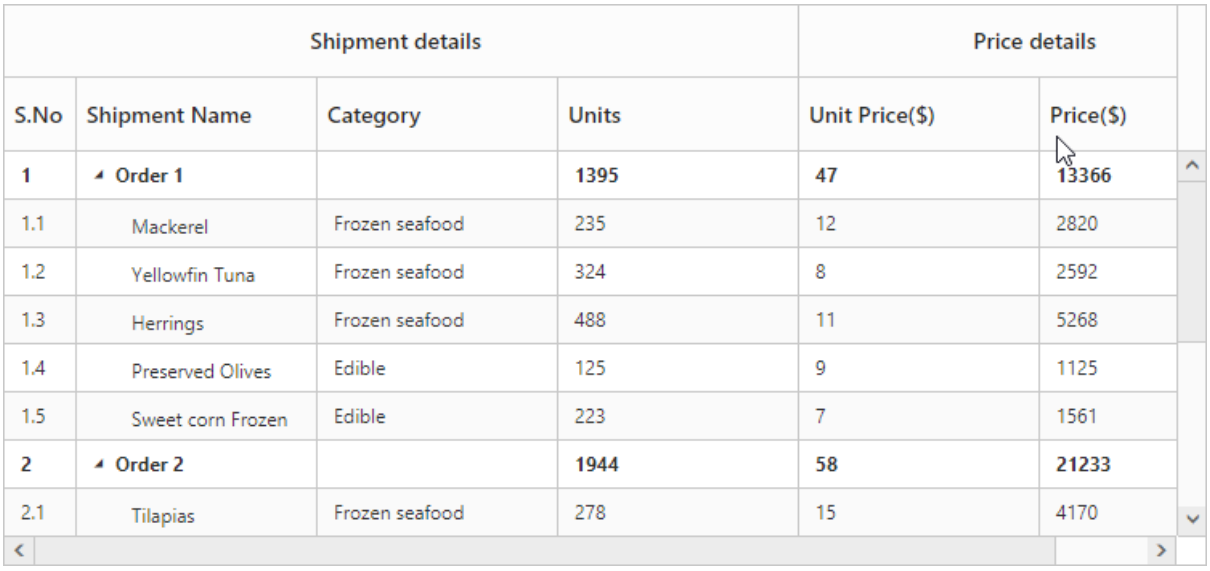
To stack columns in stacked header, you need to define `Column` property in `StackedHeaderColumns` with field names of visible columns.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//
.Columns(co =>
{
co.Field("ID").HeaderText("S.No").Width(45).Add();
co.Field("Name").HeaderText("Shipment Name").Add();
co.Field("Category").HeaderText("Category").Add();
co.Field("Units").HeaderText("Units").Add();
co.Field("UnitPrice").HeaderText("Unit Price($)").Add();
co.Field("Price").HeaderText("Price($)").Add();
}
)
.ShowStackedHeader(true)
.StackedHeaderRows(row => {
row.StackedHeaderColumns(stack =>
{
stack.HeaderText("Shipment Details").Column(col =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Add("ID");
col.Add("Name");
col.Add("Category");
col.Add("Units");
}).Add();
stack.HeaderText("Price Details").Column(col =>
{
col.Add("UnitPrice");
col.Add("Price");
}).Add();
}).Add();
})
)
```



Shipment details				Price details	
S.No	Shipment Name	Category	Units	Unit Price($)	Price($)
1	Order 1		1395	47	13366
1.1	Mackerel	Frozen seafood	235	12	2820
1.2	Yellowfin Tuna	Frozen seafood	324	8	2592
1.3	Herrings	Frozen seafood	488	11	5268
1.4	Preserved Olives	Edible	125	9	1125
1.5	Sweet corn Frozen	Edible	223	7	1561
2	Order 2		1944	58	21233
2.1	Tilapias	Frozen seafood	278	15	4170

Stacked header column customization

we can customize the stacked header cells with more options as described below.

CSS Class

You can provide external CSS styles to the stacked header with the help of CssClass property.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//
.ShowStackedHeader(true)
.StackedHeaderRows(row => {
row.StackedHeaderColumns(stack =>
{
stack.HeaderText("Shipment Details").Column(col =>
{
col.Add("ID");
col.Add("Name");
col.Add("Category");
col.Add("Units");
}).CssClass("grouphead").Add();
stack.HeaderText("Price Details").Column(col =>
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
col.Add("UnitPrice");
col.Add("Price");
}).Add();
}).Add();
})
)
<style>
.grouphead {
background-color: #ffb3b3;
}
</style>
```

Text Align

There is an option to align the stacked header text inside the header cell using TextAlign property as follows.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//
.ShowStackedHeader(true)
.StackedHeaderRows(row => {
row.StackedHeaderColumns(stack =>
{
stack.TextAlign(TextAlign.Right).HeaderText("Shipment
Details").Column(col =>
{
col.Add("ID");
col.Add("Name");
col.Add("Category");
col.Add("Units");
}).Add();
stack.TextAlign(TextAlign.Left).HeaderText("Price Details").Column(col =>
{
col.Add("UnitPrice");
col.Add("Price");
}).Add();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}).Add();
})
)
```

Shipment details		Price details	
S.No	Shipment Name	Unit Price($)	Price($)
1	Order 1	47	13366
1.1	Mackerel	12	2820
1.2	Yellowfin Tuna	8	2592
1.3	Herrings	11	5268
1.4	Preserved Olives	9	1125
1.5	Sweet corn Frozen	7	1561
2	Order 2	58	21233
2.1	Tilapias	15	4170
2.2	White Shrimp	7	3920

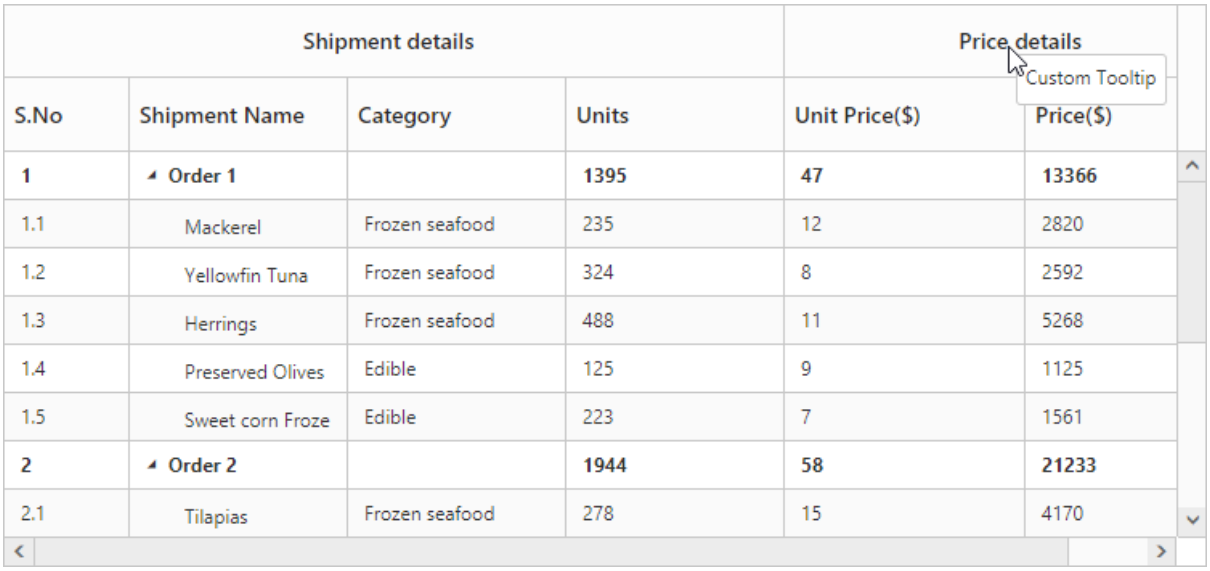
Tooltip

We can have the customized tooltip for the stacked header text with the help of ToolTip property. JsRender template script id can be assigned to this property to get tooltip.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
//
.ShowGridCellTooltip(true)
.ShowStackedHeader(true)
.StackedHeaderRows(row => {
row.StackedHeaderColumns(stack =>
{
stack.HeaderText("Shipment Details").Column(col =>
{
col.Add("ID");
col.Add("Name");
col.Add("Category");
col.Add("Units");
}).Add();
stack.HeaderText("Price Details").Column(col =>
{
col.Add("UnitPrice");
col.Add("Price");
}).Tooltip("#tooltip").Add();
}).Add();
})
)
<script id="tooltip" type="text/x-jsrender">
<div>Custom Tooltip</div>
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.



Note:

To enable stacked header tooltip we need to set ShowGridCellTooltip as true.

Click here to view the demo sample for stacked header.

Context Menu

The **Context menu** in TreeGrid control is used to manipulate (add, edit and delete) the TreeGrid rows. In TreeGrid, context menu can be enabled with ContextMenuSettings property. The ContextMenuSettings property contains two inner properties ShowContextMenu and ContextMenuItems.

The ShowContextMenu property is used to **enable or disable** the context menu, default value for this property is false.

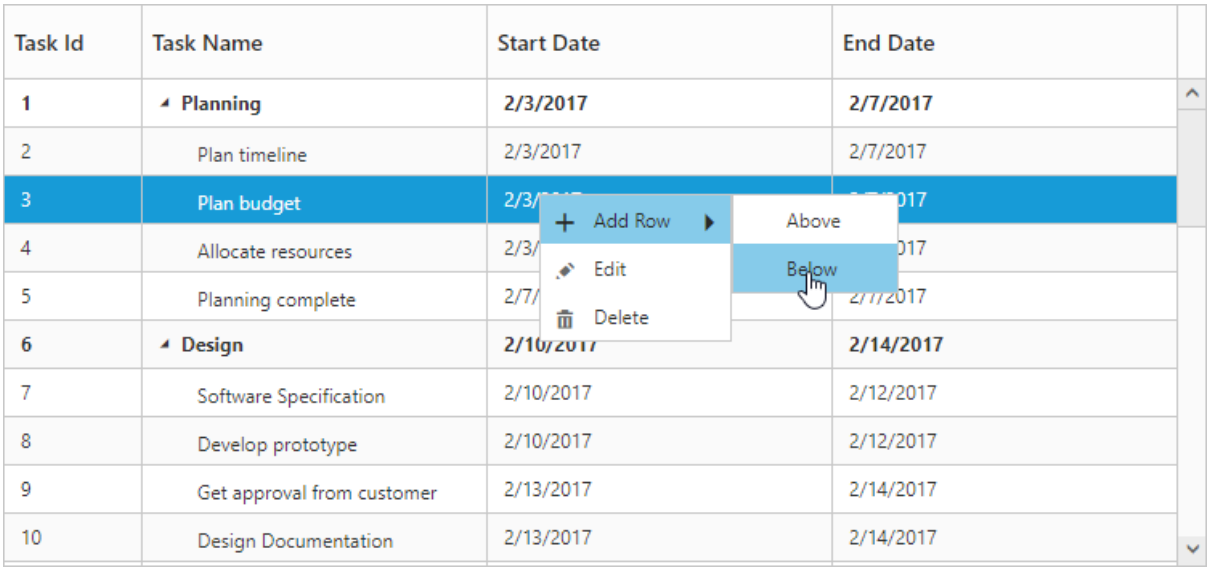
The ContextMenuItems property is used to add the menu items to context menu, this property renders Add and Delete by default when the menu items are not provided.

ASPX-CS

```
@(Html.EJ().TreeGrid("treegrid1")
.EditSettings(edit=>
{
edit.AllowEditing(true);
edit.EditMode(TreeGridEditMode.RowEditing);
})
.ContextMenuSettings(context =>
{
context.ShowContextMenu(true);
context.ContextMenuItems(new List<TreeGridContextMenuItems>(){
TreeGridContextMenuItems.Add,
TreeGridContextMenuItems.Edit,
TreeGridContextMenuItems.Delete
});
})
)
@(Html.EJ().ScriptManager())
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot displays the Context menu in TreeGrid control.



ContextMenu Customization

The Context menu can be customized by adding a new custom menu item to it. In TreeGrid, context menu can be customized using the ContextMenuOpen client-side event. This event is triggered when the context menu is rendered with mouse right click action. The following properties are available in the event.

- headerText: Display text for menu item.
- iconPath: Image location for menu item.
- eventHandler: Client-side event for menu item click.

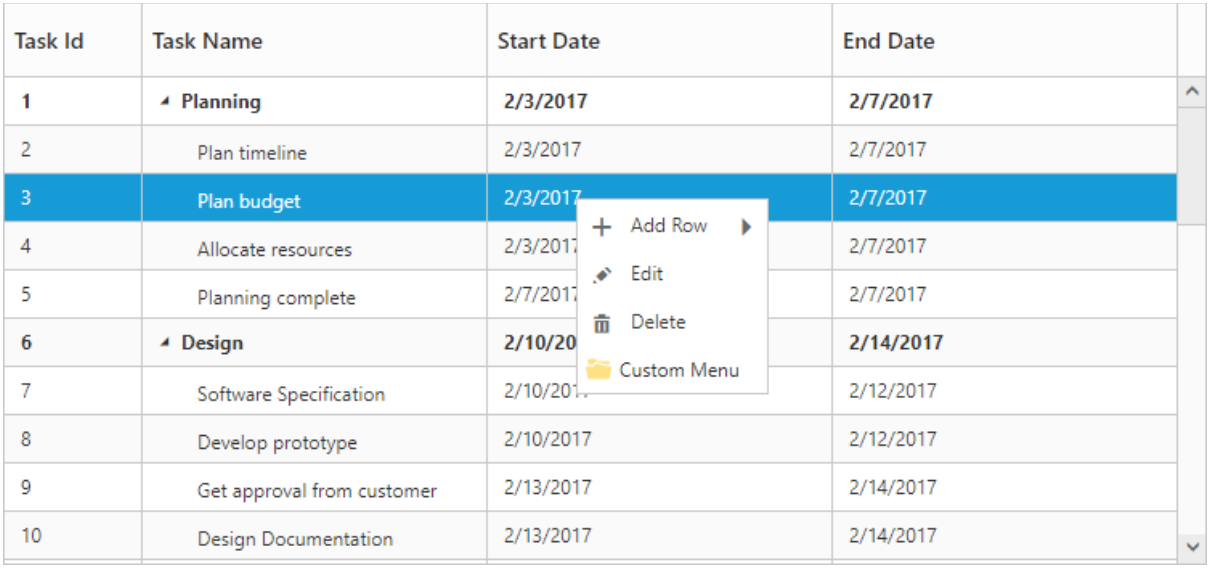
ASPX-CS

```
@(Html.EJ().TreeGrid("treegrid1")
.ContextMenuSettings(context =>
{
context.ShowContextMenu(true);
})
.ClientSideEvents(eve=>
{
eve.ContextMenuOpen("contextMenuOpen");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function contextMenuOpen(args) {
args.contextMenuItems.push({
headerText: "Custom Menu",
iconPath: "url(../content/images/treegrid/Folder.png)",
eventHandler: customMenuClick,
});
}
function customMenuClick(args) {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//Bind actions for custom menu here
}
</script>
```

The following screenshot displays the customization of Context menu in TreeGrid control.



Header Context Menu

Header context menu can be enabled by setting ShowContextMenu as true. The default value of the ShowContextMenu property is false.

Following options are shown in header context menu.

- **Column Chooser** - Display all the column names; you can enable or disable a column by select or deselect the respective column name in the column chooser menu. This option is default option of header context menu.
- **Sort Ascending & Sort Descending** - Used to sort the items in the column. These menu options will be displayed only when you enable the AllowSorting property. To perform multilevel sorting, the AllowMultiSorting property should be enabled.
- **Freeze, Unfreeze & Freeze Preceding Columns** - Used to freeze or unfreeze the columns. These set of menu options will be displayed in all the columns when IsFrozen property is enabled in any of the columns. However you can control the visibility of these menu options in a particular column by enabling/disabling the AllowFreezing property of that specific column.

The below code snippet explains how to enable header context menu in TreeGrid

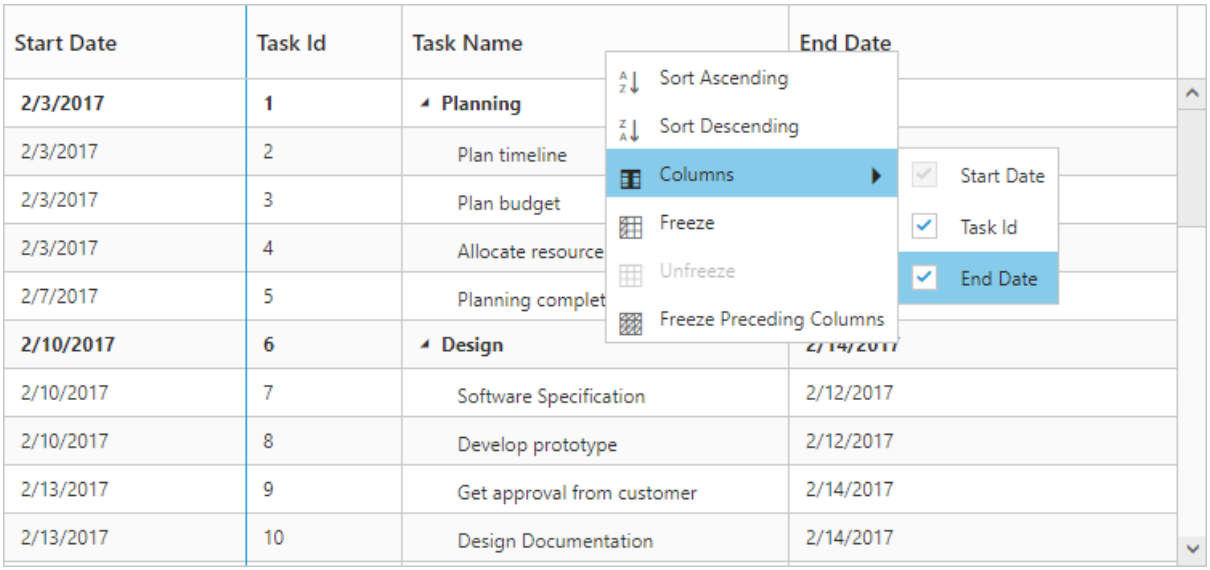
ASPX-CS

```
@(Html.EJ().TreeGrid("treegrid1")
.AllowSorting(true)
.Columns(co =>
{
co.Field("StartDate").HeaderText("Start
Date").IsFrozen(true).EditType(TreeGridEditingType.Datepicker).Add();
})
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.ContextMenuSettings(context =>
{
context.ShowContextMenu(true);
})
)
@(Html.EJ().ScriptManager())
```

The following screenshot displays the Header context menu in TreeGrid control.



Printing

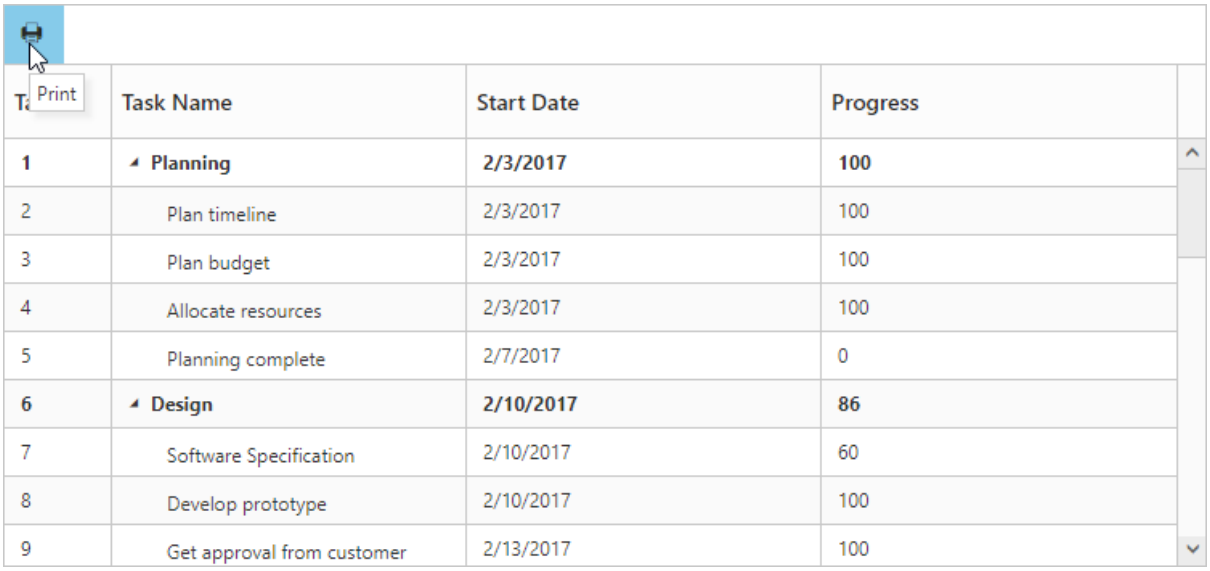
TreeGrid provides support to print the contents. To print the TreeGrid the print toolbar item must be added to ToolbarSettings.ToolbarItems property. The below code example shows how to enable print in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGrid")
.ToolbarSettings(tool => {
tool.ShowToolbar(true);
tool.ToolbarItems(new List<TreeGridToolBarItems>(){
TreeGridToolBarItems.Print
});
})
)
```

The below screen shot shows TreeGrid with printing enabled.

Copyright © 2001 - 2020 Syncfusion Inc.



The print preview window will be opened by clicking on this toolbar icon.

Print Mode

It is possible to set the printMode in PageSettings property, to give printing preference, as to print current page alone or all the pages in case of paging enabled in TreeGrid. The following code example explains this.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGrid")
.AllowPaging(true)
.PageSettings(pg=>pg.PrintMode(TreeGridPrintMode.CurrentPage))
.ToolbarSettings(tool => {
tool.ShowToolbar(true);
tool.ToolbarItems(new List<TreeGridToolBarItems>(){
TreeGridToolBarItems.Print
});
})
)
```

In this case only the visible records in the current page will be send to printing.

BeforePrint Event

BeforePrint event will be triggered once after printing initiated in TreeGrid. This event contains the treegrid element which is going to be printing. The following code explains this.

JS

```
@(Html.EJ().TreeGrid("TreeGrid")
.ClientSideEvents(cl => {
cl.BeforePrint("beforePrint");
})
.ToolbarSettings(tool => {
tool.ShowToolbar(true);
tool.ToolbarItems(new List < TreeGridToolBarItems > () {
TreeGridToolBarItems.Print
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
})
)
<script>
function beforePrint(args) {
//will be triggered before printing the TreeGrid
}
</script>
```

Click here to view the online demo sample Printing.

Appearance and Styling

The look and feel of the TreeGrid control can be customized by applying themes.

The following are the available themes in TreeGrid control.

1. Flat Azure
2. Flat Azure Dark
3. Flat Lime
4. Flat Lime Dark
5. Flat Saffron
6. Flat Saffron Dark
7. Gradient Azure
8. Gradient Azure Dark
9. Gradient Lime
10. Gradient Lime Dark
11. Gradient Saffron
12. Gradient Saffron Dark
13. Bootstrap
14. High Contrast 01
15. High Contrast 02
16. Material
17. Office-365

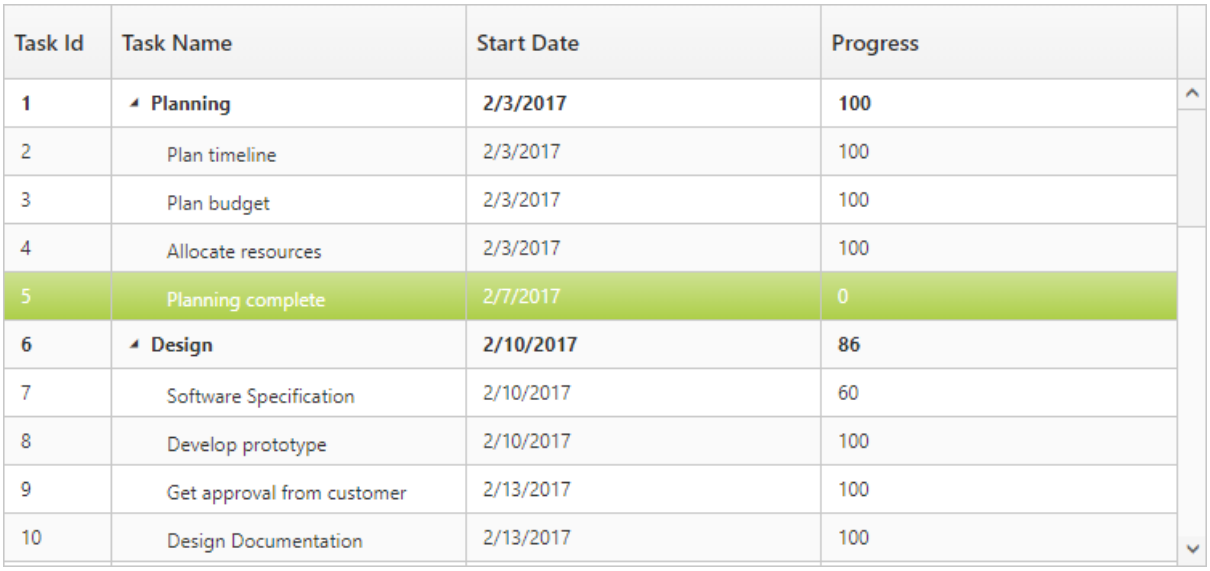
You can apply the theme (Gradient lime) to the TreeGrid control by using the style sheet from the online link as follows.

ASPX-CS

```
<!DOCTYPE html>
<html xmlns="http://www.w3.org/1999/xhtml">
<head>
<title>Getting Started with TreeGrid Control for JavaScript</title>
<!-- style sheet for default theme(gradient lime) -->
<link href=" http://cdn.syncfusion.com/{{ site.releaseversion
}}/js/web/flat-azure/ej.web.all.min.css" rel="stylesheet">
</html>
```

The following screenshot shows the TreeGrid control with Gradient-lime theme.

Copyright © 2001 - 2020 Syncfusion Inc.



Task Id	Task Name	Start Date	Progress
1	Planning	2/3/2017	100
2	Plan timeline	2/3/2017	100
3	Plan budget	2/3/2017	100
4	Allocate resources	2/3/2017	100
5	Planning complete	2/7/2017	0
6	Design	2/10/2017	86
7	Software Specification	2/10/2017	60

9	Get approval from customer	2/13/2017	100
10	Design Documentation	2/13/2017	100

Configuring CSS class

In TreeGrid CssClass property is used to apply different custom styles to multiple TreeGrid controls available in the webpage.

The following code example shows how to apply different background color for each TreeGrid control's toolbar element.

ASPX-CS

```
<style>
.c-class1.e-treegrid .e-toolbar {
background-color: rgba(169, 45, 45, 0.31);
}
.c-class2.e-treegrid .e-toolbar {
background-color: rgba(0, 128, 0, 0.2);
}
</style>
@(Html.EJ().TreeGrid("TreeGridContainer")
.CssClass("c-class1")
)
@(Html.EJ().TreeGrid("TreeGridContainer1")
.CssClass("c-class2")
)
@(Html.EJ().ScriptManager())
```

The below screenshot shows the output of above code example.

Copyright © 2001 - 2020 Syncfusion Inc.

Customize rows and cells

In TreeGrid, while rendering rows `RowDataBound` event will be triggered for rows. Similarly `QueryCellInfo` event will be triggered for every cells. Using these events we can customize the TreeGrid rows and cells at initial load.

The below code example shows how to customize the rows and cells in TreeGrid.

ASPX-CS

```
@(Html.EJ().TreeGrid("TreeGridContainer")
.ClientSideEvents(eve=>
{
eve.QueryCellInfo("queryCellInfo");
```

```
eve.RowDataBound("rowDataBound");
})
)
@(Html.EJ().ScriptManager())
<script type="text/javascript">
function queryCellInfo(args) {
if (args.column.mappingName == "progress") {
if (args.data.item["progress"] < 75)
$(args.cellElement).css("background-color", "rgba(255, 0, 0, 0.12)");
else
$(args.cellElement).css("background-color", "rgba(86, 226, 86, 0.25)");
}
}
function rowDataBound(args) {
if (args.data.item["taskID"] == 5)
$(args.rowElement).css("background-color", "rgba(251, 255, 0, 0.24)");
}
</script>
```

The below screenshot shows the output of above code example.

Task Id	Task Name	startDate	End Date	Progress
1	Planning	2/3/2017	2/7/2017	100
2	Plan timeline	2/3/2017	2/7/2017	60
3	Plan budget	2/3/2017	2/7/2017	40
4	Allocate resources	2/3/2017	2/7/2017	70
5	Planning complete	2/7/2017	2/7/2017	40
6	Design	2/10/2017	2/14/2017	86
7	Software Specificati	2/10/2017	2/12/2017	60
8	Develop prototype	2/10/2017	2/12/2017	100

10	Design Documentat	2/13/2017	2/14/2017	75

Keyboard navigation

TreeGrid control supports the following keyboard shortcuts for performing various actions and keyboard navigation can be enabled/disabled by AllowKeyboardNavigation property

Home : To select the first row.

End : To select the last row.

F2 : For editing the focused cell of the selected row.

Enter : To save the edited cell.

Delete : To delete the selected row.

Copyright © 2001 - 2020 Syncfusion Inc.

Ctrl + Down Arrow : To expand all the parent row.

Ctrl + Up Arrow : To collapse all the parent row.

Left Arrow : To collapse the selected parent row.

Right Arrow : To expand the selected parent row.

Click here to view the online demo sample for Keyboard Navigation.

How to

Rendering the TreeGrid control using TreeGridProperties in server-side

The TreeGridProperties helps to render the TreeGrid control in server-side.

The following code example explains how to render the TreeGrid control in server-side.

RAZOR

```
@(Html.EJ().TreeGrid("TreeGridControl", ViewBag.TreeGridModel))
```

C#

```
namespace TreeGrid_MVC.Controllers
{
public class TreegridController : Controller
{
public ActionResult TreeGrid()
{
TreeGridProperties treegrid = new TreeGridProperties();
List<TreeGridColumn> colList = new List<TreeGridColumn>();
colList.Add(new TreeGridColumn() { Field = "TaskId", HeaderText = "ID",
Width = 45 });
colList.Add(new TreeGridColumn() { Field = "TaskName", HeaderText = "Task
Name" });
colList.Add(new TreeGridColumn() { Field = "StartDate", HeaderText =
"Start Date" });
colList.Add(new TreeGridColumn() { Field = "EndDate", HeaderText = "End
Date" });
colList.Add(new TreeGridColumn() { Field = "Progress", HeaderText =
"Progress" });
treegrid.TreeColumnIndex = 1;
treegrid.Columns = colList;
treegrid.ChildMapping = "Children";
treegrid.SizeSettings.Width = "750px";
treegrid.SizeSettings.Height = "350px";
treegrid.DataSource = GetDefaultData();
ViewBag.TreeGridModel = treegrid;
return View();
}
}
}
```

The below screenshot shows the output of above code example.

TreeView

Overview

The EJ MVC TreeView component provides all the functionalities that is available in EJ TreeView, since it is a server side wrapper of EJ TreeView widget. It represents hierarchical data in a tree-like structure and allows to edit, drag n drop, selection with checkboxes and more. TreeView can be generated from the specified item list, list of objects or using OData services.

Key features

- Data population
- Node manipulations
- Drag and drop
- Template
- Checkbox
- Accessibility
- Appearance and styling

Getting started

This section explains briefly about how to create a TreeView in ASP.NET MVC platform.

Create your first TreeView in MVC

Create a MVC Project and add necessary assemblies, CSS and scripts with the help of the given MVC-Getting Started documentation. After creating this project, you can create a TreeView in following ways.

TreeView using Helper element

You can create a tree using “Items” API of TreeView control. Here there is no necessary to use a data source for rendering TreeView.

In the view page, add TreeView helper as shown below. It will render the TreeView with specified items.

RAZOR

```
@Html.EJ().TreeView("tree").Items(items =>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
items.Add().Text("Item 1").Children(child =>
{
child.Add().Text("Item 1.1").Children(child1 =>
{
child1.Add().Text("Item 1.1.1");
});
});
items.Add().Text("Item 2").Children(child =>
{
child.Add().Text("Item 2.1");
child.Add().Text("Item 2.2");
});
items.Add().Text("Item 3").Children(child =>
{
child.Add().Text("Item 3.1");
});
})
```

TreeView using Data Binding

Another way of creating TreeView is binding with the data source, you can bind local data source to create a TreeView.

The beforeLoad event will be triggered before loading nodes into TreeView.

Render TreeView with local data source.

In the model page, specify the TreeView node properties as shown below.

C#

```
public class LoadData
{
public int Id { get; set; }
public int Parent { get; set; }
public string Text { get; set; }
}
```

In the controller page, create a data list which contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
load.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1" });
load.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 2" });
load.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 3" });
load.Add(new LoadData { Id = 4, Parent = 1, Text = "Item 1.1" });
load.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.2" });
load.Add(new LoadData { Id = 6, Parent = 3, Text = "Item 3.1" });
ViewBag.datasource = load;
return View();
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

Above data can be directly assigned to DataSource property and mapping data fields with respect to the mapper field in order to form TreeView.

RAZOR

```
@(Html.EJ().TreeView("tree")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
)
```

Create Instance for TreeView

You can create an instance for existing TreeView in following ways. Once a reference has been established, you can use the API's of TreeView to control its behavior.

JAVASCRIPT

```
<script type="text/javascript">
//Specify this after your TreeView creation
//create instance for TreeView
var treeObj = $("#treeView").ejTreeView('instance');
//or
var treeObj1 = $("#treeView").data("ejTreeView");
</script>
```

Note: To configure the API settings after TreeView creation, please refer API configuration, Invoking Methods.

TreeView events

EJ MVC TreeView supports all the events which is available in EJ TreeView. Refer the following code example to specify an event using HTML helper of EJ MVC TreeView.

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.ClientSideEvents(events =>
events.NodeExpand("onNodeExpanded")
.NodeCollapse("onNodeCollapsed")
.NodeSelect("onNodeSelected")
)
)
<script type="text/javascript">
function onNodeCollapsed(args) {
//Handle the node collapse event
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
function onNodeExpanded(args) {
//Handle the node expand event
}
function onNodeSelected(args) {
//Handle the node select event
}
</script>
```

Populate Data

TreeView can be populated with local or remote data source using a property DataSource, which is the member of "**TreeViewFields**" property.

In TreeView, you should use "**TreeViewFields**" property to go with data source. It specifies the mapping fields for the data source to receive the data, query to process the data and field mappers to map the data members.

Fields

Below table list outs the field members with description.

Properties	**Description**
DataSource	The data source contains the list of data for generating the TreeView list. Also contains properties to load data from remote data source.
Query	It specifies the query to retrieve the data from the online server.
TableName	It specifies the name of the table from which data to be processed from given data source.
Id	It specifies the ID of the node.
ParentId	It specifies the parent id of the node
Text	It specifies the text content of the node.
HasChild	It specifies the node has child (which is the nested or inner level of nodes). Also itâ€™s used in load on demand of tree data.
Expanded	It specifies the tree node to be in expanded state
Selected	It specifies the select node at initialize. [note: only one node get selected]
IsChecked	It specifies the node to be in checked state, if tree node represented with checkboxes.
ImageUrl	It defines the image location.
ImageAttribute	It defines the image attributes such as height, width, styles, etc.
SpriteCssClass	It defines the sprite CSS for the image tag.

Copyright © 2001 - 2020 Syncfusion Inc.

HtmlAttribute	It defines the HTML attributes such as class and styles for a node ("li" tag).
LinkAttribute	It defines the HTML attributes such as class and styles for a link tag, which is child of node.
Child	It used to specify the properties of child nodes in TreeView

Mapping all fields with data source

In the model page, specify the TreeView node properties as shown below.

C#

```
public class LoadData
{
public int Id { get; set; }
public int Parent { get; set; }
public string Text { get; set; }
public string SpriteImage { get; set; }
public string ImageURL { get; set; }
public bool HasChild { get; set; }
public bool Expanded { get; set; }
public bool Selected { get; set; }
public bool NodeChecked { get; set; }
public object NodeProperty { get; set; }
public object LinkProperty { get; set; }
public object ImageProperty { get; set; }
}
```

In the controller page, create a data list which contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> treeData = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
treeData.Add(new LoadData
{
Id = 1,
Parent = 0,
Text = "Item 1",
Expanded = true,
NodeProperty = new Dictionary<string, string>() {
{ "class", "text-blue" },
{ "value", "Item 1" }
}
});
treeData.Add(new LoadData
{
Id = 2,
Parent = 0,
Text = "Item 2",
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
LinkProperty = new Dictionary<string, string>() {
{ "class", "text-underline" },
{ "href", "http://www.syncfusion.com" },
{ "target", "_blank"}
}
});
treeData.Add(new LoadData
{
Id = 3,
Parent = 0,
Text = "Item 3",
Selected = true,
SpriteImage = "mailicon sprite-calendar"
});
treeData.Add(new LoadData
{
Id = 4,
Parent = 0,
Text = "Item 4",
NodeChecked = true,
ImageProperty = new Dictionary<string, string>() {
{ "width", "20px" },
{ "height", "20px" }
},
ImageURL = "http://cdn.syncfusion.com/13.3.0.7/js/web/flat-
azure/images/ajax-loader.gif"
});
treeData.Add(new LoadData
{
Id = 5,
Parent = 1,
Text = "Item 1.1"
});
treeData.Add(new LoadData
{
Id = 6,
Parent = 1,
Text = "Item 1.2"
});
treeData.Add(new LoadData
{
Id = 7,
Parent = 1,
Text = "Item 1.3"
});
treeData.Add(new LoadData
{
Id = 8,
Parent = 3,
Text = "Item 3.1"
});
treeData.Add(new LoadData
{
Id = 9,
Parent = 3,
Text = "Item 3.2"
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
treeData.Add(new LoadData
{
Id = 10,
Parent = 5,
Text = "Item 1.1.1"
});
ViewBag.datasource = treeData;
return View();
}
}
```

In the view page, add TreeView helper and map the properties defined to the corresponding fields in data source.

RAZOR

```
@using TreeView_Doc.Models
<div style="width: 250px">
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
.Expanded("Expanded")
.IsChecked("NodeChecked")
.Selected("Selected")
.SpriteCssClass("SpriteImage")
.ImageUrl("ImageURL")
.LinkAttribute("LinkProperty")
.HtmlAttribute("NodeProperty")
.ImageAttribute("ImageProperty")
)
.ShowCheckbox(true)
)
</div>
```

Note: If you want to display nodes in root level, exclude parent attribute or specify “0” in corresponding value.

Local data

TreeView can be rendered from a self-referential data by providing the two required fields “**id**”and “**parent**”.

In the controller page, create a data list which contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
load.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1" });
load.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 2" });
load.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 3" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
load.Add(new LoadData { Id = 4, Parent = 1, Text = "Item 1.1" });
load.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.2" });
load.Add(new LoadData { Id = 6, Parent = 3, Text = "Item 3.1" });
ViewBag.datasource = load;
return View();
}
}
```

Above data can be directly assigned to DataSource property and mapping data fields with respect to the mapper field in order to form TreeView.

RAZOR

```
@(Html.EJ().TreeView("tree")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
)
```

Nested Object Support

The nested object support is provided for the TreeView component. Please find the following data list which contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
load.Add(new LoadData { Id = 1, Parent = 0, Text = new InnerData {
nodeName = "Item 1" } });
load.Add(new LoadData { Id = 2, Parent = 0, Text = new InnerData {
nodeName = "Item 2" } });
load.Add(new LoadData { Id = 3, Parent = 0, Text = new InnerData {
nodeName = "Item 3" } });
load.Add(new LoadData { Id = 4, Parent = 1, Text = new InnerData {
nodeName = "Item 1.1" } });
load.Add(new LoadData { Id = 5, Parent = 1, Text = new InnerData {
nodeName = "Item 1.2" } });
load.Add(new LoadData { Id = 6, Parent = 3, Text = new InnerData {
nodeName = "Item 3.1" } });
ViewBag.datasource = load;
return View();
}
}
public class LoadData
{
public int Id { get; set; }
public int Parent { get; set; }
public InnerData Text { get; set; }
}
public class InnerData
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
public string nodeName { get; set; }
}
```

Above data can be directly assigned to DataSource property and mapping data fields with respect to the mapper field in order to form TreeView.

RAZOR

```
@(Html.EJ().TreeView("tree")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text.nodeName")
)
)
```

Remote Data

When using remote data binding, the adaptor of ej.DataManager plays vital role in processing queries to make them suitable to sends along with data request and also process the response data from the server.

The following steps explain how you can bind remote data to TreeView control.

- In the view page, add TreeView helper to configure TreeView.
- In the DataSource field assign remote data source. Here DataManager gets the remote web service and filters the data using Query API. The select property of ej.Query is used to retrieve the specified columns from the data source.
- Assign DataSource and Query property values to bind the remote data. Map the corresponding fields in TreeView control

OData

OData is a standardized protocol for creating and consuming data. You can bind OData service data to TreeView in two ways using DataSource API of “TreeView” control.

Using Datasource(DataSource) API

Create an object for DataSource class using OData service URL and then assign it to DataSource API of “TreeView”.

RAZOR

```
@{
DataSource treeData = new DataSource();
treeData.URL = "//js.syncfusion.com/demos/ejServices/Wcf/Northwind.svc/";
}
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource(treeData)
.Query("ej.Query().from('Categories').select('CategoryID,CategoryName').t
ake(3)")
.Id("CategoryID")
.Text("CategoryName")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Child(childField =>
childField.Datasource(treeData)
.TableName("Products")
.Id("ProductID")
.ParentId("CategoryID")
.Text("ProductName")
)
)
)
```

Using Datasource(Action<DataSourceBuilder>) API

Here directly, you can specify the OData service URL using Action<DataSourceBuilder>

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource(data =>
data.URL("//js.syncfusion.com/demos/ejServices/Wcf/Northwind.svc/")
)
.Query("ej.Query().from('Categories').select('CategoryID,CategoryName').t
ake(3)")
.Id("CategoryID")
.Text("CategoryName")
.Child(childField =>
childField.Datasource(data =>
data.URL("//js.syncfusion.com/demos/ejServices/Wcf/Northwind.svc/")
)
.TableName("Products")
.Id("ProductID")
.ParentId("CategoryID")
.Text("ProductName")
)
)
)
```

In above methods, you may also specify the **adaptor** as ODataAdaptor and it is optional to specify.

You can provide adaptor value either as string value (“ODataAdaptor”) or Enum type (AdaptorType.ODataAdaptor)

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource(data =>
data.URL("//js.syncfusion.com/demos/ejServices/Wcf/Northwind.svc/")
.Adaptor(AdaptorType.ODataAdaptor)
)
.Query("ej.Query().from('Categories').select('CategoryID,CategoryName').t
ake(3)")
.Id("CategoryID")
.Text("CategoryName")
.Child(childField =>
childField.Datasource(data =>
data.URL("//js.syncfusion.com/demos/ejServices/Wcf/Northwind.svc/")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Adaptor(AdaptorType.ODataAdaptor)
)
.TableName("Products")
.Id("ProductID")
.ParentId("CategoryID")
.Text("ProductName")
)
)
)
```

Note: You can use above code until OData service version 3. For OData Service version 4 End Point, we have created a separate adaptor ej.ODataV4Adaptor for data binding.

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource(data =>
data.URL("//js.syncfusion.com/demos/ejServices/Wcf/Northwind.svc/Categori
es")
.Adaptor(AdaptorType.ODataV4Adaptor)
)
.Query("ej.Query().from('Categories').select('CategoryID,CategoryName').t
ake(3)")
.Id("CategoryID")
.Text("CategoryName")
.Child(childField =>
childField.Datasource(data =>
data.URL("//js.syncfusion.com/demos/ejServices/Wcf/Northwind.svc/Products
")
.Adaptor(AdaptorType.ODataV4Adaptor)
)
.TableName("Products")
.Id("ProductID")
.ParentId("CategoryID")
.Text("ProductName")
)
)
)
```

Web API

Using ej.WebApiAdaptor, you can bind Web API service data to TreeView as shown in below code example.

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource(data =>
data.URL("http://mvc.syncfusion.com/OdataServices/treeView/TreeViewData/G
etAllData")
.Adaptor(AdaptorType.WebApiAdaptor)
.CrossDomain(true)
)
.Id("id")
.Text("name")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.ParentId("pid")
)
)
```

Other Restful web services

The Custom Adaptor concept of ej.DataManager allow you to customize or generate your own adaptor which is used to process query and result data.

http://helpjs.syncfusion.com/js/datamanager/data-adaptors#custom-adaptor

When using remote data binding, the adaptor of ej.DataManager plays vital role in processing queries to make them suitable to sends along with data request and also process the response data from the server.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
load.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1" });
load.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 2" });
load.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 3" });
load.Add(new LoadData { Id = 4, Parent = 1, Text = "Item 1.1" });
load.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.2" });
load.Add(new LoadData { Id = 6, Parent = 3, Text = "Item 3.1" });
ViewBag.datasource = load;
return View();
}
}
```

In the view page, add TreeView helper and specify the custom adaptor as shown below.

RAZOR

```
@(Html.EJ().TreeView("tree")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.ClientSideEvents(events =>
events.Create("onCreate")
)
)
<script type="text/javascript">
function onCreate() {
var treeObj = $("#tree").ejTreeView("instance");
var treeData = treeObj.model.fields.dataSource;
var customAdaptor = new ej.Adaptor().extend({
insert: function (dataManagerObj, data) {
return dataManagerObj.dataSource.json.push(data);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
},
processQuery: ej.JsonAdaptor.prototype.processQuery
});
var dataManager = new ej.DataManager(treeData);
dataManager.adaptor = new customAdaptor();
dataManager.insert({ Id: 7, Text: "CustomData", Parent: 0 });
treeObj.option("fields", { dataSource: dataManager });
}
</script>
```

Load on demand

Load on demand is a technique (Lazy load) that is used to reduce the bandwidth size of consuming huge data. You can load data on demand in TreeView by using "**LoadOnDemand**" property when you're going to use huge data.

For local data source, TreeView loads the first level nodes initially. While expand a parent node then TreeView loads it's their child nodes from the data source based on the parentId member. It reduces the time to render TreeView with huge data.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public class HomeController : Controller
{
List<loadOnDemand> data = new List<loadOnDemand>();
public ActionResult Index()
{
data.Add(new loadOnDemand { id = 1, name = "Local Disk(C:)", hasChild =
true });
data.Add(new loadOnDemand { id = 2, name = "Local Disk(D:)", hasChild =
true });
data.Add(new loadOnDemand { id = 3, name = "Local Disk(E:)", hasChild =
true });
data.Add(new loadOnDemand { id = 4, parentId = 1, name = "Folder 1",
hasChild = true });
data.Add(new loadOnDemand { id = 5, parentId = 1, name = "Folder 2" });
data.Add(new loadOnDemand { id = 6, parentId = 1, name = "Folder 3" });
data.Add(new loadOnDemand { id = 7, parentId = 2, name = "Folder 4" });
data.Add(new loadOnDemand { id = 8, parentId = 2, name = "Folder 5",
hasChild = true });
data.Add(new loadOnDemand { id = 9, parentId = 2, name = "Folder 6" });
data.Add(new loadOnDemand { id = 10, parentId = 3, name = "Folder 7" });
data.Add(new loadOnDemand { id = 11, parentId = 3, name = "Folder 8" });
data.Add(new loadOnDemand { id = 12, parentId = 3, name = "Folder 9",
hasChild = true });
data.Add(new loadOnDemand { id = 13, parentId = 4, name = "File 1" });
data.Add(new loadOnDemand { id = 14, parentId = 4, name = "File 2" });
data.Add(new loadOnDemand { id = 15, parentId = 4, name = "File 3" });
data.Add(new loadOnDemand { id = 16, parentId = 8, name = "File 4" });
data.Add(new loadOnDemand { id = 17, parentId = 8, name = "File 5" });
data.Add(new loadOnDemand { id = 18, parentId = 8, name = "File 6" });
data.Add(new loadOnDemand { id = 19, parentId = 12, name = "File 7" });
data.Add(new loadOnDemand { id = 20, parentId = 12, name = "File 8" });
data.Add(new loadOnDemand { id = 21, parentId = 12, name = "File 9" });
ViewBag.datasource = data;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
return View();
}
}
public class loadOnDemand
{
public int id { get; set; }
public int? parentId { get; set; }
public string name { get; set; }
public bool? hasChild { get; set; }
public bool? expanded { get; set; }
public bool? ischecked { get; set; }
public bool? selected { get; set; }
public string spriteCss { get; set; }
}
```

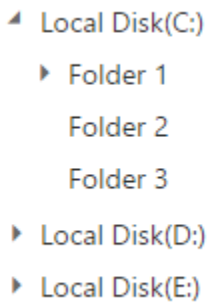
In the view page, add TreeView helper and map the properties defined in to the corresponding fields in “Datasource” with that enable load on demand option.

RAZOR

```
@Html.EJ().TreeView("tree").LoadOnDemand(true).TreeViewFields(field =>
field.Datasource((IEnumerable<loadOnDemand>)ViewBag.datasource)
.Id("id").Text("name").ParentId("parentId").HasChild("hasChild")
)
```

The following screenshot displays the load on demand for local data source in TreeView control.

While expanding the parent node



After expanding the parent node

For more details about load on demand for local data source, refer the sample here.

For remote data source, TreeView loads the first level nodes initially. While expand the node from TreeView, the data manager passes the query to the controller. Based on this query, you can filter the data from table and return to TreeView.

Copyright © 2001 - 2020 Syncfusion Inc.

Refer below code example to load data on demand from remote data source.

RAZOR

```
@(Html.EJ().TreeView("treeView").LoadOnDemand(true).TreeViewFields(field
=>
field.Datasource(data =>
data.URL("//js.syncfusion.com/demos/ejServices/Wcf/Northwind.svc/"))
.Query("ej.Query().from('Categories').select('CategoryID,CategoryName').t
ake(3)")
.Id("CategoryID").Text("CategoryName").HasChild("CategoryName").Child(chi
ld =>
child.Datasource(childData =>
childData.URL("//js.syncfusion.com/demos/ejServices/Wcf/Northwind.svc/"))
.TableName("Products").ParentId("CategoryID").Text("ProductName")))
)
```

For URL Adaptor, TreeView loads the first level nodes initially. While expand the node from TreeView, the data manager passes the Data Manager instance to the controller. The Data Manager instance contains the parent Id and filter options. Based on the Data Manager instance, you can filter the data from data source and return to TreeView.

In the controller page, create a data list that contains the details about tree nodes and create method to handle client side request.

C#

```
public class HomeController : Controller
{
public ActionResult Index()
{
return View();
}
public JsonResult Data(DataManager dataManagerObj)
{
List<loadOnDemand> treeData = GetTreeData();
IEnumerable<loadOnDemand> results;
if (dataManagerObj.Where == null)
{
//return the first level nodes
results = treeData.Where(item => item.parentId == null);
}
else
{
//return the nodes which has parentId as you request
results = treeData.Where(s => s.parentId ==
Convert.ToInt32(dataManagerObj.Where[0].value));
}
return Json(results, JsonRequestBehavior.AllowGet);
}
List<loadOnDemand> data = new List<loadOnDemand>();
public List<loadOnDemand> GetTreeData()
{
data.Add(new loadOnDemand { id = 1, name = "Local Disk(C:)", hasChild =
true });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
data.Add(new loadOnDemand { id = 2, name = "Local Disk(D:)", hasChild =
true });
data.Add(new loadOnDemand { id = 3, name = "Local Disk(E:)", hasChild =
true });
data.Add(new loadOnDemand { id = 4, parentId = 1, name = "Folder 1",
hasChild = true });
data.Add(new loadOnDemand { id = 5, parentId = 1, name = "Folder 2" });
data.Add(new loadOnDemand { id = 6, parentId = 1, name = "Folder 3" });
data.Add(new loadOnDemand { id = 7, parentId = 2, name = "Folder 4" });
data.Add(new loadOnDemand { id = 8, parentId = 2, name = "Folder 5",
hasChild = true });
data.Add(new loadOnDemand { id = 9, parentId = 2, name = "Folder 6" });
data.Add(new loadOnDemand { id = 10, parentId = 3, name = "Folder 7" });
data.Add(new loadOnDemand { id = 11, parentId = 3, name = "Folder 8" });
data.Add(new loadOnDemand { id = 12, parentId = 3, name = "Folder 9",
hasChild = true });
data.Add(new loadOnDemand { id = 13, parentId = 4, name = "File 1" });
data.Add(new loadOnDemand { id = 14, parentId = 4, name = "File 2" });
data.Add(new loadOnDemand { id = 15, parentId = 4, name = "File 3" });
data.Add(new loadOnDemand { id = 16, parentId = 8, name = "File 4" });
data.Add(new loadOnDemand { id = 17, parentId = 8, name = "File 5" });
data.Add(new loadOnDemand { id = 18, parentId = 8, name = "File 6" });
data.Add(new loadOnDemand { id = 19, parentId = 12, name = "File 7" });
data.Add(new loadOnDemand { id = 20, parentId = 12, name = "File 8" });
data.Add(new loadOnDemand { id = 21, parentId = 12, name = "File 9" });
return data;
}
}
public class loadOnDemand
{
public int id { get; set; }
public int? parentId { get; set; }
public string name { get; set; }
public bool? hasChild { get; set; }
public bool? expanded { get; set; }
public bool? ischecked { get; set; }
public bool? selected { get; set; }
public string spriteCss { get; set; }
}
```

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in “Datasource” with that enable load on demand option.

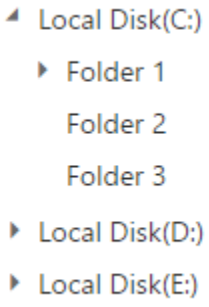
RAZOR

```
@Html.EJ().TreeView("tree").LoadOnDemand(true).TreeViewFields(field =>
field.Datasource(data =>
data.URL("/Home/Data").Adaptor(AdaptorType.UrlAdaptor)
).Text("name").Id("id").ParentId("parentId").HasChild("hasChild"))
```

The following screenshot displays the load on demand for URL adaptor in TreeView control.

Copyright © 2001 - 2020 Syncfusion Inc.

While expanding the parent node



After expanding the parent node

Tree Node

TreeView node is structured with expand/ collapse arrow, checkbox, image and text as shown in below.

Also TreeView node object holds the following properties.

Properties	Data Type	Description
checked	Boolean	Checked state of the node
count	Number	Number of child
expanded	Boolean	Expanded state of the node

Copyright © 2001 - 2020 Syncfusion Inc.

index	Number	Index of the node
level	Number	Level of the node
id	String	Node id
parentId	String	Parent id of the node
selected	Boolean	Selected state of the node

Get / Set Node Value

TreeView provides a set of options to configure all its properties by setting and getting values at initialization or dynamically.

To get the node value, you can use getNode method as shown in the below code example, in which on button click action the node value has retrieved.

Also you can get the text value of tree node by using getText method.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
load.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1" });
load.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 2" });
load.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 3" });
load.Add(new LoadData { Id = 4, Parent = 1, Text = "Item 1.1" });
load.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.2" });
load.Add(new LoadData { Id = 6, Parent = 3, Text = "Item 3.1" });
ViewBag.datasource = load;
return View();
}
}
```

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source.

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
)
```

In the view page, specify following method in script tag to get node value

Copyright © 2001 - 2020 Syncfusion Inc.

RAZOR

```
<script type="text/javascript">
//bind below onClick action to button to get node at button click or else
in any action
function onClick() {
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
//get node object using getNode method
var node = treeObj.getNode("1");
}
</script>
```

Note: Existing TreeView instance can be created by jQuery.data() and you can control the API's of TreeView behavior.

To edit the node text, you can use updateText method as shown below code example.

RAZOR

```
<script type="text/javascript">
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
//get node object using getNode method
var node = treeObj.getNode("2");
//sets text to existing node
treeObj.updateText(node.id, "updated Item");
</script>
```

Get Parent Node

To get current parent node of a particular node, you can use the getParent method as shown in below code example

RAZOR

```
<script type="text/javascript">
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
//get parent node using getParent method
var node = treeObj.getParent("4");
</script>
```

Get Node Index

To get node index, you can use the getNodeIndex as shown in below code example

You can use getNodeByIndex method to get TreeView node by using index position.

RAZOR

```
<script type="text/javascript">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
//get node object using getNode method
var node = treeObj.getNode("4");
//gets the index of node
treeObj.getNodeIndex(node.id);
</script>
```

Node Manipulations

You can perform following operation in tree nodes and the modified node values can be saved in database.

Add or Remove nodes

To add/remove nodes programmatically, use addNode and removeNode methods of the TreeView.

JAVASCRIPT

```
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
var newNode = { Id: 11, Text: "Item 2.1" };
//to add tree node
treeObj.addNode(newNode, "2");
//to remove node
treeObj.removeNode("4");
```

You can able to add a new node after or before some TreeView node by using insertAfter and insertBefore methods.

JAVASCRIPT

```
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
var newNode = { Id: 12, Text: "Item 2.2" };
//to add tree node after some element, which having id 2
treeObj.{{'**insertAfter(newNode, "2");**'| markdownify }}
var newNode = { Id: 13, Text: "Item 2.3" };
//to add tree node before some element, which having id 2
treeObj.{{'**insertBefore(newNode, "2");**'| markdownify }}
```

Move node

You can also achieve cut and paste operation by using moveNode method.

JAVASCRIPT

```
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
//to move tree node which having id 5, to child of node which having id
2.
treeObj.moveNode("5", "2");
```

Expand or Collapse node

Tree nodes can be expanded or collapsed by clicking the expand/collapse icon of the node or in code behind by using the following methods.

Methods	Description
expandNode	Expands the node with specified id
collapseNode	Collapse the node with specified id
expandAll	Expands all the node
collapseAll	Collapse all the node

Also you can get all the expanded nodes index in tree by using getExpandedNodesIndex method, which returns the array of expanded node indices.

Prevent multiple node expand

You can able to prevent multiple expand of TreeView nodes by specifying enableMultipleExpand as false.

For example, if you want to allow only one node to be expanded in TreeView at a time. Refer the below code block for more details.

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.EnableMultipleExpand(false)
)
```

Get updated node collection

You can get the updated node values after manipulating or editing the node of TreeView using getTreeData method. It returns the JSON data represented as in tree with modified structure.

You can also get the updated data source for remote data binding after performing the operation like editing, selecting/unselecting, expanding/collapsing, checking/unchecking and removing node. You cannot get the updated data source when you perform operation like drag and drop, adding node for remote data binding.

The updated data source also contains custom attributes if you return these from server.

JAVASCRIPT

```
//create an instance from an existing TreeView.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
//to get TreeView data
treeObj.getTreeData();
```

Editing

You can directly edit the tree node's text in-place by double-click on the tree node or select the tree node and press F2 key. The editing works only if the allowEditing property is true in TreeView control. When editing is completed by focus out or "enter" key press, the modified node's text is saved automatically. The nodeEdit event will be triggered whenever edited the TreeView node.

Also beforeEdit event will be triggered before the TreeView node change into editing mode.

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.AllowEditing(true)
)
```

Selection

You can select a specific node by using selectedNode property or selectNode method. To get the selected status of a given TreeView node you have to use isSelected method.

The nodeClick event will be triggered whenever TreeView node is clicked. The beforeSelect event will be triggered before the TreeView node is selected.

The nodeSelect/nodeUnselect events will be triggered based on the TreeView node click operations.

JAVASCRIPT

```
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
//to select node
treeObj.selectNode(2);
```

Ensure Visibility

To get the visibility status of the given TreeView node, you can use isVisible method.

You can ensure the specified tree node is visible by using ensureVisible method, which expands tree nodes and scrolls the TreeView control as necessary.

Also you can use getVisibleNodes method to get currently visible nodes in TreeView.

RAZOR

```
<script type="text/javascript">
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
function onClick() {
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
//to ensure the visibility of node
treeObj.ensureVisible("4");
}
</script>
```

Checkboxes

TreeView consists of built-in checkbox option and it can be displayed to the left of the tree node by setting the **ShowCheckbox** property as true. It allows you to select more than one node at a time.

Indeterminate Checkboxes

TreeView supports tristate checkboxes in addition with standard two state checkboxes. By default Treeview has been enabled with tristate in checkboxes. You can enable 2-state checkboxes by using **AutoCheckParentNode** as false.

RAZOR

```
@*initialize and bind the TreeView with local data*@
@*shows each node with check boxes*@
@*enable 2-state check boxes*@
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.ShowCheckbox(true)
.AutoCheckParentNode(false)
)
```

Auto Checkable

By default checkbox state of child nodes depends up on parent node checkbox state and also parent node state gets updated based on child nodes state. You can turn off this option by setting **AutoCheck** as false to make independent parent and child nodes checkboxes.

RAZOR

```
@*initialize and bind the TreeView with local data*@
@*shows each node with check boxes*@
@*turns off auto check of parent and child nodes*@
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.ShowCheckbox(true)
.AutoCheck(false)
)
```

Copyright © 2001 - 2020 Syncfusion Inc.

Check or Uncheck Node

Tree node can be checked or unchecked using checkNode and uncheckNode methods while showCheckbox property is enabled in TreeView. Also you can get or set the checked nodes of TreeView using checkedNodes property, which indicates the checked nodes index collection as array. The nodeCheck and nodeUncheck event occurs based on checkbox state.

You can use isNodeChecked method to check the particular TreeView node is checked or unchecked. Also you can use checkAll method to check all the nodes in TreeView.

JAVASCRIPT

```
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
//to check node
treeObj.checkNode("2");
//to uncheck node
treeObj.uncheckNode("2");
```

Get Checked Nodes

To get checked nodes of TreeView, you can use getCheckedNodes method. It returns the collection of checked tree nodes. Also you can get currently checked nodes indexes in TreeView by using getCheckedNodesIndex method.

RAZOR

```
<script type="text/javascript">
function onClick() {
//create an instance from an existing TreeView.
// only after control creation you can get treeObj otherwise it throws
exception.
treeObj = $("#treeView").ejTreeView('instance');
//to get checked nodes
treeObj.getCheckedNodes();
}
</script>
```

Drag and Drop

To perform drag and drop operation in TreeView specify **AllowDragAndDrop** as true. It allows you to drag and drop node in all level of same TreeView.

The nodeDrag, nodeDragStart, nodeDragStop and

nodeDropped event occurs based on Treeview node drag and drop state.

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
.AllowDragAndDrop(true)
)
```

Note: TreeView provides much easier option to drop the dragged nodes at any levels by indicator lines with icons.

Position Indicators

TreeView provides much easier option to drop the dragged nodes at any levels by indicator lines with icons such as line, plus/ minus and restrict icons while dragging and dropping the nodes. It represents exact position where the node to be dropped as sibling or child.

Indicators	description
Plus icon	represents the dragged node to be added as child of targeted node
Minus with restrict icon	represents the dragged node not to be dropped at the hovered region
In between icon	represents the dragged node to be dropped in between the nodes as siblings

Restriction

You can restrict the dragged nodes to be dropped at siblings or children's level by using **AllowDropSibling** and **AllowDropChild** properties.

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.AllowDragAndDrop(true)
.AllowDropSibling(true)
.AllowDropChild(false)
)
```

Drag and drop between Trees

You can drag and drop tree nodes between two TreeView by setting **AllowDragAndDrop** as true along with **AllowDragAndDropAcrossControl** as true.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> tree1 = new List<LoadData>();
List<LoadData> tree2 = new List<LoadData>();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult TreeViewFeatures()
{
tree1.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1" });
tree1.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 2" });
tree1.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 3" });
tree1.Add(new LoadData { Id = 4, Parent = 0, Text = "Item 4" });
tree1.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.1" });
tree1.Add(new LoadData { Id = 6, Parent = 1, Text = "Item 1.2" });
tree1.Add(new LoadData { Id = 7, Parent = 1, Text = "Item 1.3" });
tree1.Add(new LoadData { Id = 8, Parent = 3, Text = "Item 3.1" });
tree1.Add(new LoadData { Id = 9, Parent = 3, Text = "Item 3.2" });
tree1.Add(new LoadData { Id = 10, Parent = 5, Text = "Item 1.1.1" });
ViewBag.datasource1 = tree1;
tree2.Add(new LoadData { Id = 11, Parent = 0, Text = "Item 5" });
tree2.Add(new LoadData { Id = 12, Parent = 0, Text = "Item 6" });
tree2.Add(new LoadData { Id = 13, Parent = 0, Text = "Item 7" });
tree2.Add(new LoadData { Id = 14, Parent = 0, Text = "Item 4" });
tree2.Add(new LoadData { Id = 15, Parent = 11, Text = "Item 5.1" });
tree2.Add(new LoadData { Id = 16, Parent = 11, Text = "Item 5.2" });
tree2.Add(new LoadData { Id = 17, Parent = 11, Text = "Item 5.3" });
tree2.Add(new LoadData { Id = 18, Parent = 13, Text = "Item 7.1" });
tree2.Add(new LoadData { Id = 19, Parent = 13, Text = "Item 7.2" });
tree2.Add(new LoadData { Id = 10, Parent = 15, Text = "Item 5.1.1" });
ViewBag.datasource2 = tree2;
return View();
}
}
```

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source and specify the drag and drop settings.

RAZOR

```
@(Html.EJ().TreeView("treeViewDrag")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource1)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.AllowDragAndDrop(true)
.AllowDropSibling(true)
.AllowDropChild(true)
.AllowDragAndDropAcrossControl(true)
)
<br />
<br />
@(Html.EJ().TreeView("treeViewDrop")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource2)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.AllowDragAndDrop(true)
.AllowDropSibling(true)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.AllowDropChild(true)
.AllowDragAndDropAcrossControl(true)
)
```

Auto node structuring

You may not need to have two TreeView to be in same structured node while drag and drop the nodes between them. But after the node has been dropped, it should get structure of the TreeView node in which dropped. By default TreeView auto structure the node whenever you drop a node from different tree.

RAZOR

```
@(Html.EJ().TreeView("treeViewDrag")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource1)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.AllowDragAndDrop(true)
.AllowDropSibling(true)
.AllowDropChild(true)
.AllowDragAndDropAcrossControl(true)
.ShowCheckbox(true)
)
<br />
<br />
@(Html.EJ().TreeView("treeViewDrop")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource2)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.AllowDragAndDrop(true)
.AllowDropSibling(true)
.AllowDropChild(true)
.AllowDragAndDropAcrossControl(true)
)
```

Note: Auto node structure only applicable for well-structured node object.

Multiple Selection

TreeView supports to select the multiple nodes by specifying allowMultiSelection as true. It allows you to select more than one nodes in TreeView.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
// GET: Custom
List<LoadData> tree1 = new List<LoadData>();
public ActionResult Index()
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
tree1.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1" });
tree1.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 2" });
tree1.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 3" });
tree1.Add(new LoadData { Id = 4, Parent = 0, Text = "Item 4" });
tree1.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.1" });
tree1.Add(new LoadData { Id = 6, Parent = 1, Text = "Item 1.2" });
tree1.Add(new LoadData { Id = 7, Parent = 1, Text = "Item 1.3" });
tree1.Add(new LoadData { Id = 8, Parent = 3, Text = "Item 3.1" });
tree1.Add(new LoadData { Id = 9, Parent = 3, Text = "Item 3.2" });
tree1.Add(new LoadData { Id = 10, Parent = 5, Text = "Item 1.1.1" });
ViewBag.datasource = tree1;
return View();
}
}
public class LoadData
{
public int Id { get; set; }
public int? Parent { get; set; }
public string Text { get; set; }
public bool? hasChild { get; set; }
public bool? expanded { get; set; }
public bool? ischecked { get; set; }
public bool? selected { get; set; }
public string spriteCss { get; set; }
}
```

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source and specify the **AllowMultiSelection** property.

RAZOR

```
@Html.EJ().TreeView("treeMultiSelect").TreeViewFields(fields =>
fields.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
).AllowMultiSelection(true)
```

Select Nodes

To select more than one nodes of TreeView, you can use selectedNodes property. It will select the TreeView nodes from the given indexes.

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source and we you can select the specific nodes in TreeView by using **selectedNodes** property.

RAZOR

```
@Html.EJ().TreeView("treeMultiSelect").TreeViewFields(fields =>
fields.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
).AllowMultiSelection(true)
```

Copyright © 2001 - 2020 Syncfusion Inc.

JS

```
$(function () {
// create instance for TreeView
var treeObj = $("#treeMultiSelect").data("ejTreeView");
treeObj.option("selectedNodes", [0, 5, 6]); //select the TreeView nodes
from the given indexes
});
```

Get Selected Nodes

To get the selected Nodes of TreeView, you can use getSelectedNodes method. It returns the collections of TreeView selected nodes.

You can use getSelectedNodesIndex method to get the index positions of currently selected nodes.

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source and we you can get selected nodes from TreeView by using **getSelectedNodes** method.

RAZOR

```
@Html.EJ().TreeView("treeMultiSelect").TreeViewFields(fields =>
fields.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
).AllowMultiSelection(true)
```

JS

```
$(function () {
// create instance for TreeView
var treeObj = $("#treeMultiSelect").data("ejTreeView");
treeObj.getSelectedNodes(); //returns the collections of TreeView
selected nodes
});
```

Drag and Drop Multiple Nodes

TreeView supports to drag and drop multiple nodes by specifying allowMultiSelection as true along with allowDragAndDrop as true. It allows you to drag and drop multiple nodes in TreeView.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> tree1 = new List<LoadData>();
List<LoadData> tree2 = new List<LoadData>();
public ActionResult Index()
{
tree1.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1" });
tree1.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 2" });
tree1.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 3" });
tree1.Add(new LoadData { Id = 4, Parent = 0, Text = "Item 4" });
tree1.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.1" });
tree1.Add(new LoadData { Id = 6, Parent = 1, Text = "Item 1.2" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
tree1.Add(new LoadData { Id = 7, Parent = 1, Text = "Item 1.3" });
tree1.Add(new LoadData { Id = 8, Parent = 3, Text = "Item 3.1" });
tree1.Add(new LoadData { Id = 9, Parent = 3, Text = "Item 3.2" });
tree1.Add(new LoadData { Id = 10, Parent = 5, Text = "Item 1.1.1" });
ViewBag.datasource1 = tree1;
tree2.Add(new LoadData { Id = 11, Parent = 0, Text = "Item 5" });
tree2.Add(new LoadData { Id = 12, Parent = 0, Text = "Item 6" });
tree2.Add(new LoadData { Id = 13, Parent = 0, Text = "Item 7" });
tree2.Add(new LoadData { Id = 14, Parent = 0, Text = "Item 4" });
tree2.Add(new LoadData { Id = 15, Parent = 11, Text = "Item 5.1" });
tree2.Add(new LoadData { Id = 16, Parent = 11, Text = "Item 5.2" });
tree2.Add(new LoadData { Id = 17, Parent = 11, Text = "Item 5.3" });
tree2.Add(new LoadData { Id = 18, Parent = 13, Text = "Item 7.1" });
tree2.Add(new LoadData { Id = 19, Parent = 13, Text = "Item 7.2" });
tree2.Add(new LoadData { Id = 10, Parent = 15, Text = "Item 5.1.1" });
ViewBag.datasource2 = tree2;
return View();
}
}
public class LoadData
{
public int Id { get; set; }
public int? Parent { get; set; }
public string Text { get; set; }
public bool? hasChild { get; set; }
public bool? expanded { get; set; }
public bool? ischecked { get; set; }
public bool? selected { get; set; }
public string spriteCss { get; set; }
}
```

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source and specify the multiple drag and drop settings.

RAZOR

```
@Html.EJ().TreeView("treeViewDrag").TreeViewFields(fields =>
fields.Datasource((IEnumerable<LoadData>)ViewBag.datasource1)
.Id("Id")
.ParentId("Parent")
.Text("Text")
).AllowMultiSelection(true).AllowDragAndDrop(true)
<br />
@Html.EJ().TreeView("treeViewDrop").TreeViewFields(fields =>
fields.Datasource((IEnumerable<LoadData>)ViewBag.datasource2)
.Id("Id")
.ParentId("Parent")
.Text("Text")
).AllowMultiSelection(true).AllowDragAndDrop(true)
```

Full Row Selection

The TreeView control provides the option to highlight a full row of tree view nodes. When **FullRowSelect** is **true**, a selection highlights the entire width of the tree view, display instead of the width of just the tree node text. It makes selection easier.

Copyright © 2001 - 2020 Syncfusion Inc.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
// GET: MultiSelection
List<loadOnDemand> fullRowData = new List<loadOnDemand>();
public ActionResult FullRowSelection()
{
fullRowData.Add(new loadOnDemand { id = 1, name = "Discover Music",
hasChild = true, expanded = true });
fullRowData.Add(new loadOnDemand { id = 2, parentId = 1, name = "Hot
Singles", selected = true });
fullRowData.Add(new loadOnDemand { id = 3, parentId = 1, name = "Rising
Artists" });
fullRowData.Add(new loadOnDemand { id = 4, parentId = 1, name = "Live
Music" });
fullRowData.Add(new loadOnDemand { id = 6, parentId = 1, name = "Best of
2013 So Far" });
fullRowData.Add(new loadOnDemand { id = 7, name = "Sales and Events",
hasChild = true, expanded = true });
fullRowData.Add(new loadOnDemand { id = 8, parentId = 7, name = "100
Albums - $5 Each" });
fullRowData.Add(new loadOnDemand { id = 9, parentId = 7, name = "Hip-Hop
and R&B Sale" });
fullRowData.Add(new loadOnDemand { id = 10, parentId = 7, name = "CD
Deals" });
fullRowData.Add(new loadOnDemand { id = 11, name = "Categories", hasChild
= true });
fullRowData.Add(new loadOnDemand { id = 12, parentId = 11, name = "Songs"
});
fullRowData.Add(new loadOnDemand { id = 13, parentId = 11, name =
"Bestselling Albums" });
fullRowData.Add(new loadOnDemand { id = 14, parentId = 11, name = "New
Releases" });
fullRowData.Add(new loadOnDemand { id = 15, parentId = 11, name =
"Bestselling Songs" });
fullRowData.Add(new loadOnDemand { id = 16, name = "MP3 Albums", hasChild
= true });
fullRowData.Add(new loadOnDemand { id = 17, parentId = 16, name = "Rock"
});
fullRowData.Add(new loadOnDemand { id = 18, parentId = 16, name =
"Gospel" });
fullRowData.Add(new loadOnDemand { id = 19, parentId = 16, name = "Latin
Music" });
fullRowData.Add(new loadOnDemand { id = 20, parentId = 16, name = "Jazz"
});
fullRowData.Add(new loadOnDemand { id = 21, name = "More in Music",
hasChild = true });
fullRowData.Add(new loadOnDemand { id = 22, parentId = 21, name = "Music
Trade-In" });
fullRowData.Add(new loadOnDemand { id = 23, parentId = 21, name = "Redeem
a Gift Card" });
fullRowData.Add(new loadOnDemand { id = 24, parentId = 21, name = "Band
T-Shirts" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
fullRowData.Add(new loadOnDemand { id = 25, parentId = 21, name = "Mobile
MVC" });
ViewBag.datasource = fullRowData;
return View();
}
}
public class loadOnDemand
{
public int id { get; set; }
public int? parentId { get; set; }
public string name { get; set; }
public bool? hasChild { get; set; }
public bool? expanded { get; set; }
public bool? ischecked { get; set; }
public bool? selected { get; set; }
public string spriteCss { get; set; }
}
```

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source and specify the **FullRowSelect** property.

RAZOR

```
@Html.EJ().TreeView("fullRowTree").TreeViewFields(field =>
field.Datasource((IEnumerable<loadOnDemand>)ViewBag.datasource)
.Id("id").ParentId("parentId").Text("name")
.HasChild("hasChild").Expanded("expanded")
).FullRowSelect(true)
```

For more details about full row selection in TreeView, refer the sample here.

Customization

You can customize the TreeView full row selection for template support by using **CssClass** property. Based on this custom class, you can customize the height of the highlighting TreeView node.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
// GET: MultiSelection
List<loadOnDemand> fullRowData = new List<loadOnDemand>();
public ActionResult FullRowSelection()
{
fullRowData.Add(new loadOnDemand { id = 1, name = "Browsers", className =
"browser", hasChild = true, expanded = true });
fullRowData.Add(new loadOnDemand { id = 2, parentId = 1, name = "Internet
Explorer", className = "internet-explorer-browser", selected = true });
fullRowData.Add(new loadOnDemand { id = 3, parentId = 1, name = "Chrome",
className = "chrome-browser" });
fullRowData.Add(new loadOnDemand { id = 4, parentId = 1, name =
"Firefox", className = "firefox-browser" });
fullRowData.Add(new loadOnDemand { id = 6, parentId = 1, name = "Bitty",
className = "bitty-browser" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
fullRowData.Add(new loadOnDemand { id = 7, parentId = 1, name = "Opera",
className = "opera-browser" });
ViewBag.datasource = fullRowData;
return View();
}
}
public class loadOnDemand
{
public int id { get; set; }
public int? parentId { get; set; }
public string name { get; set; }
public bool? hasChild { get; set; }
public bool? expanded { get; set; }
public bool? ischecked { get; set; }
public bool? selected { get; set; }
public string spriteCss { get; set; }
public string className { get; set; }
}
```

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source and specify the **CssClass** property.

RAZOR

```
@Html.EJ().TreeView("fullRowTree").TreeViewFields(field =>
field.Datasource((IEnumerable<loadOnDemand>)ViewBag.datasource)
.Id("id").ParentId("parentId").Text("name")
.HasChild("hasChild").Expanded("expanded")
).FullRowSelect(true).CssClass("custom").Template("#treeTemplate")
<script id="treeTemplate" type="text/x-jsrender">
{{"{"}}if !hasChild{{}}}}
<span class="con-image {{"{"}}>className{{}}}}"></span>
{{"{"}}/if{{}}}}
{{"{"}}>name{{}}}}
</script>
```

CSS

```
<style>
.custom .con-image {
background-image:
url("http://mvc.syncfusion.com/demos/web/images/toolbar/browserl.png");
background-repeat: no-repeat;
height: 32px;
width: 32px;
display: inline-block;
overflow: hidden;
background-repeat: no-repeat;
text-align: center;
vertical-align: middle;
}
.custom .e-li-active > .e-text-wrap .con-image {
background-image:
url("http://mvc.syncfusion.com/demos/web/images/toolbar/browserh.png");
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.custom .e-li-hover > .e-text-wrap .con-image, .e-fullrow-wrap .e-li-
focus > .e-text-wrap .con-image {
background-image:
url("http://mvc.syncfusion.com/demos/web/images/toolbar/browserl.png");
}
.custom .internet-explorer-browser {
background-position: -84px 0px;
}
.custom .chrome-browser {
background-position: -42px 0px;
}
.custom .firefox-browser {
background-position: 0px 0px;
}
.custom .bitty-browser {
background-position: -126px 0px;
}
.custom .opera-browser {
background-position: -168px 0px;
}
/*customize the height of highlighting TreeView node*/
.custom.e-fullrow-wrap .e-item ul .e-fullrow {
margin-top: -36px;
height: 36px;
}
</style>
```

Template Option

Tree nodes can be customized by using **Template** property. Treeview template option requires addition JS library called **JsRender**, which helps to create the structured way of tree nodes with simple codes and increased performance. To know more about JsRender - http://www.jsviews.com/ .

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> treeData = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
treeData.Add(new LoadData {
Id = 1,
Name = "UK",
ClassName = "uk-style",
HasChild = true,
Expanded = true
});
treeData.Add(new LoadData {
Id = 2,
PId = 1,
ImgId = "1",
Name = "Steven John",
City = "London",
Phone = "555-5665-2323"
});
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
treeData.Add(new LoadData {
Id = 3,
Name = "USA",
ClassName = "usa-style",
HasChild = true,
Expanded = true
});
treeData.Add(new LoadData {
Id = 5,
PId = 3,
ImgId = "3",
Name = "Andrew",
City = "Capital way",
Phone = "934-8374-2455"
});
treeData.Add(new LoadData {
Id = 4,
PId = 3,
ImgId = "2",
Name = "Angelica",
City = "Dayton",
Phone = "988-4243-0806"
});
ViewBag.datasource = treeData;
return View();
}
}
```

In the view page, specify template format and add TreeView helper.

RAZOR

```
<script id="treeTemplate" type="text/x-jsrender">
{{"{{"}}if HasChild{{}}}}
<div class={{"{{"}}>ClassName{{}}}}>{{"{{"}}>Name{{}}}}</div>
{{"{{"}}else{{}}}}
<div class="cont-list">
<img class="con-image"
src="http://mvc.syncfusion.com/demos/web/images/treeview/template-image-
{{"{{"}}>ImgId{{}}}}.png" />
<div class="cont-delete"></div>
<b>{{"{{"}}>Name{{}}}}</b><br />
<span>{{"{{"}}>City{{}}}}</span>
<br />
<span>{{"{{"}}>Phone{{}}}}</span>
</div>
<div class="treeFooter"></div>
{{"{{"}}/if{{}}}}
</script>
<div style="width: 250px">
@(Html.EJ().TreeView("treeview")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("PId")
.Text("Name")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.HasChild("HasChild")
.Expanded("Expanded")
)
.Template("#treeTemplate")
.ClientSideEvents(events =>
events.Create("onCreate")
)
)
</div>
<style class="cssStyles">
.e-treeview .e-node-hover, .e-treeview .e-active {
background: transparent;
border-color: transparent;
}
.e-treeview .e-node-hover {
opacity: 0.8;
}
.con-image {
float: left;
}
.cont-list {
background: none repeat scroll 0 0 white;
border: 1px solid #BBBCBB;
height: 85px;
width: 200px;
color: #5c5c5c;
line-height: 17px;
}
.cont-details {
margin-top: 12px;
font-size: 13px;
}
.uk-style {
background-color: #74A247 !important;
color: #FFFFFF !important;
}
.usa-style {
background-color: #12A99A !important;
color: #FFFFFF !important;
}
.cont-delete {
background-image:
url("http://mvc.syncfusion.com/demos/web/images/treeview/remove-
icon.png");
background-position: -6px -10px;
background-repeat: no-repeat;
float: right;
height: 16px;
width: 16px;
cursor: pointer;
}
.cont-list .treeFooter {
height: 5px;
width: 100%;
background-color: gray;
margin-top: 17px;
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</style>
<script>
function onCreate(args) {
var treeObj = $("#treeview").data("ejTreeView");
$("#treeview").find(".cont-delete").bind("click", function (e) {
e.preventDefault();
treeObj.removeNode($(e.target).parents("li").first());
});
}
</script>
```

Custom action in nodes

You can able to perform custom action in TreeView template node. You can able to perform node delete operation while clicking delete icon by using removeNode method TreeView as shown in below code example.

JAVASCRIPT

```
function onCreate(args) {
var treeObj = $("#treeview").data("ejTreeView");
$("#treeview").find(".cont-delete").bind("click", function (e) {
e.preventDefault();
treeObj.removeNode($(e.target).parents("li").first());
});
}
```

State Persistence

TreeView state can be persisted by using '**EnablePersistence**'. In which user intractable model values only has been persisted in order to maintain performance.

The model values of below are maintained through id basis of tree node.

- selected
- checked
- expanded/ collapsed state

Note: In "UL" "li" template state has been persisted by index.

TreeView stores its model in local storage / cookies of browser before page refreshes and reinitialized with their stored model after refresh.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> treeData = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
treeData.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1" });
treeData.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 2" });
treeData.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 3" });
treeData.Add(new LoadData { Id = 4, Parent = 0, Text = "Item 4" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
treeData.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.1" });
treeData.Add(new LoadData { Id = 6, Parent = 1, Text = "Item 1.2" });
treeData.Add(new LoadData { Id = 7, Parent = 1, Text = "Item 1.3" });
treeData.Add(new LoadData { Id = 8, Parent = 3, Text = "Item 3.1" });
treeData.Add(new LoadData { Id = 9, Parent = 3, Text = "Item 3.2" });
treeData.Add(new LoadData { Id = 10, Parent = 5, Text = "Item 1.1.1" });
ViewBag.datasource = treeData;
return View();
}
}
```

In the view page, add TreeView helper with following properties.

RAZOR

```
@(Html.EJ().TreeView("treeViewDrag")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.EnablePersistence(true)
)
```

Right to Left Align

TreeView supports right to left align and it can be applied by specifying **EnableRTL** as true.

RAZOR

```
@(Html.EJ().TreeView("treeViewDrag")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
)
.EnableRTL(true)
)
```

How To

Update the modified data from tree to database.

TreeView allows us to get the updated tree data after performing such operation like node editing, drag and drop, add and remove node. Using getTreeData method you can get the updated tree data.

Refer the following code block to know how to get updated data from TreeView.

In the controller page, create a data list that contains the details about tree nodes and specify the method to store modified data.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult TreeViewFeatures()
{
var storedData = System.Web.HttpContext.Current.Session ["modifiedData"];
if (storedData == null)
{
load.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1", Expanded =
true });
load.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 2" });
load.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 3" });
load.Add(new LoadData { Id = 4, Parent = 0, Text = "Item 4" });
load.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.1" });
load.Add(new LoadData { Id = 6, Parent = 1, Text = "Item 1.2" });
load.Add(new LoadData { Id = 7, Parent = 1, Text = "Item 1.3" });
load.Add(new LoadData { Id = 8, Parent = 3, Text = "Item 3.1" });
load.Add(new LoadData { Id = 9, Parent = 3, Text = "Item 3.2" });
load.Add(new LoadData { Id = 10, Parent = 5, Text = "Item 1.1.1" });
ViewBag.datasource = load;
}
else
ViewBag.datasource = storedData;
return View();
}
public ActionResult StoreData(List<LoadData> data)
{
System.Web.HttpContext.Current.Session ["modifiedData"] = data;
return View("TreeViewFeatures");
}
}
```

In the view page, add TreeView helper and specify the scripts for sending modified data through AJAX action with that also specify clear cache option.

RAZOR

```
@using TreeView_Doc.Models
<div style="width: 250px">
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
.Expanded("Expanded")
)
.ClientSideEvents(events =>
events.Create("onCreate")
)
)
@(Html.EJ().Button("move")
.Text("Move Node")
.Size(ButtonSize.Normal)
.ClientSideEvents(events =>
events.Click("moveNode")
)
)
@(Html.EJ().Button("clear")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Text("Clear Cache")
.Size(ButtonSize.Normal)
.ClientSideEvents(events =>
events.Click("clearCache")
)
)
</div>
<script type="text/javascript">
var treeObj;
function onCreate() {
treeObj = $("#treeView").data('ejTreeView');
}
function moveNode() {
treeObj.moveNode($('#4'), $('#1'), 11);
var updatedData = treeObj.getTreeData();
ajaxRequest(updatedData);
}
function ajaxRequest(updatedData) {
$.ajax({
url: "StoreData",
data: JSON.stringify({ data: updatedData }),
type: "POST",
contentType: "application/json",
dataType: "JSON"
});
}
function clearCache() {
treeObj.destroy();
ajaxRequest();
}
</script>
```

You can also get the updated data source for remote data binding after performing the operation like editing, selecting/unselecting, expanding/collapsing, checking/unchecking and removing node. You cannot get the updated data source when you perform operation like drag and drop, adding node for remote data binding.

The updated data source also contains custom attributes ("ContactTitle", "OrderID", "EmployeeID", "Freight") if you return these from server.

Refer the following code block to know more about how to get updated data with custom attributes from TreeView for remote data binding.

In the view page, add TreeView helper and specify the scripts for getting updated data source.

RAZOR

```
<button id="btn1"
onclick="getSelectedNodeObject()">GetSelectedNodeObject</button>
@Html.EJ().TreeView("tree1").TreeViewFields(s => s.Datasource(data =>
data.URL("//js.syncfusion.com/ejServices/Wcf/Northwind.svc/").CrossDomain
(true))
.Query("ej.Query().from('Orders').select('CustomerID,OrderID,EmployeeID,F
reight').take(3)").Id("CustomerID").Text("CustomerID")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.Child(c => c.Datasource(childData =>
childData.URL("//js.syncfusion.com/ejServices/Wcf/Northwind.svc/").CrossD
omain(true))
.Query("ej.Query().from('Customers').select('CustomerID,ContactTitle,Cont
actName,Country')").Id("Country").ParentId("CustomerID").Text("ContactNam
e")))
<script>
function getSelectedNodeObject() {
var treeObj = $("#tree1").data("ejTreeView");
var nodeId = treeObj.getSelectedNode().attr("id"); //get selected node id
if (nodeId != null) {
var node = treeObj.getTreeData(nodeId); //get the given node object
if (node[0].OrderID != null)
alert("The OrderID of node '" + node[0].CustomerID + "' is: '" +
node[0].OrderID + "'");
else
alert("The ContactTitle of node '" + node[0].ContactName + "' is: '" +
node[0].ContactTitle + "'");
} else
alert("Select any node");
}
</script>
```

TreeView context menu to process node operations.

TreeView control is availed with the context menu options that open on right-click, over the node. Other than the default menu items available, you can add the new node dynamically in TreeView and also delete the item, enable and disable the item in TreeView. It is achieved by adding the Context Menu option to the TreeView.

Menu Item

By default, the context menu options are provided with four items namely: Add New Item, Delete Item, Enable Item and Disable Item. When you want to customize and use your own custom menu items, then you can customize the TreeView with the desired collections.

The following code example illustrates how to configure the context menu elements for the TreeView and in the following example, you have to specify the menu type as ej.MenuType.ContextMenu and in the menuClick function, you can check the cases with add, delete, remove or enable item in TreeView.

And each functionality in the context menu option is done by specific methods. For example, you have added the new item in TreeView by using the addNode() method, delete the item using removeNode() method, disable the item using disableNode() method and enable the item enableNode() method respectively.

The following steps explain how you can enable the **ShowCheckbox** property for TreeView.

In the view page, add TreeView helper and specify context menu.

RAZOR

```
<div style="width: 250px">
@Html.EJ().TreeView("treeview").Items(items =>
{
items.Add().Text("Favorites").Expanded(true).Children(child =>
{
child.Add().Text("Desktop");
```

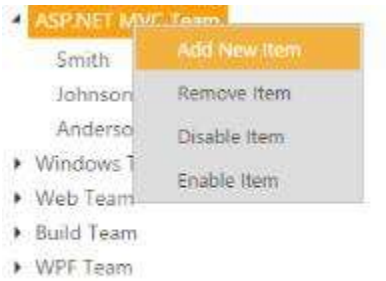
Copyright © 2001 - 2020 Syncfusion Inc.

```
child.Add().Text("Downloads");
child.Add().Text("Recent places");
});
items.Add().Text("Libraries").Expanded(true).Children(child =>
{
child.Add().Text("Documents").Children(child1 =>
{
child1.Add().Text("My Documents");
child1.Add().Text("Public Documents");
});
child.Add().Text("Pictures").Children(child1 =>
{
child1.Add().Text("My Pictures");
child1.Add().Text("Public Pictures");
});
child.Add().Text("Music").Children(child1 =>
{
child1.Add().Text("My Music");
child1.Add().Text("Public Music");
});
child.Add().Text("Subversion");
});
items.Add().Text("Computer").Children(child =>
{
child.Add().Text("Folder(C)");
child.Add().Text("Folder(D)");
child.Add().Text("Folder(E)");
});
})
</div>
<div>
@(Html.EJ().Menu("treeviewMenu")
.Items(items =>
{
items.Add().Text("Add New Item");
items.Add().Text("Remove Item");
items.Add().Text("Disable Item");
items.Add().Text("Enable Item");
})
.OpenOnClick(false)
.MenuType(MenuType.ContextMenu)
.ShowSubLevelArrows(true)
.ContextMenuTarget("#treeview")
.ClientSideEvents(events =>
events.Click("menuClick")
.BeforeOpen("beforeOpen")
)
)
</div>
<script type="text/javascript">
//Define the events for menu click in the script section as follows,
var tabIndex = 1, treeviewObj, selectedNode;
function beforeOpen(args) {
var treeviewObj = $("#treeview").data("ejTreeView");
if (!$(args.target).hasClass("e-text"))
args.cancel = true;
else {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
selectedNode = args.target;
treeviewObj.selectNode(selectedNode);
}
}
function menuClick(args) {
var treeviewObj = $("#treeview").data("ejTreeView");
if (args.events.text == "Add New Item") {
treeviewObj.addNode("Item" + tabIndex, selectedNode);
tabIndex++;
}
else if (args.events.text == "Remove Item") {
treeviewObj.removeNode(selectedNode);
}
else if (args.events.text == "Disable Item") {
treeviewObj.disableNode(selectedNode)
}
else if (args.events.text == "Enable Item") {
treeviewObj.enableNode(selectedNode)
}
}
</script>
```

The output for the context menu for TreeView control is as follows.



Sorted data using refresh method

TreeView allows you to refresh the entire tree data by using refresh method. Refer the below code block to know how to sort entire tree data using refresh method.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
load.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1", Expanded =
true });
load.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 3" });
load.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 2" });
load.Add(new LoadData { Id = 4, Parent = 0, Text = "Item 4" });
load.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.1" });
load.Add(new LoadData { Id = 6, Parent = 1, Text = "Item 1.2" });
load.Add(new LoadData { Id = 7, Parent = 1, Text = "Item 1.3" });
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
load.Add(new LoadData { Id = 8, Parent = 3, Text = "Item 3.1" });
load.Add(new LoadData { Id = 9, Parent = 3, Text = "Item 3.2" });
load.Add(new LoadData { Id = 10, Parent = 5, Text = "Item 1.1.1" });
ViewBag.datasource = load;
return View();
}
}
```

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source with that specify the scripts for sorting and refreshing tree data.

RAZOR

```
<div style="width: 250px">
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
.Expanded("Expanded")
)
)
@(Html.EJ().Button("move")
.Text("Sort Countries")
.Size(ButtonSize.Normal)
.ClientSideEvents(events =>
events.Click("sortCountries")
)
)
</div>
<script type="text/javascript">
function sortCountries() {
window.tree = $("#treeView").data("ejTreeView");
TreeNodeData = sortResults(tree.model.fields.dataSource, "Text", true);
tree.model.fields.dataSource = TreeNodeData;
tree.refresh();
}
//Sorting the tree data based on ascending order
function sortResults(data, fieldName, ascOrder) {
return data.sort(function (a, b) {
if (ascOrder) return (a[fieldName] > b[fieldName]);
else return (b[fieldName] > a[fieldName]);
});
}
</script>
```

Persist updated data after edit, add and remove node

TreeView allows us to persist the updated data after performing some tree operations like node add and delete. Refer the following code block to know how to persist updated tree data after refresh.

The nodeAdd, nodeCut, nodeDelete and nodePaste events occurs based on Treeview node manipulation. The beforeAdd,

Copyright © 2001 - 2020 Syncfusion Inc.

beforeCut, beforeDelete and beforePaste events are triggered before the TreeView component node manipulation.

In the controller page, create a data list that contains the details about tree nodes and specify the method to store modified data.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
var storedData = System.Web.HttpContext.Current.Session["modifiedData"];
if (storedData == null)
{
load.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1", Expanded =
true });
load.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 2" });
load.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 3" });
load.Add(new LoadData { Id = 4, Parent = 0, Text = "Item 4" });
load.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.1" });
load.Add(new LoadData { Id = 6, Parent = 1, Text = "Item 1.2" });
load.Add(new LoadData { Id = 7, Parent = 1, Text = "Item 1.3" });
load.Add(new LoadData { Id = 8, Parent = 3, Text = "Item 3.1" });
load.Add(new LoadData { Id = 9, Parent = 3, Text = "Item 3.2" });
load.Add(new LoadData { Id = 10, Parent = 5, Text = "Item 1.1.1" });
ViewBag.datasource = load;
}
else
ViewBag.datasource = storedData;
return View();
}
public ActionResult StoreData(List<LoadData> data)
{
System.Web.HttpContext.Current.Session["modifiedData"] = data;
return View("TreeViewFeatures");
}
}
```

In the view page, add TreeView helper and specify the scripts for sending modified data through AJAX action.

RAZOR

```
@using TreeView_Doc.Models
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
.Expanded("Expanded")
)
.ClientSideEvents(events =>
events.Create("onCreate")
.NodeAdd("updateData")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.NodeEdit("updateData")
.NodeDelete("updateData")
)
)
@(Html.EJ().Button("clear")
.Text("Clear Cache")
.Size(ButtonSize.Normal)
.ClientSideEvents(events =>
events.Click("clearCache")
)
)
@(Html.EJ().Button("add")
.Text("Add Node")
.Size(ButtonSize.Normal)
.ClientSideEvents(events =>
events.Click("addNode")
)
)
@(Html.EJ().Button("remove")
.Text("Remove Node")
.Size(ButtonSize.Normal)
.ClientSideEvents(events =>
events.Click("removeNode")
)
)
<script type="text/javascript">
var treeObj;
function onCreate() {
treeObj = $("#treeView").data('ejTreeView');
}
function updateData() {
var updatedData = treeObj.getTreeData();
ajaxRequest(updatedData);
}
function addNode() {
treeObj.addNode({ Id: 11, Text: "NewNode1" });
}
function removeNode() {
treeObj.removeNode();
}
function ajaxRequest(updatedData) {
$.ajax({
url: "StoreData",
data: JSON.stringify({ data: updatedData }),
type: "POST",
contentType: "application/json",
dataType: "JSON"
});
}
function clearCache() {
treeObj.destroy();
ajaxRequest();
}
</script>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Filtering nodes in TreeView

You can able to filter TreeView nodes based on node text. Refer the below code blocks to filter tree nodes based on the node text.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
load.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1", Expanded =
true });
load.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 3" });
load.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 2" });
load.Add(new LoadData { Id = 4, Parent = 0, Text = "Item 4" });
load.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.1" });
load.Add(new LoadData { Id = 6, Parent = 1, Text = "Item 1.2" });
load.Add(new LoadData { Id = 7, Parent = 1, Text = "Item 1.3" });
load.Add(new LoadData { Id = 8, Parent = 3, Text = "Item 3.1" });
load.Add(new LoadData { Id = 9, Parent = 3, Text = "Item 3.2" });
load.Add(new LoadData { Id = 10, Parent = 5, Text = "Item 1.1.1" });
ViewBag.datasource = load;
return View();
}
}
```

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source with that specify the script for filtering tree nodes.

RAZOR

```
<div style="margin: 20px; padding: 20px; height: 2000px;">
<div class="heading">
Treeview with Filtering Nodes
</div>
<div class="treeviewfilter">
<!-- TextBox Element -->
@(Html.EJ().MaskEdit("inputBox")
.Width("100%")
.InputMode(InputMode.Text)
.MaskFormat("")
.ClientSideEvents(events =>
events.Change("searchNodes")
)
)
<!-- TreeView Element -->
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
.Expanded("Expanded")
)
```

var treeObj = $("#treeView").data("ejTreeView");
var id = treeObj.getSelectedNode()[0].id;
treeObj.removeNode(treeObj.getSelectedNode());  // Two way binding when
remove node
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
};
// Delete from outside tree
$scope.delete = function (iconId) {
for (var i = $scope.dataList.length - 1; i > -1; i--) {
if ($scope.dataList[i].iconId === iconId)
$scope.dataList.splice(i, 1); // Delete parent node
}
for (var i = $scope.dataList.length - 1; i > -1; i--) {
if ($scope.dataList[i].parentId === iconId)
$scope.dataList.splice(i, 1); // Delete child nodes
}
};
});
</script>
```

Set tooltip for TreeView nodes

TreeView allows you to set tooltip option to TreeView nodes using fields.linkAttribute property of TreeView. Refer the below code block to know how to set tooltip for TreeView nodes.

In the model page, add a class and define the properties as shown below.

C#

```
namespace TreeView_Doc.Models
{
public class LoadData
{
public int Id { get; set; }
public int Parent { get; set; }
public string Text { get; set; }
public bool Expanded { get; set; }
public object LinkAttribute { get; set; }
}
public class LinkAttribute
{
public string Title { get; set; }
}
}
```

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
load.Add(new LoadData
{
Id = 1,
Parent = 0,
Text = "Item 1",
Expanded = true,
LinkAttribute = new LinkAttribute()
{
```

```
Title = "First Item"
}
});
load.Add(new LoadData
{
Id = 2,
Parent = 0,
Text = "Item 2",
LinkAttribute = new LinkAttribute()
{
Title = "Second Item"
}
});
load.Add(new LoadData
{
Id = 3,
Parent = 0,
Text = "Item 3"
});
load.Add(new LoadData
{
Id = 4,
Parent = 0,
Text = "Item 4"
});
load.Add(new LoadData
{
Id = 5,
Parent = 1,
Text = "Item 1.1"
});
load.Add(new LoadData
{
Id = 6,
Parent = 1,
Text = "Item 1.2"
});
load.Add(new LoadData
{
Id = 7,
Parent = 1,
Text = "Item 1.3"
});
load.Add(new LoadData
{
Id = 8,
Parent = 3,
Text = "Item 3.1"
});
load.Add(new LoadData
{
Id = 9,
Parent = 3,
Text = "Item 3.2"
});
load.Add(new LoadData
{
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
Id = 10,
Parent = 5,
Text = "Item 1.1.1"
});
ViewBag.datasource = load;
return View();
}
}
```

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source

RAZOR

```
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
.Expanded("Expanded")
.LinkAttribute("LinkAttribute")
)
)
```

Auto hide/show the expand/collapse icon of TreeView

You can able to display expand icon on mouse entering into TreeView and hide while leaving from the TreeView. Refer the below code block to know how to hide/ show the expand/collapse icons automatically based on mouse position.

In the controller page, create a data list that contains the details about tree nodes.

C#

```
public partial class TreeViewController : Controller
{
List<LoadData> load = new List<LoadData>();
public ActionResult TreeViewFeatures()
{
load.Add(new LoadData { Id = 1, Parent = 0, Text = "Item 1", Expanded =
true });
load.Add(new LoadData { Id = 2, Parent = 0, Text = "Item 3" });
load.Add(new LoadData { Id = 3, Parent = 0, Text = "Item 2" });
load.Add(new LoadData { Id = 4, Parent = 0, Text = "Item 4" });
load.Add(new LoadData { Id = 5, Parent = 1, Text = "Item 1.1" });
load.Add(new LoadData { Id = 6, Parent = 1, Text = "Item 1.2" });
load.Add(new LoadData { Id = 7, Parent = 1, Text = "Item 1.3" });
load.Add(new LoadData { Id = 8, Parent = 3, Text = "Item 3.1" });
load.Add(new LoadData { Id = 9, Parent = 3, Text = "Item 3.2" });
load.Add(new LoadData { Id = 10, Parent = 5, Text = "Item 1.1.1" });
ViewBag.datasource = load;
return View();
}
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source with that specify the scripts to hide and show the icons of tree nodes.

RAZOR

```
<div style="width: 150px">
<!-- TreeView Element -->
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
.Expanded("Expanded")
)
.ClientSideEvents(events =>
events.Create("onCreate")
)
)
</div>
<script type="text/javascript">
function onCreate(args) {
this.element.find(".e-item > div > .e-plus, .e-minus").css("visibility",
"hidden");
var treeObj = $("#treeView").data("ejTreeView");
$("#treeView").on("mouseenter", function () {
treeObj.element.find(".e-item > div > .e-plus, .e-
minus").css("visibility", "");
});
$("#treeView").on("mouseleave", function () {
treeObj.element.find(".e-item > div > .e-plus, .e-
minus").css("visibility", "hidden");
});
}
</script>
```

Customize the expand/collapse icons of TreeView

You can able to customize the TreeView expand and collapse icon by using “cssClass” property of TreeView. Refer the below code block to know how to customize the expand/collapse icons.

In the view page, add TreeView helper and map the properties defined in to the corresponding fields in data source with that specify the styles for customizing expand/ collapse icon of TreeView.

RAZOR

```
<div style="width: 150px">
<!-- TreeView Element -->
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<LoadData>)ViewBag.datasource)
.Id("Id")
.ParentId("Parent")
.Text("Text")
.Expanded("Expanded")
)
.CssClass("customize")
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
)
</div>
<style type="text/css">
.customize .e-icon {
width: 16px;
height: 16px;
background-repeat: no-repeat;
background-image:
url("http://jsplayground.syncfusion.com/13.3.0.7/themes/web/images/ui-
icons/ui-icons-default.png");
}
.customize .e-icon.e-plus:before, .customize .e-icon.e-minus:before {
content: "";
}
.customize .e-icon.e-plus {
background-position: -80px -46px;
}
.customize .e-icon.e-minus {
background-position: -132px -46px;
}
</style>
```

In form post, how to get all checked nodes details of TreeView in server end

You have to create a hidden element for storing custom details of checked nodes and add it to the form element. These details will be sent to server at the time of form submit.

Refer the following code block to know how to get checked nodes details in server end

In the view page, add TreeView helper and specify the scripts for adding checked node details in form element.

RAZOR

```
<div style="width: 250px">
<form action="\TreeView\CheckedNodes" method="post" id="myForm">
@Html.EJ().TreeView("tree").Items(items =>
{
items.Add().Text("Item 1").Children(child =>
{
child.Add().Text("Item 1.1").Children(child1 =>
{
child1.Add().Text("Item 1.1.1");
});
});
items.Add().Text("Item 2").Expanded(true).Children(child =>
{
child.Add().Text("Item 2.1");
child.Add().Text("Item 2.2");
});
items.Add().Text("Item 3").Children(child =>
{
child.Add().Text("Item 3.1");
});
}).ShowCheckbox(true)
<input type="submit" id="submit" value="GetCheckedNodes" />
</form>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</div>
<script>
$('#submit').click(function () {
tree = $("#tree").data("ejTreeView");
checkedNodes = tree.getCheckedNodes();
for (i = 0; i < checkedNodes.length ; i++) {
var checkedNode = checkedNodes[i];
var nodeData = tree.getNode(checkedNode);
var parentNode = tree.getParent(checkedNode);
if (parentNode.length > 0)
$('#myForm').append('<input type="hidden" name="checkedNodes" value="' +
parentNode[0].id + '/' + nodeData.id + '" />');
else
$('#myForm').append('<input type="hidden" name="checkedNodes" value=" No
Parent /' + nodeData.id + '" />');
}
});
</script>
```

In the controller page, configure following settings to get the checked node details in form submit.

C#

```
public partial class TreeViewController : Controller
{
public ActionResult TreeViewFeatures()
{
return View();
}
// on data all checkedNodes are received
public ActionResult CheckedNodes(List<string> checkedNodes)
{
ViewBag.CheckedNodes = checkedNodes;
return PartialView();
}
}
```

Using following partial view page, you can display the custom details of checked nodes.

RAZOR

```
<html>
<body>
<h3>Checked node ID</h3>
<ul>
@*using ViewBag, we can get the checked node details*@
@if (ViewBag.CheckedNodes != null)
{
foreach (var nodes in ViewBag.CheckedNodes)
{
<li>@nodes</li>
}
}
</ul>
</body>
</html>
```

Copyright © 2001 - 2020 Syncfusion Inc.

Populate data for TreeView using AJAX

TreeView provides AJAX action supports to populate the data for rendering TreeView nodes. Refer the following code blocks to achieve this behavior.

In the model page, specify the TreeView node properties as shown below.

C#

```
public class TreeViewData
{
public int id { get; set; }
public int parentId { get; set; }
public string name { get; set; }
public bool hasChild { get; set; }
public bool expanded { get; set; }
}
```

In the controller page, create a data list which contains the details about tree nodes and specify AJAX action handling method.

C#

```
public partial class TreeViewController : Controller
{
public ActionResult TreeViewFeatures()
{
return View();
}
List<TreeViewData> m_templateData;
public List<TreeViewData> TemplateData
{
get
{
if (m_templateData == null)
InitializeTemplateData();
return m_templateData;
}
}
private void InitializeTemplateData()
{
m_templateData = new List<TreeViewData>();
m_templateData.Add(new TreeViewData
{
id = 1,
parentId = 0,
name = "Local Disk(C:)",
hasChild = true
});
m_templateData.Add(new TreeViewData
{
id = 2,
parentId = 1,
name = "Folder 1"
});
m_templateData.Add(new TreeViewData
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
id = 3,
parentId = 1,
name = "Folder 2"
});
m_templateData.Add(new TreeViewData
{
id = 4,
parentId = 1,
name = "Folder 3",
hasChild = true
});
m_templateData.Add(new TreeViewData
{
id = 20,
parentId = 4,
name = "File 1"
});
m_templateData.Add(new TreeViewData
{
id = 21,
parentId = 4,
name = "File 2"
});
m_templateData.Add(new TreeViewData
{
id = 22,
parentId = 4,
name = "File 3"
});
m_templateData.Add(new TreeViewData
{
id = 5,
parentId = 0,
name = "Local Disk(D:)",
hasChild = true
});
m_templateData.Add(new TreeViewData
{
id = 6,
parentId = 5,
name = "Folder 4",
hasChild = true
});
m_templateData.Add(new TreeViewData
{
id = 7,
parentId = 6,
name = "File 4"
});
m_templateData.Add(new TreeViewData
{
id = 8,
parentId = 6,
name = "File 5"
});
}
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
public ActionResult GetAllData()
{
return Json(TemplateData, JsonRequestBehavior.AllowGet);
}
}
```

In the view page, add TreeView helper and map the properties defined to the corresponding fields in data source.

RAZOR

```
@using TreeView_Doc.Models
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource(data =>
data.URL(@Url.Content("GetAllData"))
)
.Id("id")
.ParentId("parentId")
.Text("name")
.HasChild("hasChild")
.Expanded("expanded")
)
)
```

Populate data for TreeView using XML data source

TreeView provides XML data binding support to populate the data for rendering TreeView nodes, so that values can be mapped to the TreeView fields from an existing XML data source as below.

RAZOR

```
@* In the View page, add TreeView helper and map the properties defined
to the corresponding fields in data source.*@
@(Html.EJ().TreeView("treeView")
.TreeViewFields(field =>
field.Datasource((IEnumerable<FileList>)ViewBag.datasource)
.Id("Name")
.ParentId("Parent")
.Text("Name")
)
)
```

C#

```
//In controller part, need to convert XML data into List of Objects for
specifying the list data in TreeView DataSource.
public partial class TreeViewController : Controller
{
public ActionResult TreeViewFeatures()
{
XElement element =
XElement.Load(Server.MapPath("~/App_Data/XMLFile1.xml"));
List<FileList> fileList = ToFileList(element);
ViewBag.datasource = fileList;
return View();
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
//Convert XML element to List of Objects
private List<FileList> ToFileList(XElement element)
{
if (element != null && element.HasElements)
{
List<FileList> employees = new List<FileList>();
AddChildElements(element, employees);
return employees;
}
return null;
}
private FileList ToFileItem(XElement element, string parentId)
{
return new FileList()
{
Name = element.Attribute("Text").Value,
Parent = parentId
};
}
private void AddChildElements(XElement element, List<FileList> employees)
{
foreach (var child in element.Elements("RootItem"))
{
var employee = ToFileItem(child, element.Attribute("Text").Value);
employees.Add(employee);
AddChildElements(child, employees);
}
foreach (var child in element.Elements("Item"))
{
var employee = ToFileItem(child, element.Attribute("Text").Value);
employees.Add(employee);
}
}
}
```

XML

```
<?xml version="1.0" encoding="utf-8" ?>
<items Text="0">
<RootItem Text="Favorites" Url="#">
<Item Text="Desktop" Url="#"></Item>
<Item Text="Downloads" Url="#"></Item>
<Item Text="Recent places" Url="#"></Item>
</RootItem>
<RootItem Text="Libraries" Url="#">
<RootItem Text="Documents" Url="#">
<Item Text="My Documents" Url="#"></Item>
<Item Text="Public Documents" Url="#"></Item>
</RootItem>
<RootItem Text="Pictures" Url="#">
<Item Text="My Pictures" Url="#"></Item>
<Item Text="Public Pictures" Url="#"></Item>
</RootItem>
<RootItem Text="Music" Url="#">
<Item Text="My Music" Url="#"></Item>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<Item Text="Public Music" Url="#"></Item>
</RootItem>
</RootItem>
<RootItem Text="Computer" Expanded="True" Url="#">
<Item Text="Folder(C)" Url="#"></Item>
<Item Text="Folder(D)" Url="#"></Item>
<Item Text="Folder(F)" Url="#"></Item>
</RootItem>
</items>
```

UploadBox

UploadBox

The UploadBox control supports uploading files into the designated server, regardless of the file format and size. The UploadBox control helps you with the selection of files to upload to the server. The UploadBox control has theme support.

Key Features

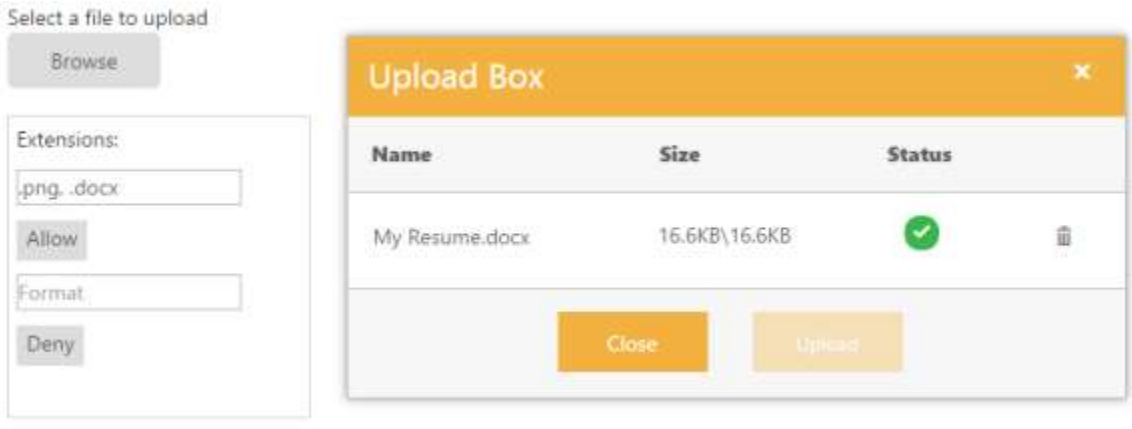
- Modern look: Rich appearance with theme support.
- RTL: Supports right-to-left alignment.
- Auto Upload: Support for manual and automatic uploading of files are included.
- Sync/Async Upload: Supports synchronous and asynchronous uploading of files.
- Multiple files: Supports uploading multiple files.

Getting Started

This section explains briefly about how to create an UploadBox in ASP.NET MVC application .

Create your first UploadBox in MVC

ASP.NET MVC UploadBox provides support to upload the files or photos within your web page. From the following guidelines, you can learn how to upload the file that is used in a Resume Upload scenario. This helps you to restrict some file extensions, while uploading the resume in the server by using UploadBox control. The following screenshot demonstrates the functionality of UploadBox with file extension.



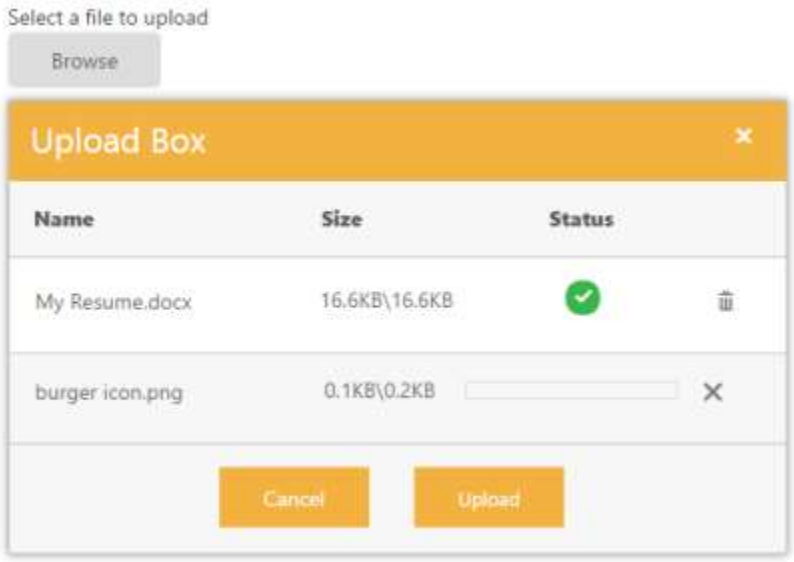
In the above screenshot, you can upload a resume. It allows .png and .docx file extension. This enables you to avoid unsupported resume formats to be uploaded in the server.

Copyright © 2001 - 2020 Syncfusion Inc.

Create UploadBox widgets

ASP.NET MVC UploadBox basically renders built-in features like upload multiple files, and deletes the files from Uploadbox. You can know the status of the file whether it is complete or fail and also can retry the upload if it failed. You can easily create the UploadBox widget by using the following steps.

You can create an MVC project and add necessary assemblies, styles, and scripts with the help of the given MVC-Getting Started Documentation.



Add the following code example to the corresponding view page to render the UploadBox.

ASPX-CS

```
@Html.EJ().Uploadbox("UploadDefault").SaveUrl(@Url.Action("SaveDefault"))
.RemoveUrl(@Url.Action("RemoveDefault"))
```

Add the following ActionResult in your controller.

C#

```
public ActionResult SaveDefault(IEnumerable<HttpPostedFileBase>
UploadDefault)
{
foreach (var file in UploadDefault)
{
var fileName = Path.GetFileName(file.FileName);
var destinationPath = Path.Combine(Server.MapPath("~/App_Data"),
fileName);
file.SaveAs(destinationPath);
}
return Content("");
}
```

Add the following Remove ActionResult in your controller page.

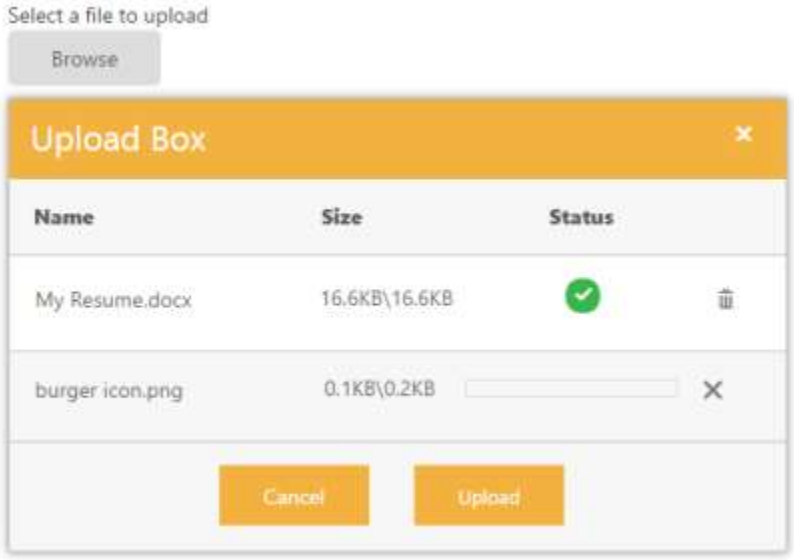
C#

```
public ActionResult RemoveDefault(string[] fileNames)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
{
foreach (var fullName in fileNames)
{
var fileName = Path.GetFileName(fullName);
var physicalPath = Path.Combine(Server.MapPath("~/App_Data"), fileName);
if (System.IO.File.Exists(physicalPath))
{
System.IO.File.Delete(physicalPath);
}
}
return Content("");
}
```

Execute the project to render the following output for the given steps. The file is being uploaded.



UploadBox after uploading

Set Restriction for File Extension

In a real-time scenario, some file extensions are restricted. You can either allow files or restrict files by using **extensionsAllow** and **extensionsDeny** respectively in **Uploadbox**.

Note: The SaveUrl and RemoveUrl are the same as above

Add the following elements in the view page.

ASPX-CS

```
<div id="targetElement">
<table id="uploadTable">
<tr>
<td>
Extensions:
</td>
<td></td>
</tr>
<tr>
<td>
```

```
<input type="text" id="Allow" class="ejinputtext" placeholder="Format" />
@(Html.EJ().Button("upbutton1").Text("Allow").ClientSideEvents(c =>
c.Click("allow")))
</td>
<td></td>
</tr>
<tr>
<td>
<input type="text" id="Deny" class="ejinputtext" placeholder="Format" />
@(Html.EJ().Button("upbutton2").Text("Deny").ClientSideEvents(c =>
c.Click("deny")))
</td>
<td>
@Html.EJ().Uploadbox("UploadDefault").SaveUrl(@Url.Action("SaveDefault"))
.RemoveUrl(@Url.Action("RemoveDefault")))
</td>
</tr>
</table>
</div>
```

Add the following code example in script section.

JS

```
var object;
$(function () {
object = $("#UploadDefault").data("ejUploadbox");
$("#upbutton1").ejButton({
click: "allow",
});
$("#upbutton2").ejButton({
click: "deny",
});
});
function allow() {
object.option('extensionsAllow', $("#Allow").val());
object.option('extensionsDeny', "");
}
function deny() {
object.option('extensionsAllow', "");
object.option('extensionsDeny', $("#Deny").val());
}
```

Add the given styles to display the **Uploadbox** with margin alignments.

CSS

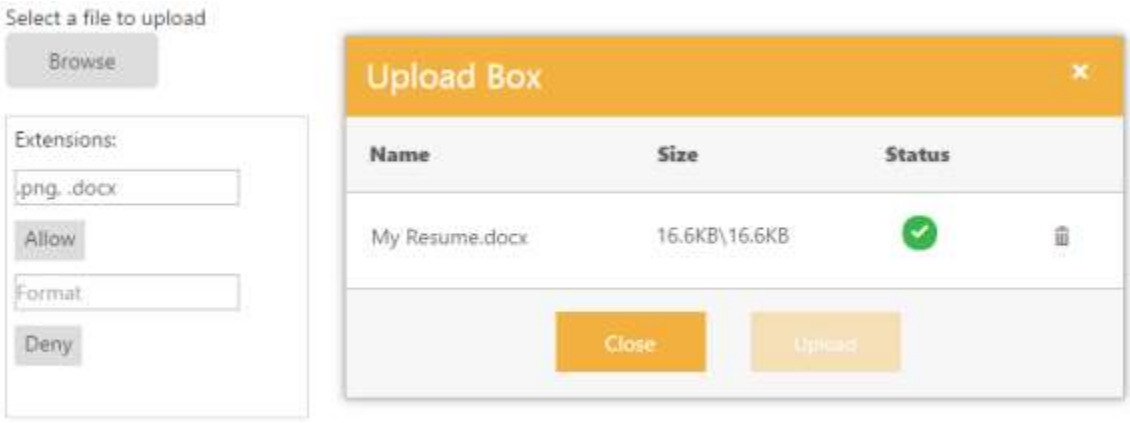
```
#targetElement {
width: 520px;
height: 500px;
margin: 0 auto;
}
#UploadDefault {
float: right;
}
#uploadTable {
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
width: 100%;
}
#Allow, #Deny {
width: 150px;
height: 20px;
padding: 5px;
}
```

Note: You can restrict one or more different extension files by giving file extension separated by comma (,)

The following screenshot displays an **Uploadbox** control with the file extension.



The above screenshot shows the **Uploadbox** that allows ".**docx**" and "**.png"** files.

Upload Multiple Files

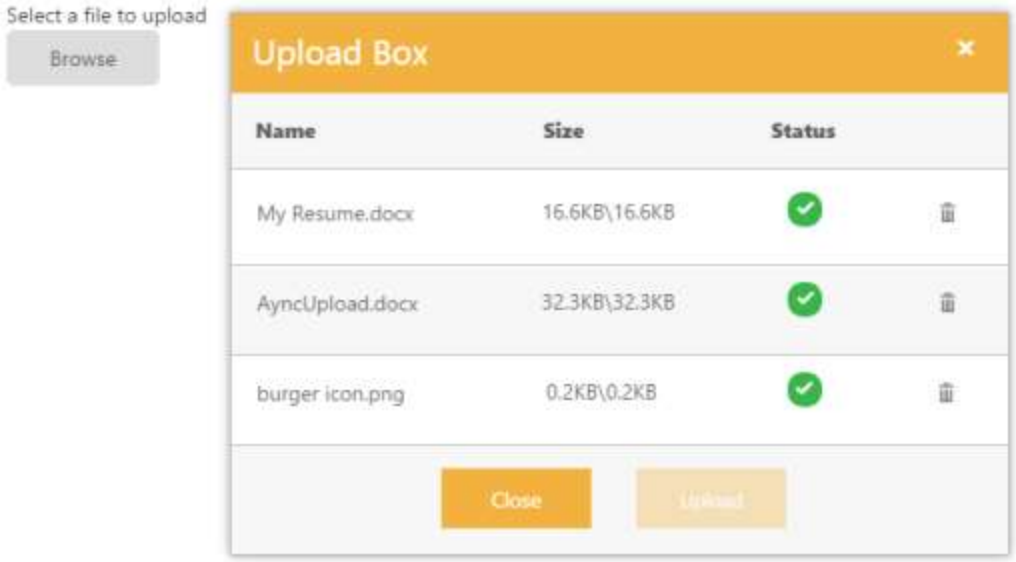
To upload multiple files in UploadBox control, click the Browse button and select multiple files from file explorer window

The following screenshot displays an UploadBox control with multiple files selected.

ASPX-CS

```
@Html.EJ().Uploadbox("UploadDefault").SaveUrl(@Url.Action("Save")).Remove
Url(@Url.Action("Remove")).MultipleFilesSelection(true)
```

Copyright © 2001 - 2020 Syncfusion Inc.



Display uploaded File Details

To display the details of the uploaded files below the control, add an container element to display the details below the uploadbox control. Using the ClientSide success event we can access the details of the uploaded file and display it in the container element. Refer the following code.

ASPX-CS

```
<div class="frame">
<div class="control">
Select a file to upload
<div class="posupload">
@Html.EJ().Uploadbox("UploadDefault").SaveUrl("SaveDefault").RemoveUrl("R
emoveDefault").AutoUpload(true).UploadBoxDialogAction(act =>
act.CloseOnComplete(true)).ClientSideEvents(e => e.Success("onSuccess"))
</div>
</div>
<br />
<ul id="uploaded" ></ul>
</div>
```

JS

```
function onSuccess(args) {
var msg = "<li class='green'><span style='display:inline-block;'><span
class='e-icon e-file-empty'></span></span><span style='display:inline-
block;margin-left:20px;'><span style='display:block'>" + args.files.name
+ "</span><span style='display:block;font-size:
10px;'>"+(args.files.size/1024).toFixed(2)+"KB</span></li>"
$("#uploaded").append(msg);
}
```

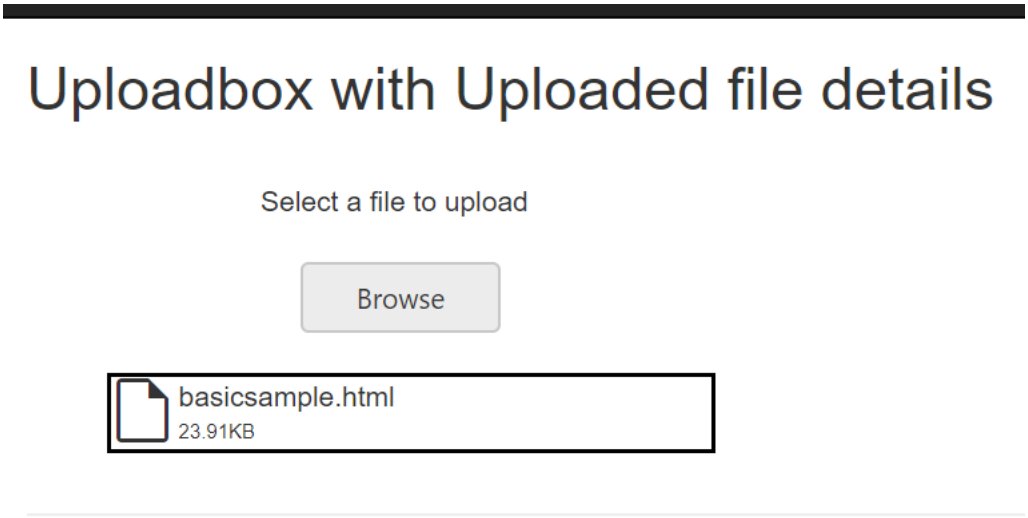
CSS

```
#uploaded li {
list-style: none;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
border: 2px solid black;
width:300px;;
}
.e-icon.e-file-empty:before {
font-size: 32px;
}
```

The following screenshot displays an UploadBox control with file details of the uploaded file.



[Sample link]

File Actions

Save File Action

To save the uploaded file in MVC, create an ActionResult and trigger the same in SaveUrl property. In ActionResult, save and specify the target location as App_Data folder for the uploaded files. The data type is string.

The following steps explain the configuration of SaveUrl property in the UploadBox.

1. In the VIEW page, add the below script to configure the UploadBox element.

ASPX-CS

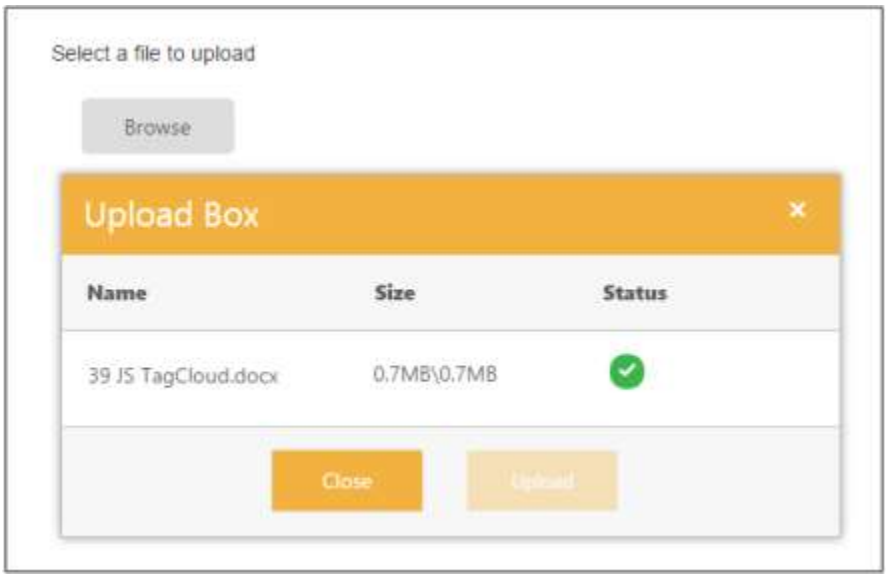
```
// In the CSHTML page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox")
.SaveUrl("Uploadbox/Save")
.RemoveUrl("Uploadbox/Remove")
```

CSHARP

```
// Configure the ActionResult to save the file in App_Data location. In
the following code example, the uploaded files is saved in App_Data
folder.
public ActionResult Save(IEnumerable<HttpPostedFileBase> uploadbox)
{
foreach (var file in uploadbox)
```

```
{
var fileName = Path.GetFileName(file.FileName);
var destinationPath = Path.Combine(Server.MapPath("~/App_Data"),
fileName);
file.SaveAs(destinationPath);
}
return Content("");
}
```

2. The following screenshot displays the output.



Remove File Action

To remove the uploaded file in MVC, create ActionResult and trigger the same in RemoveUrl property. This action removes the uploaded file from where it is saved. This is achieved by clicking remove button on upload dialog. The data type is string.

The following steps explain the configuration of RemoveUrl property in UploadBox.

ASPX-CS

```
// In the CSHTML page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox")
.SaveUrl("Uploadbox/Save")
.RemoveUrl("Uploadbox/Remove")
```

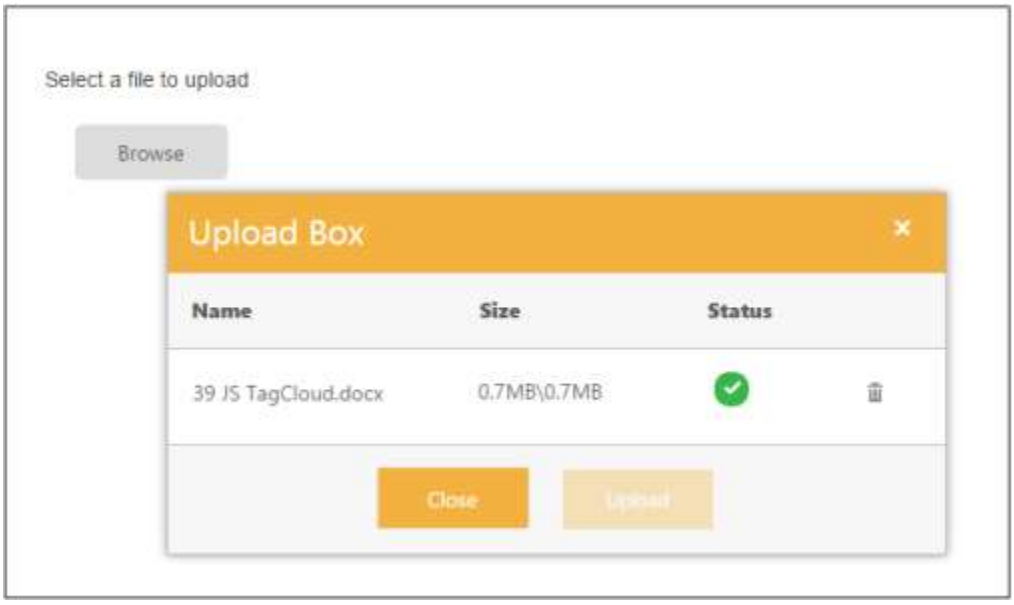
C#

```
// Configure the action to remove the file in target location. From that
location, the file is searched and removed from the App_Data folder.
public ActionResult Remove(string[] fileNames)
{
foreach (var fullName in fileNames)
{
var fileName = Path.GetFileName(fullName);
var physicalPath = Path.Combine(Server.MapPath("~/App_Data"), fileName);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
if (System.IO.File.Exists(physicalPath))
{
System.IO.File.Delete(physicalPath);
}
}
return Content("");
}
```

The following screenshot displays the output.



AutoUpload

The UploadBox widget provides support to upload the file automatically once file is selected by using Browse button, that is, without clicking upload button. To achieve this, set the AutoUpload property to ‘true’. The data type is Boolean. By default, the value is set to ‘false’, so Upload button is clicked to upload the files.

The following steps explain the configuration of AutoUpload property in UploadBox

1. In the VIEW page, add the below script to configure the UploadBox element.

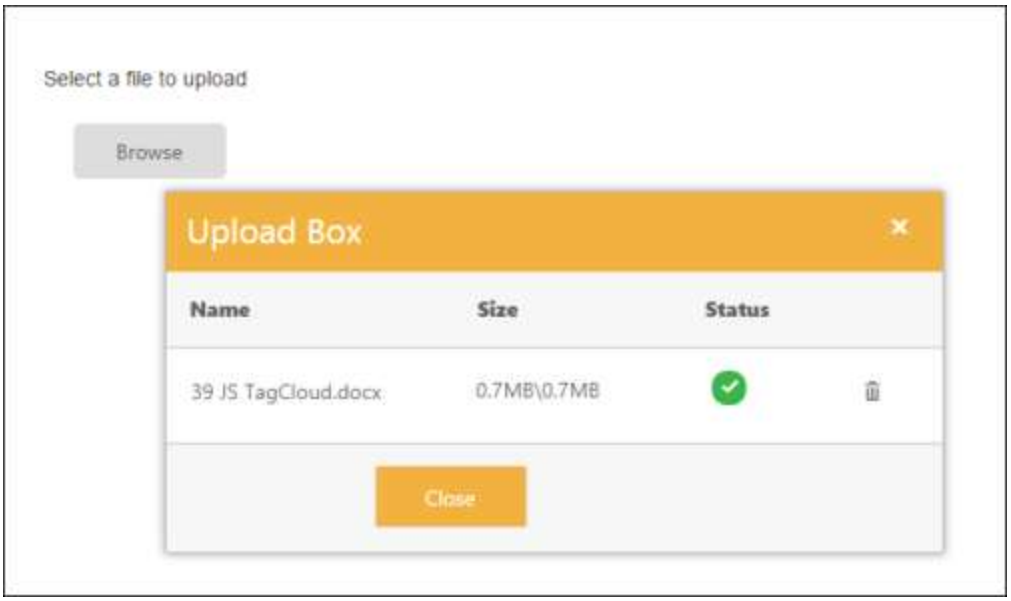
ASPX-CS

```
// In the CSHTML page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").AutoUpload(true)
```

2. For MVC, configure SaveActionResult and RemoveActionResult files as mentioned in Save file action and Remove file action respectively.

The following screenshot displays the output.

Copyright © 2001 - 2020 Syncfusion Inc.



Restricting uploading files based on its extension

Allow Extension

Files are filtered before they are uploaded. You can select the files to be filtered by using browse button. The ExtensionsAllow property allows upload of the selected extensions only. You can give multiple extensions by using comma (,). The data type is string.

Note: Prepend dot (.) symbol with extension like ".pdf".

The following steps explain the configuration of ExtensionsAllow property in UploadBox.

1. In the VIEW page, add the below script to configure the UploadBox element.

ASPX-CS

```
// In the CSHTML page, add UploadBox element.
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").ExtensionsAllow(".docx,.pdf")
```

Deny Extension

Files are filtered before they are uploaded. You can select the files to be filtered by using browse button. The ExtensionsDeny property denies upload of the selected extensions. You can give multiple extensions by using comma (,). The data type is string.

Note: Prepend dot (.) symbol with extension like ".pdf".

The following steps explain the configuration of ExtensionsDeny property in UploadBox

1. In the VIEW page, add the below script to configure the UploadBox element.

ASPX-CS

```
// In the CSHTML page, add UploadBox ox element.
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").ExtensionsDeny(".docx,.pdf")
```

Note: When **ExtensionsDeny** and **ExtensionsAllow** properties have same file extension, the extension will be allowed.

File Size

Maximum File Size for UploadBox

In the UploadBox control, you can browse files with the size going up to gigabytes. You can restrict the files from being browsed using the FileSize property. When you do not use this property, it takes a default size, 31457280B, that is, 31MB. When this size exceeds, we cannot browse the file.

1. Add the following code example to the corresponding View page to render the UploadBox control with the customized file size.

ASPX-CS

```
<div class="control">
@Html.EJ().Uploadbox("UploadBox")
.SaveUrl("Uploadbox/Save")
.RemoveUrl("UploadBox/Remove")
.FileSize(848576)
.ClientSideEvents(e => e.Error("error"))
</div>
<script type="text/javascript">
function error(e)
{
alert(e.error);
}
</script>
```

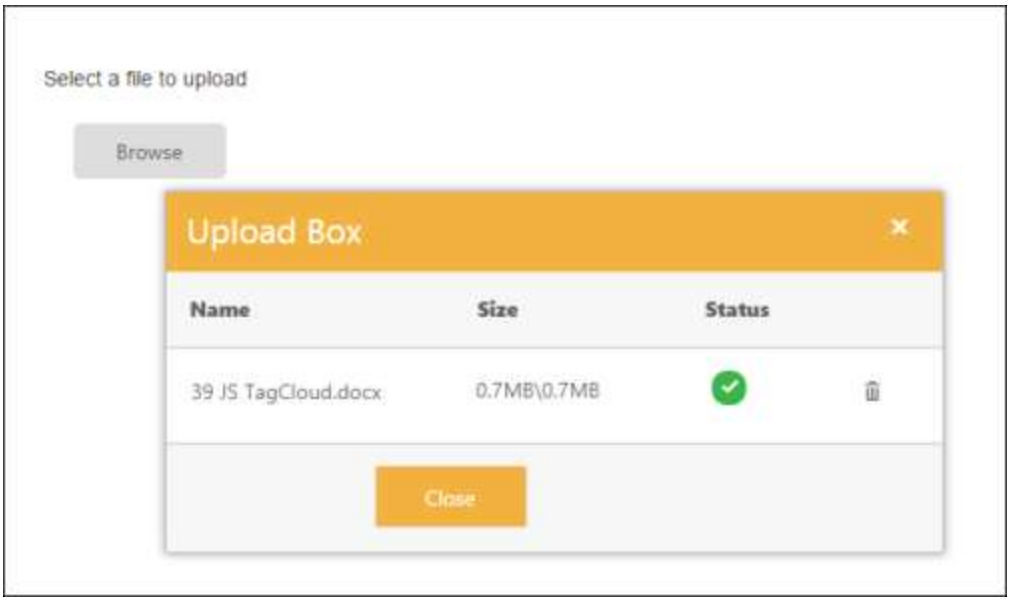
To know about file action, we need to refer link:

http://help.syncfusion.com/aspnetmvc/uploadbox/file-size

The following screenshot displays UploadBox control with customized file size.

When you want to browse the file within the fileSize, you can browse and upload the files.

Copyright © 2001 - 2020 Syncfusion Inc.

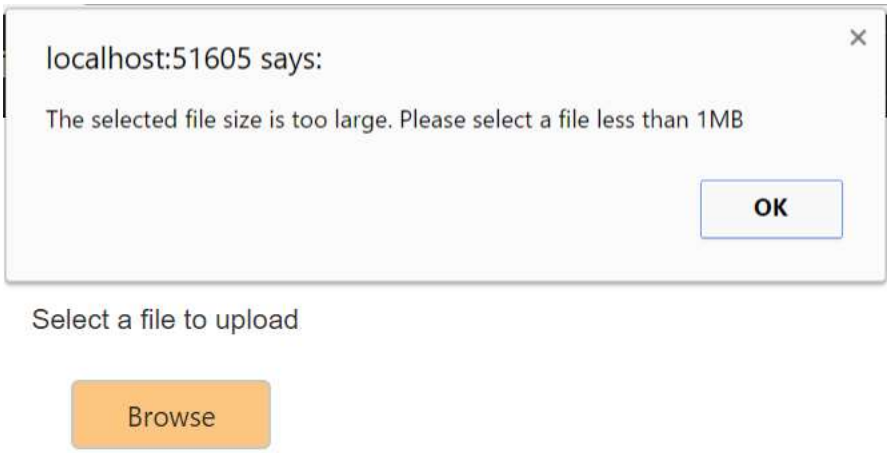


When you try to browse the file with exceeded FileSize, an error message will be displayed as an alert.You can customize the error message by converting the file size into mb and display the corresponding value in error message.

ASPX-CS

```
<script type="text/javascript">
function fileUploadError(e)
{
alert("The selected file size is too large. Please select a file less
than " + Math.round(e.model.fileSize / (1024 * 1024)) + "MB");
}
</script>
```

Now you will get the error message as shown in the below image



Note: By default, UploadBox will display the file size as bytes value in error message.

Copyright © 2001 - 2020 Syncfusion Inc.

Enable or Disable the UploadBox

The Enabled property is Boolean type, which allow us to set the enable or disable the UploadBox. By default value of Enabled property is true.

The following steps explain the configuration of Enabled property in UploadBox.

1. In the VIEW page, add below script to configure the UploadBox element.

ASPX-CS

```
// In the CSHTML page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").Enabled(false)
```

2. The following screenshot displays the output.

Asynchronous Upload

The AsyncUpload property is Boolean type, which allow us to upload and remove files asynchronously.When multiple files are chosen in Asynchronous upload,files will be uploaded one by one to the server.User interaction with the page will not be interrupted at the time of upload.User can also remove the file even after uploading.This is the best way of file upload when compared to synchronous so by default UploadBox works with asynchronous upload option only.To achieve this, set the AsyncUpload property to ‘true’. The default value of AsyncUpload property is ‘true’.

The following steps guide you in uploading the file asynchronously.

1. In the VIEW page, add the below script to configure the UploadBox element.

ASPX-CS

```
// In the view page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").AsyncUpload(true)
```

Synchronous Upload

This features allow you to upload and remove the files synchronously.When multiple files are chosen in Synchronous upload,all files will be uploaded only on form submission.Multitasking is not possible here.To achieve this, set the AsyncUpload property to ‘false’. The data type is Boolean.

Note: By default, UploadBox widget works with asynchronous upload option only.

The following steps guide you in uploading the file synchronously.

1. In the VIEW page, create a form with action and post method and then add the script into the form to configure the UploadBox element.

Copyright © 2001 - 2020 Syncfusion Inc.

ASPX-CS

```
// In the CSHTML page, create a form with action and post method and then
add the UploadBox element.
@using (Html.BeginForm("Index","Home",FormMethod.Post))
{
@Html.EJ().Uploadbox("uploadbox").AsyncUpload(false)
<input type="submit" value="Submit" />
}
```

Once the form is submitted by using Submit button, it triggers the post method and the files can be saved by using the below code.

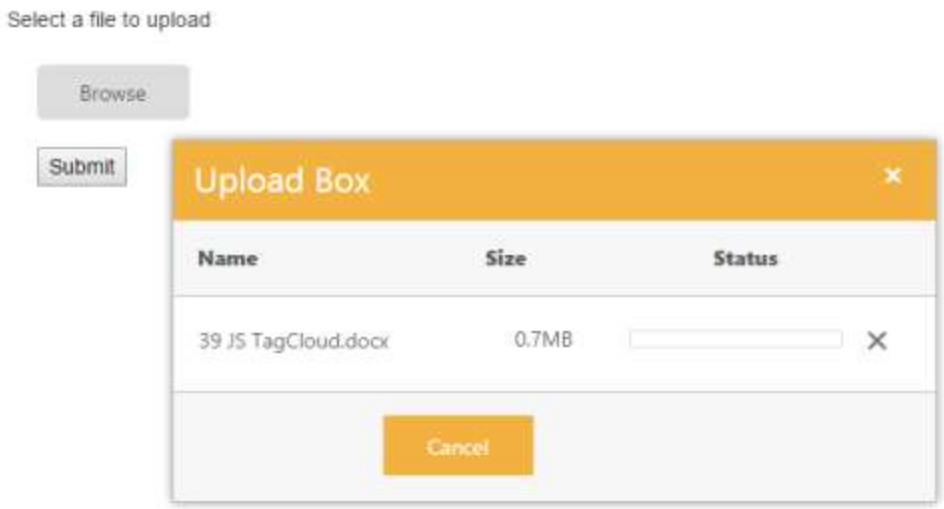
C#

```
public ActionResult Index()
{
if (string.IsNullOrEmpty((string)TempData["status"]))
ViewBag.status = string.Empty;
else
ViewBag.status = (string)TempData["status"];
return View();
}
[HttpPost]
public ActionResult Index(IEnumerable<HttpPostedFileBase> uploadbox)
{
if (uploadbox != null)
{
if (uploadbox != null)
{
foreach (var file in uploadbox)
{
var fileName = Path.GetFileName(file.FileName);
var destinationPath = Path.Combine(Server.MapPath("~/App_Data"),
fileName);
file.SaveAs(destinationPath);
}
TempData["status"] = "Successfully Uploaded";
return RedirectToAction("FileUploadFeatures");
}
else
{
TempData["status"] = "Select a file to upload";
return RedirectToAction("FileUploadFeatures");
}
}
return View();
}
```

Refer here for online demo

The following screenshot displays the output.

Copyright © 2001 - 2020 Syncfusion Inc.



Multiple files upload

The UploadBox widget provides support to upload multiple files spontaneously. The MultipleFilesSelection property enables you to select multiple files while browsing. To achieve this, set the MultipleFilesSelection property to 'true'. The data type is Boolean.

Note: The Multiple file selection supports all the latest versions of browser except Internet Explorer 9 and its previous versions.

The following steps explain the configuration of MultipleFilesSelection property in UploadBox.

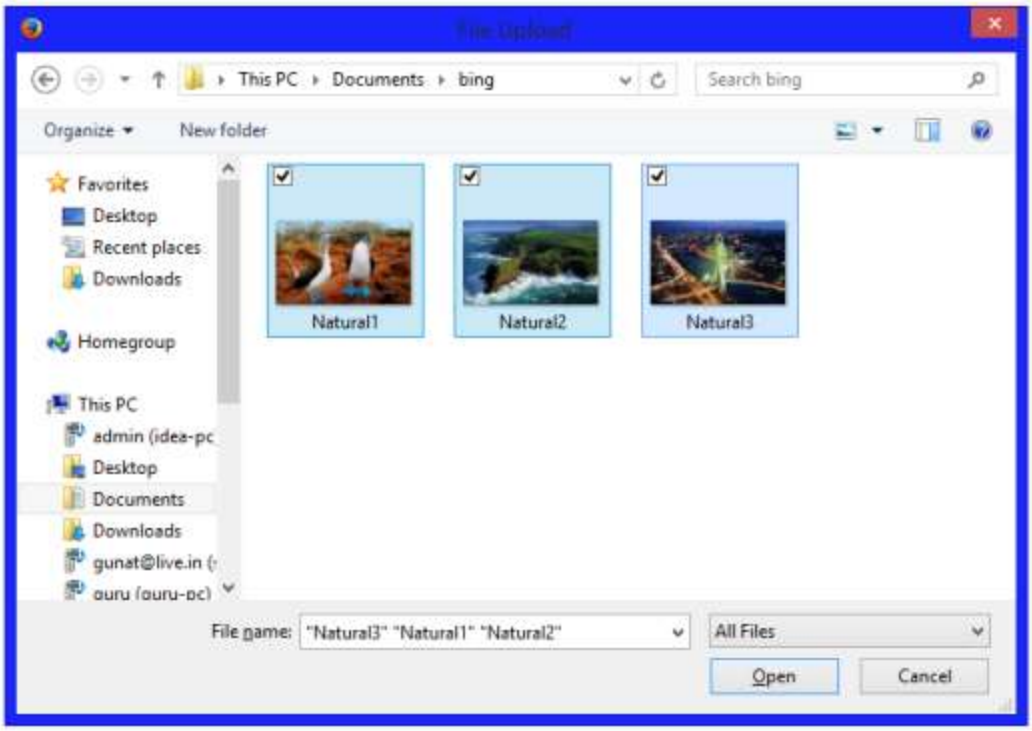
1. In the VIEW page, add the below script to configure the UploadBox element.

ASPX-CS

```
// In the CSHTML page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").MultipleFilesSelection(true)
```

The following screenshot displays the output.

Copyright © 2001 - 2020 Syncfusion Inc.



Drag and Drop Support

The UploadBox control provides the drag and drop support. You can simply drag-and-drop files, directly from the computer and can be dropped into the droppable area. A list of files can be dragged and dropped when you enable the MultipleFilesSelection property.

The following screenshot displays the drag and drop support.

Copyright © 2001 - 2020 Syncfusion Inc.

Enable drag and drop

AllowDragAndDrop property is Boolean type which allow us to enable or disable the Drag and Drop. When you want to drag and drop multiple files, you can enable multiple file selection by setting MultipleFilesSelection as true in theUploadBox control. By default the AllowDragAndDrop property is set as false in the UploadBox control.

The following steps explain how to enable the drag and drop in the UploadBox control.

1. In the VIEW page, add the below script to enable the drag and drop in UploadBox control.

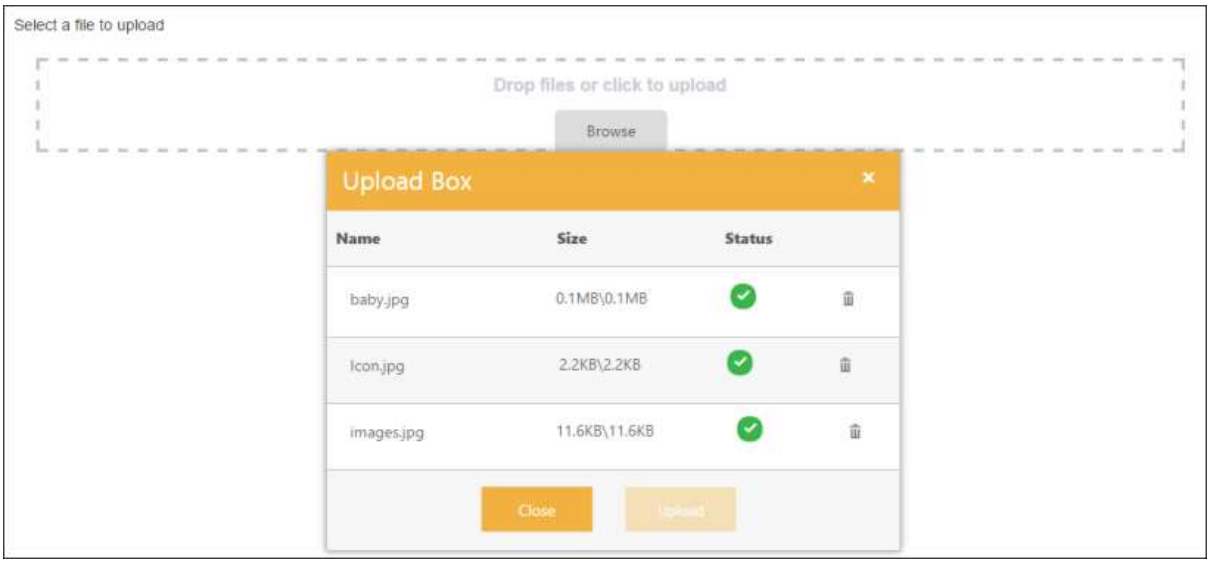
ASPX-CS

```
//Add the following code example to the corresponding CSHTML page to
render UploadBox with drag and drop support
<div class="frame">
<div class="control">
@Html.EJ().Uploadbox("uploadbox")
.SaveUrl("Uploadbox/Save")
.RemoveUrl("UploadBox/Remove")
.AllowDragAndDrop(true).MultipleFilesSelection(true)
</div>
</div>
```

To know about file action, refer to the following link:
http://help.syncfusion.com/aspnetmvc/uploadbox/drag-and-drop-support

2. The following screenshot displays the output for the above code.

Copyright © 2001 - 2020 Syncfusion Inc.



Drag Area text

You can change the drag area text by using the DragAreaText property. By default, the DragAreaText (string) property is Drop files or click to upload in the UploadBox control.

In the VIEW page, add the below script to enable the drag and drop in the UploadBox control.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render UploadBox with drag and drop support
<div class="frame">
<div class="control">
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save")
.RemoveUrl("Uploadbox/Remove")
.AllowDragAndDrop(true)
.MultipleFilesSelection(true)
.DragAreaText("Drop files here")
</div>
</div>
```

3. The following screenshot displays the output for the above code.

Copyright © 2001 - 2020 Syncfusion Inc.

Adjust Drop area size

The UploadBox control provides the ability to change or adjust the drop area size. The DropAreaHeight andDropAreaWidth properties in the UploadBox control allows you to set the maximum height and maximum width for the drop area. The value set to this property is string or number type.

The following steps explain you on how to adjust the Drop Area Size.

In the VIEW page, add the below script to enable the drag and drop in UploadBox control.

ASPX-CS

```
// Add the following code example to the corresponding CSHTML page to
render UploadBox with drag and drop support.
<div class="frame">
<div class="control">
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").AllowDragAndDrop(true).MultipleFilesSelection(true).Drop
AreaHeight("300px").DropAreaWidth("600px")
</div>
</div>
```

4. The following screenshot displays the output for the above code.

Drop area with Browse button behavior

You can click anywhere in the droppable area to browse and upload the files. The droppable area behaves like a browse button.

Enable the AllowDragAndDrop property to achieve this feature. Next, set the ShowBrowseButton as false in UploadBox Control.

The following steps explains the droppable area containing the browse button behavior

In the VIEW page, add the below script to enable drag and drop in the UploadBox control.

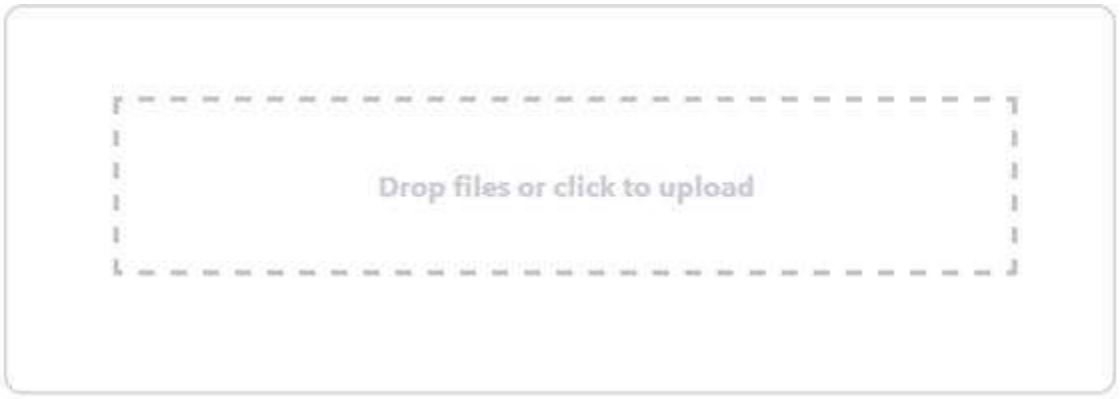
ASPX-CS

```
//Add the following code example to the corresponding CSHTML page to
render UploadBox with drag and drop support.
<div class="control">
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save")
.RemoveUrl("Uploadbox/Remove")
.AllowDragAndDrop(true)
.MultipleFilesSelection(true)
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
.ShowBrowseButton(false)
</div>
```

5. The following screenshot displays the output for the above code.



Appearance and styling

The UploadBox widget provides support to customize the dialog box text and button text.

Customizing Button Text

The following table contains the sub properties available under UploadBox ButtonText property. To customize the text, pass the alternate text with corresponding sub properties.

Sub-properties under buttonText property

Name	Description	Data Type
Browse	Sets the alternative text for browse button.	String
Upload	Sets the alternative text for upload button.	String
Cancel	Sets the alternative text for cancel button.	String

The following steps explain the configuration of UploadBoxButtonText property in UploadBox.

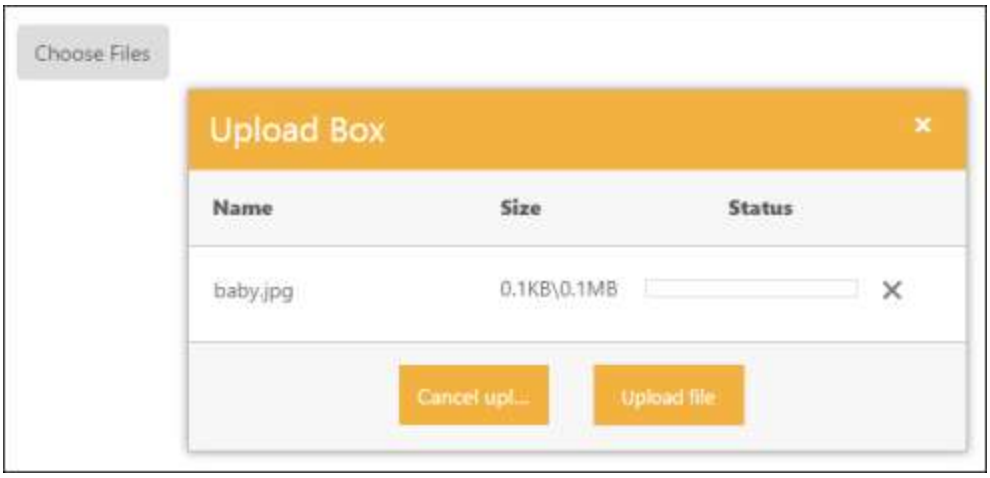
1. In the VIEW page, add the below script to configure the UploadBox element.

ASPX-CS

```
// In the CSHTML page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").UploadBoxButtonText(text=>text.Browse("Choose
Files").Cancel("Cancel upload").Upload("Upload file"))
```

The following screenshot displays the output.

Copyright © 2001 - 2020 Syncfusion Inc.



Customizing Upload Dialog

The following table contains the sub properties available under UploadBox DialogText property. To customize the text, pass the alternate text with corresponding sub properties.

Sub properties under dialogText property

Name	Description
Title	Sets the alternative text for Title of UploadBox dialog.
Name	Sets the alternative text for Name column.
Size	Sets the alternative text for Size column.
Status	Sets the alternative text for status column.

The following steps explain the configuration of UploadBoxDialogText property in UploadBox.

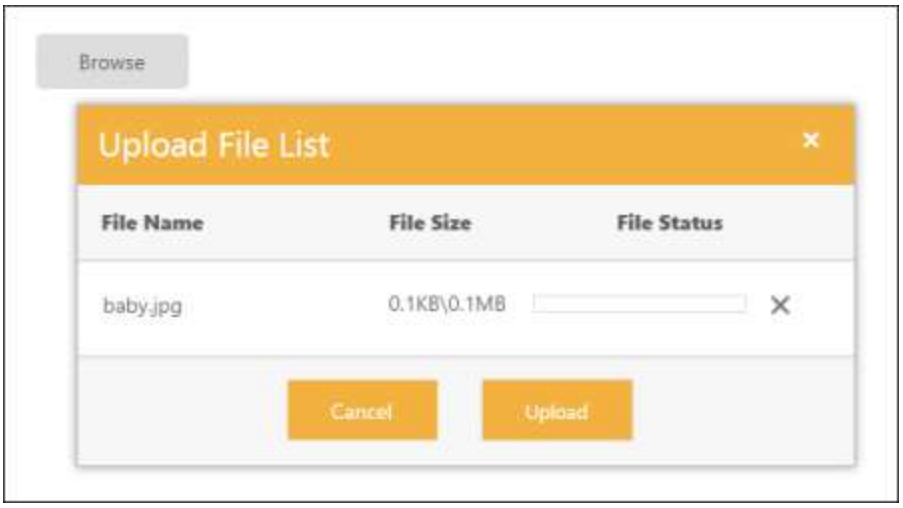
1. In the VIEW page, add the below script to configure the UploadBox element.

ASPX-CS

```
// In the CSHTML page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").UploadBoxDialogText(text=>text.Title("Upload File
List").Name("File Name").Size("File Size").Status("File Status"))
```

The following screenshot displays the output.

Copyright © 2001 - 2020 Syncfusion Inc.



Show or Hide File details

The ShowFileDetails property is Boolean type, which allow us to show or hide file details in the uploaded file list dialog. To hide the uploaded file details, set ShowFileDetails property is set to ‘false’. By default value of ShowFileDetails property is set to ‘true’.

The following steps explains the configuration of ShowFileDetails property in UploadBox.

1. In the VIEW page, add the below script to configure the UploadBox element.

ASPX-CS

```
// In the CSHTML page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").ShowFileDetails(false)
```

Theme

UploadBox control’s style and appearance are controlled based on CSS classes. In order to apply styles to the UploadBox control, you can refer to two files namely, ej.widgets.core.min.css and ej.theme.min.css. When the file ej.widgets.all.min.css is referred, then it is not necessary to include the files ej.widgets.core.min.css and ej.theme.min.css in your project, as ej.widgets.all.min.css is the combination of these both files.

By default, there are 12-theme support available for UploadBox control namely,

- Default-theme
- Flat-azure-dark
- Fat-lime
- Flat-lime-dark
- Flat-saffron
- Flat-saffron-dark
- Gradient-azure
- Gradient-azure-dark
- Gradient-lime
- Gradient-lime-dark
- Gradient-saffron

Copyright © 2001 - 2020 Syncfusion Inc.

- Gradient-saffron-dark

Custom CSS

CssClass customizes the UploadBox control's appearance. Define a CssClass as per the requirement and assign the class name to CssClass property. The data type is string.

The following steps explain the configuration of CssClass property in UploadBox.

1. In the View page, add the below script to configure the UploadBox element.

ASPX-CS

```
// In the CSHTML page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").CssClass("custom")
```

2. In CSS, configure Custom Styles for the UploadBox.

CSS

```
<style class="cssStyles">
.custom.e-uploadbox.e-widget .e-selectpart.e-select
{
background-color: #FFFFCC;
font-weight: bold;
font-family: sans-serif;
}
.custom.e-uploadbox.e-widget .e-selectpart.e-select:hover .e-inputbtn
{
background-color: #1e90ff;
}
</style>
```

The following screenshot displays the output.

RTL Support

The EnableRTL property is Boolean type, which allow us to change of left-to-right alignment of the UploadBox widget to right-to-left (RTL). That is, it sets the UploadBox to right-to-left actions. Default value of EnableRTL property is false.

The following steps explain the configuration of EnableRTL property in UploadBox.

In the VIEW page, add the below script to configure the UploadBox element.

ASPX-CS

```
// In the CSHTML page, add the UploadBox element.
@Html.EJ().Uploadbox("uploadbox").SaveUrl("Uploadbox/Save").RemoveUrl("Up
loadbox/Remove").EnableRTL(true)
```

Copyright © 2001 - 2020 Syncfusion Inc.

The following screenshot displays the output.

How To

Render UploadBox from code behind

UploadBox can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of UploadBox using UploadBox properties from code behind.

RAZOR

```
@{
Html.EJ().Uploadbox("UploadDefault",
(Syncfusion.JavaScript.Models.UploadboxProperties)ViewData["upload"]).Ren
der();
}
```

C#

```
public ActionResult Index()
{
UploadboxProperties upload = new UploadboxProperties();
upload.ExtensionsAllow = ".jpg,.png";
upload.SaveUrl = "SaveDefault";
upload.RemoveUrl = "RemoveDefault";
ViewData["upload"] = upload;
return View();
}
public ActionResult SaveDefault(IEnumerable<HttpPostedFileBase>
UploadDefault)
{
foreach (var file in UploadDefault)
{
var fileName = Path.GetFileName(file.FileName);
var destinationPath = Path.Combine(Server.MapPath("~/App_Data"),
fileName);
file.SaveAs(destinationPath);
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
}
return Content("");
}
public ActionResult RemoveDefault(string[] fileNames)
{
foreach (var fullName in fileNames)
{
var fileName = Path.GetFileName(fullName);
var physicalPath = Path.Combine(Server.MapPath("~/App_Data"), fileName);
if (System.IO.File.Exists(physicalPath))
{
System.IO.File.Delete(physicalPath);
}
}
return Content("");
}
```

Upload a file using pushFile property

Raw file details sent from client side will be updated as file details in web method. So, pass the raw file details through push file property and upload the file to server.

The following code illustrates the way to use pushFile property for Upload.

RAZOR

```
<div id = "ControlRegion">
<div class="frame">
<div class="control">
<table>
<tbody>
<tr>
<td>
<h3>Choose a file here to update file details.</h3>
</td>
<td>
<input type="file" id="select" />
</td>
</tr>
<tr>
<td  style="padding-right:30px">
<h3>Click push button to push selected files</h3>
</td>
<td>
<button id="push" onclick="push()">Push selected file to
ejUploadBox</button>
</td>
</tr>
<tr>
<td>
<h3>Syncfusion UploadBox</h3>
</td>
<td>
<div class="posupload">
@Html.EJ().Uploadbox("UploadDefault").SaveUrl("SaveDefault").RemoveUrl("R
emoveDefault"))
</div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
</td>
</tr>
</tbody>
</table>
</div>
</div>
<script>
var details;
var fileName;
$("#select").on("change", function () {
details = this.files[0]; //get file details selected through input
fileName = $('input[type=file]').val().replace(/C:\\fakepath\\/i, '');
//get selected filename
});
function push() {
if (fileName && details != null) {
var Files = { name: fileName, rawFile: details } //Files structure
var push = $("#UploadDefault").data("ejUploadbox");
push.setModel({ pushFile: { Files } });//push files to UploadBox
}
else
alert("Please select a file to push");
}
</script>
```

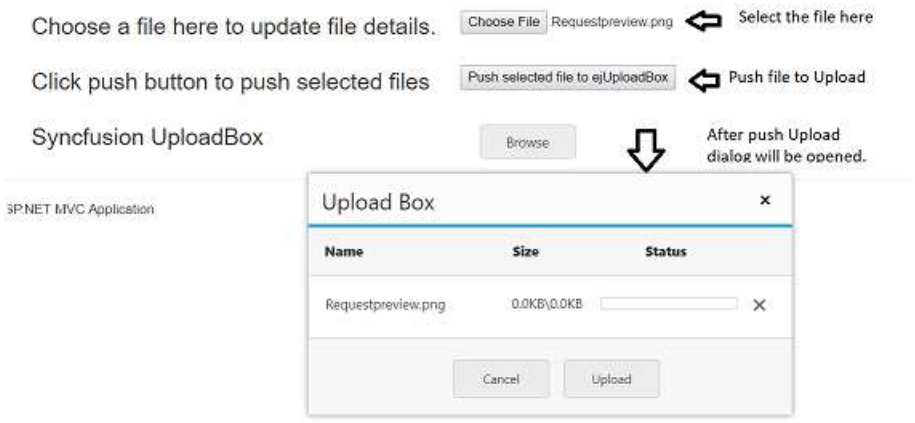
C#

```
public ActionResult Index()
{
return View();
}
public ActionResult SaveDefault(IEnumerable<HttpPostedFileBase>
UploadDefault)
{
var path="";
foreach (var file in UploadDefault)
{
var fileName = Path.GetFileName(file.FileName);
var destinationPath = Path.Combine(Server.MapPath("~/App_Data"),
fileName);
path = destinationPath;
file.SaveAs(destinationPath);
}
return Content(path);
}
public ActionResult RemoveDefault(string[] fileNames)
{
foreach (var fullName in fileNames)
{
var fileName = Path.GetFileName(fullName);
var physicalPath = Path.Combine(Server.MapPath("~/App_Data"), fileName);
if (System.IO.File.Exists(physicalPath))
{
System.IO.File.Delete(physicalPath);
}
}
```

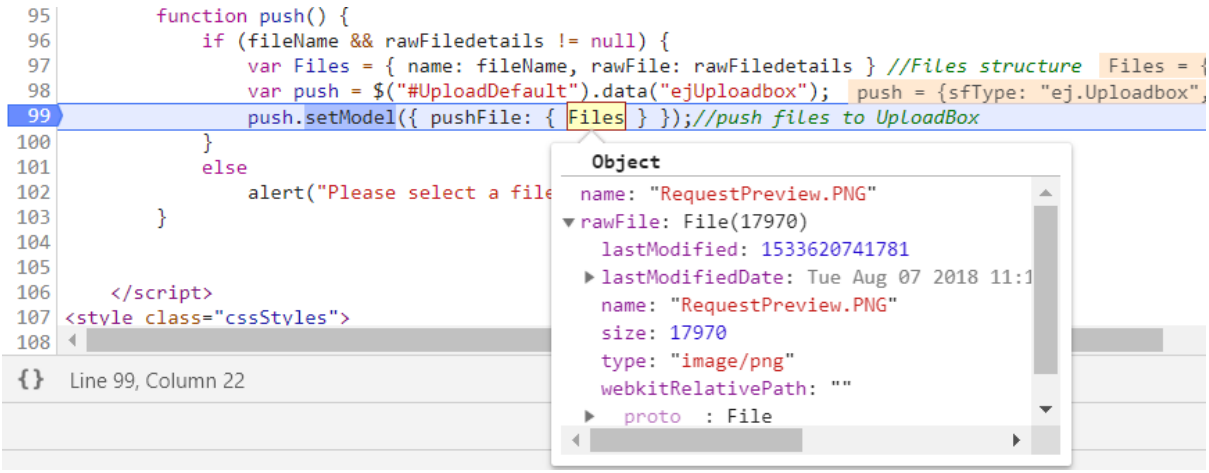
Copyright © 2001 - 2020 Syncfusion Inc.

```
return Content("");
}
```

Choose the file through input and push this file using pushFile property



Pass the file details from client side in the below format



Now the file details can be received in the controller as shown below

Use Synchronous upload with drag and drop

Drag and Drop is supported with Synchronous upload from 16.1.0.32 version. Refer to the below given code for uploading a file through drag and drop with Synchronous upload.

RAZOR

```
@using (Html.BeginForm("SaveSynchronous", "FileUpload", FormMethod.Post,
null))
{
<div class="control">
<div class="element">Select a file to upload</div>
<div class="posupload">
@Html.EJ().Uploadbox("Synchronous").AllowDragAndDrop(true).AsyncUpload(fa
lse)@*Uploading files will be done only on clicking submit button after
selecting the files*@
@Html.EJ().Button("post").Type(ButtonType.Submit).Text("Submit")
</div>
<div id="successmsg">@ViewBag.status</div>
</div>
}
```

C#

```
public ActionResult FileUploadFeatures()
{
if (string.IsNullOrEmpty((string)TempData["status"]))
ViewBag.status = string.Empty;
else
ViewBag.status = (string)TempData["status"];
return View();
}
public ActionResult SaveSynchronous(IEnumerable<HttpPostedFileBase>
Synchronous)
{
if (Synchronous != null)
{
foreach (var file in Synchronous)
{
var fileName = Path.GetFileName(file.FileName);
var destinationPath = Path.Combine(Server.MapPath("~/App_Data"),
fileName);
file.SaveAs(destinationPath);
}
TempData["status"] = "Successfully Uploaded";
return RedirectToAction("FileUploadFeatures");
}
else
{
TempData["status"] = "Select a file to upload";
return RedirectToAction("FileUploadFeatures");
}
}
```

WaitingPopup

WaitingPopup

The WaitingPopup control for MVC is a visual element that provides support for displaying a pop-up indicator over a target area and preventing the end user's interaction with the target area while loading.

Copyright © 2001 - 2020 Syncfusion Inc.

Key Features

- Custom text: Supports custom text inside the pop-up panel.
- Template: Supports including HTML content instead of the default image.
- Transparency: Supports customizing the transparency and opacity level.
- Themes: JavaScript controls include 12 built-in themes (6 flat and 6 gradient effects) and also support the custom skin option to set user-defined themes.

Getting Started

This section explains briefly about how to create a WaitingPopup in your application with ASP.NET MVC.

Create your first Waiting Popup in MVC

ASP.NET MVC Waiting Popup provides support to display Waiting Popup within your web page. From the following guidelines, you can learn how to create a Waiting Popup in a real-time Login page scenario. This helps you in authentication model. The following screenshot illustrates the functionality of a Waiting Popup in a Login page scenario.

In the above screenshot, you can give the Username and Password. When you click the Login button, the Waiting Popup appears. After loading, the alert box appears with a message “Signed in successfully”.

Create Waiting Popup

ASP.NET MVC Waiting Popup widget has a built-in feature to block all other actions until the page is loaded. You can easily create the Waiting Popup control by using simple HTML Helper element as follows

1. You can create an MVC Project and add necessary assemblies, styles, and scripts with the help of MVC-Getting Started Documentation.

Create Login Page

In a real-time Login page scenario, when you click on the Login button, the Waiting Popup is displayed. This is achieved by using the button Click.

1. Add the following code example to the corresponding view page to create Login page with username and password.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div class="content-container-fluid">
<div class="row">
<div class="cols-sample-area">
<table id="target">
<tr>
<td>Username</td>
<td><input type="text"></td>
</tr>
<tr>
<td>Password</td>
<td><input type="password"></td>
</tr>
<tr>
<td></td>
<td>
@Html.EJ().Button("button").Text("Login").Size(ButtonSize.Large).ClientSi
deEvents(e =>e.Create("load").Click("Click"))
</td>
@Html.EJ().WaitingPopup("target").ShowOnInit(false)
</tr>
</table>
</div>
</div>
</div>
```

2. Add the following styles in the view page to show the Waiting Popup.

CSS

```
<style type="text/css" class="cssStyles">
#target
{
margin: 0 auto;
}
#target_WaitingPopup .e-image
{
display: block;
height: 70px;
}
#popup
{
height: auto;
width: auto;
margin-top: 100px;
}
</style>
```

3. Add the following script in the view page.

JS

```
<script>
function Click(e)
```

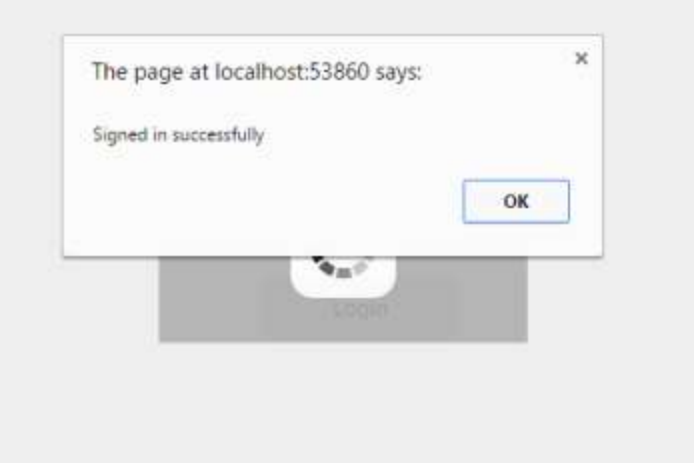
Copyright © 2001 - 2020 Syncfusion Inc.

```
{
var popup = $("#target").data("ejWaitingPopup");
popup.show();
setTimeout(success, 5000);
}
function success()
{
alert("Signed in successfully");
var popup = $("#target").ejWaitingPopup("hide");
}
</script>
```

4. The following screenshot displays the User login.

5. The following screenshot shows the Waiting Popup

The following screenshot displays an alert box displayed with the message “Signed in successfully” after loading.



Behavior and Settings

Automatic Initializing WaitingPopup widget

WaitingPopup widget contains ShowOnInit property that allows the popup to display over a target on page load automatically. By default, ShowOnInit property is set as false.

The following steps explains you on how to display the WaitingPopup on page load.

1. In an VIEW page, add a helper element to render WaitingPopup widget.

ASPX-CS

```
<div id="target">
@Html.EJ().WaitingPopup("target").ShowOnInit(true)
</div>
```

2. Add the following styles to render WaitingPopup widget.

CSS

```
<style type="text/css" class="cssStyles">
#control
{
height: 320px;
width: 600px;
}
</style>
```

The following screenshot illustrates the WaitingPopup when ShowOnInit is set to “true”.

Copyright © 2001 - 2020 Syncfusion Inc.

WaitingPopup with enabled showOnInit property

Enable / Disable Popup Indicator

You can show or hide the popup indicator of WaitingPopup widget using ShowImage property. By default, ShowImage property is set as true.

The following steps explains you to enable / disable popup indicator in WaitingPopup widget.

1. In the VIEW page, add a helper element to render WaitingPopup widget.

ASPX-CS

```
Enable popup indicator:
<div id="target">
@Html.EJ().WaitingPopup("target").ShowOnInit(true).ShowImage(true).Text("
Loading... Please wait...")
</div>
Disable popup indicator:
<div id="target">
@Html.EJ().WaitingPopup("target").ShowOnInit(true).ShowImage(false).Text(
"Loading... Please wait...")
</div>
```

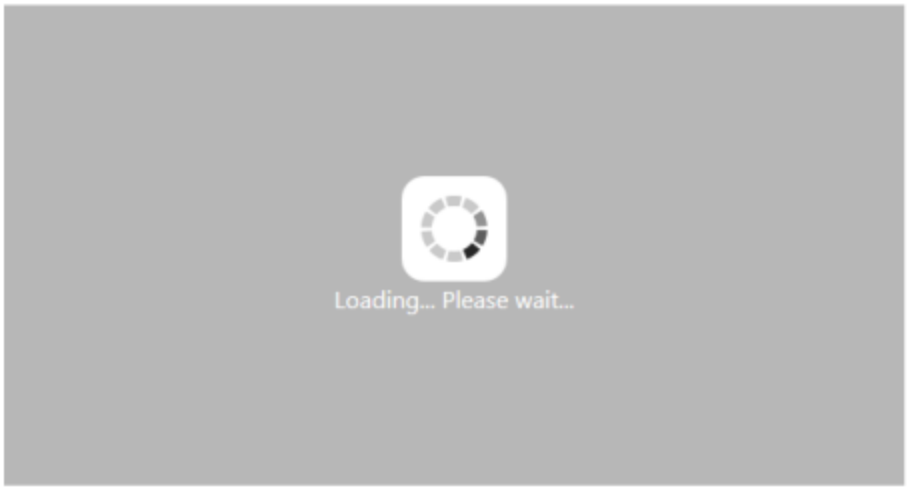
2. Add the following styles to render WaitingPopup widget.

CSS

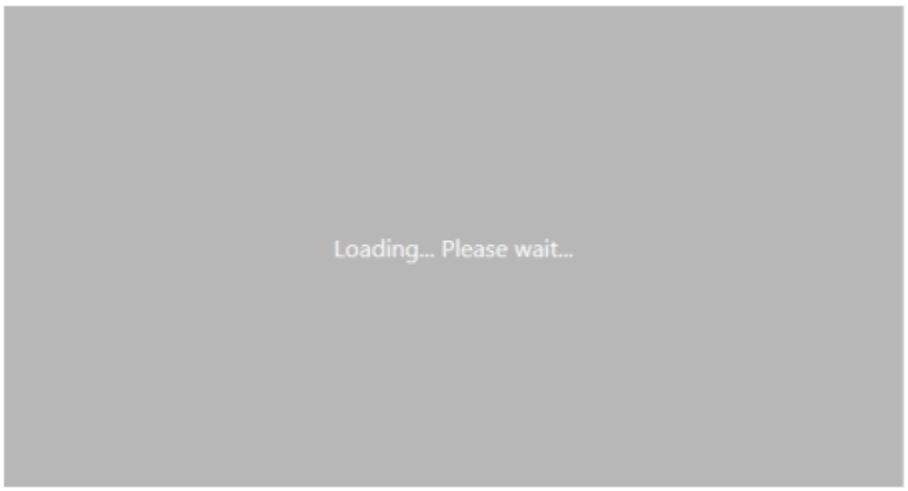
```
<style type="text/css" class="cssStyles">
#control
{
height: 320px;
width: 600px;
}
</style>
```

Execute the above code to render the following output.

Copyright © 2001 - 2020 Syncfusion Inc.



Enabled popup indicator WaitingPopup widget



Disabled popup indicator WaitingPopup widget

Show / Hide WaitingPopup

Using Show() and Hide() methods, you can display or hide the WaitingPopup widget over the target area.

The following steps explains you to show / hide the WaitingPopup widget.

1. In the VIEW page, add a helper element to render WaitingPopup widget.

ASPX-CS

```
<div id="target">
@Html.EJ().WaitingPopup("target").ShowOnInit(true)
</div>
Show WaitingPopup:
<script type="text/javascript">
var popUpObj;
$(function () {
$("#target").ejWaitingPopup();
popUpObj = $("#target").data("ejWaitingPopup");
```

```
popUpObj.show();
});</script>Hide WaitingPopup:<script type="text/javascript">
var popUpObj    $(function () {
$("#target").ejWaitingPopup();
popUpObj = $("#target").data("ejWaitingPopup");
popUpObj.hide();
});
</script>
```

2. Add the following styles to render WaitingPopup widget.

CSS

```
<style type="text/css" class="cssStyles">
#control
{
height: 320px;
width: 600px;
}
</style>
```

The following screenshot illustrates a WaitingPopup when Show() method is invoked.

WaitingPopup with Show() method

Appearance and Styling

Custom Text

WaitingPopup control provides support for Custom Text to mention any message inside the pop-up panel. You can specify a custom text through the option Text that displays when the Waiting Popup is loading.

The following steps explains you the configuration of the custom text for WaitingPopup control.

1. In the VIEW page, add a helper element to render WaitingPopup widget.

ASPX-CS

Copyright © 2001 - 2020 Syncfusion Inc.

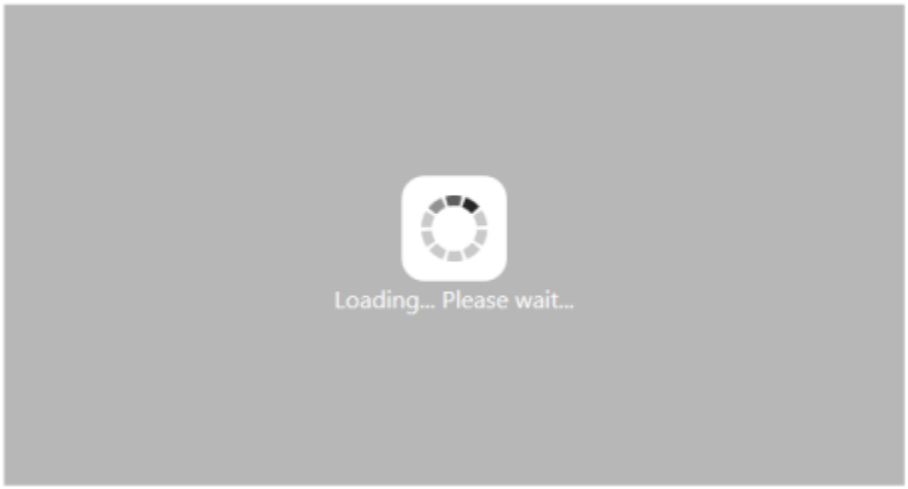
```
<div id="target">
@Html.EJ().WaitingPopup("target").ShowOnInit(true).Text("Loading...
Please wait...")
</div>
```

2. Add the following styles to render WaitingPopup widget.

CSS

```
<style type="text/css" class="cssStyles">
#control
{
height: 320px;
width: 600px;
}
</style>
```

Execute the above code to render the following output.



Custom Text in WaitingPopup

Template

WaitingPopup widget provides support for Template to customize the appearance of it by including HTML content instead of the default image.

The following steps explains you on how to define template to display a text and image for WaitingPopup control.

1. In the VIEW page, add a helper element to configure WaitingPopup widget.

ASPX-CS

```
<div id="target">
@Html.EJ().WaitingPopup("target").ShowOnInit(true).Template("#content")
<div id="content">
<div class="block">
<div class="logo"></div>
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
<div class="txt">
<p>Create cutting edge </p>
<p><b>HTML5</b> web application </p>
<p>with ease </p>
</div>
</div>
<div class="loader"></div>
</div>
</div>
```

2. In CSS, you can configure the custom styles for WaitingPopup.

Note: Images for this sample are available ‘installed location /Content/images’ and we need to define images in mentioned CSS. Henceforth the images will display._

CSS

```
<style type="text/css" class="cssStyles">
#waitingPopUp
{
height: 320px;
width: 600px;
margin: 0 auto;
}
.block
{
height: 76px;

```
{
cursor: default;
height: 112px;
width: 275px;
}
</style>
```

Execute the above code to render the following output.

WaitingPopup with Custom Template

CSS Class

You can use the CSS class to customize the WaitingPopup control appearance. Define a CSS class as per requirement and assign the class name to CssClass property.

The following steps allows you to configure CSS class for an auto-complete textbox.

1. In the VIEW page, add a helper element to configure WaitingPopup widget.

ASPX-CS

```
<div id="target">
@Html.EJ().WaitingPopup("target").ShowOnInit(true).CssClass("custom").Tex
t("Loading... Please wait...")</div>
```

2. Define CSS class for customizing the WaitingPopup widget.

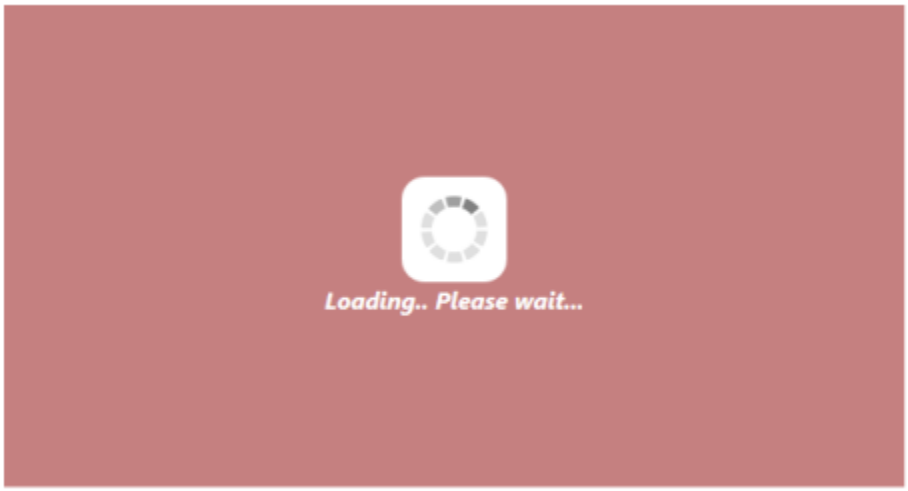
CSS

```
<style type="text/css" class="cssStyles">
/*Customize the panel property*/
#waitingPopUp
{
height: 320px;
width: 600px;
```

Copyright © 2001 - 2020 Syncfusion Inc.

```
margin: 0 auto;
}
/* Customize the WaitingPopup */
.customStyle
{
background-color:darkred;
font-style:italic;
font-weight:bolder;
opacity:0.5;
}
</style>
```

The following screenshot displays the output for the above code.



WaitingPopup with customized CSS

How To

Render WaitingPopup from code behind

WaitingPopup can be rendered from the code behind by initializing the required properties in controller and passing those properties via ViewData or Model to the client side

The following code illustrates the rendering of WaitingPopup using WaitingPopup properties from code behind.

RAZOR

```
<div id="target">
@{Html.EJ().WaitingPopup("target", Model).Render();}
</div>
```

C#

```
public ActionResult Index()
{
WaitingPopupProperties Obj = new WaitingPopupProperties();
Obj.ShowOnInit = true;
return View(Obj);
}
```
